If additional queries arrive that need to be serviced, and no queries can be jostled out, the new queries are dropped

Jostle Timeout
Timeout in milliseconds used when the server is very busy. This protects against denial of service by slow queries or high query rates. The default value is *200* milliseconds.

Set to a value that approximates the round-trip time to the authority servers. As new queries arrive, 50% are allowed to run and 50% are replaced by new queries if they are older than the stated timeout.

Maximum TTL for RRsets and Messages
The Maximum Time to Live (TTL) for RRsets and messages in the cache, specified in seconds. The default is `86400` seconds (1 day).

When the internal TTL expires the cache item is expired. This can be configured to force the resolver to query for data more often and not trust very large TTL values

Minimum TTL for RRsets and Messages
The Minimum Time to Live for RRsets and messages in the cache, specified in seconds. The default is `0` seconds.

If a record has a TTL lower than the configured minimum value, data can be cached for longer than the domain owner intended, and thus less queries are made to look up the data. The `0` value ensures the data in the cache is not kept longer than the domain owner intended.

> **Warning:** High values can lead to trouble as the data in the cache may not match up with the actual data if it changes.

TTL for Host Cache Entries
Time to Live, in minutes, for entries in the infrastructure host cache. The default value is *15 minutes*.

The infrastructure host cache contains round trip timing, lameness, and EDNS support information for DNS servers.

Number of Hosts to Cache
Number of infrastructure hosts for which information is cached. The default is *10,000*.

Unwanted Reply Threshold
Controls whether or not Unbound tracks the total number of unwanted replies in every thread. The default is disabled

When the threshold is reached, a defensive action is taken and a warning is printed to the log file. The defensive action is to clear the RRSet and message caches, hopefully flushing away any poison.

If enabled, a value of 10 million is the best starting value.

Log Level
Controls the verbosity of data logged by Unbound. Default is *Level 1*.

Level 0
No logging, only errors.

Level 1
Basic operational information.

Level 2
Detailed operational information.

Level 3
Query level information, output per query.

Level 4
Algorithm level information.

Level 5
Logs client identification for cache misses.

Disable Auto-added Access Control
Controls whether or not Unbound uses automatic access control entries. The default is unchecked.

The automatic access control entries permit queries from IPv4 and IPv6 networks residing on internal interfaces of this firewall, and on certain known subnets used for VPNs.

When checked, networks from which queries are allowed must be manually configured on the **Access Lists** tab.

Disable Auto-added Host Entries
Controls whether or not Unbound registers primary IPv4 and IPv6 addresses of this firewall as records for the system domain as configured in **System > General Setup**.

When checked, these automatic entries are omitted from the configuration.

Experimental Bit 0x20 Support
Use `0x20` encoded random bits in the DNS query to foil spoofing attempts. See the implementation draft dns-0x20 for more information:

DNS64 Support
Controls whether or not Unbound enables support for DNS64 (RFC 6147). This is typically used with features such as *NAT64* to enable communication from IPv6-only clients to IPv4-only servers.

See also:

- *NAT64*
- *Configuring NAT64 for IPv6-only Clients*

22.5.6 DNS Resolver Access Lists

Unbound requires access lists (ACLs) to control which clients are allowed to submit queries. By default, IPv4 and IPv6 networks residing on internal interfaces of this firewall are permitted. Additional networks must be allowed manually.

Note: The automatic ACLs may be disabled using the **Disable Auto-added Access Control** option on the **Advanced Settings** tab.

To manage access lists for the DNS Resolver, navigate to **Services > DNS Resolver**, **Access Lists** tab. This page has controls to add new entries as well as edit or delete existing entries.

When adding or editing an entry, the following options are available:

Access List Name
The name for the access list, which appears as a comment in the access list configuration file.

Action
Controls how Unbound will handle queries for networks contained in this access list.

Deny
Stops queries from clients in the configured networks

Refuse
Stops queries from clients in the configured networks and sends back a `REFUSED` response code

Allow
Allows queries from clients in the configured networks

Allow Snoop
Allows recursive and non-recursive queries from clients in the configured networks, used for cache snooping, and typically only configured on administrative hosts.

Deny Nonlocal
Allow only authoritative local-data queries from hosts within the network on this ACL. Unbound will drop disallowed messages.

Refuse Nonlocal
Allow only authoritative local-data queries from hosts within the network on this ACL. Unbound sends back a `REFUSED` response code for disallowed messages.

Description
A longer text field for reference notes about this entry.

Networks
A list of IPv4 or IPv6 networks governed by this access list entry.

22.5.7 CLI Commands

Unbound provides various command line utilities to manage the DNS Cache server. The following control commands are currently not available in the webGUI but can be executed from the command line.

Note: Unbound does not use the default conf file location; Use the `-c` flag to tell Unbound the configuration file location:

```
unbound-control -c /var/unbound/unbound.conf <unbound-command-to-run>
```

Remove <name> from the cache, all record types which include A, AAAA, NS SOA, CNAME, DNAME, MX, PTR, SRV and NAPTR records:

```
unbound-control -c /var/unbound/unbound.conf flush <name>
```

Remove the <name> and <type> from the cache where <type> is a particular record type:

```
unbound-control -c /var/unbound/unbound.conf flush_type <name> <type>
```

Remove all information at or below the <name> from cache. For example, .com will remove all entries below .com. Note this process is slow as the entire cache must be inspected:

```
unbound-control -c /var/unbound/unbound.conf flush_zone <name>
```

Reload Unbound and clear the entire cache:

```
unbound-control -c /var/unbound/unbound.conf reload
```

Determine the name servers Unbound will Query to lookup a zone:

```
unbound-control -c /var/unbound/unbound.conf lookup <name>
```

- *DNS Resolver Status*

22.6 DNS Forwarder

The DNS Forwarder in pfSense® software utilizes the dnsmasq daemon, which is a caching DNS forwarder.

Unlike the DNS Resolver, the DNS Forwarder can only act in a forwarding role as it does not support acting as a resolver.

The DNS Forwarder uses *DNS Servers* configured at **System > General Setup** and those obtained automatically from an ISP for dynamically configured WAN interfaces (DHCP, PPPoE, etc).

See also:

- *DNS Resolution Process*
- *DNS Rebinding Protections*

Note: This service is disabled by default. The *DNS Resolver* (unbound) is the default DNS service.

The DNS Forwarder remains enabled on upgraded installations where it was active before the upgrade.

22.6.1 DNS Forwarder Configuration

To configure the DNS Forwarder, navigate to **Services > DNS Forwarder**

The available options for the DNS Forwarder are:

Enable
Controls whether or not the DNS Forwarder service is enabled.

Checking this box turns on the DNS Forwarder, or uncheck to disable this service.

Two DNS services cannot both be active at the same time on the same ports. This includes, but is not limited to, the DNS Resolver, the DNS Forwarder, and the BIND package. Ensure other services are disabled or moved to different ports before attempting to enable the DNS Forwarder.

DHCP Registration
Controls whether or not internal machine names for DHCP clients are registered in the DNS Forwarder. The domain name from **System > General Setup** is used as the domain name on the hosts.

This feature allows systems using the DNS Forwarder as their DNS server to resolve these names using DNS.

Note: This only works for clients that specify a hostname in their DHCP requests.

Static DHCP
This works the same as **Register DHCP leases in DNS forwarder**, except that it registers the DHCP static mapping addresses.

Prefer DHCP
Controls whether DNS records from DHCP sources are returned before host overrides if both use the same name.

When one IP address has multiple hostnames, doing a reverse lookup may give an unexpected result if one of the hostname is in host overrides and the system uses another hostname over DHCP. Checking this option will place the DHCP obtained hostnames above the static mappings in the hosts file on the firewall, causing them to be consulted first.

This only affects reverse lookups (PTR), since they only return the first result and not multiple. For example, this would yield a result of `labserver01.example.com`, a test server DHCP obtained IP address, rather than a host override name of `testwww.example.com` that would be returned otherwise.

Query DNS servers sequentially
Controls whether the DNS Forwarder queries all DNS servers at the same time, or in sequence.

By default the firewall queries all DNS servers simultaneously and uses the fastest result. This is not always desirable, especially if there is a local DNS server with custom hostnames that could by bypassed if a faster public DNS server replies first.

Checking this option causes queries to be made to each DNS server in sequence from the top down, and the firewall waits for a timeout before moving on to the next DNS server in the list. This results in more predictable responses but may be considerably slower if a server high in the list is unreachable.

Require domain
Controls whether or not the DNS Forwarder requires a domain name on hostnames to be forwarded to upstream DNS servers.

When checked, hosts without a domain name will still be checked against host overrides and DHCP results, but they will not be queried against name servers. If a short hostname does not exist locally, an NXDOMAIN result (“Not Found”) is returned to the client.

Do not forward private reverse lookups
Controls whether or not the DNS Forwarder will make reverse DNS (PTR Record) lookups for RFC1918 private IP addresses to upstream name servers.

The DNS Forwarder will still return results from local entries in either case.

Tip: Use a domain override entry for the reverse lookup zone, e.g. `1.168.192.in-addr.arpa`, to make the DNS Forwarder send queries for a specific subnet to a DNS server.

Listen Port
The TCP and UDP port on which the DNS Forwarder will listen for queries from clients. By default this is port `53`. This is the normal port for any DNS server, as it is the port expected by clients.

Certain use cases may involve moving the DNS Forwarder to another Listen Port, such as `5353` or `54`, and then specific sources may be forwarded there via port forwards.

Interfaces
The network interface(s) to which the DNS Forwarder will bind when listening for queries from clients.

By default the DNS Forwarder listens on every available interface and IPv4 and IPv6 address. This option limits the interfaces where the DNS Forwarder will accept and answer queries. This can be used to increase security in addition to firewall rules.

If specific interfaces are selected, both the IPv4 and IPv6 addresses on those interfaces will be used for answering queries. Queries sent to other IP addresses on the firewall will be silently discarded.

Strict Interface Binding
Controls how the `dnsmasq` daemon binds to interfaces when deciding how to handle queries.

When set, the DNS forwarder will only bind to the interfaces containing the IP addresses selected in the **Interface** control, rather than binding to all interfaces and discarding queries to other addresses.

This can be used similarly to the **Listen Port** for controlling the way that the service binds so that it can coexist with other DNS services that have similar options.

Note: This option is not compatible with IPv6. If this is checked, the `dnsmasq` daemon will not bind to any IPv6 addresses.

Advanced Options

Custom `dnsmasq` configuration parameters that are not configurable in the GUI can be placed in **Advanced Options**. Separate each command by either a space or a newline.

For example, to set a lower TTL for DNS records:

```
max-ttl=30
```

To craft a wildcard DNS record resolving `*.lab.example.com` to `192.2.5.6`:

```
address=/lab.example.com/192.2.5.6
```

See also:

For more information on the possible parameters that may be used, consult the dnsmasq documentation.

22.6.2 Host Overrides

Host override entries provide a means to configure customized DNS entries. The configuration is identical to *Host Overrides* in the DNS Resolver, refer there for details. The main difference is that overrides in the DNS Forwarder only support a single address per entry.

22.6.3 Domain Overrides

Domain overrides configure an alternate DNS server to use for resolving a specific domain. The configuration is similar to *Domain Overrides* in the DNS Resolver, but there are a few differences:

IP Address
This field can be used in one of three ways to control how the DNS Forwarder handles queries for the given **Domain**:

- To specify the IP Address of a DNS server to which the DNS Forwarder will send queries for hostnames in the **Domain**.
- To override another entry by entering `#`.

  For example, to forward `example.com` to `192.2.66.2`, but have `lab.example.com` forward on to the standard name servers, enter a `#` in this field.
- To prevent non-local lookups by entering a `!`.

  If host override entries exist for `www.example.org` and `mail.example.org`, but other lookups for hosts under *example.org* must not be forwarded on to remote DNS servers, enter a `!` in this field.

Source IP
The source IP address that the DNS Forwarder will use when sending queries to the DNS server in this domain override.

This field is optional and primarily used to contact a DNS server across a VPN where the VPN requires queries to have a specific source.

22.6.4 DNS Forwarder Behavior

By default, the DNS Forwarder queries all DNS servers at once and it uses and caches only the first response it receives. This results in much faster DNS service from a client perspective, and can help smooth over problems that stem from DNS servers which are intermittently slow or have high latency, especially in Multi-WAN environments. This behavior can be disabled by activating the **Query DNS servers sequentially** option.

See also:

- *Interface and DNS Configuration*

22.7 Dynamic DNS

The Dynamic DNS client built into pfSense® software registers the IP address of a WAN interface with a variety of dynamic DNS service providers. This is used to remotely access services on hosts that have WANs with dynamic IP addresses, most commonly VPNs, web servers, and so on.

Any number of Dynamic DNS clients may be configured using any of over 20 different Dynamic DNS providers, or even custom Dynamic DNS providers. Dynamic DNS clients can use any WAN, and can even register the real public IP address in environments where the firewall receives a private IP address for its WAN and is NATed upstream.

In addition to the typical HTTP/HTTPS-based Dynamic DNS providers, pfSense software also supports RFC 2136 style Dynamic DNS updates directly to DNS servers.

22.7.1 Configuring a Dynamic DNS Client

pfSense® software supports Dynamic DNS to automatically update DNS providers when an interface address changes. This allows remote clients to reference a constant hostname instead of a dynamic IP address which could change over time.

This service is located in the GUI at **Services > Dynamic DNS**.

Choosing a Dynamic DNS Provider

pfSense software allows registration with many different dynamic DNS providers. The available providers may be viewed by clicking the **Service Type** selector. More information about the providers may be found by searching for their name to find their web site. Several offer a basic level service at no cost, and some offer additional premium services at a cost. There is also a *Custom* option that allows for a custom URL to accommodate an unsupported provider.

Select a provider, visit their website, register for an account, and setup a hostname. The procedures for this vary with each provider, but they all have instructions on their websites. After configuring a hostname with a provider, configure the firewall with matching settings.

Dynamic DNS Settings

Most providers have the same, or similar options. There are a few types with custom options that will be covered later in this section.

Disable
: Check to disable the entry, or leave unchecked so it will be active.

Service Type
: Select the dynamic DNS provider here.

Interface to Monitor
: Select the interface that has the IP address to keep updated, such as WAN, or an OPTx interface. Selecting a gateway group for the interface allows the Dynamic DNS entry to switch between WANs so it can allow inbound Multi-WAN failover of services on this hostname.

Hostname
: Enter the hostname created at the dynamic DNS provider. This is typically the complete fully qualified domain name, such as `myhost.example.com`, except for Namecheap where this is only the host portion of the address.

Domain Name
: For Namecheap hosts, this box must be set to the domain part of the full hostname.

MX
An MX (Mail Exchanger) record is how Internet mail servers know where to deliver mail for a domain. Some dynamic DNS providers will let MX records be configured via the dynamic DNS client. If the chosen provider allows this, enter the host name of the mail server that will receive Internet mail for the dynamic DNS domain.

Wildcards
When wildcard DNS is enabled on a dynamic DNS name, all host name queries under the given domain will resolve to the IP address of the dynamic DNS host name. For example, if the host name is `example.dyndns.org`, enabling wildcard will make `*.example.dyndns.org` (`a.example.dyndns.org`, `b.example.dyndns.org`, etc.) resolve the same as `example.dyndns.org`.

Verbose Logging
Check this option to increase the logging for the Dynamic DNS update process, which is useful for troubleshooting update problems.

Verify SSL Peer
When checked, the SSL certificate of the DynDNS provider server will be validated. Some servers with self-signed certificates, or those using a less common CA, may require this to be set.

Username
Enter the username for the dynamic DNS provider. Provider-specific requirements:

Namecheap, FreeDNS
Leave blank

Route 53
Enter the **Access Key ID**

GleSYS
Enter the **API user**

Custom
The username is used with basic HTTP authentication and may be left blank.

Password
Enter the password for the dynamic DNS provider. Provider-specific requirements:

Namecheap, FreeDNS
This is the **Authentication Token**

Route 53
Enter the **Secret Access Key**

GleSYS
Enter the **API Key**

DNSimple
Enter the **API Token**

Description
A text field for reference.

Providers with Extra or Different Settings

Some providers have special settings or certain fields that need to be set in a specific way that may not be obvious. The differences are outlined in this section.

Namecheap

As mentioned in the settings, Namecheap requires that the fully qualified domain name be split into the hostname part and domain name part in separate fields.

When setting up Dynamic DNS for a *Namecheap* domain, an authentication token is given by Namecheap. This goes in the **Password** field, and the **Username** field is left blank.

HE.net Tunnelbroker

The *HE.net Tunnelbroker* choice updates an IPv6 tunnel endpoint IP address when the WAN IP changes. The **Hostname** in this case is the **Tunnel ID** from HE.net.

Route 53

When using an Amazon *Route 53* type, the Username is the **Access Key ID** provided by Amazon.

The following additional options are available when using *Route 53*:

Verify SSL Peer
: Enable to verify the server certificate when using HTTPS.

Zone ID
: Received when creating the domain in Route 53.

  This field is required.

TTL
: Time to Live for the DNS record.

Custom

The *Custom* Dynamic DNS type configures options that allow for updating otherwise unsupported services. When using the custom Dynamic DNS type, the **Username** and **Password** fields are sent using HTTP basic authentication.

The following additional options are available when using *Custom*:

Interface to send update from
: Almost always the same as the Interface, but can be changed as needed.

Force IPv4 Resolving
: When checked, the update host will only be resolved using IPv4

Verify SSL Peer
: Enable to verify the server certificate when using HTTPS

Update URL
: The URL given by the Dynamic DNS provider for updates. If the IP address must appear in the URL, enter it as `%IP%` and the real value will be substituted as needed.

Result Match
Defines expected output from the Dynamic DNS query. If it succeeds and matches the output given, then the firewall will know that the update was successful. If it does not match exactly, then it is assumed that the update failed. Leave empty to disable result checking.

DNSSimple

Verify SSL Peer
Enable to verify the server certificate when using HTTPS.

Zone ID
Received when creating the domain.

TTL
Time to Live for the DNS record.

Configuring a Dynamic DNS Entry

To configure a Dynamic DNS client:

- Navigate to **Services > Dynamic DNS**
- Click  **Add** to add a new entry
- Configure the Dynamic DNS entry with general and provider-specific settings
- Click **Save**

22.7.2 Configuring RFC 2136 Dynamic DNS updates

RFC 2136 Dynamic DNS registers a hostname on any DNS server supporting RFC 2136 style updates. This can be used to update DNS records on BIND and Windows Server DNS servers, amongst others.

RFC 2136 Dynamic DNS entries may be used at the same time as regular style Dynamic DNS service providers, and like those, any number of entries can be created. RFC 2136 will update the A record, and the AAAA record if IPv6 is configured on the monitored interface.

See also:

Configuring the server infrastructure for RFC 2136 Dynamic DNS hosting is beyond the scope of this documentation, but there is a basic how-to in the recipes section: *Configuring BIND as an RFC 2136 Dynamic DNS Server*.

RFC 2136 Settings

Enable
Controls whether or not the entry is active. If it is unchecked, updates will not be performed for this entry.

Interface
The IP address on the chosen interface will be sent when performing the DNS update.

Hostname
The fully qualified domain name (FQDN) of the dynamic DNS entry to update. For example, `myhost.example.com`.

Zone
The hostname of the zone to update (optional).

TTL
The Time To Live for the DNS entry, in seconds. Higher values will be cached longer by other name servers, so lower values are better to be sure that DNS updates are picked up in a timely manner by other servers. Usually a value between `30` and `180` seconds is reasonable, depending on how often the IP address changes.

Key Name
The name of the key as specified in the DNS server configuration. For Host keys, this is typically the FQDN, so it would be identical to the value in the **Hostname** field. For Zone keys this would be the name of the DNS zone.

Key Algorithm
The algorithm used for the key.

Key
Secret TSIG domain key. Contains the actual text of the key, e.g. `/0/4bxF9A08n/zke/vANyQ==`. This value is generated by the DNS server or administrator.

Server
The IP address or hostname of the DNS server to which updates are sent.

Protocol
When unchecked, the DNS update is sent over UDP, when checked it uses TCP instead.

Use Public IP
By default, the interface IP address is always sent to the name server for the DNS update. If this box is checked, when a private IP address is detected on the selected **Interface**, a check is done to determine what the actual public IP address is, and then that IP address is used for the DNS update.

Update Source
Interface or address from which the firewall will send the DNS update request.

Update Source Family
Address family to use for sourcing updates (IPv4 or IPv6)

Record Type
Determines which record(s) will be updated for this entry. For the IPv4 address, use *A*, for IPv6, use *AAAA*, or choose *Both*.

Description
A free-text description of the entry for reference.

Configuring an RFC 2136 Client

To configure an RFC 2136 Dynamic DNS client:

- Navigate to **Services > Dynamic DNS**
- Click the **RFC 2136** tab
- Click  **Add** to add a new entry
- Configure the options
- Click **Save**

As with the other Dynamic DNS types, RFC 2136 updates are performed only when an IP address change is detected, or once every 25 days.

22.7.3 Configuring IP Address Check Services for Dynamic DNS

pfSense® software supports custom IP address check services. These services are used by Dynamic DNS clients to determine the public IP address of the firewall when a WAN interface is behind an upstream NAT device.

To create or edit one of these services, navigate to **Services > Dynamic DNS** on the **Check IP Services** tab.

Settings

The following settings are available for a service entry:

Enable
Allow this service to be used by Dynamic DNS clients.

Name
A short name to identify this service.

URL
The full URL to the IP address check page.

Username/Password
Optional authentication to use when accessing the URL.

Verify SSL Peer
Check this box if the server has a self-signed SSL certificate or a certificate from a CA that is not trusted by the firewall.

Description
A longer description of this service.

Once a service is defined, it may be selected on individual Dynamic DNS service entries.

Server-Side Configuration Examples

Hosting one of these services is very simple. The server page need only print the requesting client IP address in the expected format:

```
Current IP Address: x.x.x.x
```

nginx (internal/native)

```
location /ip {
    default_type text/html;
    return 200 "<html><head><title>Current IP Check</title></head><body>Current IP␣
↪Address: $remote_addr</body></html>";
}
```

nginx (internal with LUA)

```
location = /ip {
    default_type text/html;
    content_by_lua '
        ngx.say("<html><head><title>Current IP Check</title></head><body>Current IP␣
↪Address: ")
        ngx.say(ngx.var.remote_addr)
        ngx.say("</body></html>")
    ';
}
```

PHP

```
<html>
     <head>
             <title>Current IP Check</title>
     </head>
     <body>
             Current IP Address: <?=$_SERVER['REMOTE_ADDR']?>
     </body>
</html>
```

22.8 SNMP

The Simple Network Management Protocol (SNMP) daemon enables remote monitoring of certain pfSense® software parameters. The SNMP daemon supports monitoring network traffic, network flows, pf queues, and general system information such as CPU, memory, and disk usage.

The SNMP implementation is bsnmpd, which by default only has the most basic management information bases (MIBs) available, and is extended by loadable modules. In addition to acting as an SNMP daemon, it can also send traps to an SNMP server for certain events. These vary based on the modules loaded. For example, network link state changes will generate a trap if the MIB II module is loaded.

The SNMP service can be configured by navigating to **Services > SNMP**.

The easiest way to see the available data is to run `snmpwalk` against the firewall from another host with `net-snmp` or an equivalent package installed. The full contents of the MIBs available are beyond the scope of this documentation, but there are plenty of print and online resources for SNMP, and some of the MIB trees are covered in RFCs. For example, the Host Resources MIB is defined by RFC 2790.

See also:

The Hangouts Archive contains a video which covers monitoring via SNMP.

22.8.1 SNMP Daemon

These options dictate if, and how, the SNMP daemon will run.

Enable
Controls whether or not the SNMP daemon will run.

Polling Port
SNMP connections are made using only UDP, and SNMP clients default to using UDP port 161. This setting controls which port the SNMP daemon uses when listening for client queries.

SNMP clients and/or polling agents must be set to match this value.

System location
A string to return when an SNMP client requests the system location.

Any text may be used here. For some devices a city or state may be close enough, while others may need more specific detail such as which rack and position in which the system resides.

System contact
A string defining contact information for the system. It can be a name, an e-mail address, a phone number, or whatever is needed.

Read Community String
With SNMP, the community string acts as a kind of username and password in one. SNMP clients will need to use this community string when polling.

Tip: The default value of `public` is common, so the best practice is to use a different value in addition to restricting access to the SNMP service with firewall rules.

22.8.2 SNMP Traps

Controls SNMP Trap behavior.

Enable
When set, the SNMP daemon will generate SNMP traps. Additionally, when set, the GUI displays options to control SNMP trap behavior.

Trap server
The hostname or IP address to which the SNMP daemon will forward SNMP traps.

Trap server port
The port on which the trap server is listening for traps.

By default, SNMP traps are set on UDP port `162`. If the SNMP trap server is set for a different port, adjust this setting to match.

SNMP trap string
The SNMP daemon sends this string along with any SNMP trap.

22.8.3 Modules

Loadable modules allow the SNMP daemon to understand and respond to queries for additional system information. Each loaded module consumes additional resources. As such, ensure that only required modules are loaded.

MibII
: This module provides information specified in the standard MIB II tree, which covers networking information and interfaces. Having this module loaded will provide network interface information including status, hardware and IP addresses, the amount of data transmitted and received, and much more.

Netgraph
: The netgraph module provides netgraph-related information such as netgraph node names and statuses, hook peers, and errors.

PF
: The PF module provides a wealth of information about the `pf` packet filter. The MIB tree covers aspects of the ruleset, states, interfaces, tables, and ALTQ queues.

Host Resources
: This module provides information about the host itself. This includes uptime, load average and processes, storage types and usage, attached system devices, and even installed software.

Note: This module requires MibII. If MibII is unchecked when this option is checked, MibII will be checked automatically.

UCD
: This module provides various system information knows as the `ucdavis` MIB, or UCD-SNMP-MIB. It provides information about memory usage, disk usage, running programs, and more.

Regex
: The Regex module is reserved for future use or use by users customizing the code to their needs. It allows creating SNMP counters from log files or other text files.

22.8.4 Interface Binding

Binding to a specific local interface can ease communication over VPN tunnels as it eliminates the need for *workarounds like static routes*. It also provides extra security by not exposing the service to other interfaces. It can also improve communication over multiple local interfaces, since the SNMP daemon will reply from the "closest" address to a source IP address and not the IP address to which a client sent its query.

Internet Protocol
: This controls whether the SNMP daemon will listen for queries on IPv4, IPv6, or both.

Bind Interfaces
: This option configures the SNMP daemon to listen only on the chosen interface or virtual IP address. All interfaces with IP addresses, CARP VIPs, and IP Alias VIPs are displayed in the drop-down list.

22.9 UPnP IGD & PCP

Universal Plug and Play Internet Gateway Device (UPnP IGD) and *Port Control Protocol* (PCP) are network protocols which allow local software and devices to configure each other when attaching to a network. This includes autonomously creating dynamic NAT rules to redirect and pass incoming connections from remote hosts.

Note: PCP is the successor to NAT Port Mapping Protocol (NAT-PMP) and is compatible with clients using NAT-PMP.

The UPnP IGD & PCP service, located at **Services > UPnP IGD & PCP**, enables client devices such as computers and game consoles to autonomously allow required inbound traffic and can account for outbound NAT on traffic using the same ports. There are many popular programs and platforms which support UPnP IGD & PCP, such as Steam/Steam Deck, Nintendo consoles, PlayStation consoles, XBox consoles, video conferencing apps, torrent clients, and more. PCP is supported primarily by Apple products but can also be found in other applications and devices.

See also:

For advice on specific consoles and games, see *Configuring pfSense Software for Online Gaming*.

22.9.1 UPnP IGD & PCP Service Ports

The UPnP IGD daemon used by pfSense® software, `miniupnpd`, uses several ports to communicate with clients. UPnP IGD employs the Simple Service Discovery Protocol (SSDP) for network discovery, which uses UDP port `1900`. PCP uses UDP port `5351`. The daemon also uses TCP port `2189` for HTTP and SOAP queries.

Table 1: UPnP IGD & PCP Ports

Protocol	Port	Service
UDP	1900	SSDP
TCP	2189	HTTP/SOAP
UDP	5351	PCP

When using a strict LAN firewall ruleset, manually add rules to allow access to these services, especially if the default LAN-to-any rule has been removed, or in bridge configurations.

22.9.2 UPnP IGD & PCP with IPv6

As of this writing, the UPnP IGD & PCP service on current versions of pfSense software supports IPv6, but client support is still rare.

Note: IPv6 UPnP IGD & PCP client traffic will almost always require manual rules to pass. Clients are likely to use a link-local source going to a multicast destination, which is not covered by the default interface rules.

22.9.3 Security Concerns

UPnP IGD & PCP are a classic example of the "Security vs. Convenience" trade-off. By their very nature, these services are insecure. Any program on the network can allow in and forward any traffic – a potential security nightmare. On the other side, it can be a chore to enter and maintain NAT port forwards and their associated rules, especially when it comes to game consoles. There is a lot of guesswork and research involved to find the proper ports and settings, but UPnP IGD & PCP *just works* and requires little administrative effort. Manual port forwards to accommodate these scenarios tend to be overly permissive, potentially exposing services that should not be open from the Internet. Manual port forwards are also always enabled, where UPnP IGD & PCP rules may be temporary.

Access controls in the UPnP IGD & PCP service configuration can lock down which devices are allowed to make port mappings and for which ports. Over and above the built-in access controls, further control may be exerted with firewall rules. When properly controlled, UPnP IGD & PCP can also be a little more secure by allowing programs to pick and listen on random ports, instead of always having the same port open and forwarded.

22.9.4 Configuration Options

Service Settings

Enable port mapping service
: Master control for the entire UPnP IGD & PCP daemon. Also requires enabling one or both of the UPnP IGD or PCP/NAT-PMP protocols.

  When unchecked, all of the services on this page are disabled.

Allow UPnP IGD Port Mapping
: When checked, the service enables support for client requests using Universal Plug and Play Internet Gateway Device (UPnP IGD).

Allow PCP/NAT-PMP Port Mapping
: When checked, the service enables support for client requests using Port Control Protocol (PCP) and client requests using PCP-compatible protocols, such as the older NAT-PMP standard.

External Interface
: The interface for **outgoing** traffic. This must be set to the single WAN containing the default gateway.

Internal Interfaces
: The **local** interfaces where clients allowed to use UPnP IGD & PCP reside. Multiple interfaces may be selected.

Note: When using a bridge configuration, only select the bridge interface with an IP address.

External Address Settings

Port mapping with the UPnP IGD & PCP service requires a routable public IP address capable of receiving incoming connections from remote hosts. If this device is behind NAT, port forwarding may still be possible provided the upstream router can forward traffic using an additional layer of NAT.

As the public address is key to its operation, the UPnP IGD & PCP port mapping service **must** be able to locate its routable public IP address or it will refuse to allow port mapping.

If the **External Interface** has a public IP address, the settings in this section may be left empty or disabled (default) since the service can recognize that the interface address is public. If the interface has a private address, the service will refuse to map any ports without additional configuration.

If the **External Interface** is behind unrestricted NAT (e.g. 1:1 NAT), and the upstream router forwards incoming traffic to this device without any filtering, this service can still function so long as it can locate the correct public IP address.

The service can learn the public IP address and NAT type using an external server via the STUN protocol or if the address is static it can be hard-coded using the **Override WAN Address** setting.

Enable STUN
Enables retrieving the external IP address from a remote STUN server. When checked, the service will query an external STUN server to locate the routable public IP address for the external interface. This also tests inbound NAT connectivity to ensure forwarded traffic is delivered to this device.

This is useful for devices behind 1:1 NAT with a dynamic public address.

> **Warning:** The service will disable port mapping if NAT testing determines inbound connections are not being forwarded to this device.

STUN Server
The hostname or IP address of a remote STUN server.

There are public STUN servers available, including:

- `stun.counterpath.com`
- `stun.cloudflare.com`

STUN Port
The UDP port on which the STUN server is listening for client connections. The default port number is `3478`.

Override WAN Address
This option manually configures a public routable IP address this device can use to accept inbound connections.

This address can be an upstream static routable IP address with traffic forwarded to this device via NAT, or it can be an alternate routable IP address on this device, such as a virtual IP address.

Advanced Settings

Download Speed
Value to report when clients query the maximum link download speed, specified in Kbit/s.

The default value is the link speed of the interface.

Upload Speed
Value to report when clients query the maximum link upload speed, specified in Kbit/s.

The default value is the link speed of the interface.

Traffic Shaping
The name of an ALTQ (not Limiter) traffic shaping queue in which the firewall will place traffic passed by rules created via UPnP IGD & PCP.

Note: Exercise caution when selecting this queue. UPnP IGD & PCP can by used by traffic such as game consoles, which need high priority, and also by file transfer clients which may need low priority.

Custom Presentation URL
A custom URL this daemon presents to UPnP IGD & PCP clients who click this device when listing devices on the local network. For example, when browsing the network in Windows Explorer.

When left blank, the daemon uses the URL of the GUI on this device.

Custom Model Number
A custom model number presented to clients who click this device when listing devices on the local network. For example, when browsing the network in Windows Explorer.

When left blank, the daemon uses the current firmware version of this device.

Firewall Logs
When checked, rule generated by UPnP IGD & PCP will be set to log, so each connection matching these rules will appear in the firewall logs.

Note: The firewall logs can be viewed at **Status > System Logs**, on the **Firewall** tab.

Uptime
By default, the UPnP IGD & PCP daemon reports the service uptime when queried rather than the system uptime. Checking this option will cause it to report the system uptime (since last boot) instead.

Service Access Control Lists

Default Deny
When checked, UPnP IGD & PCP only allows access to client requests matching configured access control lists. This is a more secure method of controlling the service, but as discussed above, is also less convenient.

ACL Entries
ACL entries grant or deny access to the port mapping service based on several criteria.

> **Warning:** These entries only control access for IPv4 clients, they do not apply to IPv6 clients.

Rules are formulated using the following format:

```
<[allow|deny]> <[external port|range]> <[internal IP|IP/CIDR]> <[internal␣
↪port|range]>
```

Click  **Add** to create additional rules.

Note: If the **Default Deny** option is enabled, rules must be set to allow access.

UPnP IGD & PCP User Permission Examples

Deny access to external port `80` forwarding from everything on the LAN, `192.168.1.0`, with a `/24` subnet, to local port `80`:

```
deny 80 192.168.1.0/24 80
```

Allow `192.168.1.10` to forward any unprivileged port:

```
allow 1024-65535 192.168.1.10 1024-65535
```

22.9.5 Configuration Procedure

To configure UPnP IGD & PCP:

- Navigate to **Services > UPnP IGD & PCP**
- Configure the options as needed
- Click **Save**

The UPnP IGD & PCP service will be started automatically.

22.9.6 UPnP IGD & PCP Status

To view a list of currently forwarded ports and clients, navigate to **Status > UPnP IGD & PCP**. The output will be similar to *UPnP IGD & PCP Status Screen Showing Client PCs With Forwarded Ports*.

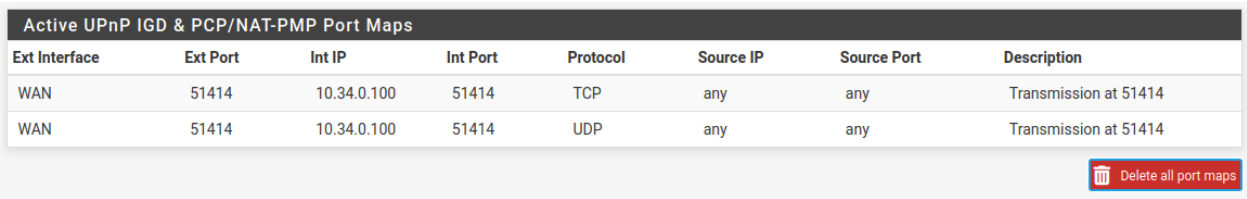

Fig. 1: UPnP IGD & PCP Status Screen Showing Client PCs With Forwarded Ports

View the status of the UPnP IGD & PCP daemon at **Status > Services**. The Service Status page shows if the daemon is running or stopped, and allows the service to be stopped, started or restarted. Under normal circumstances, manually managing the daemon is not necessary.

22.9.7 Troubleshooting

Most issues with UPnP IGD & PCP tend to involve clients not being able to communicate with the service. It is important to have firewall rules allow UPnP IGD traffic on UDP port `1900`. Since UPnP IGD uses multicast traffic, the destination will be the broadcast address for the subnet, or in some cases a destination of *any* will be necessary.

Note: For IPv6, it's important to note that the traffic will almost always require manual rules to pass the traffic. Clients are likely to use a link-local source going to a multicast destination. That source is not covered by the default interface rules.

Consult the firewall logs at **Status > System Logs**, on the **Firewall** tab to see if traffic is being blocked. Pay particular attention to the destination address, as it may be different than expected.

Further trouble with game consoles may also be alleviated by switching to manual outbound NAT and enabling Static Port. See *Static Port* for more details.

If the WAN does not have a public address, or if the STUN NAT test fails, the service can fail to add NAT mappings when clients make requests. The routing log will contain messages such as `Failed to add`. The routing log also contains other messages from the daemon at startup indicating these test results.

See also:

For advice on specific consoles and games, see *Configuring pfSense Software for Online Gaming*.

22.10 NTPD

The NTP service is a Network Time Protocol (NTP) daemon which will listen for requests from clients and allow them to synchronize their clock with that of a firewall running pfSense® software. By running a local NTP server and using it for local clients, it reduces the load on the lower-stratum servers and can ensure that local systems can always reach a time server. Before delegating this task to a firewall running pfSense, the best practice is to ensure that the firewall has an accurate clock and keeps time reasonably.

22.10.1 Clock Bootstrap Behavior

The firewall bootstraps its clock at boot in two ways and the firewall performs both of these actions once per boot before it starts the NTP daemon.

- The firewall checks a few commonly modified files on the filesystem and sets the clock to whichever value is latest if it's also later than the clock. This action is taken early in the boot process just after the firewall has mounted its filesystems.

  This ensures that the clock is set to a reasonably close value to current so long as the firewall has been active recently. This works even if there is no network connection available at boot time. The longer it has been since the firewall was last active, the less accurate this method becomes.

- The firewall performs a one-time sync to multiple NTP servers with static IP addresses from Google Public NTP. This avoids a chicken-and-egg problem where the firewall cannot resolve NTP servers because DNSSEC, which is enabled by default, cannot function when the clock is inaccurate. This happens much later in the boot process because it cannot be performed until after the firewall has configured its interfaces and routing.

  This gets the clock as close to accurate as possible without a persistent NTP daemon. There is a hard timeout of 30 seconds in case the upstream servers are unreachable.

Changing Clock Bootstrap Behavior

The NTP clock bootstrap behavior can easily be disabled or changed if an administrator does not want a firewall to contact the default list of servers.

To disable the bootstrap, create the file `/conf/ntp-boot-time-servers` as an empty file. If the file exists and is empty the firewall will skip the initial sync.

To use alternate servers, create the file `/conf/ntp-boot-time-servers` and add in one or more **IP addresses** separated by a single space each. If this file contains a list of space-separated IP addresses, the firewall will use those for the bootstrap sync instead.

22.10.2 NTP Server Configuration

The NTP server is located in the GUI at **Services > NTP**.

NTP Server Settings

The NTP server has the following options:

Interface
Select the interface(s) to use for NTP. The NTP daemon binds to all interfaces by default to receive replies properly. This may be minimized by selecting at least one interface to bind, but that interface will also be used to source the NTP queries sent out to remote servers, not only to serve clients. Deselecting all interfaces is the equivalent of selecting all interfaces.

Time Servers
A list of servers to query in order to keep the clock of this firewall synchronized. This list is initially pulled from the entries under **System > General Setup**. For best results, the best practice is to use at least three servers, but no more than five. Click  **Add** to configured additional time servers.

Prefer
When checked, this NTP server entry is favored by the NTP daemon over others.

No Select
When checked, this NTP server is not used for time synchronization, but only to display statistics.

Orphan Mode
Orphan mode uses the system clock when no other clocks are available, otherwise clients will not receive a response when other servers are unreachable. The value entered here is the stratum used for **Orphan Mode**, and is typically set high enough that live servers are preferred. The default value is `12`.

NTP Graphs
Check to enable RRD graphs for NTP server statistics.

Logging
When logging options are active, NTP logs are written using syslog and may be found under **Status > System Logs**, on the **NTP** tab.

Log Peer Messages
When checked, NTP will log messages about peer events, information, and status.

Log System Messages
When checked, NTP will log messages about system events, information, and status.

Statistics Logging

Click  **Show Advanced** to view these options. When enabled, NTP will create persistent daily log files in `/var/log/ntp` to keep statistics data. The format of the statistics records in the log files can be found in the ntp.conf man page

Log reference clock statistics
When checked, NTP records clock driver statistics on each update.

Log clock discipline statistics
When checked, NTP records loop filter statistics on each update of the local clock.

Log NTP Peer Statistics
When checked, NTP records statistics for all peers of the NTP daemon, along with special signals.

Leap Seconds

Click **Show Advanced** to view these options. Defines the contents of the Leap Second file, used by NTP to announce upcoming leap seconds to clients. This is typically used only by stratum 1 servers. The exact format of the file may be found on the IETF leap second list

Access Restrictions

Access restrictions (ACLs) are configured on the **ACL** tab under **Services > NTP**. These ACLs control how NTP interacts with clients.

Default Access Restrictions
Control behavior for all clients by default.

Kiss-o'-Death
When set, NTP will send a KoD packet when an access violation occurs. Such packets are rate limited and no more than one per second will be sent.

Modifications
When set, `ntpq` and `ntpdc` queries that attempt to change the configuration of the server are denied, but informational queries are returned.

Queries
When set, all queries from `ntpq` and `ntpdc` are denied.

> **Warning:** Setting this will effectively disable the NTP status page, which relies on `ntpq`.

Service
When set, NTP will deny all packets except queries from `ntpq` and `ntpdc`.

Peer Association
When set, NTP denies packets that would result in a new peer association, including broadcast and symmetric active packets for peers without an existing association.

Trap Service
When set, NTP will not provide mode 6 control message trap service, used for remote event logging.

Custom Access Restrictions

Defines the behavior for specific client addresses or subnets. Click **Add** to add a new network definition.

Network/mask
The subnet and mask to define the client controlled by the restrictions in this entry.

Restrictions
The option names are abbreviated versions of those in the default list, in the same order.

22.10.3 Serial GPS

If this firewall has an available serial port, a Serial GPS may be used to provide a reference clock for the firewall. If the GPS also supports a Pulse Per Second (PPS) signal, that may also be used as a PPS clock reference.

> **Warning:** USB GPS units may function, they are not desirable time sources due to USB timing issues. The overhead of USB makes its unreliable as a clock or timing source.

For best results, the best practice is to configure at least three NTP servers under **System > General Setup** or **Services > NTP** to avoid loss of sync if the GPS data is not valid over time. Otherwise the NTP daemon may only use values from the unsynchronized local clock when providing time to clients.

Serial GPS Settings

GPS Type
Select the make and model of the GPS unit. If the model is unknown, use the *Default* choice. If the model is known but not listed, use *Custom*.

Serial Port
All serial ports detected on the firewall are listed. Select the port with the GPS attached. On-board hardware serial ports start with `cuau`, USB serial ports are prefixed with `cuaU`.

Baud Rate
Enter the serial speed for the GPS, typically a low value such as `4800`

NMEA Sentences
By default, NTP will listen for all supported NMEA sentences. To limit this to specific types, select them from the list.

Fudge Time 1
Specifies a constant to be added to the GPS PPS signal as an offset.

Fudge Time 2
Specifies a constant to be added to the GPS time as an offset.

Stratum
Used to configure the stratum of the GPS clock. The default value is `0` so the GPS is preferred over all others. If another clock must be preferred instead, set the stratum value higher than the stratum of the preferred clock.

Flags
These options provide additional tweaks to fine-tune the GPS behavior:

Prefer this clock
Marks the reference clock as preferred by NTP.

Do not use this clock
Prevents the clock from being used by NTP for time synchronization, it is only displayed for reference.

PPS signal processing
Enables processing of the Pulse Per Second (PPS) signal in the GPS driver. Only enable this if the GPS is known to output a usable PPS signal.

Falling edge PPS signal processing
When set, the falling edge of the PPS signal is used for timing, rather than the rising edge.

Kernel PPS clock discipline
When set, the OS Kernel will use PPS directly for timing.

Obscure location in timestamp
Obscures the GPS data so the location of the clock cannot be determined.

Log the sub-second fraction of the received time stamp
When checked, this can rapidly fill the log, but can be useful for fine tuning of **Fudge Time 2**.

Clock ID
A 1-4 character identifier used to change the GPS Clock ID. The default value is `GPS`.

GPS Initialization
Contains the initialization string sent to the GPS at start up to configure its behavior. When using the *Custom* GPS type, a proper initialization string for the GPS must be entered manually.

NMEA Checksum Calculator
Calculates a checksum for use when crafting new **GPS Initialization** values or adjusting existing values.

Configuring a Serial GPS

To configure a GPS for use by NTP:

- Navigate to **Services > NTP**
- Click the **Serial GPS** tab
- Configure the settings
- Click **Save**

22.10.4 PPS Source (Non-GPS)

A non-GPS PPS Source, such as a radio, may also be used for clock timing. It cannot be used for synchronization since there is no time data, but it can be used to ensure a clock ticks accurately.

PPS Source Settings

Serial Port
All serial ports detected on the firewall are listed. Select the port with the GPS attached. On-board hardware serial ports start with `cuau`, USB serial ports are prefixed with `cuaU`.

Fudge Time 1
Specifies a constant to be added to the PPS signal as an offset, to account for delay between the transmitter and receiver.

Stratum
Used to configure the stratum of the PPS source. The default value is `0` so the PPS source is preferred over all others. If another clock must be preferred instead, set the stratum value higher than the stratum of the preferred clock.

Flags

Falling edge PPS signal processing
When set, the falling edge of the PPS signal is used for timing, rather than the rising edge.

Kernel PPS clock discipline
When set, the OS Kernel will use PPS directly for timing.

Record a timestamp
Record a timestamp once for each second, which is useful for constructing Allan deviation plots.

Clock ID
A 1-4 character identifier used to change the PPS Clock ID. The default value is PPS.

Configure a PPS Source

To configure a Non-GPS PPS source:

- Navigate to **Services > NTP**
- Click the **PPS** tab
- Configure the settings
- Click **Save**

See also:

- *NTP Daemon Status*

22.11 Wake on LAN

The Wake on LAN (WOL) page at **Services > Wake on LAN** can wake up computers from a powered-off state by sending special "Magic Packets".

The network interface card in the client computer that is to be woken up must support WOL and it must be configured properly. Typically there is a BIOS setting to enable WOL, and non-integrated adapters often require a WOL cable connected between the NIC and a WOL header on the motherboard.

WOL has many potential uses. Typically, workstations and servers are kept running because of services they provide, files or printers they share, or for convenience. Using WOL would allow these to remain in a sleep state to conserve power. When a service is required, the system can be woken up when needed. Another example would be if someone needs remote access to a system, but the user shut it down before leaving the office. Using WOL the target system can be awoken, and it may then be accessed once it has booted.

Warning: WOL offers no inherent security. Any system on the same layer 2 network may transmit a WOL packet, and the packet will be accepted and obeyed. It is best to only configure WOL in the BIOS for machines that need it, and disable it in all others. There are some vendor-specific WOL extensions that provide extra security, but nothing universally supported.

22.11.1 Wake Up a Single Machine

To wake up a single machine:

- Navigate to **Services > Wake on LAN**
- Set the options as follows:

  Interface
  The interface through which the firewall can reach the target host.

  MAC Address
  The **MAC address** of the target host in the format `xx:xx:xx:xx:xx:xx`.

- Click **Send**

pfSense® software will transmit a WOL Magic Packet out the chosen interface, and if everything went as planned, the system will power on and start to boot. Keep in mind that systems will take some time to boot. It may be several minutes before the target system is available.

22.11.2 Storing MAC Addresses

To store a MAC address for convenience:

- Navigate to **Services > Wake on LAN**
- Click  **Add** under the list of stored MAC addresses to add a new entry
- Configure the entry as follows:

  Interface
  The interface through which the firewall can reach the target host.

  MAC Address
  The **MAC address** of the target host in the format `xx:xx:xx:xx:xx:xx`.

  Description
  Text describing the entry, such as the target system hostname, owner, or location. For example: "Pat's PC" or "Sue's Server"

- Click **Save**

Once saved, the entry will be available on the list at **Services > Wake on LAN**.

Maintaining the entries is similar to other tasks in pfSense: Click  to edit an existing entry, and click  to remove an entry.

22.11.3 Wake a Single Stored Machine

To send a WOL Magic Packet to a system that has been previously stored:

- Navigate to **Services > Wake on LAN**
- Locate the desired entry in the list
- Click the **MAC address** or the  icon in the **Actions** column

The WOL page will reload, and the Magic Packet will be sent. The status of the WOL attempt will also be displayed.

22.11.4 Wake All Stored Machines

To send a WOL Magic Packet to all stored systems at once:

- Navigate to **Services > Wake on LAN**
- Click  **Wake All Devices** under the list of stored addresses.

22.11.5 Wake from DHCP Leases View

To send a WOL Magic Packet from the DHCP Leases view:

- Navigate to **Status > DHCP Leases**
- Locate the desired system in the list
- Click  at the end of the lease row to send a WOL Magic Packet

---

Note: The WOL function is only available for systems marked **offline**, meaning they are not in the ARP table on the firewall. If a system was very recently powered off, it can take a few minutes for the ARP entry to expire before it will be marked offline.

If a system has been powered off for quite some time, clicking  **Show all configured leases** might be required to see the previous lease.

When the link is clicked, the browser will return to the WOL page, and the Magic Packet will be sent.

22.11.6 Save from DHCP Leases View

A MAC address and hostname may be copied to a new WOL mapping entry while viewing the DHCP leases.

- Navigate to **Status > DHCP Leases**
- Locate the desired system in the list
- Click  at the end of lease entry
- Confirm the values on the page, and enter any missing information.
- Click **Save**

22.12 PPPoE Server

pfSense® software can act as a PPPoE server, accepting and authenticating connections from PPPoE clients on a local interface, in the role of an access concentrator (LAC). This feature can be used to force users to authenticate before gaining network access, or otherwise control their login behavior.

The PPPoE Server is located at **Services > PPPoE Server**.

22.12.1 PPPoE Server Settings

The PPPoE Server page has several options, which fall into multiple categories.

Server Settings

These options control the general behavior of the PPPoE Server.

Enable
When checked, this PPPoE Server instance will be active.

Interface
The single interface upon which PPPoE service will be available.

Total User Count
Determines how many clients in total are allowed to connect to this instance.

User Max Logins
Determines how many times a single client may login concurrently.

Server Address
The IP address which the firewall will send to the PPPoE clients to use as their gateway.

> **Warning:** This IP address **must not** be an IP address currently in use on the firewall.

Remote Address Range
The IP address for the start of the PPPoE client subnet. Together with the Subnet Mask it defines the network used by the PPPoE clients.

Subnet Mask
Defines the CIDR mask assigned to PPPoE clients.

Description
Optional explanatory text for this server instance.

DNS Servers
Optional fields used to send specific DNS servers to the PPPoE clients, otherwise the firewall IP address will be sent to the client for DNS if the DNS Forwarder or DNS Resolver are enabled. If the DNS Forwarder and DNS Resolver are both disabled, then the DNS servers configured on the firewall will be sent instead.

RADIUS Settings

These options configure RADIUS authentication for the server.

Use RADIUS Authentication
Check to configure the PPPoE server to use at least one RADIUS server for Authentication instead of local users.

Use RADIUS Accounting
Optional, sends RADIUS accounting data to the RADIUS server to note items such as login and logout times, and bandwidth used.

Use a Backup RADIUS Authentication Server
A second RADIUS server to use if the primary RADIUS server fails.

NAS IP Address
Optional, sends a specific IP address to the RADIUS server for the NAS-IP-Address attribute.

RADIUS Accounting Update
The interval at which accounting data is sent to the RADIUS server, in seconds.

RADIUS Issued IP Addresses
When checked, IP addresses can be assigned to users via RADIUS reply attributes.

Primary RADIUS Server
The preferred RADIUS server to use for Authentication.

IP Address
The IP address of the RADIUS server.

Authentication Port
The port used for authentication (typically `1812`).

Accounting Port
The port used for accounting data (typically `1813`).

Primary RADIUS Server Shared Secret
The shared secret configured for this firewall on the RADIUS server. The same value must be entered in the Confirm box.

Secondary RADIUS Server
Same type of settings as the primary, but defines the secondary RADIUS server.

Users

The user list defines account credentials the server will allow when not using RADIUS authentication.

Username
The username for the user account.

Password
The password for the user account.

IP Address
An optional static IP address to assign the user at login.

22.12.2 PPPoE Server Configuration

Multiple PPPoE servers may be configured on separate interfaces. Each of the available options are covered above.

To begin setting up a PPPoE server:

- Navigate to **Services > PPPoE Server**
- Click  **Add** to add a new server entry
- Configure the PPPoE Server settings
- Choose an authentication source, either RADIUS or manually defined users
  - Configure **RADIUS** if that will be utilized for user authentication
  - Add users to the server to utilize local authentication if not using RADIUS
    - Click  **Add User**
    - Fill in the credentials and settings for the user.
    - Repeat as needed
- Click **Save**

22.13 IGMP Proxy

The Internet Group Management Protocol (IGMP) Proxy provides a means to proxy multicast traffic between network segments.

The IGMP Proxy service can be found at **Services > IGMP Proxy**.

22.13.1 IGMP Proxy Settings

The IGMP Proxy service has the following settings:

Interface
The interface to be used for this instance

Description
Optional text to describe this instance

Type
The type of network interface defined by this instance

Upstream Interface
The outgoing interface which is responsible for communicating to available multicast data **sources**. There can only be **one** upstream interface.

Downstream Interface
The distribution interfaces to the **destination** networks, where multicast **clients** can join groups and receive multicast data. One or more downstream interfaces must be configured.

Note: For a working IGMP Proxy configuration, one upstream and at least one downstream interface must be defined.

Threshold
The TTL threshold for forwarded data on an interface, to prevent looping from occurring. Packets with a TTL lower than the value in this field will be ignored. The default TTL is 1 if the field is left blank.

Networks
A list of CIDR-masked Network entries to control what subnets are allowed to have their multicast data proxied. Click  **Add Network** to enter additional networks.

22.13.2 IGMP Proxy Configuration

To configure the IGMP Proxy:

- Navigate to **Services > IGMP Proxy**
- Click  **Add** to create a new interface instance
- Configure the instance
- Click **Save**

IGMP requires a firewall rule on the **Downstream** side (e.g. *LAN*) to pass its multicast traffic. In the *Advanced Options* of the firewall rule, **Allow packets with IP Options** must be enabled.

The base install of pfSense® software includes services which add fundamental functionality and flexibility to the firewall. The topics in this chapter discuss services in the base installation that the firewall provides for other hosts on the network. These services include allocating IPv4 and IPv6 addresses via DHCP, DNS resolution and Dynamic DNS, SNMP, UPnP and more. Additional services can also be added with packages.

CHAPTER

TWENTYTHREE

DHCP

Dynamic Host Configuration Protocol (DHCP), allows a device such as pfSense® software to dynamically allocate IP addresses to clients from predefined pools of addresses. DHCP also sends configuration information to clients such as a gateway, DNS servers, domain name, and other useful settings.

There are currently two available DHCP backends: Kea DHCP and ISC DHCP. Kea is more modern and well supported, but not fully implemented yet. ISC DHCP is deprecated but contains functionality not yet implemented in Kea. The backend can be changed under **System > Advanced**, **Networking** tab (*Server Backend*).

23.1 Kea Settings Tab

When using the Kea DHCP backend (*Server Backend*) there is a **Settings** tab with global options to control DHCP server behavior not specific to a given interface.

Note: Currently there are separate pages for DHCPv4 and DHCPv6 and they operate independently, but the options on each page are identical otherwise. Differences between DHCPv4 and DHCPv6, if any, are noted when appropriate.

23.1.1 General Settings

DHCP Client DNS Registration with the DNS Resolver

The DNS Registration options control the default Kea behavior for registering DHCP client hostnames with the *DNS Resolver* so that other clients using this firewall for DNS resolution can resolve these hostnames.

This implementation with Kea works with both DHCPv4 and DHCPv6 client lease data.

Note: When using the Kea DHCP daemon, pfSense software dynamically updates these hostnames with the DNS Resolver without restarting the daemon. DNS updates are seamless and not disruptive, unlike the previous implementation with the ISC DHCP daemon.

Kea DNS Registration also respects the domain name configured in DHCP settings for an interface or static mapping. If no domain is set in the DHCP lease, it falls back to checking for a search domain or, as a last resort, the domain name configured on the firewall.

DNS updates are also kept up-to-date between High Availability failover peers.

DNS Registration
: Controls the default DNS Registration behavior on all interfaces with DHCP enabled. When checked,

Kea will automatically register hostnames from DHCP leases on all interfaces with the DNS Resolver by default.

The setting can be overridden on a per-interface basis in either direction. This allows selectively enabling or disabling DNS Registration for specific interfaces as needed.

Early DNS Registration
Controls whether or not Kea will register hostnames from DHCP static mappings with the DNS Resolver at startup by default. The setting can be overridden on a per-interface basis in either direction.

When unchecked, Kea does not register the hostname until the client requests a DHCP lease.

With this setting enabled a client does not need to have DHCP enabled for its hostname to be available via the DNS Resolver. This was the default behavior of the ISC DHCP daemon when it performed DNS registration.

23.1.2 High Availability

The **High Availability** section of the page configures the daemon for high availability failover with a peer. This operates in "Hot Standby" mode where one node hands out addresses and they both share lease data while monitoring the other peer. If the active primary node becomes unresponsive, the standby node will take over handing out leases to clients. As the two nodes share lease data, failover is seamless and clients can obtain addresses so long as one of the two nodes is online and functional.

Note: Most of these settings will synchronize via XMLRPC configuration synchronization, except for the TLS Transport options which are per-node options and do not synchronize.

The **High Availability** section contains the following options:

Enable
When checked, enables hot-standby high availability (HA) for Kea DHCP services.

Node Role
Chooses the role for this node when performing high availability.

Primary
This node will serve leases for clients when both nodes are online and functioning properly.

Standby
This node will only serve leases when the primary node is down.

Local Name
The name of this device, such as its hostname.

Local Address
The IP address of this node upon which it will listen for failover data from the peer.

Note: This is typically the local IP address on the Sync interface.

The address family of this IP address does not need to match the address family of the DHCP service. Both DHCPv4 and DHCPv6 can exchange HA data with IPv4 or IPv6 peers.

Remote Name
The name of the remote peer, such as its hostname.

Remote Address
The IP address where the remote peer is listening for failover data from this node.

Note: This is typically the IP address of the Sync interface on the peer.

The address family of this IP address does not need to match the address family of the DHCP service. Both DHCPv4 and DHCPv6 can exchange HA data with IPv4 or IPv6 peers.

When these settings synchronize via XMLRPC configuration synchronization, the values are swapped – the secondary node is configured with the opposite settings so it will have appropriate settings from its frame of reference.

Advanced Options

Heartbeat Delay
Specifies a duration in milliseconds between sending the last heartbeat and the next heartbeat. Default value is `10000` (10 seconds).

The heartbeats are sent periodically to gather the status of the partner and to verify whether the partner is still operating.

Max Response Delay
Specifies a duration in milliseconds since the last successful communication with the partner, after which the server assumes that communication with the partner is interrupted. Default value is `60000` (60 seconds).

> **Warning:** This duration should be greater than the heartbeat delay.

Max Ack Delay
Specifies the maximum time in milliseconds for the client to try to communicate with the DHCP server, after which this server assumes that the client failed to communicate with the DHCP server (is "unacked"). Default value is `60000` (60 seconds).

Max Unacked Clients
Specifies how many unacknowledged clients are allowed before this server assumes that the partner is offline and transitions to the `partner-down` state. Default value is `0` (takes over immediately).

> **Warning:** Do not set this higher than the typical number of clients which would make a DHCP request in a short time frame. Otherwise clients can be left without an address until additional clients also fail to obtain addresses, which could be a significant amount of time on a small or quiet network. See *Secondary Does Not Enter partner-down State* for more details.

Max Rejected Updates
Specifies how many lease updates for distinct clients can fail, due to a conflict between the lease and the partner configuration or state, before the server transitions to the terminated state. Default value is `10`.

These settings synchronize as-is over XMLRPC configuration synchronization.

TLS Transport

Configures optional encryption and certificate-based authentication to protect the DHCP HA data exchanged between failover peers.

These settings **do not** synchronize over XMLRPC configuration synchronization.

Enable
When checked, enables TLS encryption for DHCP HA data requests. This encrypts the lease data and heartbeat traffic exchanged between the peers.

Server Certificate
The certificate to use for the local DHCP HA server.

Mutual TLS
When checked, configures the Kea HA client to send a client certificate which allows the peer to verify that it is communicating with the expected client.

This ensures that only authorized peers can communicate with the DHCP HA services.

Client Certificate
The client certificate which identifies this node.

23.1.3 Custom Configuration

The KEA GUI allows administrators to configure Kea directly with JSON-formatted configuration snippets. The Kea GUI in pfSense software does not support some features or options which are possible directly in Kea. As the Kea GUI develops further, the GUI will support more of these features. These snippets allow administrators more control in the meantime.

Tip: These snippets can be used to add functionality such as custom DHCP options, dynamic DNS registration, and fine-tune lease behavior.

These fields are present on each Kea page and the system adds the contents of each configuration snippet to a different section of the Kea configuration file based on the Kea configuration page:

Table 1: Kea Configuration Settings Sections by Page

Kea GUI Page	Kea Configuration Section
DHCPv4 Settings	`Dhcp4`
DHCPv6 Settings	`Dhcp6`
DHCPv4/v6 interfaces	`subnet`
DHCPv4/v6 Pools	`pool`
DHCPv4/v6 static mappings	`reservation`

Warning: These configuration fields must contain well-formed JSON objects and must not include the name of the section itself.

The system adds these snippets to the Kea configuration after the settings from the GUI for each section. So not only can these snippets enable new features, but they also allow administrators to modify or override the base configuration.

These configuration snippets are held in `config.xml`, so they are backed up and restored along with other Kea settings.

The system tests the configuration before attempting to start Kea. If the configuration test fails with the custom snippets, the system files a notice alerting administrators to the problem and then it attempts to start Kea without including the custom configuration snippets.

23.2 Using DHCP Search Domains on Windows DHCP Clients

The DNS Search Domain functionality present in the DHCP Server settings in pfSense® software is only supported by some DHCP clients; pfSense software uses the standard DHCP option `119` mechanism to deliver the search domains to clients which request them.

Support for Option `119` was finally added in Windows 10 version 1803 released in April 2018. Unfortunately, older versions of the Microsoft Windows DHCP client **do not support** requesting option `119`, so no matter which DHCP server is used, clients running older versions of Microsoft Windows can never receive or use a search domain list from DHCP. Upgrade clients to a supported release to use this functionality.

Tip: If older clients must use these settings and they cannot be upgraded, the setting can be pushed via GPO instead of DHCP.

23.3 Static Mappings Inside DHCP Pools

While the ISC DHCP daemon will allow a static mapping to be defined inside the DHCP range/pool in its configuration, doing so can result in unexpected behavior.

A static mapping entry in the ISC DHCP daemon **is not** a reservation and it **does not** remove that IP address from the pool. The daemon only checks via ICMP ping to ensure that an IP address is not actively in use when making assignments. The static mapping only represents a *preference* for IP address assignment and it **does not** prevent the daemon from assigning the IP address to other client devices when it is not actively in use by the intended device defined in the static mapping.

Example: The DHCP configuration contains a pool from `192.168.0.10` to `192.168.0.250` with a static mapping defined for `192.168.0.25`. If the device which normally has `192.168.0.25` is ever offline another device could be assigned `192.168.0.25` in its absence. When the original client device reconnects it will not be able to get `192.168.0.25` because it is currently in use, and will instead receive another random address from the pool.

Due to this behavior the best practice is to **only** make assignments **outside** the range/pool and the GUI enforces this practice.

If a use case requires assignments inside the pool and the administrators do not care about the risks involved and want to do so anyway, the input validation check can be removed from the PHP file that drives the DHCP editor page. The details of this unsupported change will not be covered in documentation.

CHAPTER

TWENTYFOUR

DNS

DNS, or Domain Name System, is the mechanism by which a network device resolves a name like `www.example.com` to an IP address such as `198.51.100.25`, or vice versa. Clients must have functional DNS if they are to reach other devices such as servers using their hostnames or fully qualified domain names.

24.1 DNS Resolver/Forwarder

These topics cover using pfSense® software to handle DNS requests from local clients as either a caching DNS resolver or forwarder. When acting as a resolver or forwarder, pfSense software will performs DNS resolution directly or hand off queries to an upstream DNS forwarding server.

24.1.1 DNS Resolution Process

Every DNS query must be resolved. Depending on which DNS service is in use on the firewall and its configuration, this resolution may happen locally or it may happen on an upstream forwarding server. The *DNS Resolver* can act in either a resolver or forwarder role, while the *DNS Forwarder* can only act as a forwarder.

Note: Some of the concepts and processes in this document are simplified to make them easier to understand.

Terms

The terms used in this section have specific meanings, though some terms are frequently used interchangeably or in ambiguous ways. The following definitions cover roles involved in DNS resolution and how they process queries.

Client
: A device that wants to translate a hostname into an IP address. This could be a PC, handheld device, a server, etc.

  A client will typically be configured with one or more forwarding DNS servers to which it will send DNS queries.

DNS Server
: A server involved in handling DNS queries. The term "DNS server" is ambiguous because a server involved in DNS can act in one or more specific roles which differ significantly. Used generally, this may refer to servers handling unknown or multiple types of DNS queries.

  The term "DNS Server" can also vary based on context. When talking about clients it usually refers to upstream forwarders or resolvers. When talking about resolvers or DNS infrastructure it usually refers to authoritative DNS servers. Where possible, it is best to use a more specific term.

Forwarder
A forwarder is a type of DNS server which accepts recursive queries from clients and makes its own queries to an upstream DNS server, which could be another forwarder or a resolver. A forwarder will typically cache results so clients get faster responses for frequently resolved queries.

Note: A forwarder does not perform DNS resolution itself, it passes a query along to another forwarder or resolver unless it has the answer in its cache.

Resolver
A DNS server acting as a resolver will accept recursive queries from clients and/or forwarders and perform DNS resolution by making iterative queries to root and authoritative DNS servers in search of an answer. Like a forwarder it will typically cache results for increased performance.

A resolver maintains a list of root servers in its "root hints" list. Resolvers will typically ship with a stock list but update it periodically from a trusted source.

Root Server
Authoritative name servers which serve queries for the DNS root zone (`.`). Though it is held as a short list of servers (`a.root-servers.net` through `m.root-servers.net`) there are hundreds of servers worldwide handling the requests.

These servers are a starting point for queries and will direct resolvers to authoritative DNS servers for zones which can answer their queries.

Glue Records
Entries in domain name registries which associate specific authoritative DNS servers with a domain name. These are used by the DNS servers for a TLD to determine which servers are authorized to answer queries for a given domain name.

Authoritative Server
A name server which has direct knowledge of hosts in a zone and the proper responses for queries. This could be for one or more domain names, subdomains, and so on. It could be run by a company operating a domain directly, a dedicated DNS provider, or a hosting company on their behalf.

An authoritative server will not make queries of its own to locate an answer. Instead, it either responds with a direct answer to the query or points the resolver to another authoritative server.

Recursive Query
A query for which the answer is not local to the forwarder or resolver. A forwarder or resolver will in turn make a query to another server to obtain an answer.

It is recursive in that if a forwarding server does not know the answer the *forwarding server* makes a recursive query to another upstream forwarder or resolver to obtain the answer, which is then passed back to a client. The client and every forwarder involved each only make one query upstream until the query eventually reaches a resolver.

Recursive queries can be handled by forwarders or resolvers.

Iterative Query
A query where a resolver asks a root or authoritative server for either a direct answer or for information about how to find the answer.

If the response points the resolver to another authoritative server, the *resolver* will send an additional query to that server. This process is repeated until the resolver obtains a final answer from an authoritative server. The answer is then passed back to the host which queried the resolver.

This process is iterative, rather than recursive, as each query is performed by the resolver and the *resolver* takes further action depending upon the result. The authoritative servers do not make queries

of their own, they only give answers they know locally, which may be the answer to a query or a pointer to another source.

DNS Resolution Steps

This is a somewhat simplified version of the process that takes place when a client attempts to resolve a hostname.

- The client checks its own DNS configuration to see how it should handle queries. This typically involves a local `hosts` file and a list of servers which it will contact to resolve queries.

  Note: Some operating systems support other methods for resolving names which are not a part of this process, such as mDNS or NBNS. These methods are omitted from this document but may occur before remote DNS servers are contacted. Check the operating system documentation for details.

  Local DNS configuration on the client may also include a default domain name which it will append to hostnames to form a fully qualified domain name (FQDN) for a DNS query.

- The client looks in its own `hosts` file to see if a local answer exists. If it does, the answer is used. If it does not, it proceeds to the next step.
- The client contacts the first server in its list and sends a query. If it does not receive a response, it will query the next server in the list.

  The client does not need to know or care if this server is a forwarder or resolver. Either way it gets an answer to its query.
- If the server contacted by the client is a forwarder, the forwarder will make a query to one of its own configured upstream DNS servers.

  As with a client these upstream servers could be additional forwarders or resolvers. If the upstream server is a forwarder, this step is repeated recursively until the query reaches a resolver.
- Once the query reaches a resolver, the resolver attempts to track down the answer by making iterative queries to servers in an attempt to track down a definitive answer.
- The resolver consults its list of root DNS servers in the hints file and contacts one to locate information on how to proceed.
- The resolver asks a root DNS server for information about the top level domain (TLD) in the requested FQDN (e.g. `.com`).
- The root DNS server returns a list of authoritative servers which have information about the TLD.
- The resolver queries one of the TLD servers from the response to ask about the domain name.
- The TLD servers consult glue records under the TLD to locate one or more authoritative DNS servers which can answer queries for the domain.
- The TLD server returns the list of authoritative DNS servers to the resolver.
- The resolver contacts one of the authoritative DNS servers for a domain and asks for a response to the original query.

  If the query is for an FQDN in a subdomain this may result in more steps as the authoritative server may tell the resolver to contact a different authoritative server which has knowledge of the subdomain. This process will be repeated until the resolver reaches the authoritative server with the answer to the query.
- The authoritative DNS server for the domain or subdomain responds to the resolver with the answer to the query.
- The resolver passes the response back to the host which submitted the request. The resolver may opt to cache the response.

- If the request came from a forwarder, it is passed back again to the host which submitted the request. The forwarder may opt to cache the response.

  If multiple forwarding servers were involved in the query this step is repeated until it reaches the original source of the query.

- The response to the query arrives back at the client.

All of this can happen quite fast. Even with multiple servers involved the entire process can be completed in fractions of a second.

24.1.2 DNS Rebinding Protections

pfSense® software includes built in methods of protection against DNS rebinding attacks.

A DNS rebinding attack is when someone with control over DNS responses for a domain feeds a client an address on the local network of the client – or even the client computer itself – as a response for a hostname in the domain controlled by the attacker. This would happen when the client requests a page in the malicious domain. Because the server run by the attacker and the hostname pointing to the client network are in the same domain from the perspective of the browser, the browser may allow scripts from the malicious server to run and access the other host. This can trigger the client to unintentionally exploit a device that would otherwise be unreachable from the Internet directly.

DNS rebinding attack protection is active by default. This behavior is controlled by the **DNS Rebind Check** option under **System > Advanced**, **Admin Access** tab.

DNS protection

When active, this protection causes the DNS resolver and forwarder to strip addresses from DNS responses for local and private IP addresses which should not normally be received from public DNS servers.

Tip: This is the safest and best practice as responses to DNS queries made through *public* DNS servers should never include *private* IP addresses.

For a list of addresses including in this protection, see the following table:

Table 1: Addresses included in DNS Rebinding Protection

Address	Description
127.0.0.0/8	RFC 1122 Loopback Addresses (Localhost)
10.0.0.0/8	RFC 1918 Private Addresses
::ffff:a00:0/104	IPv6 Representation of 10.0.0.0/8
172.16.0.0/12	RFC 1918 Private Addresses
::ffff:ac10:0/108	IPv6 Representation of 172.16.0.0/12
192.168.0.0/16	RFC 1918 Private Addresses
::ffff:a9fe:0/112	IPv6 Representation of 192.168.0.0/16
169.254.0.0/16	RFC 3927 IPv4 Link Local Addresses
::ffff:c0a8:0/112	IPv6 Representation of 169.254.0.0/16
fd00::/8	RFC 4193 IPv6 Unique Local Unicast Addresses (ULA)
fe80::/10	RFC 4291 IPv6 Link Local Addresses

There are some cases when public DNS servers give responses containing private IP addresses in replies. This may be the case for private internal hostnames under domains owned by an organization that does not use split DNS. It is

also common in DNS-based block lists such as those for e-mail spam prevention (DNSBL, RBL, etc.). In these cases overrides can be set for individual domains. The exact method depends on which DNS service is active.

Note: This behavior is automatically overridden for domains in the DNS Resolver and DNS Forwarder domain override lists as the most common usage of that functionality is to resolve internal DNS hostnames.

DNS Resolver

When DNS rebinding attack protection is active the *DNS Resolver* strips private addresses from DNS responses. Additionally, the DNSSEC validator may mark the answers as bogus. This is handled automatically using a list of `private-address` directives maintained by the firewall.

To exclude a domain from DNS rebinding protection, use the **Custom Options** box in the DNS resolver settings. Enter one domain per line in the following format, preceded by the `server:` line.

```
server:
private-domain: "example.com"
private-domain: "dnsbl.example"
```

DNS forwarder

The *DNS Forwarder* uses the option `--stop-dns-rebind` by default, which rejects and logs addresses from upstream name servers which are in private address ranges.

To exclude a domain from DNS rebinding protection, use the DNS forwarder **Advanced Settings** box as follows:

```
rebind-domain-ok=/example.com/
rebind-domain-ok=/dnsbl.example/
```

Additionally, it is possible to exclude the loopback range (`127.0.0.0/8`) from protection using the DNS forwarder **Advanced Settings** box as follows:

```
rebind-localhost-ok
```

Note: Rather than exclude the entire loopback range, it's generally better to allow such responses on a per-domain basis instead.

GUI protection

For those not using the DNS resolver or forwarder, and as an additional layer of checks, the GUI will block access attempts using unknown hostnames. In this case the GUI will deny access and display "Potential DNS Rebind Attack Detected".

By default the GUI only accepts the hostname and domain configured under **System > General Setup**. For instance if `firewall.example.com` is configured as the firewall hostname, and the GUI is loaded in a browser using `fw1.example.com`, the GUI will reject that attempt. Define additional hostnames under **System > Advanced**, **Admin Access** tab in the **Alternate Hostnames** field.

Tip: If a user encounters this error they can log into the GUI using the IP address of the firewall rather than the hostname.

If a client encounters this message when attempting to access a forwarded service (Port forward, 1:1 NAT, etc) it indicates that the request did not match any NAT rules. From the inside of the network, this would require NAT reflection or split DNS to accomplish.

See also:

Accessing Port Forwards from Local Networks

24.1.3 Creating Wildcard Records in DNS Forwarder/Resolver

A wildcard DNS record resolves `<anything>.example.com` to a single IP address, which can be useful in certain cases.

DNS Resolver (Unbound)

To create a wildcard entry the DNS Resolver (Unbound), use the following directives in the custom options box:

```
server:
local-zone: "example.com" redirect
local-data: "example.com 86400 IN A 192.168.1.54"
```

That makes any host under `example.com` resolve to `192.168.1.54`. For example, `www.example.com`, `thissitedoesnotexist.example.com`, `mystuff.example.com`, and so on.

If there are existing **Host Override** or **Domain Override** entries for the same domain, these custom options may not function as expected. When overrides are present, the zone will already be defined but with a different zone type set. For domains associated with host overrides, the default behavior of the local zones can be altered with the **System Domain Local Zone Type** setting in the *DNS Resolver Configuration*.

DNS Forwarder (dnsmasq)

To create a wildcard entry in the DNS Forwarder, use the following directives in the advanced options:

```
address=/example.com/192.168.1.54
```

If a specific host override is set for example:

```
specific.example.com 192.168.1.100
knownhost.example.com 192.168.1.101
```

Then those would be returned when doing a query for those hosts, only when no specific host has been specified in the host overrides would the advanced wildcard entry be used.

To resolve the domain to an IP address:

```
example.com 192.168.1.45
```

Leave the host field blank in the host overrides. So if the query is now for `example.com` the forwarder will return `192.168.1.45`. If a client requests `knownhost.example.com` then `192.168.1.101` would be returned instead.

If a blank hostname `example.com` host override entry has not been created, then a query for `example.com` would return the wildcard IP address set in the advanced option.

If a client queries for `madeupname.example.com` then since no specific host record for `madeupname` exists in the host overrides. The forwarder will return the wildcard entry of `192.168.1.54`.

24.3 Dynamic DNS

Dynamic DNS updates an external DNS server with an interface IP address when it changes. This enables a firewall with a dynamic WAN such as DHCP or PPPoE to host public services even when its IP address changes periodically.

CHAPTER

TWENTYFIVE

TRAFFIC SHAPER

25.1 What the Traffic Shaper can do for a Network

The basic idea of traffic shaping is raising and lowering the priorities of packets or keeping them under a certain speed. This concept seems simple, however, the number of ways in which this concept can be applied is vast. These are but a few common examples that have proven popular with users of pfSense® software.

25.1.1 Keep Browsing Smooth

Asymmetric links, where the download speed differs from the upload speed, are commonplace, especially with DSL. Some links are so out of balance that the maximum download speed is almost unattainable because it is difficult for a firewall to send out enough ACK (acknowledgement) packets to keep traffic flowing. ACK packets are transmitted back to the sender by the receiving host to indicate that data was successfully received, and to signal that it is OK to send more. If the sender does not receive ACKs in a timely manner, congestion control mechanisms in TCP will kick in and slow down the connection.

This type of situation is common: When uploading a file over a link that has asymmetric throughput capability, browsing and downloading slows to a crawl or stalls. This happens because the uploading portion of the circuit is full from the file upload and there is little room to send ACK packets which allow downloads keep flowing. By using the shaper to prioritize ACK packets, the firewall can enable faster, more stable download speeds on asymmetric links.

This is not as important on symmetric links where the upload and download speed are the same, but may still be desirable if the available outgoing bandwidth is heavily utilized.

25.1.2 Keep VoIP Calls Clear

If Voice over IP calls use the same circuit as data, then uploads and downloads may degrade call quality. pfSense software can prioritize the call traffic above other protocols, and ensure that the calls make it through clearly without breaking up, even while streaming hi-def video from Netflix at the same time. Instead of the call breaking up, the shaper reduces speed of the other transfers to leave room for the calls.

25.1.3 Reduce Gaming Lag

The shaper also has options to give priority to the traffic associated with network gaming. Similar to prioritizing VoIP calls, the effect is that even if users on the network are downloading while playing, the response time of the game should still be nearly as fast as if the rest of the connection were idle.

25.1.4 Keep P2P Applications In Check

By lowering the priority of traffic associated with known peer-to-peer ports, administrators can rest easier knowing that even if those programs are in use, they won't hinder other traffic on the network. Due to its lower priority, other protocols will be favored over P2P traffic, which will be limited when any other services need the bandwidth.

25.1.5 Enforce Bandwidth Limits

Limiters can apply a bandwidth limit to a group of devices, such as all traffic on an interface, or masking on limiters can apply them on a per-IP address or per-network basis. This way the firewall can ensure that no one person can consume all available bandwidth.

25.2 Hardware Limitations

One mechanism pfSense® software can use for traffic shaping is **ALTQ**. Unfortunately, only a subset of all supported network cards are capable of using these features because the drivers must be altered to support ALTQ shaping. The following network cards are capable of using traffic shaping:

> `ae(4)`, `age(4)`, `alc(4)`, `ale(4)`, `an(4)`, `aue(4)`, `axe(4)`, `bce(4)`, `bfe(4)`, `bge(4)`, `bnxt(4)`, `bridge(4)`, `cas(4)`, `cc(4)`, `cpsw(4)`, `cxl(4)`, `dc(4)`, `de(4)`, `ed(4)`, `em(4)`, `ep(4)`, `epair(4)`, `et(4)`, `fxp(4)`, `gem(4)`, `hme(4)`, `hn(4)`, `igb(4)`, `igc(4)`, `ix(4)`, `jme(4)`, `l2tp(4)`, `le(4)`, `lem(4)`, `msk(4)`, `mxge(4)`, `my(4)`, `ndis(4)`, `nfe(4)`, `ng(4)`, `nge(4)`, `npe(4)`, `nve(4)`, `ql(4)`, `ovpnc(4)`, `ovpns(4)`, `ppp(4)`, `pppoe(4)`, `pptp(4)`, `re(4)`, `rl(4)`, `sf(4)`, `sge(4)`, `sis(4)`, `sk(4)`, `ste(4)`, `stge(4)`, `ti(4)`, `tun(4)`, `txp(4)`, `udav(4)`, `ural(4)`, `vge(4)`, `vlan(4)`, `vmx(4)`, `vr(4)`, `vte(4)`, `vtnet(4)`, `wlan(4)`, `xl(4)`

Note: This list is based on the contents of the `is_altq_capable()` function in `interfaces.inc`. If a driver is not in the list above, it is possible that it was added to the source in a later version. Check the source on Github for the most accurate and up-to-date list of ALTQ-capable drivers.

Another type of traffic shaping on pfSense software is **Limiters**. Limiters use a different backend, operating through `dummynet` pipes and not **ALTQ**. Limiters do not have the same limitation as ALTQ, any network card is capable of using Limiters.

25.3 Network Interface Drivers with ALTQ Traffic Shaping Support

The intention of this page is to provide information regarding ALTQ-enabled drivers in FreeBSD, what they do, and how they work.

25.3.1 Information

The ALTQ framework is used for queuing/traffic shaping. In pfSense® software, this is utilized by the Shaper Wizard and the Queues/Interfaces tabs under **Firewall > Traffic Shaper**.

See the altq(4) or the altq(9).

On that page, select the *version of FreeBSD that corresponds to the pfSense software version being run*.

In addition to the drivers listed as supporting ALTQ in FreeBSD, pfSense software also includes support for ALTQ on vlan(4) and IPsec enc(4) interfaces.

If the NIC being used does not support ALTQ, *Limiters* may be used instead.

25.4 ALTQ Scheduler Types

pfSense® software contains several ALTQ scheduler types to cover a large range of shaping scenarios. The options for ALTQ are:

Priority Queuing (PRIQ)
: Manages prioritization of connections

Class-Based Queuing (CBQ)
: Supports bandwidth sharing between queues and bandwidth limits

Hierarchical Fair Service Curve (HFSC)
: Supports real-time bandwidth guarantees along with a hierarchical tree of nested queues.

Controlled Delay (CoDel)
: Attempts to combat bufferbloat.

Fair Queuing (FAIRQ)
: Attempts to fairly distribute bandwidth among all connections.

PRIQ, CBQ, and HFSC are selectable in the shaper wizards and the wizards will show the proper options and create the queues based on the chosen ALTQ discipline.

25.4.1 Performance Caveats

Enabling ALTQ traffic shaping places an extra burden on the hardware, and there will be an overall potential network performance loss. On systems that have horsepower to spare, this may not be noticeable. On systems that operate close to their specification limits the firewall may see a degradation of performance. Whether the loss is worse than working without shaping depends on the individual workload.

25.4.2 Priority Queuing (PRIQ)

PRIQ is one of the easiest disciplines to configure and understand. The queues are all directly under the root queue, there is no structure to have queues under other queues with PRIQ as there is with HFSC and CBQ. It does not care about bandwidth on interfaces, only the priority of the queues. The values for priority go from `0` to `15`, and the higher the priority number, the more likely the queue is to have its packets processed.

PRIQ can be harsh to lesser queues, starving them when the higher priority queues need the bandwidth. In extreme cases, it is possible for a lower priority queue to have little or no packets handled if the higher priority queues are consuming all available resources.

25.4.3 Hierarchical Fair Service Curve (HFSC)

The HFSC traffic shaping discipline is very powerful. It is useful for services such as VoIP and video to deliver a minimum guaranteed amount of bandwidth.

Queues in HFSC are arranged in a hierarchy, or a tree, with root queues for each interface, parent queues underneath, and child queues nested under the parent queues (etc.). Each queue can have a set bandwidth and related options.

HFSC-specific Queue Options

HFSC supports a few queue options that are not supported by other disciplines. It is through these options that it achieves guaranteed real-time processing and link sharing.

The Service Curve (sc) is where bandwidth requirements for this queue are tuned.

m1
: Burstable bandwidth limit

d
: Time limit for bandwidth burst, specified in milliseconds. (e.g. 1000 = 1 second)

m2
: Normal bandwidth limit

For example, a connection needs **m1** bandwidth within **d** time, but a normal maximum of **m2**. Within the initial time set by **d**, **m2** is not checked, only **m1**. After **d** has expired, if the traffic is still above **m2**, it will be shaped. Most commonly, **m1** and **d** are left blank, so that only **m2** is checked.

Each of these values may be set for the following uses:

Upper Limit
: Maximum bandwidth allowed for the queue. Will do hard bandwidth limiting. The **m1** parameter here can also be used to limit bursting. In the time frame **d** a connection will not get more than **m1** bandwidth.

Real Time
: Minimum bandwidth guarantee for the queue. This is only valid for child queues. The **m1** parameter will always be satisfied in time frame **d**, and **m2** is the maximum that this discipline will allow to be used. Note The value for **m2** cannot exceed 30% of the available bandwidth from the parent queue.

Link Share
: The bandwidth share of a backlogged queue. Will share bandwidth between classes if the **Real Time** guarantees have been satisfied. The **m2** value for **Link Share** will override the **Bandwidth** setting for the queue. These two settings are the same, but if both are set, **m2** from **Link Share** is used.

By combining these factors, a queue will get the bandwidth specified by the **Real Time** factors, plus those from **Link Share**, up to a maximum of **Upper Limit**. It can take a lot of trial and error, and perhaps a lot of arithmetic, but it

may be worth it to ensure that network traffic is governed properly. For more information on **m1**, **d**, and **m2** values for different scenarios, visit the Traffic Shaping forum category.

25.4.4 Class-Based Queuing (CBQ)

Class-Based Queuing, or CBQ, is similar to HFSC in that is can have a tree of queues nested under other queues. It supports bandwidth limits (not guarantees like HFSC), priorities for queues, and it has the ability to allow queues to borrow bandwidth from their parent. Because of the simpler queue configuration, it can be a good alternative to HFSC especially if the firewall does not need to guarantee minimum bandwidths.

With CBQ, queue priorities range from `0` to `7` with higher numbers indicating higher priority. Queues of an equal priority are processed in a round-robin fashion.

Note: Though child queues can borrow from their parent queue, the sum of the bandwidth of the child queues cannot exceed the bandwidth of the parent. Therefore, CBQ is not an alternative to limiters for individual (e.g. per-IP address) bandwidth limits.

CBQ-Specific Queue Options

The CBQ discipline supports the concept of *borrow*, meaning that if the **Borrow from other queues when available** checkbox on the queue is enabled, then the queue will be able to borrow other available bandwidth from its parent queue. This will only allow a child queue to obtain up to the bandwidth of its *immediate* parent, if available, it will not borrow from other parent queues.

25.4.5 CoDel Active Queue Management

The CoDel Active Queue Management (AQM) discipline is short for Controlled Delay and is pronounced “coddle”. It was designed to combat problems associated with bufferbloat in networking infrastructure.

See also:

Bufferbloat is described in detail at http://www.bufferbloat.net/projects/bloat/wiki/Introduction.

Put simply, traffic can pile up and go in chunks rather than a smooth stream due to the size of buffers in network equipment. By controlling the delay of the traffic this effect can be lessened.

CoDel has no specific configuration controls or options. When activated for a queue, it will automatically attempt to manage traffic as described in the CoDel wiki at http://www.bufferbloat.net/projects/codel/wiki. It attempts to keep traffic delays low but does permit bursting, it controls delays but it does not pay attention to round-trip delay, load, or link speed, and it can automatically adjust if the link speed changes.

The target for CoDel is mid-range networking. It does not work well at very low bandwidth (1Mbit/s or less) and it does not gracefully handle large numbers of simultaneous flows or datacenter-grade traffic loads.

CoDel is not configurable using the wizard, but it does not require complex setup:

- Navigate to **Firewall > Traffic Shaper**, **By Interface** tab
- Select an interface (e.g. **WAN**)
- Set the **Scheduler Type** to *CODEL*
- Set an appropriate value for **Bandwidth**
- Click **Save**

- Repeat as needed for all other active WAN-type interface(s)

25.4.6 Fair Queuing (FAIRQ)

In FAIRQ, queues are monitored from highest to lowest priority, but the scheduler attempts to fairly distribute bandwidth among all connections.

When there is no contention for bandwidth, FAIRQ will send all waiting packets. When there is contention for bandwidth FAIRQ will start looking for queues that are not exceeding their limits, first starting with high priority queues and working toward lower queues. A packet in a full high priority queue is processed *after* a packet from a lower priority queue which is not full. If all queues are full, then FAIRQ will send a packet from the highest priority queue.

FAIRQ allows connections to exceed queue bandwidth, but will maintain an average consumption equal to the defined queue bandwidth.

FAIRQ is not currently supported in the traffic shaper wizard and it requires a manual configuration.

25.5 Advanced Customization

The rules and queues generated by the shaper wizard may not be an exact fit for a network. Network devices may use services that need shaped which are not listed in the wizard, games that use different ports, or other protocols that need limiting.

After the basic rules have been created by the wizard, it is relatively easy to edit or copy those rules to make adjustments for other protocols.

25.5.1 Editing Shaper Queues

Queues are where bandwidth and priorities are allocated by the shaper. Each queue has settings specific to the scheduler that was chosen in the wizard (*ALTQ Scheduler Types*). Queues can also be assigned other attributes that control how they behave. Queues may be managed at **Firewall > Traffic Shaper**. Click on a queue name in the list or tree shown on the **By Interface** or **By Queue** tabs, as seen in Figure *Traffic Shaper Queues List*

> **Warning:** Creating or editing queues is for advanced users only. It is a complex task with powerful results, but without thorough understanding of the settings involved the best practice is to stick with queues generated by the wizard rather than trying to make new queues.

To edit a queue, click its name in the list/tree.

To delete a queue, click it once to edit the queue, then click  **Delete This Queue**. Do not delete a queue if it is still being referenced by a firewall rule.

To add a new queue, click the interface or parent queue under which the new queue will be placed, and then click 
Add New Queue.

When editing a queue, each of the options must be carefully considered. For more information about these settings than is mentioned here, visit the PF Packet Queuing and Prioritization FAQ or read *The OpenBSD PF Packet Filter* book.

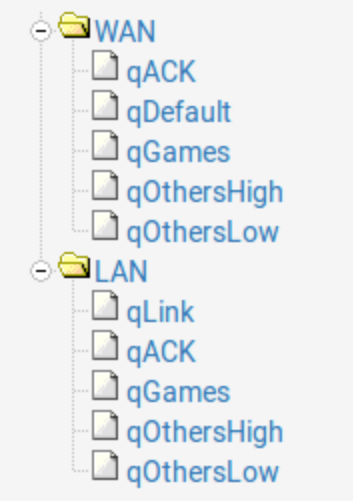

Fig. 1: Traffic Shaper Queues List

Name
The queue name must be between 1-15 characters and cannot contain spaces. The most common convention is to start the name of a queue with the letter "q" so that it may be more readily identified in the ruleset.

Priority
The priority of the queue. Can be any number from 0-7 for CBQ and 0-15 for PRIQ. Though HFSC can support priorities, the current code does not honor them when performing shaping. Queues with higher numbers are preferred by the shaper when there is an overload, so situate queues accordingly. For example, VoIP traffic is the highest priority, so it would be set to a `7` on CBQ or `15` on PRIQ. Peer-to-peer network traffic, which can be delayed in favor of other protocols, would be set at `1`.

Bandwidth (root queues)
The amount of bandwidth available on this interface in the **outbound** direction. For example, WAN-type interface root queues list upload speed. LAN type interfaces list the sum total of all WAN interface download bandwidth.

Queue Limit
The number of packets that can be held in a queue waiting to be transmitted by the shaper. The default size is `50`.

Scheduler Options
There are five different Scheduler Options that may be set for a given queue:

Default Queue
Selects this queue as the default, the one which will handle all unmatched packets on an interface. Each interface must have one and only one default queue.

Random Early Detection (RED)
A method to avoid congestion on a link. When set, the shaper will actively attempt to ensure that the queue does not get full. If the bandwidth is above the maximum given for the queue, drops will occur. Also, drops may occur if the average queue size approaches the maximum. Dropped packets are chosen at random, so connections using more bandwidth are more likely to see drops. The net effect is that the bandwidth is limited in a fair way, encouraging a balance. RED should only be used with TCP connections since TCP is capable of handling lost packets, and hosts can resend TCP packets when needed.

Random Early Detection In and Out (RIO)
Enables RED with in/out, which results in having queue averages being maintained and checked against incoming and outgoing packets.

Explicit Congestion Notification (ECN)
Along with RED, it allows sending of control messages that will throttle connections if both ends support ECN. Instead of dropping the packets as RED will normally do, it will set a flag in the packet indicating network congestion. If the other side sees and obeys the flag, the speed of the ongoing transfer will be reduced.

Codel Active Queue
A flag to mark this queue as being the active queue for the Codel shaper discipline.

Description
Optional text describing the purpose of the queue.

Bandwidth (Service Curve/Scheduler)
The Bandwidth setting should be a fraction of the available bandwidth in the parent queue, but it must also be set with an awareness of the other neighboring queues. When using percentages, the total of all queues under a given parent cannot exceed 100%. When using absolute limits, the totals cannot exceed the bandwidth available in the parent queue.

Scheduler-specific Options
Next are scheduler-specific options. They change depending on whether a queue is using HFSC, CBQ, or PRIQ. They are all described in *ALTQ Scheduler Types*.

Click **Save** to save the queue settings and return to the queue list, then click **Apply Changes** to reload the queues and activate the changes.

25.5.2 Editing Shaper Rules

Traffic shaping rules control how traffic is assigned into queues. If a new connection matches a traffic shaper rule, the firewall will assign packets for that connection into the queue specified by that rule.

Packet matching is handled by firewall rules, notably on the **Floating** tab. To edit the shaper rules:

- Navigate to **Firewall > Rules**
- Click the **Floating** Tab
- Find the rule to edit in the list, as shown in Figure *Traffic Shaper Rules List*
- Click  to edit an existing rule or  to create a copy of a rule
- Make any required adjustments to match different connections
- Save and Apply Changes as usual when editing firewall rules

Queues may be applied using *pass* rules on interface tabs, but the wizard only creates rules on the **Floating** tab using the *match* action that does not affect whether or not a connection is passed or blocked; it only queues traffic. Because these rules operate the same as any other rules, any criteria used to match connections may be used to queue.

See also:

For more information on floating rules, see *Floating Rules* and *Configuring Firewall Rules* for information on firewall rules in general.

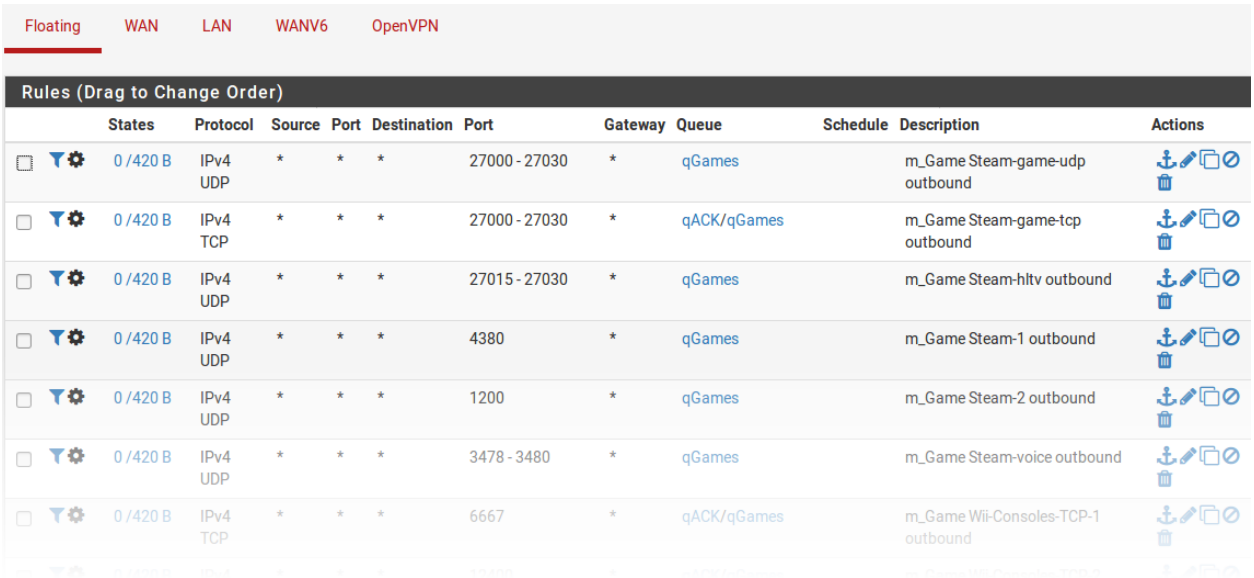

Fig. 2: Traffic Shaper Rules List

Shaper Rule Matching Tips

Connections can be tricky to match properly due to several factors, including:

- NAT applies before outbound firewall rules can match connections, so for connections that have outbound NAT applies as they leave a WAN-type interface, the private IP address source is hidden by NAT and cannot be matched by a rule.
- Some protocols such as Bittorrent will use random ports or the same ports as other services.
- Multiple protocols using the same port cannot be distinguished by the firewall.
- A protocol may use a range of ports so wide that it cannot be distinguished from other traffic.

While many of these cannot be solved by the firewall directly, there are ways to work around these limitations in a few cases.

To match by a private address source outbound in WAN floating rules, first tag the traffic as it passes in on a local interface. For example, match inbound on LAN and use the advanced **Tag** field to set a value, and then use the **Tagged** field on the WAN-side floating rule to match the same connection as it exits the firewall. Alternately, queue the traffic as it enters the LAN with a pass rule instead of when it exits a WAN.

Match by address instead of port/protocol where possible to sort out ambiguous protocols. In these cases, either the local source or the remote destination may be a single address or a small set of addresses. For example, matching VoIP traffic is much simpler if the firewall can match the remote SIP trunk or PBX rather than attempting to match a wide range of ports for RTP (e.g. `10000-20000`).

If bittorrent is allowed on a network but must be shaped, then dedicate a specific local device that is allowed to use bittorrent and then shape all connections to/from that device as Peer-to-Peer traffic.

25.5.3 Removing Traffic Shaper Settings

To remove all traffic shaper queues and rules created by the wizard:

- Navigate to **Firewall > Traffic Shaper**
- Click the **By Interface** tab
- Click  **Remove Shaper**
- Click **OK** on the confirmation prompt

25.6 Traffic Shaping with Differentiated Services (DiffServ) Identifiers

pfSense® software supports **Differentiated services** (**DiffServ**) for traffic filtering or queue assignments. DiffServ takes the place of the outdated **Type of service** (**TOS**). DiffServ uses the upper six bits of the TOS field in the IP header (the six bits being called the *DiffServ Code Point field*), while the lower two bits are reserved for Explicit Congestion Notification (ECN).

Unless appropriately configured, pfSense software ignores the content of the DiffServ Code Point (DSCP) field. To prioritize traffic, the *Traffic Shaper* needs to be set up accordingly.

Warning: pfSense software *does not* support setting or changing DiffServ values, only matching.

25.6.1 Supported DiffServ Code Point Values

Note that the interpretations of the DSCP values, as provided by the various RFCs, are only given as a reference. How the DSCP values are interpreted in any specific setup is entirely up to the user or end nodes.

The **Assured Forwarding** (AF) Behavior Group is recommended in RFC 2597.

Table 1: Assured Forwarding (AF) Behavior Group values

Precedence	Class 1 (lowest)	Class 2	Class 3	Class 4 (highest)
Low Drop	AF11 (10/0x0a)	AF21 (18/0x12)	AF31 (26/0x1a)	AF41 (34/0x22)
Med Drop	AF12 (12/0x0c)	AF22 (20/0x14)	AF32 (28/0x1c)	AF42 (36/0x24)
High Drop	AF13 (14/0x0e)	AF23 (22/0x16)	AF33 (30/0x1e)	AF43 (38/0x26)

For low-drop/low-latency traffic, use EF and VA DSCP values.

Table 2: Expedited Forwarding (EF) and Voice Admit (VA) values

PHB	DSCP Value	RFC
Expedited Forwarding (EF)	46/0x2e	RFC 3246
Voice Admit (VA)	44/0x2c	RFC 5865

The Class Selector (CS) PHB group has been retained from TOS.

Table 3: Class Selector (CS) values

Class Selector	DSCP Value
CS1	8/0x08
CS2	16/0x10
CS3	24/0x18
CS4	32/0x20
CS5	40/0x28
CS6	48/0x30
CS7	56/0x38

To provide limited backward comparability to TOS, pfSense software also recognizes the following DSCP/TOS values.

Table 4: TOS Compatibility values

TOS	DSCP Value	TOS value
reliability	1/0x01	4/0x04
throughput	2/0x02	8/0x08
lowdelay	4/0x04	16/0x10

pfSense software only matches exact values. All six bit in the DSCP field must match.

25.6.2 Caveats

By default, pfSense software only matches the **first packet** of a connection, which is the packet that creates an entry in the state table. If a connection starts with a different DSCP value, has no DSCP value in the starting packet, or otherwise changes DSCP values during the connection, the traffic will not be classified as expected.

Tip: This can be worked around by using "no state" rules, but crafting these rules in a secure manner is difficult, so it is not a viable workaround for most environments.

25.6.3 RFCs

- RFC 2474 — Definition of the Differentiated Services Field (DS Field) in the IPv4 and IPv6 Headers
- RFC 2475 — An Architecture for Differentiated Services
- RFC 2597 — Assured Forwarding PHB Group
- RFC 2983 — Differentiated Services and Tunnels
- RFC 3086 — Definition of Differentiated Services Per Domain Behaviors and Rules for their Specification
- RFC 3140 — Per Hop Behavior Identification Codes (replaces RFC 2836)
- RFC 3246 — An Expedited Forwarding PHB (Per-Hop Behavior) (obsoletes RFC 2598)
- RFC 3247 — Supplemental Information for the New Definition of the EF PHB (Expedited Forwarding Per-Hop Behavior)
- RFC 3260 — New Terminology and Clarifications for Diffserv (updates
- RFC 2474, RFC 2475 and RFC 2597)

- RFC 4594 — Configuration Guidelines for DiffServ Service Classes
- RFC 5865 — A Differentiated Services Code Point (DSCP) for Capacity-Admitted Traffic (updates RFC 4542 and RFC 4594)
- RFC 3289 — Management Information Base for the Differentiated Services Architecture
- RFC 3290 — An Informal Management Model for Diffserv Routers
- RFC 3317 — Differentiated Services Quality of Service Policy Information Base

25.7 Limiters

Limiters are an alternate method of traffic shaping. Limiters use dummynet(4) to enact bandwidth limits and perform other prioritization tasks, and they do not rely on ALTQ. Limiters are currently the only way to achieve per-IP address or per-network bandwidth rate limiting using pfSense® software. Limiters are also used internally by Captive Portal for per-user bandwidth limits.

Limiters are managed at **Firewall > Traffic Shaper** on the **Limiters** tab.

Like HFSC and CBQ, Limiters may be nested with queues inside other queues. Root-level limiters (Also called Pipes), may have bandwidth limits and delays, while child limiters (Also called queues), may have priorities (Also called weights). Bandwidth limits can be optionally masked by either the source or destination IP address, so that the limits can be applied on a per-IP address or network basis instead of as a general group.

Limiters are nearly always used in pairs: One for incoming traffic and one for outgoing traffic.

According to its man page the dummynet(4) system was originally designed as a means to test TCP congestion control and it grew up from there. Due to this purpose, a unique feature of limiters is that they can be used to induce artificial packet loss and delay into network traffic. That is primarily used in troubleshooting and testing (or being evil and playing a prank on someone), and not often found in production.

25.7.1 Uses for Limiters

The primary use for limiters is to apply bandwidth limits for users or specific protocols, e.g. "Maximum of 1Mbit/s for SMTP", or "Joe's PC only can use 5Mbit/s". Limiters can apply a per-IP address or per-network limit, such as "All Users in 192.168.50.0/24 can use a maximum of 3Mbit/s each" or "The guest network and public network can use 1Mbit/s for each segment".

Limiters are the only type of shaper available in pfSense software which is capable of oversubscription in this manner. The ALTQ shaper requires all child queues to sum up to no more than the speed of the parent queue, but masked limiters allow a set limit to as many IP addresses as can be funneled through the limiter by firewall rules.

Conceptually, consider a limiter as a bucket of bandwidth. All traffic flowing through an unmasked limiter draws bandwidth from the same bucket. Masking a limiter effectively sets up multiple buckets of the same size, one per masked group. Whether that is a single host or an entire network depends on the mask value.

Limiters can also allow for reserved bandwidth by limiting everything *except* a specific protocol which can then consume all remaining bandwidth. In this type of setup on a 10Mbit/s link the firewall would pass traffic from, for example, a SIP server with no limiter. Then the firewall would use a pass rule for all other traffic with a limit of 8Mbit/s. This would let the SIP server use all of the bandwidth it wanted, but it would always have a minimum of 2Mbit/s to itself.

Limiters can also help with issues such as Bufferbloat by controlling the delay of certain packets, using the CoDel algorithm similar to the one available in ALTQ (*CoDel Active Queue Management*).

See also:

- *Configuring CoDel Limiters for Bufferbloat*

25.7.2 How Limiters Work

Limiters, like ALTQ, hold traffic to a certain point by dropping or delaying packets to achieve a specific line rate. Usually taking advantage of built-in mechanisms from protocols that detect the loss and back off to a sustainable speed.

In situations where packets are queued under the same parent pipe, the firewall considers their weights when ordering the packets before it sends them. Unlike priorities in CBQ and PRIQ, the weight of a queue in a limiter will never starve it for bandwidth.

25.7.3 Limiters and IPv6

Limiters work with IPv6, though it requires separate IPv4 and IPv6 rules to apply limiters properly.

25.7.4 Limitations

Limiter pipes do not have a concept of borrowing bandwidth from other pipes. A limit is always a hard upper limit.

Limiters use `dummynet` pipes, so there will be additional (though small) overhead from the extra packet processing involved.

Limiters cannot effectively guarantee a minimum bandwidth amount for a pipe or queue, only a maximum.

Child queues cannot have bandwidth values, so a pipe cannot be split into smaller pipes by queues. Child queues can only use weights to prioritize packets inside a pipe.

The overhead from delaying and queuing packets can cause increased mbuf usage. For more information on increasing the amount of available mbufs, see *Hardware Tuning and Troubleshooting*.

25.7.5 Limiters and Multi-WAN

When using limiters with Multi-WAN, limits for non-default gateways must be applied using floating rules set for the *out* direction and configured with the appropriate gateway.

25.7.6 Creating Limiters

Limiters are managed under **Firewall > Traffic Shaper** on the **Limiters** tab.

To create a new root-level limiter (pipe), click  **New Limiter**.

To create a child limiter (queue), click an existing limiter under which it can be created, and click  **Add New Queue**.

Tip: In nearly all cases, limiters exist in pairs at the same level (e.g. two pipes, or two queues): One for inbound traffic and one for outbound traffic. When creating new limiters or queues, create one for each direction.

Enable
Check the box to enable this limiter. If the limiter is disabled, it will not be available for use by firewall rules.

Name
This defines the name of the limiter, as it will appear for selection on firewall rules.

The name must be alphanumeric, and may also include - and _.

Tip: When choosing a name, avoid using `In` and `Out` since the same limiter, if used on both WAN and LAN, would be used in the *In* direction on one interface and the *Out* direction on another. The best practice is to use `Down` or `Download` and `Up` or `Upload`.

Bandwidth (Pipes)
This section defines a bandwidth value for the pipe, or multiple bandwidths if schedules are involved. This option does not appear when editing a child limiter (queue).

Bandwidth
The numerical part of the bandwidth for the pipe, e.g. `3` or `500`.

Bw Type
The units for the **Bandwidth** field, such as *Mbit/s*, *Kbit/s*, or *Bit/s*.

Schedule
If the firewall has schedules defined (*Time Based Rules*), the firewall offers them in this list. When schedules are in use by the firewall, the limiter can have a bandwidth value for each potential schedule. Define these by clicking  **Add Schedule** to add another bandwidth definition.

If a limiter contains multiple bandwidth specifications, they must each use a different schedule. For example if the firewall has a "Work Day" schedule, then it must also have an "Off Hours" schedule that contains all of the time not included in "Work Day" for the second bandwidth specification.

Mask
This drop-down list controls how the limiter will mask addresses in the pipe or queue.

None
When set to *none*, the limiter does not perform any masking. The pipe bandwidth will be applied to all traffic as a whole.

Source / Destination address
When a limiter is set for *Source Address* or *Destination Address*, the pipe bandwidth limit will be applied on a per-IP address basis or a subnet basis, depending on the masking bits, using the direction chosen in the masking.

In general, a limiter should mask the **Source Address** on **Upload** (In) limiters for LAN-type interfaces, and **Destination Address** on **Download** (Out) limiters on LAN-type interfaces. Similar to swapping the directionality of the limiters when applying to LAN and WAN, masking is swapped as well, so the same masked limiter set for **In** on LAN should be used for **Out** on WAN.

Mask Bits
There are separate boxes to control the address masking for IPv4 and IPv6. For IPv4 a value of *32* for **IPv4 mask bits** sets up a per-IPv4 address limit, which is the most common usage. For a per-IPv6-address limit, use *128* as the **IPv6 mask bits** value.

To create per-subnet or similar masks, enter the subnet bits in the appropriate field for either IPv4 or IPv6 mask bits, such as *24* to limit IPv4 in groups of /24 subnets.

Description
An optional bit of text to explain the purpose for this Limiter.

Advanced Options
Additional options that vary when editing a pipe or a queue.

Delay (Pipes)
The **Delay** option is only found on limiter pipes. It introduces an artificial delay (latency), specified in milliseconds, into the transmission of any packets in the limiter pipe. This is typically left blank so that packets are transmitted as fast as possible by the firewall. This can be used to simulate high-latency connections such as satellite uplinks for lab testing.

Weight (Queues)
The **Weight** option is only found on child limiters (queues). This value can range from 1 to 100. Higher values give more precedence to packets in a given queue. Unlike PRIQ and CBQ priorities, a lowly-weighted queue is not in danger of being starved of bandwidth by the firewall.

Packet loss rate
Another method of artificially degrading traffic. The **Packet Loss Rate** can be configured to drop a certain fraction of packets that enter the limiter. The value is expressed as a decimal representation of a percentage, so `0.01` is 1%, or one packet out of a hundred dropped. This field is typically left empty so every packet is delivered by the firewall.

Queue Size
Sets the size of the queue, specified in queue slots, used for handling queuing delay. Left blank, it defaults to `50` slots, which is the recommended value. Slow speed links may need a lower queue size to operate efficiently. High speed links may need more slots.

Tip: In cases where there are several limiters or limiters with large **Queue Size** values, a **System Tunable** may need set to increase the value of `net.inet.ip.dummynet.pipe_slot_limit` above the total number of configured queue lots among all pipes and queues.

Bucket Size
The **Bucket Size**, also specified in slots, sets the size of the hash table used for queue storage. The default value is `64`. It must be a numeric value between `16` and `65536`, inclusive. This value is typically left blank.

See also:

For more information about these values, consult the ipfw(8) man page, in the section titled "Traffic Shaper (Dummynet) Configuration". Though current versions of pfSense software utilize dummynet through `pf` instead of `ipfw`, the configuration options are the same.

25.7.7 Assigning and Using Limiters

Limiters are assigned using firewall rules via the **In/Out Pipe** selectors under **Advanced Options**. Any potential matching criteria that a firewall rule supports can assign traffic to a limiter.

The most important thing to remember when assigning a limiter to a rule is that the **In** and **Out** fields are designated **from the perspective of the firewall itself**.

For example, in a firewall configuration with a single LAN and single WAN, inbound traffic on a LAN interface is leaving toward the Internet, i.e. *uploaded* data. Outbound traffic on the LAN interface is going toward the client PC, i.e. *downloaded* data. On the WAN interface the directionality is reversed; Inbound traffic is coming from the Internet to the client (download), and outbound traffic is going from the client to the Internet (upload).

In most cases, a firewall rule will have both an **In** limiter and **Out** limiter, but only the **In** limiter is required by the firewall to limit traffic in a single direction.

Limiters may be applied on normal interface rules, or on floating rules. On floating in the *out* direction, the In/Out selections are flipped conceptually.

25.7.8 Checking Limiter Usage

Information about active limiters may be found under **Diagnostics > Limiter Info**. Here, each limiter and child queue is shown in text format.

The set bandwidth and parameters for each limiter are displayed by the page, along with the current traffic level moving inside the limiter. In the case of masked limiters, the firewall displays the bandwidth of each IP address or masked group.

25.8 Traffic Shaping and VPNs

The following discussions pertain primarily to ALTQ shaping. Limiters will work fine with VPNs as they would with any other interface and rules. Only the ALTQ shaper requires special consideration.

Traffic shaping with VPNs is a tricky topic because VPN traffic is considered separate from, but also a part of, the WAN traffic through which it also flows. If WAN is 10 Mbit/s, then the VPN can also use 10Mbit/s, but there is not actually 20Mbit/s of bandwidth to consider, only 10Mbit/s. As such, methods of shaping that focus more on prioritization than bandwidth are more reliable, such as PRIQ or in some cases, CBQ.

If all traffic inside the VPN must be prioritized by the firewall, then it is enough to consider only the VPN traffic itself directly on WAN, rather than attempting to queue traffic on the VPN separately. In these cases, use a floating rule on WAN to match the VPN traffic itself. The exact type of traffic varies depending on the type of VPN. IPsec and PPTP traffic on WAN can both be prioritized by the shaper wizard, and these rules can be used as an example to match other protocols.

25.8.1 OpenVPN

With OpenVPN, multiple interfaces exist on the operating system, one per VPN. This can make shaping easier in some cases. Features of OpenVPN can also make it easier to shape traffic on WAN and ignore the tunnel itself.

Shaping inside the tunnel

If multiple classes of traffic are carried on the tunnel, then prioritization must be done to the traffic inside the tunnel. In order for the wizard to consider the traffic in this way, the VPN must be assigned as its own interface in the GUI. To accomplish this, assign it as described in *Interface assignment and configuration*, and then use the shaper wizard as if it were a separate WAN interface, and classify the traffic as usual.

Shaping outside the tunnel (passtos)

If the primary concern is shaping VoIP traffic over a VPN, another choice to consider is the `passtos` option in OpenVPN, called **Type-of-Service** in the OpenVPN client or server options. This option copies the TOS bit from the inner packet to the outer packet of the VPN. Thus, if the VoIP traffic has the TOS (DSCP) portion of the packet header set, then the OpenVPN packets will also have the same value.

This option is more useful for signaling intermediate routers about the QoS needs, however. Though the DSCP option on firewall rules can match based on TOS bits, as described in *Diffserv Code Point*, such matching would have to occur in the packet creating a firewall state, and not on specific packets flowing through that state.

Note: Because this option tells OpenVPN to copy data from the inner packet to the outer packet, it does expose a little information about the type of traffic crossing the VPN. Whether or not the information disclosure, though minor, is worth the risk for the gains offered by proper packet prioritization depends on the needs of the network environment.

25.8.2 IPsec

IPsec is presented to the operating system on a single interface no matter how many tunnels are configured and no matter which WANs are used by the tunnels. This makes shaping IPsec traffic difficult, especially when trying to shape traffic inside one particular IPsec tunnel.

The IPsec interface is also not possible to use on its own as an interface with the wizard. Floating rules can match and queue traffic on the IPsec interface, but in most cases only inbound traffic will be queued as expected. Actual results may vary.

25.9 Traffic Shaping UPnP IGD & PCP Connections

UPnP IGD & PCP rules are generated dynamically by the UPnP IGD & PCP daemon. These dynamic rules exist outside of user-defined firewall rules and cannot be edited manually. There is a configuration option for UPnP IGD & PCP where a queue can be defined to which UPnP IGD & PCP will direct traffic matching the rules it creates. This may be set through the pfSense® software GUI at **Services > UPnP IGD & PCP**, and type in a valid **Traffic Shaping Queue**.

See also:

- *ALTQ Traffic Shaper Queue Monitoring*
- *Using the Shaper Wizard to Configure ALTQ Traffic Shaping*
- *Configuring CoDel Limiters for Bufferbloat*
- *Troubleshooting Traffic Shaping*
- *Troubleshooting Traffic Shaping Graphs*

Traffic shaping, or network Quality of Service (QoS), is a means of prioritizing network traffic. Without traffic shaping, packets are processed on a first in/first out basis by the firewall. QoS offers a means of prioritizing different types of traffic, ensuring that high priority services receive the bandwidth they need before lesser priority services.

For simplicity, the traffic shaping system in pfSense® software may also be referred to as the “shaper”, and the act of traffic shaping may be called “shaping”.

25.10 Traffic Shaping Types

There are two types of QoS available in pfSense software: ALTQ and Limiters.

The **ALTQ** framework is handled through `pf` and is closely tied to network card drivers. ALTQ can handle several types of schedulers and queue layouts. The traffic shaper wizard configures ALTQ and gives firewall administrators the ability to quickly configure QoS for common scenarios, and it allows custom rules for more complex tasks. ALTQ is inefficient, however, so the maximum potential throughput of a firewall is lowered significantly when it is active.

pfSense software also supports a separate shaper concept called **Limiters**. Limiters enforce hard bandwidth limits for a group or on a per-IP address or network basis. Inside of those bandwidth limits, limiters can also manage traffic priorities.

25.11 Traffic Shaping Basics

For administrators who are unfamiliar with traffic shaping, it is like a bouncer at an exclusive club. The VIPs (Very Important Packets) always make it in first and without waiting. The regular packets have to wait their turn in line, and "undesirable" packets can be kept out until after the real party is over. All the while, the club is kept at capacity and never overloaded. If more VIPs come along later, regular packets may need to be tossed out to keep the place from getting too crowded.

ALTQ shaping concepts can be counter-intuitive at first because the traffic has to be queued in a place where the operating system can control the flow of packets. Incoming traffic from the Internet going to a host on the LAN (downloading) is shaped *leaving* the LAN interface from the firewall. In the same manner, traffic going from the LAN to the Internet (uploading) is shaped when leaving the WAN.

For ALTQ, there are traffic shaping queues, and traffic shaping rules. The queues allocate bandwidth and priorities. Traffic shaping rules control how traffic is assigned into those queues. Rules for the shaper work the same as firewall rules, and allow the same matching characteristics. If a packet matches a shaper rule, it will be assigned into the queues specified by that rule. In pfSense software, shaper rules are mostly handled on the **Floating** tab using the *Match* action that assigns the traffic into queues, but rules on any interface can assign traffic into queues using the *Pass* action.

Limiter rules are handled differently. Limiters apply on regular pass rules and enforce their limits on the traffic as it enters and leaves an interface. Limiters almost always exist in pairs: One for the "download" direction traffic and one for the "upload" direction traffic.

CHAPTER

TWENTYSIX

CAPTIVE PORTAL

26.1 Captive Portal Zones

Captive Portal zones define separate portals for different sets of interfaces. For example, LAN and Wireless could use one portal, while a conference room would get a separate portal page. Each zone has separate settings for HTML pages, authentication, allowed addresses, and so on. A zone must be created before its settings can be changed.

Note: A zone may have multiple interfaces, but an interface may only be a member of one zone. Attempting to add the same interface to multiple zones will result in an error.

26.1.1 Managing Captive Portal Zones

Captive Portal zones are managed at **Services > Captive Portal**. A list of zones is displayed there, and zones may be added, edited, or deleted from that list.

To create a new Captive Portal zone:

- Navigate to **Services > Captive Portal**
- Click  **Add**
- Enter a **Zone Name**, which may only consist of letters, digits, numbers, and underscores. Spaces and other special characters may not be used
- Enter an optional **Zone Description** to further describe the zone, if desired
- Click **Save & Continue** to move on to the portal settings for the zone

To edit an existing zone, click  at the end of its row.

To delete an existing zone, click  at the end of its row, and then click to confirm the action.

26.2 Common Captive Portal Scenarios

The following are some basic, common scenarios for the use of a Captive Portal. The details of how to perform all of the actions described will be covered throughout this chapter.

26.2.1 Portal Configuration Without Authentication

For a simple portal without authentication:

- Create a new Zone
- Check **Enable captive portal**
- Select an **Interface**
- Upload an HTML page with the portal contents as described in *Portal page without authentication*
- Click **Save**

Additional configuration options may be added as detailed in *Zone Configuration Options*.

26.2.2 Portal Configuration Using Local Authentication or Vouchers

To setup a portal with local authentication:

- Create a Zone
- Check **Enable captive portal**
- Select an **Interface**
- Set **Authentication Method** to **Local User Manager / Vouchers**
- Upload an HTML page with the portal contents as described in *Portal page with authentication*.

Additional configuration options may be added as detailed in *Zone Configuration Options*. Then configure the local users in the **User Manager** (*User Management and Authentication*).

To use vouchers, proceed to the **Vouchers** tab and create them there. See *Vouchers* for more information on Vouchers, and use the sample portal page HTML code from *Portal page with Vouchers*.

26.2.3 Portal Configuration Using RADIUS Authentication

To setup a portal using RADIUS authentication:

- Configure the RADIUS server to allow requests from the firewall
- Create a Zone
- Check **Enable captive portal**
- Select an **Interface**
- Set **Authentication Method** to **RADIUS Authentication**
- Fill in the settings for **Primary RADIUS Server** under **Primary Authentication Source**

Read the next section for information on specific configuration options.

26.3 Zone Configuration Options

This section describes each of the configuration options for a Captive Portal zone. Options for a zone are independent of those for other zones. For example, allowed IP address entries in a zone only affect that specific zone.

To reach this page, navigate to **Services > Captive Portal** and edit an existing zone from the list with  , or click  **Add** to create a new zone.

Enable
Check to enable this Captive Portal zone.

Description
Brief text describing the purpose of the zone.

Interface
Determines the interfaces that used by this Captive Portal zone. This **cannot** be a WAN interface. It can be a bridge interface so long as it is the actual bridge (e.g. `bridge0`) and the bridge interface has an IP address assigned.

Maximum concurrent connections
Specifies the maximum number of concurrent connections to the portal web server per IP address. The default value is 4, which is sufficient for most environments. This limit exists to prevent a single host from exhausting all resources on the firewall, whether inadvertent or intentional.

One example where this would otherwise be a problem is a host infected with a worm. The thousands of connections issued will cause the captive portal page to be generated repeatedly if the host is not authenticated already, which would otherwise generate so much load it could leave the firewall unresponsive.

Idle timeout
A timeout, specified in minutes, after which idle users will be disconnected by the portal. Users may log back in immediately.

Hard timeout
A timeout, specified in minutes, after which the portal will forcefully log off users.

Tip: Set either a hard timeout, idle timeout, or both to ensure sessions are removed by the portal when users do not log off manually.

Users may log back in immediately after the hard timeout if their credentials are still valid (for local accounts, not expired, and for RADIUS authentication, user can still successfully authenticate to RADIUS).

Note: If a timeout value is set, the timeout must be less than the DHCP lease time or captive portal sessions can remain active for IP addresses that have switched to different devices. Setting the timeout lower will ensure that the portal sessions end before the lease would be reallocated to a new client.

Traffic Quota
An amount of traffic which, when exceeded by a client, will trigger a disconnect of that client by the portal. This includes both upload and download traffic. Users may log back in immediately if their credentials are still valid

Pass-Through Credits
: These credits give devices a grace period before they must authenticate via the portal. For example, a device could connect 3 times within a day without seeing the portal page, but any more than that and they must login. By setting the hard timeout to a value such as 1 hour, the portal would effectively limit a client to three hours of access before forcing it to authenticate. By default this is disabled, and all clients are presented with the portal login page and must login.

Note: For this to be effective, set a hard timeout and/or idle timeout.

Pass-through credits allowed per MAC address
: The number of times a specific MAC address may connect through the portal. Once the client uses its credits, it can only log in with valid credentials until the waiting period has expired.

Waiting period to restore pass-through credits
: The number of hours after which the portal will restore the pass-through credits for a client to the original count after it uses the first one. This must be above `0` hours.

Reset waiting period on attempted access
: If enabled, the waiting period is reset by the portal to the original duration if access is attempted when all pass-through credits have already been exhausted. This prevents people who repeatedly attempt to access the portal from gaining open access too quickly.

Logout popup window
: When checked, the portal attempts to show a logout pop up window to the user which allows clients to explicitly disconnect themselves before the idle or hard timeout occurs. Unfortunately, since most browsers block pop up windows, this window may not work for most clients unless.

Pre-authentication redirect URL
: As the name implies, this option redirects users to the specified URL *before* they authenticate. Commonly, this is used to display a custom landing page describing the device location hosted on a server locally or elsewhere. That landing page must contain a link which in turn redirects the users back to the portal page, e.g. `http://x.x.x.x:8002/index.php?zone=somezone&redirurl=http%3A%2F%2Fsomesite.example.com`.

  See also:

  See *Allowed Hostnames* to allow hostnames through the portal without authentication, and *Allowed IP Address* for IP addresses.

  The custom captive portal page must have extra code at the top to properly handle this redirect. In the example code below, the pre-authentication redirect target page must also put its own URL in the `redirurl` parameter of its link back to the portal in order for the login page to appear.

```
<?php
require_once("globals.inc");
$request_uri = urldecode(str_replace("/index.php?zone={$_REQUEST['zone']}&redirurl=", "",
↪ $_SERVER["REQUEST_URI"]));
$portal_redirurl = urldecode("$PORTAL_REDIRURL$");
if(!stristr($portal_redirurl, $request_uri)) {
     Header("Location: $PORTAL_REDIRURL$");
     exit;
}
?>
```

After authentication Redirection URL
: After authenticating or clicking through the portal, it will redirect users to this URL rather than the

one they originally tried to access. If this field is left blank, the portal will redirect the user to the URL they initially attempted to access.

Blocked MAC address redirect URL
URL to which the portal will redirect users with blocked MAC addresses when they attempt access through the portal.

Preserve user database
When set, the database containing logged-in users is preserved by the portal when the firewall reboots.

Concurrent user logins
Controls whether or not users are allowed to connect multiple times. This is not a total limit for the entire portal, but a per-account limit.

May be set to one of the following:

Disabled
The portal will not allow concurrent logins for a user or voucher.

Multiple
(Default) The portal does not enforce any restrictions on concurrent logins by a user or voucher.

Last Login
The portal will only allow only one login per user account or voucher. The most recent login is permitted and any previous logins are disconnected.

First Login
The portal will only allow only one login per user account or voucher. The portal permits the first login and denies any subsequent login attempt.

MAC filtering
When set, the portal disables MAC address filtering. This is necessary in cases where the MAC address cannot reliably be determined, such as when multiple subnets exist behind a separate router using the portal. In that type of situation, all users behind a router will show up to the portal with the MAC address of the intermediate router. If this option is set, the portal will not attempt to ensure that the MAC address of clients stay the same while they are logged into the portal.

Note: This option is not compatible with RADIUS MAC authentication.

Pass-through MAC Auto Entry
In certain use cases, users may only need to authenticate once per device, and then the client should not see the portal login again unless they change devices. Setting up pass-through MAC entries can automatically achieve this goal.

Pass-through MAC automatic additions
If this option is set, the portal automatically adds a MAC passthrough entry after the user has successfully authenticated. Users of that MAC address will never have to authenticate again so long as the entry is present in the configuration. To remove the passthrough MAC entry, log in and remove it manually from the Pass-through MAC tab.

Note: This option is not compatible with RADIUS MAC authentication or the logout window.

Pass-through MAC automatic addition with username
If this option is set, the portal saves the username used during authentication along

with the pass-through MAC entry. To remove the passthrough MAC entry, log in and remove it manually from the Pass-through MAC tab.

Per-user bandwidth restrictions
Captive Portal can also optionally rate-limit users to keep them from using too much bandwidth. The **Default download** and **Default upload** fields define the default values for user bandwidth, specified in Kilobits per second. These values can be overridden by RADIUS (*Passing back configuration from RADIUS Servers*) for different limits for specific users. If the fields are blank or set to `0`, then users have unlimited bandwidth.

Use Custom Captive Portal Page
When set, enables upload controls for manually crafted portal pages. See *HTML Page Contents* for details. When unset, simple portal page customization controls are available (*Captive Portal Login Page*).

26.3.1 Captive Portal Login Page

These simple customization controls enable small changes to the portal page without writing custom HTML. For more complicated portal pages, see *HTML Page Contents*.

Display Custom Logo Image
When set, the portal page includes the custom image from **Logo Image** instead of the default logo.

Logo Image
Upload control for setting a custom logo image.

Display Custom Background Image
When set, the portal page includes the custom image from **Background Image** instead of the default background.

Background Image
Upload control for setting a custom background image.

Terms and Conditions
Text displayed by the portal to the user to which the user must agree before they are permitted to login.

26.3.2 Authentication

This section configures authentication for Captive Portal. If authentication is required for the zone it may be handled by the local user database, RADIUS, or LDAP.

Authentication Method

Use an Authentication backend
This option allows users to authenticate with a username and password or vouchers. The authentication is handled by the local user database (*User Management and Authentication*) or an authentication server (*Authentication Servers*).

Vouchers are pre-generated access codes which grant short-term access to users. Vouchers may be used in addition to, or instead of, user authentication. For more information on using vouchers, see *Vouchers* later in this section.

None, don't authenticate users
The portal only requires users to click through the login page for access. The form must still be submitted, but it does not need to have any user entry fields, only a submit button.

Use RADIUS MAC Authentication
The portal attempts to authenticate users by sending their MAC address as the username and the password entered into **MAC authentication secret** to the RADIUS server.

Note: Users must still attempt an HTTP connection so the portal will see the attempt and perform the initial authentication.

See *RADIUS MAC Authentication Options* for additional options.

This option is not available if MAC filtering is disabled.

Authentication Server
A multi-select control where one or more primary authentication servers, or the local database, can be set for use by the portal. See *Primary Authentication Source* for more information.

Local Database
Captive Portal users in this mode are managed in the pfSense® software GUI. Local users are added in the User Manager (*Manage Local Users*).

Additionally, the **Local Authentication Privileges** option can limit access to only users who possess the proper access privileges.

LDAP Server
When an LDAP server is active in the control, it is used by the portal for authentication as-is. There are no additional options for LDAP server behavior.

RADIUS Server
When a RADIUS server is active in the control, numerous RADIUS server options are displayed by the GUI and Captive Portal users in this zone will be validated against the configured RADIUS server(s).

Secondary Authentication Server
Similar to **Authentication Server**, but sets up an additional separate means of authentication using distinct fields. See *Secondary Authentication Source* for more information.

Primary Authentication Source

The Primary/Secondary authentication servers are used for the main username and password fields on the login form, `auth_user` and `auth_pass`, such as:

```
<tr>
     <td align="right">Username:</td>
     <td><input name="auth_user" type="text" style="border: 1px dashed;"></td>
 </tr>
<tr>
     <td align="right">Password:</td>
     <td><input name="auth_pass" type="password" style="border: 1px dashed;"></td>
</tr>
```

If the first server is down, the portal will attempt authentication using the other servers in the list, in order (top down).

Secondary Authentication Source

The secondary authentication source defines a completely separate authentication setup from the primary. For example, the primary source could be traditional usernames and passwords, while the secondary could be pre-paid card numbers or PINs.

The secondary authentication source uses the form fields `auth_user2` and `auth_pass2` in the captive portal HTML, such as:

```
<tr>
     <td align="right">Username:</td>
     <td><input name="auth_user2" type="text" style="border: 1px dashed;"></td>
</tr>
<tr>
     <td align="right">Password:</td>
     <td><input name="auth_pass2" type="password" style="border: 1px dashed;"></td>
</tr>
```

If the first server is down, the portal will attempt authentication using the other servers in the list, in order (top down).

Local Database Options

Local Authentication Privileges
When **Allow only users/groups with 'Captive portal login' privilege set** is active, the portal will limit access to only users who have Captive Portal privilege. The privilege can be directly on their account or inherited via group membership..

RADIUS Authentication Options

RADIUS is a means of authenticating users against a central server that contains account information. There are many implementations of RADIUS, such as FreeRADIUS, Radiator, and NPS on Windows servers.

RADIUS accounting can be enabled to send usage information for each user to the RADIUS server. Refer to documentation for the RADIUS server for more information.

See also:

To add or edit RADIUS server entries on pfSense software, see *Authentication Servers*.

See also:

For those with a Microsoft Active Directory network infrastructure, RADIUS can be used to authenticate captive portal users from Active Directory using Microsoft NPS. This is described in *Authenticating from Active Directory using RADIUS/NPS*.

Passing back configuration from RADIUS Servers

Some default Captive Portal settings can be overridden by reply attributes from RADIUS servers. The exact attributes can vary by vendor, and may not be supported by all RADIUS servers.

User bandwidth restrictions
: Defines the bandwidth for the user, drawn from common options such as `WISPr-Bandwidth-Max-Up`/`WISPr-Bandwidth-Max-Down`, or `ChilliSpot-Bandwidth-Max-Up`/`ChilliSpot-Bandwidth-Max-Down`.

Session Timeout
: Drawn from the RADIUS attribute `Session-Timeout`, it will disconnect the user after the time specified by the RADIUS server.

Idle Timeout
: Drawn from the RADIUS attribute `Idle-Timeout`, it will disconnect the user after the time specified by the RADIUS server.

Accounting Interval Interim
: Taken from `Acct-Interim-Interval`, it directs the portal to send interim accounting updates at the specified interval.

URL Redirection
: Allows the after-authentication redirect URL to be defined by the RADIUS server through `WISPr-Redirection-URL`.

RADIUS Options

These options fine-tune how RADIUS authentication behaves.

NAS Identifier
: Configures an alternate NAS Identifier to send with RADIUS requests. The default value is `CaptivePortal-<zone name>`.

Reauthentication
: If enabled, the portal sends `Access-Request` packets to the RADIUS server for each user that is logged in every minute. If an `Access-Reject` is received for a user, that user is disconnected from the captive portal immediately. This allows actively terminating user sessions from the RADIUS server.

> **Warning:** If concurrent login limits are defined in RADIUS this option may not work properly, as the additional request would fail as the reauthentication attempt would be considered a second concurrent login.

Note: If reauthentication is combined with RADIUS accounting, **Interim** accounting updates must be used to track usage during sessions, otherwise the RADIUS server will not know if a user exceeds limits until they logout.

Session-Timeout
: When set, clients will be disconnected after the amount of time set by the RADIUS `Session-Timeout` attribute sent to the portal at login.

Traffic Quota
: When set, the portal uses the `pfSense-Max-Total-Octets` reply attribute sent by the RADIUS

server to set a traffic quota for a user. This determines an amount of traffic which, when exceeded by a client, will trigger a disconnect of that client by the portal. This includes both upload and download traffic.

Per-user Bandwidth Restrictions
When set, the portal uses the `pfSense-Bandwidth-Max-Up` and `pfSense-Bandwidth-Max-Down` reply attribute sent by the RADIUS server to set per-user bandwidth restrictions.

MAC address format
This option changes the MAC address format used in RADIUS. Change this to alter the username format for RADIUS MAC authentication to one of the following styles:

Default
Colon-separated pairs of digits: `00:11:22:33:44:55`

Single Dash
Digits in two groups, separated by a single dash halfway: `001122-334455`

IETF
Hyphen-separated pairs of digits: `00-11-22-33-44-55`

Cisco
Groups of four digits separated by a period: `0011.2233.4455`

Unformatted
All digits together with no formatting or separators: `001122334455`

RADIUS MAC Authentication Options

RADIUS MAC Secret
When the portal attempts RADIUS MAC authentication, it sends the MAC Address as the username and this value as the password.

Login Page Fallback
When set, the portal will redirect a client to the login page if MAC Authentication failed.

Accounting

RADIUS accounting sends session information back to the RADIUS server indicating when a user session starts, ends, and how much data they have transmitted.

Warning: Not all RADIUS servers support or are configured to accept accounting data. Setup the RADIUS server properly before enabling this feature.

Accounting Server
An authentication server entry for a RADIUS server to which the portal will send accounting data (*Authentication Servers*).

Send Accounting Updates
Configures the specific type of accounting supported by the server.

No updates
Synonymous with disabling accounting, the portal will not send accounting updates to the server.

Stop/start
The portal sends START and STOP records for a user session only.

Stop/start (FreeRADIUS)
The portal sends START and STOP records for a user session only, in a way that is compatible with FreeRADIUS.

Interim
The portal sends START and STOP records and also periodically sends updates to the server while a user session is active. This method is less likely to lose session data if the firewall restarts without notifying the RADIUS server of a STOP message, but will cause increased database usage on the RADIUS server.

Accounting Style
When **Invert Acct-Input-Octets and Acct-Output-Octets** is enabled, data counts for RADIUS accounting packets will be taken from the client perspective, not the NAS. `Acct-Input-Octets` will represent download, and `Acct-Output-Octets` will represent upload.

Idle Time Accounting
This option changes the time sent in the STOP message for a user disconnected by the portal for idle timeout. When unset (default), the time sent is the last activity time. When set, the idle time is included.

26.3.3 HTTPS login

Login
When set, the portal will listen for and accept HTTPS requests for the portal page. This option requires an **SSL/TLS Certificate**.

HTTPS server name
The FQDN (hostname + domain) used by the portal for HTTPS. This must match the Common Name (CN) on the certificate to prevent users from receiving certificate errors.

SSL Certificate
Select the SSL certificate used by the portal for HTTPS . Certificates are managed in *Certificate Management*.

Disable HTTPS Forwards
When checked, attempts by clients to connect to HTTPS sites on port 443 are not redirected to the portal. This prevents users from receiving invalid certificate errors. Users must attempt a connection to an HTTP site, and will then be forwarded to the portal.

26.3.4 HTML Page Contents

When **Use custom captive portal page** is set on the zone, the portal displays these controls to upload custom HTML pages to alter the look of the page presented to users when they are redirected to the portal.

Customizing these pages is optional. Any page contents left blank will use internal defaults.

Portal pages may contain PHP code, and may also include other resources such as images and CSS files. See *File Manager* for more information on including additional assets in a custom portal page.

> **Warning:** Since custom portal pages can run PHP, audit the code to ensure security so the page cannot be exploited by connecting users. Also, avoid granting privileges to this page to untrusted administrators.

In each individual section, the pages can be managed by the displayed controls:

- To upload a new page, click **Browse** and select the file to upload. When the portal options are saved, the file will be copied.
- To view an existing page, click  **View Page Contents**
- To download a copy of an existing page, click  **Download**
- To erase the custom page, click  **Restore Default Page**

Portal page contents

This control is for the main portal page presented to users. Depending on the selected options for the portal, use one of the following examples as the basis for a custom page.

Portal page without authentication

This shows the HTML of a portal page that can be used without authentication.

Listing 1: Download: `example-noauth.html`

```
<html>
<head>
        <title>Welcome to our portal</title>
</head>
<body>
        <p>Welcome to our portal</p>
        <p>Click Continue to access the Internet</p>
        <form method="post" action="$PORTAL_ACTION$">
                <input name="redirurl" type="hidden" value="$PORTAL_REDIRURL$">
                <input name="zone" type="hidden" value="$PORTAL_ZONE$">
                <input name="accept" type="submit" value="Continue">
        </form>
</body>
</html>
```

Portal page with authentication

Here is an example portal page requiring authentication.

Listing 2: Download: `example-auth.html`

```
<html>
<head>
        <title>Welcome to our portal</title>
</head>
<body>
        <p>Welcome to our portal</p>
        <p>Enter your username and password and click Login to access the Internet</p>
```

(continues on next page)

(continued from previous page)

```
        <form method="post" action="$PORTAL_ACTION$">
                <input name="auth_user" type="text">
                <input name="auth_pass" type="password">
                <input name="redirurl" type="hidden" value="$PORTAL_REDIRURL$">
                <input name="zone" type="hidden" value="$PORTAL_ZONE$">
                <input name="accept" type="submit" value="Login">
        </form>
</body>
</html>
```

Portal page with Vouchers

Here is an example portal page for use with vouchers.

Listing 3: Download: `example-voucher.html`

```
<html>
<head>
        <title>Welcome to our portal</title>
</head>
<body>
        <p>Welcome to our portal</p>
        <p>Enter your voucher code and click Login to access the Internet</p>
        <form method="post" action="$PORTAL_ACTION$">
                <input name="auth_voucher" type="text">
                <input name="redirurl" type="hidden" value="$PORTAL_REDIRURL$">
                <input name="zone" type="hidden" value="$PORTAL_ZONE$">
                <input name="accept" type="submit" value="Login">
        </form>
</body>
</html>
```

Authentication error page contents

Using this control, optionally upload a custom HTML page to be displayed when authentication errors happen. An authentication error occurs when a user enters a bad username or password, or in the case of RADIUS authentication, potentially an unreachable RADIUS server.

By default, this error page is simply the login page again.

Logout page contents

The logout page is presented to the user after login and it triggers a popup window. The default code uses JavaScript to create the new window in the following way:

Listing 4: Download: `example-logout.html`

```
<html>
<head><title>Redirecting...</title></head>
```

(continues on next page)

(continued from previous page)

```
<body>
<span style="font-family: Tahoma, Verdana, Arial, Helvetica, sans-serif; font-size: 11px;
↪">
<b>Redirecting to <a href="<?=$my_redirurl;?>"><?=$my_redirurl;?></a>...</b>
</span>
<script type="text/javascript">
//<![CDATA[
LogoutWin = window.open('', 'Logout', 'toolbar=0,scrollbars=0,location=0,statusbar=0,
↪menubar=0,resizable=0,width=256,height=64');
if (LogoutWin) {
        LogoutWin.document.write('<html>');
        LogoutWin.document.write('<head><title>Logout</title></head>') ;
        LogoutWin.document.write('<body style="background-color:#435370">');
        LogoutWin.document.write('<div class="text-center" style="color: #ffffff; font-
↪family: Tahoma, Verdana, Arial, Helvetica, sans-serif; font-size: 11px;">') ;
        LogoutWin.document.write('<b>Click the button below to disconnect</b><p />');
        LogoutWin.document.write('<form method="POST" action="<?=$logouturl;?>">');
        LogoutWin.document.write('<input name="logout_id" type="hidden" value="<?=
↪$sessionid;?>" />');
        LogoutWin.document.write('<input name="zone" type="hidden" value="<?=$cpzone;?>"␣
↪/>');
        LogoutWin.document.write('<input name="logout" type="submit" value="Logout" />');
        LogoutWin.document.write('</form>');
        LogoutWin.document.write('</div></body>');
        LogoutWin.document.write('</html>');
        LogoutWin.document.close();
}

document.location.href="<?=$my_redirurl;?>";
//]]>
</script>
</body>
</html>
```

Most browsers have pop-up blockers that will most likely stop that logout window from appearing, so investigate other possible means of creating a JavaScript pop-up using similar code.

26.4 MAC Address Control

The **MACs** tab defines actions for MAC addresses that can be either passed through the portal for this zone without requiring authentication, or blocked from reaching the portal.

To manage these MAC entries:

- Navigate to **Services > Captive Portal**
- Click  on the line for the Zone to edit
- Click the **MACs** tab
- Click  **Add** to add a new entry

- Fill in the form as follows:

  Action
  Defines the action to take on this entry:

  Pass
  Always allow traffic through from this MAC address without authentication.

  Block
  Always deny traffic from this MAC address

  MAC address
  The MAC address of the device to allow. The value must be colon-separated pairs of digits, such as `00:11:22:33:44:55`.

  Description
  Some text describing the entry, if desired.

  Bandwidth up/down
  The amount of bandwidth that this device may use, specified in Kilobits per second. Leave blank to not specify a limit.

- Click **Save**

From this page, an entry may be edited by clicking  on its row, or deleted by clicking  .

26.5 Allowed IP Address

The **Allowed IP Address** tab works similarly to the **MACs** tab, except it checks IP addresses instead of MAC addresses. Traffic matching the specified IP address and the configured direction will always be allowed through the portal with no authentication in this zone.

IP Address
The IP address of the device to always pass through the portal.

Description
Some text describing the entry, if desired.

Direction
The direction to allow traffic matching this IP address.

From
Allow traffic sourced from this IP address through the portal, such as a local client IP address attempting to reach the Internet, or the IP address of a management client that must reach hosts on the portal network.

To
Allow traffic with this IP address as a destination, such as a local web server IP address that must be reached via port forward, or a remote web server IP address which clients must always reach.

Both
Allow traffic both to and from this IP address.

Bandwidth up/down
The amount of bandwidth that this device may use. Leave blank to not specify a limit.

26.6 Allowed Hostnames

Allowed Hostnames work similarly to **Allowed IP Address** entries, except they are configured by hostname instead of IP address. A daemon periodically resolves the hostnames to IP address(es) and allows them through the portal without authentication in this zone.

The most common use of this feature is to make a "walled garden" style portal, where users are permitted to access a restricted set of sites without authenticating to the portal. This is also commonly used with the **Pre-authentication Redirect URL** if that page is hosted externally.

Note: Often sites will use many hostnames, content delivery networks, or ad servers as part of their content. In order to allow a site to load fully, all of these additional sites must be added to the list of allowed hostnames.

Direction
The direction to allow traffic matching this hostname. In most typical use cases for allowing hostnames, the *To* or *Both* directions are the best fit.

To
Allow traffic from local clients to a remote site matching this hostname as a destination without authentication. For example, a remote web server that must always be reachable by local clients, even when they are not logged in.

From
Allow traffic sourced from this hostname through the portal, such as the hostname of a local client attempting to reach the Internet.

Both
Allow traffic both to and from this hostname.

Hostname
The fully qualified domain name (FQDN) of the target host or site. The hostname must exist in DNS so that it can be resolved to an IP address.

Description
Text describing the entry, if desired.

Bandwidth up/down
The amount of bandwidth that traffic to or from this hostname may use. Leave blank to not specify a limit.

26.7 Vouchers

Vouchers are single use codes used to gain Internet access through a Captive Portal. Each roll of vouchers is cryptographically generated and includes a set time limit. Vouchers are common in places where an organization wants authenticated, but time-limited, Internet access without needing to provide a username and password to users.

This type of configuration is prevalent in travel and hospitality locations such as coffee shops, hotels, and airports. Users enter a voucher code in the portal login form and are the portal grants access for the amount of time allowed by the voucher roll. Voucher rolls can be exported by the GUI as a CSV file, and some companies have even integrated the exported voucher lists into point of sale applications to print voucher codes on customer receipts.

Voucher time does not stop counting down if a user logs out; they allow access only from the start of the session until the duration of the voucher length has elapsed. During that time, the voucher can be re-used by the same or a different computer. If the voucher is used again by another computer, the previous session is stopped.

Vouchers require a public/private RSA key pair to generate and verify. A 32-bit set of keys is generated automatically by the firewall the first time the page loads. A custom key pair may be generated manually by the GUI as well. The maximum key length is 64 Bits. Using shorter keys will make the voucher codes shorter but eventually less secure.

26.7.1 Voucher Options

Voucher options are unique per Captive Portal Zone. To configure vouchers, navigate to the **Vouchers** tab when editing a Captive Portal Zone.

Voucher Rolls
Voucher rolls are managed by this section of the page. The page lists information about each roll along with a link to add new rolls. No options appear here until after the other settings are active. See *Managing Voucher Rolls* for details.

Enable
When checked, this portal zone allows vouchers as a method of authentication, and the page changes to display the other voucher options.

Voucher Keys
The keys which generate and verify vouchers. Before vouchers are active on a zone, the GUI randomly generates new values each time the page loads. After saving voucher settings, the keys are present in the configuration and remain static from that point on.

> **Warning:** Do not change the keys or other bits after creating voucher rolls. If the values change, all current voucher rolls are invalid. Create new voucher rolls using the new settings after making changes.

Voucher Public Key
This key is used by the portal to decrypt vouchers. Use the existing random key, or click **Generate new keys** to make a new public and private key pair. Users may generate keys elsewhere and paste the RSA public key (64 Bit or smaller) in PEM format here.

Voucher Private Key
This key is used by the portal to generate voucher codes and does not need to be available if the vouchers are generated by another system. Use the existing random key or paste in an RSA private key (64 Bit or smaller) in PEM format here.

Character Set
The character set defines which characters are valid for voucher text. The character set is case sensitive and should contain printable characters (numbers, lower case and upper case letters) that are hard to confuse with others. For example, avoid `0` (Digit zero), `O` (Letter O), `l` (Lowercase L), and `1` (Digit One). It cannot contain a space, double quote, or comma. A smaller character set will result in longer vouchers to ensure sufficient randomness.

Voucher Bits
The following "bit" fields control how the vouchers themselves are generated by the portal. The best practice is to leave these values at their defaults, but they may be adjusted if necessary. The total of all bit fields *must* be less than the RSA key size. For example, the default values are `16`, `10`, and `5`. The sum of these is `31`, which is one less than the default RSA key size of `32`.

# of Roll Bits
Number of bits for the Roll ID. Set this larger to have a lot of rolls active at the same time. Can be from `1-31`, the default value is `16`.

# of Ticket Bits
Number of bits for the Ticket ID. Set this larger if each roll will have a large number of

vouchers. Can be from `1-16`, the default value is `10`.

# of Checksum Bits
Reserves a range in each voucher to store a simple checksum over **Roll bits** and **Ticket bits**. Allowed range is `0-31`, the default value is `5`.

Magic Number
The magic number is present in every voucher, and is verified by the portal during voucher check. The size of the magic number depends on the number of bits remaining after adding together the number of bits for the roll, ticket, and checksum. If there are no bits remaining for use by the magic number, then the portal does not use magic numbers.

Invalid Voucher Message
This message is displayed by the portal to the user if they attempt to enter a voucher that does not exist or is not valid in any way except for being expired.

Expired Voucher Message
This message is displayed to the user by the portal if they enter a voucher that was valid, but has expired.

26.7.2 Enable Vouchers

- Use the pfSense® WebGUI to navigate to **Services > Captive Portal**
- Click  on the line for the Zone to edit
- Ensure the Zone **Authentication Method** is set to *Use an Authentication backend*, change the value and save if necessary.
- Click the **Vouchers** tab
- Check **Enable**
- Fill in the form based on the options described in *Voucher Options*. In most cases, the options may remain at their default values.
- Click **Save**

With Vouchers enabled, the voucher management controls will be active in the GUI.

26.7.3 Managing Voucher Rolls

Vouchers are created by the portal in batches called **Rolls**. Each roll has specific settings that are unique to that roll. For example, a roll can have an 8-hour time limit and a separate roll can have a 12-hour time limit. Then users may be given voucher codes depending on which level of service they purchased and they will be limited to the amount of time corresponding to the voucher roll from which their code was picked.

Voucher Roll Options

Roll #
The number of this roll. Each roll must have a unique number. This can be any number from `0` to `65535` with the default number of **Roll Bits**.

Minutes per Ticket
Defines how long the voucher lasts, in minutes. The voucher time starts counting down the moment the voucher is used, and does not stop, so plan the voucher length accordingly. Because this is defined in minutes, ensure the correct length is used, e.g. `1440` minutes is 24 hours.

Count
Defines the number of vouchers in this roll. The value can be from `0` to `1023` with the default number of **Ticket Bits**.

Note: If the count on an existing roll is changed, it will invalidate **all** other vouchers on the roll.

Comment
A description of the roll for reference, such as `2 hour vouchers for coffee purchases`.

Creating Voucher Rolls

To create a voucher roll:

- Use the pfSense® WebGUI to navigate to **Services > Captive Portal**
- Click  on the line for the Zone to edit
- Click the **Vouchers** tab
- Click  **Add** under the roll list
- Fill in the options as described in *Voucher Roll Options*
- Click **Save**

The new roll is available for immediate use by clients.

Editing Existing Rolls

To edit an existing voucher roll, click  at the end of its row, but be careful when making changes. Changing the **Roll** number or **Count** will invalidate the current vouchers on the roll.

Removing Voucher Rolls

To remove rolls of vouchers, click  at the end of their row. When a roll is removed, *all* of the vouchers in that roll become invalid. Do not remove a roll unless it has been completely used, compromised, or otherwise unnecessary.

Exporting/Downloading Voucher Rolls

Click  to download a file containing the vouchers in the specified roll. This action downloads a `.csv` (Comma Separated Value) spreadsheet containing all voucher codes for this roll.

Nearly any spreadsheet editor can open this file, such as LibreOffice Calc, Google Docs, or Excel. Programs such as those can print vouchers, feed them into a POS system, and so on.

Using Vouchers on A Portal Page

The portal page must submit voucher codes via the `auth_voucher` form field. See *Portal page with Vouchers* for an example.

Viewing Active Vouchers

To view the list of currently active vouchers and their timers, navigate to **Status > Captive Portal**, on the **Active Vouchers** tab for a zone, as seen in Figure *Active Vouchers*.

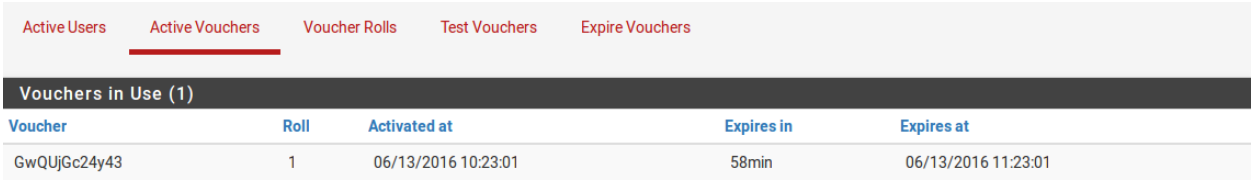

Fig. 1: Active Vouchers

Viewing Voucher Roll Utilization

To view a list of voucher rolls and usage counts, navigate to **Status > Captive Portal**, on the **Voucher Rolls** tab for a zone, as in Figure *Vouchers Roll Usage*

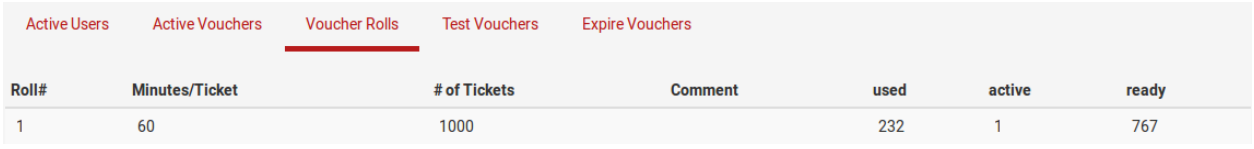

Fig. 2: Vouchers Roll Usage

Testing Vouchers

To test the validity of a voucher code, enter it at **Status > Captive Portal**, on the **Test Vouchers** tab for a zone. Upon submission, the page will display if a code is valid or not, and if it is valid, it will show the voucher time limit, as seen in Figure *Testing Vouchers*. Testing a voucher does not count it as used or expired, it is still free to be used at a later time by a client.

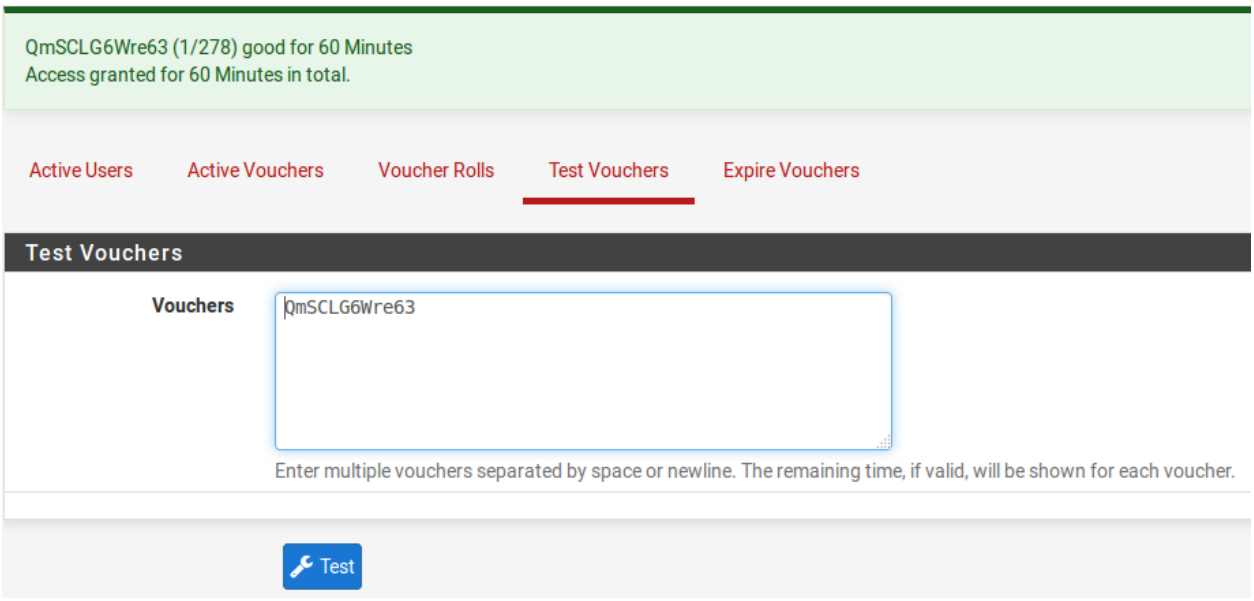

Fig. 3: Testing Vouchers

Expiring Vouchers

To invalidate vouchers, during or before use, enter them at **Status > Captive Portal**, on the **Expire Vouchers** tab for a zone. After submitting, any voucher listed in the form will no longer be allowed by the portal. Active vouchers entered on this page are also immediately expired.

The page can expire any number of vouchers in a batch. Enter vouchers separated by newlines.

26.7.4 Synchronizing Vouchers

When the High Availability option to synchronize Captive Portal data via XMLRPC is enabled on a primary node, pfSense software copies voucher data to the secondary node automatically.

If the primary node is offline, the secondary node may have new data which then must be synchronized back to the primary node. There are options to enable this "reverse" synchronization of voucher data to the primary HA node on the **High Availability** tab in the Captive Portal settings of each zone.

This works similarly to the XMLRPC configuration synchronization options in the high availability settings (*pfSense Software XMLRPC Config Sync Overview*). When active, this function copies the voucher rolls configured target node and also pushes information about active vouchers to the target node as vouchers are consumed by users.

Primary node IP
: The IP address of the primary HA node for voucher synchronization.

Primary node username
: The username for synchronization access. Must have appropriate privileges, for example, admin-level privileges or at least the `System - HA node sync` privilege.

Primary node password
: The password for the **Primary node username** account.

26.8 File Manager

The **File Manager** tab in a Captive Portal zone is used to upload files that can then be utilized inside a captive portal page, such as style sheets, image files, PHP or JavaScript files.

The total size limit for all files in a zone is **1 MB**.

26.8.1 File Name Conventions

When a file is uploaded using the File Manager, the file name will automatically be prefixed with `captiveportal-`. For example, if `logo.png` is uploaded it will become `captiveportal-logo.png`. If a file already has that prefix in its name, the name is not changed.

These files will be made available in the root directory of the captive portal server for this zone. The files may be referenced directly from the portal page HTML code using relative paths.

Example: An image with the name `captiveportal-logo.jpg` was uploaded using the file manager, It can then be included in the portal page as follows:

```
<img src="captiveportal-logo.jpg" />
```

PHP scripts may be uploaded as well, but they may need to be passed extra parameters to work as desired, for example:

```
<a href="/captiveportal-aup.php?zone=$PORTAL_ZONE$&redirurl=$PORTAL_REDIRURL$">
    Acceptable usage policy
</a>
```

26.8.2 Managing Files

To upload files:

- Navigate to **Services > Captive Portal**
- Edit the zone where the files will be uploaded
- Click the **File Manager** tab
- Click 
- Click **Browse**
- Locate and select the file to upload
- Click  **Upload**

The file will be transferred to the firewall and stored in the configuration.

To delete files:

- Navigate to **Services > Captive Portal**
- Edit the zone where the file to delete is located
- Click the **File Manager** tab
- Click  next to the file to remove
- Click **OK** to confirm the delete action

The file will be removed from the portal configuration and will no longer be available for use in portal pages.

See also:

- *Captive Portal Status*
- *Captive Portal Authentication Logs*
- *Troubleshooting Captive Portal*

Captive Portal in pfSense® software forces users on an interface to authenticate before granting access to the Internet. Where possible, the firewall automatically presents a login web page in which the user must enter credentials such as a username/password, a voucher code, or a simple click-through agreement.

This feature is commonly used throughout the hospitality industry (Hotels, restaurants, airports, and more) as well as in corporate and even home environments. It is primarily used for wireless hot spots or for additional authentication before allowing access to internal networks from wireless clients.

Captive Portal is configured under **Services > Captive Portal**.

See also:

Hangouts Archive to view the April 2015 Hangout on Captive Portal.

26.9 Limitations

The Captive Portal implementation in pfSense does have some limitations. This section covers those, and the common ways of working around them where possible.

26.9.1 Does not yet support IPv6

Currently, Captive Portal does not support IPv6.

26.9.2 Not capable of reverse portal

A reverse portal, requiring authentication for traffic coming into a local network from the Internet, is not possible.

CHAPTER

TWENTYSEVEN

HIGH AVAILABILITY

27.1 High Availability Synchronization Settings

High Availability Synchronization settings for pfSense® software are located in the GUI at **System > High Availability**.

This document covers the settings on that page, but the general topics are covered in more detail throughout this chapter.

27.1.1 State Synchronization Settings (pfsync)

The settings in this section control the behavior of state synchronization and related functions. State synchronization allows firewalls acting as HA nodes to exchange state data so that all nodes in the cluster have knowledge about network connections.

The state synchronization settings should be enabled on **all** members of an HA cluster.

See also:

For details on how state synchronization operates, see *State Synchronization (pfsync) Overview*.

Synchronize States

Controls whether or not this firewall will perform state synchronization with other HA nodes on a shared segment.

When checked, the firewall will perform state synchronization on the **Synchronize Interface**.

Synchronize Interface

Controls which interface the firewall uses to send and receive state synchronization data with other HA nodes. This interface must have an IP address.

The best practice is to use an interface directly linked between the HA nodes, or at least connected through a switch using an isolated VLAN.

Warning: pfsync does not support any method of authentication. If this option is set to anything other than an isolated segment it is possible for a user with access to the network on that interface to manipulate the state table. For example, they could insert states into the state table.

Filter Host ID

This option defines a custom pf host identifier carried in state data to uniquely identify which host created a firewall state.

Note: Each node participating in state synchronization must have a **different** filter host ID.

The host IDs from state data are shown on the *CARP status page* which allows administrators to check if an HA node is exchanging state data with other HA nodes.

Using a custom value is ideal but not required. On current versions of pfSense software the default is to use the last 8 characters of the host NDI. On previous versions the default behavior was to generate a randomized value on every filter reload.

The host ID value must be a non-zero hexadecimal string 8 characters or less (e.g. `1`, `2`, `ff01`, `abcdef01`).

pfsync Synchronize Peer IP

The IP address to which this firewall will send state synchronization data.

If left blank, the firewall will send state data using multicast to all hosts on the chosen **Synchronize Interface**.

In practice, state synchronization is more reliable when sent directly and not via multicast.

27.1.2 Configuration Synchronization Settings (XMLPRC Sync)

These settings control the behavior of XMLRPC configuration synchronization. XMLRPC configuration synchronization copies settings from supported sections of the configuration from a primary node to a secondary node.

Warning: XMLRPC configuration synchronization must only be enabled on the primary node! It is not possible to synchronize settings from a secondary node back to the primary node.

Warning: The interfaces on both nodes **must** be assigned **identically**, for example: wan=WAN, lan=LAN, opt1=Sync, opt2=DMZ. Check the `config.xml` contents directly to ensure a match.

If the interfaces do not match up exactly, firewall rules and other configuration items will appear to synchronize to the wrong interface on the secondary node.

See also:

For details on how XMLRPC configuration synchronization operates, see *pfSense Software XMLRPC Config Sync Overview*.

Synchronize Config to IP

The IP address of the firewall to which this node will synchronize its configuration via XMLRPC.

There are a few requirements for this to work properly:

- The target firewall must be running the same version of pfSense software
- The target firewall GUI must be running the same protocol (HTTPS or HTTP)
- The target firewall GUI must be running on the same port (e.g. `443` or `80`)

Remote System Username

The username to use for authenticating against the target firewall.

The sync user must either be `admin` or an account on the target firewall with the *System - HA node sync* privilege.

Note: If XMLRPC is configured to synchronize users, create the sync user on the secondary manually first, as well as on the primary. The redundant copy on the secondary will be removed during the first successful synchronization, but the initial synchronization cannot succeed without that account present.

Remote System Password

The password to use for authenticating against the target firewall.

Synchronize Admin

Controls whether or not the primary node will synchronize its `admin` account to the target node.

By default, the XMLRPC process does not synchronize the `admin` account, which allows each HA node to have a different password for its `admin` account.

Note: When set, this option automatically updates **Remote System Password** when the password changes on the **Remote System Username** account.

Options to Synchronize

This part of the options is a list of configuration sections which XMLRPC configuration synchronization can copy to the target node. These sections include:

User manager users and groups
: Synchronizes users and groups defined in the user manager.

  If users have associations to certificates (e.g. for OpenVPN), then certificates should also be synchronized.

Authentication servers
: Synchronizes Authentication servers defined in the User Manager settings. For example, LDAP and RADIUS server entries and their settings.

  If these entries require SSL/TLS and are set to use a certificate, then certificates should also be synchronized.

Certificate Authorities, Certificates, and Certificate Revocation Lists
Synchronizes the contents of the Certificate Manager.

This replaces the entire contents of the certificate manager on the target node, which may also cause it to replace the GUI certificate. There are multiple methods to work around this, such as:

- Use the same GUI certificate on both nodes after performing an initial synchronization.
- Import the GUI cert for the secondary into the primary node, allow it to synchronize, and then re-select it on the secondary node.
- Create a new certificate on the primary node and then select it for use on the secondary after it synchronizes.

Tip: Certificates are synchronized when changed, but services depending on those certificates are not automatically restarted. When renewing certificates, services on the secondary which are running must be manually restarted. For example, if the GUI certificate is renewed, then the GUI must manually be restarted on the secondary node.

Firewall rules
Synchronizes the contents of all firewall rule tabs, including assigned interfaces, floating rules, interface groups, VPNs, etc.

If any firewall rules utilize aliases or schedules, those sections should also be set to synchronize.

Firewall schedules
Synchronizes defined firewall schedules.

Firewall aliases
Synchronizes the contents of aliases.

NAT configuration
Synchronizes the contents of NAT rules, including outbound NAT, port forwards, 1:1 NAT, etc.

IPsec configuration
Synchronizes the contents of IPsec tunnels.

If any IPsec tunnels use certificates for authentication, then certificates should also be synchronized.

OpenVPN configuration
Synchronizes the contents of all OpenVPN instances (clients and servers).

When enabled this also synchronizes the contents of the certificate manager as OpenVPN configurations require the use of certificates.

DHCP Server settings
Synchronizes the contents of the IPv4 DHCP server settings.

This synchronization process automatically adjusts the value of failover settings. See *DHCPv4 Server* for details.

DHCP Relay settings
Synchronizes the contents of the IPv4 DHCP relay settings.

DHCPv6 Server settings
Synchronizes the contents of the IPv6 DHCP server and Router Advertisement settings.

This synchronization process automatically adjusts the values of failover settings. See *DHCPv6 Server* for details.

> **Warning:** This is only viable when using the Kea DHCP server backend as the ISC DHCPv6 backend does not support High Availability.

DHCPv6 Relay settings
Synchronizes the contents of the IPv6 DHCP relay settings.

WoL Server settings
Synchronizes the contents of Wake on LAN.

Static Route configuration
Synchronizes the contents of gateways and static routes.

Virtual IPs
Synchronizes the contents of Virtual IP addresses.

Different types of VIPs behave differently with regard to synchronization and some do not synchronize at all. See *Virtual IP Addresses* for details.

Traffic Shaper configuration
Synchronizes the contents of the ALTQ traffic shaper.

If firewall rules reference ALTQ traffic shaper queues, this should be enabled.

Traffic Shaper Limiters configuration
Synchronizes the contents of Limiters.

If firewall rules reference Limiters, this should be enabled.

DNS Forwarder and DNS Resolver configurations
Synchronizes the contents of the DNS Resolver and DNS Forwarder.

Captive Portal
Synchronizes the contents of Captive Portal, which includes additional exchanges of portal user and voucher usage data between HA nodes.

27.2 State Synchronization (pfsync) Overview

pfSense® software uses **pfsync** to synchronize firewall state table data between cluster nodes. Changes to the state table on the primary are sent to the secondary nodes over the Sync interface, and vice versa. When State Synchronization is active and properly configured, all nodes have knowledge of every connection flowing through the cluster. If the primary node fails, the secondary node will take over and most clients will not notice the transition since both nodes knew about the connection beforehand.

See also:

State Synchronization Settings (pfsync)

State synchronization with pfsync uses multicast by default, though an IP address can be defined to force unicast updates. This is ideal for environments with only two firewalls where multicast traffic is unnecessary and may not function properly. Any active interface can be used for sending pfsync updates, however utilizing a dedicated interface is the best practice for security and performance.

> **Warning:** pfsync does not support any method of authentication. If the interface is set to anything other than an isolated segment it is possible for a user with access to the network on that interface to manipulate the state table. For example, they could insert states into the state table.

In low throughput environments that aren't security paranoid, use of the LAN interface for this purpose may be acceptable. Bandwidth required for this state synchronization will vary significantly from one environment to another, but could be as high as 10% of the throughput traversing the firewall depending on the rate of state insertions and deletions.

Failover can still operate without state synchronization, but it will not be seamless. Without state synchronization, if a node fails and another takes over, user connections are dropped. Users may immediately reconnect through the other node, but they would be disrupted during the transition. Depending on the usage in a particular environment, this may go unnoticed or it could be a significant, but brief, outage.

When state synchronization is in use, **State Synchronization** settings *must be enabled* on **all** nodes participating in state synchronization, including secondary node(s), or state synchronization will not function properly.

27.2.1 pfsync and Firewall Rules

Traffic for pfsync must be explicitly passed on the Sync interface. The rule must pass the *pfsync* protocol from a source of the *Sync network* to *any* destination. A rule passing all traffic of any protocol would also allow the required traffic, but a more specific rule is more secure.

27.2.2 pfsync and Physical Interfaces

States contain information about the interface to which they are bound. Whether or not this impacts pfsync depends on the default State Policy for the node, which can be "Interface Bound States" or "Floating States" (*Firewall State Policy*).

If the default state policy is Floating States and no rules are set to use Interface Bound States, then there is no conflict and state synchronization will work even if the hardware on the nodes is different.

If the default policy is set to Interface Bound States, or any rules are set to use Interface Bound States, then there may be a potential conflict with High Availability nodes which have different hardware.

If the interfaces are not both physically identical and assigned in the same order on both nodes then the states will not properly sync, for example if WAN is `ix0` on one node and `igb0` on the other.

While having identical hardware is always the best practice, mismatched hardware can still function with Interface Bound States by using LAGG interfaces to abstract the assignments. LAGGs can work around this since the states would be bound to the `laggX` interface on each node rather than the underlying physical interface. For example, `lagg0` on primary contains `ix0`, `lagg0` on secondary contains `igb0`, but the states are on `lagg0` for both so sync will function.

27.2.3 pfsync and Upgrades

Normally pfSense software allows HA firewall upgrades without network disruption. Unfortunately, this isn't always the case with upgrades as the pfsync protocol can change to accommodate additional functionality. Always check the upgrade guide linked in all release announcements before upgrading to see if there are any special considerations for CARP users.

27.3 pfSense Software XMLRPC Config Sync Overview

Configuration synchronization makes it easier to maintain two nodes which are nearly identical. This synchronization is optional, but maintaining a cluster without it is significantly more work. Without synchronization, administrators would need to make every change multiple times and ensure the changes were consistent.

pfSense® software uses XMLRPC for configuration synchronization. When XMLRPC Synchronization is enabled, the primary node copies settings from supported areas to the secondary node and activates them after each configuration change.

See also:

Configuration Synchronization Settings (XMLPRC Sync)

Certain configuration areas cannot be synchronized, such as the Interface configuration, but most other areas can: Firewall rules, aliases, users, certificates, VPNs, DHCP, routes, gateways, and more. See *Options to Synchronize* for a full list. As a general rule, items specific to hardware or a particular installation, such as Interfaces or values under **System > General** or **System > Advanced** do not synchronize. The list of supported areas can vary depending on the version of pfSense software in use. For a list of areas that will synchronize, see the checkbox items on **System > High Availability** in the XMLRPC section. Most packages will not synchronize but some contain their own synchronization settings. Consult package documentation for more details.

Configuration synchronization should use the Sync interface, or if there is no dedicated Sync interface, use the same interface configured for firewall state synchronization.

In a two-node cluster the XMLRPC settings must *only* be enabled on the primary node, the secondary node must have these settings *disabled*.

For XMLRPC to function, both nodes must meet the following requirements:

- The GUI must be running on the same port and protocol, for example: HTTPS on port `443`, which is the default setting.
- The interfaces **must** be assigned **identically** on both nodes, for example: wan=WAN, lan=LAN, opt1=Sync, opt2=DMZ. Check the `config.xml` contents directly to ensure a match.

  Warning: If the interfaces do not match up exactly, firewall rules and other configuration items will appear to synchronize to the wrong interface on the secondary node. Additionally, this can also lead to failures in DHCP failover.

- The sync user must either be `admin` or an account with the *System - HA node sync* privilege.

  Note: If XMLRPC will synchronize users, create the sync user on the secondary manually first, as well as on the primary. The redundant copy on the secondary will be removed during the first successful synchronization, but the initial synchronization cannot succeed without it.

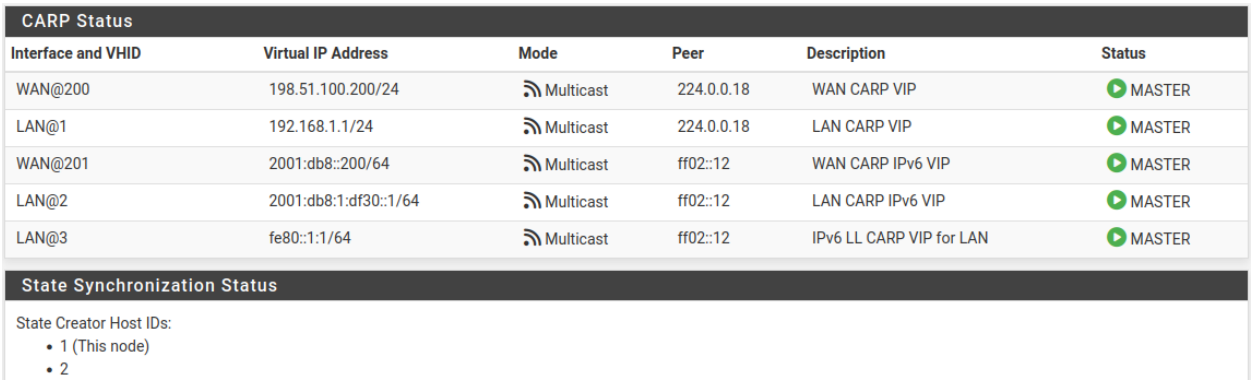
27.4 Verifying Failover Functionality

Since the goal of HA is high availability, thorough testing before placing a cluster into production is a must. The most important part of that testing is making sure that the HA peers will failover gracefully during outages.

If any actions in this section do not work as expected, see *Troubleshooting High Availability*.

27.4.1 Check CARP status

On both nodes, navigate to **Status > CARP (failover)**. If everything is working correctly, the primary will show **MASTER** for the status of all CARP VIPs and the secondary will show **BACKUP**.



CARP Status

Interface and VHID	Virtual IP Address	Mode	Peer	Description	Status
WAN@200	198.51.100.200/24	Multicast	224.0.0.18	WAN CARP VIP	MASTER
LAN@1	192.168.1.1/24	Multicast	224.0.0.18	LAN CARP VIP	MASTER
WAN@201	2001:db8::200/64	Multicast	ff02::12	WAN CARP IPv6 VIP	MASTER
LAN@2	2001:db8:1:df30::1/64	Multicast	ff02::12	LAN CARP IPv6 VIP	MASTER
LAN@3	fe80::1:1/64	Multicast	ff02::12	IPv6 LL CARP VIP for LAN	MASTER

State Synchronization Status

State Creator Host IDs:
- 1 (This node)
- 2

Fig. 1: HA CARP and State Synchronization Status (Primary Node)

If either node shows **DISABLED**, click the **Enable CARP** button, then refresh the page.

If an interface shows **INIT**, it means the interface containing the CARP VIP does not have a link. Connect the interface to a switch, or at least to the other node. If the interface will not be used for some time, remove the CARP VIP from the interface as this will interfere with normal CARP operation.

27.4.2 Check State Synchronization

The **Status > CARP** page includes **State Synchronization Status** which lists Filter Host ID values for entries in the state table. If the Filter Host ID in the High Availability settings has been changed recently, it may show both old and new values from the primary and secondary nodes. Over time the list should only reflect the current values of the Filter Host ID of each node in the cluster.

If the lists are identical or nearly identical, then state synchronization is working. If the list does not contain an entry for the Filter Host ID of the other node, then states are not being synchronized.

27.4.3 Check Configuration Replication

Navigate to key locations on the secondary node, such as **Firewall > Rules** and **Firewall > NAT** and ensure that rules created only on the primary node are being replicated to the secondary node.

If the example earlier in this chapter was followed, the "temp" firewall rule on the pfsync interface would be replaced by the rule from the primary.

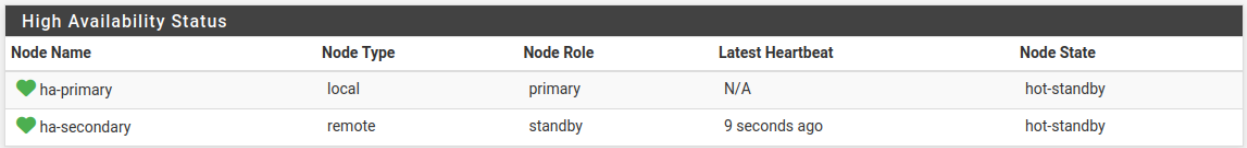
27.4.4 Check DHCP Failover Status

If DHCP failover was configured, its status can be checked at **Status > DHCP Leases** and **Status > DHCPv6 Leases**.

The exact appearance of the status depends on the DHCP service backend

Kea DHCP Failover Status

Failover status is in a section at the bottom of the DHCP and DHCPv6 Leases pages as in figure *Kea DHCP Failover Status - Primary note, both online.*. The failover status works identically for both DHCP and DHCPv6.



High Availability Status

Node Name	Node Type	Node Role	Latest Heartbeat	Node State
ha-primary	local	primary	N/A	hot-standby
ha-secondary	remote	standby	9 seconds ago	hot-standby

Fig. 2: Kea DHCP Failover Status - Primary note, both online.

See also:

See *High Availability Status – Kea DHCP Only* for more details about this section.

ISC DHCP Failover Status

Failover status is in a section at the top of the DHCP Leases page. This section contains the status of all DHCP Failover pools, as in Figure *ISC DHCP Failover Pool Status*.

Pool Status

Failover Group	My State	Since	Peer State	Since
dhcp_lan (LAN)	normal	2023/04/24 19:28:27	normal	2023/04/24 19:28:27

Fig. 3: ISC DHCP Failover Pool Status

See also:

See *Pool Status (HA/Failover) – ISC DHCP Only* for more details about this section.

27.4.5 Test CARP Failover

Now for the real failover test. Before starting, make sure that a local client behind the CARP pair on LAN can connect to the Internet with both nodes online and running. Once that is confirmed to work, it is an excellent time to make a backup.

For the actual test, unplug the primary node from the network or shut it down temporarily. The client will be able to keep loading content from the Internet through the secondary node. Check **Status > CARP (failover)** again on the backup and it will now report that it is **MASTER** for the LAN and WAN CARP VIPs.

Now bring the primary node back online and it will regain its role as **MASTER**, and the backup system will demote itself to **BACKUP** once again. At any point during this process, Internet connectivity will still work properly.

Test the HA pair in as many failure scenarios as possible. Additional tests include:

- Unplug the WAN or LAN cable
- Pull the power plug of the primary
- Disable CARP on the primary using both the temporary disable feature and maintenance mode
- Test with each system individually (power off secondary, then power back on and shut down the primary)
- Download a file or try streaming audio/video during the failover
- Run a continuous ICMP echo request (ping) to an Internet host during the failover

27.5 IPsec in High Availability Environments

IPsec is capable of supporting high availability environments on pfSense® software.

27.5.1 CARP VIP as IPsec Endpoint

CARP type virtual IP addresses are available in the **Interface** drop-down menu on IPsec phase 1 configuration entries. In high availability environments, choose an appropriate CARP VIP address for the WAN where the IPsec tunnel will terminate.

Using a CARP VIP address ensures that the IPsec tunnel will be handled by the currently active High Availability cluster member. Even if the primary node is down, the tunnel will connect to whichever cluster member has taken over the active role.

27.5.2 XMLRPC Configuration Synchronization

The IPsec configuration, static routes (for route-based IPsec), and other similar settings will synchronize via XMLRPC if those functions are enabled on the node.

Warning: When using routed IPsec (VTI) with HA, the interface assignment for the `ipsecX` interface must be performed separately on both nodes. As with all other interfaces in a cluster they must be assigned in identical order.

27.5.3 Initiation Caveats

If the cluster attempts to automatically initiate a tunnel, the cluster member in a backup state may still transmit a message which may confuse the remote peer. pfSense software attempts to minimize the chances of this happening by dynamically setting nodes in a backup state to act as a responder only as well as disabling keep alive functions. When a node becomes active it re-enables these features.

During failover the far end of a tunnel may have to wait until it fully times out before it will rebuild the tunnel to the active cluster member. This process can take several minutes depending on tunnel configuration options (i.e. DPD). This may be faster if the cluster initiates, but depends upon the configuration, environment, and what triggered the failover.

Note: Additional workarounds are present on pfSense Plus software version 22.01 and CE version 2.6.0. On older versions it was easier for the backup node to unintentionally initiate the tunnel before it could be used which delayed failover.

27.6 Layer 2 Redundancy

The diagrams earlier in this chapter did not describe layer 2 (switch) redundancy, to avoid throwing too many concepts at readers simultaneously. This section covers the layer 2 design elements to be considered when planning a redundant network. This document assumes a two node deployment.

If both redundant nodes running pfSense® software are plugged into the same switch on any interface, that switch becomes a single point of failure. To avoid this single point of failure, the best choice is to deploy two switches for each interface (other than the dedicated Sync interface).

Example High Availability Cluster Network Diagram is network-centric, not showing the switch infrastructure. The Figure *Diagram of HA with Redundant Switches* illustrates how that environment looks with a redundant switch infrastructure.

27.6.1 Switch Configuration

When using multiple switches, the switches should be interconnected. As long as there is a single connection between the two switches, and no bridge on either of the firewalls, this is safe with any type of switch. Where using bridging, or where multiple interconnections exist between the switches, care must be taken to avoid layer 2 loops. A managed switch would be required which is capable of using Spanning Tree Protocol (STP) to detect and block ports that would otherwise create switch loops. When using STP, if an active link dies, e.g. switch failure, then a backup link can automatically be brought up in its place.

pfSense software supports *lagg(4)* link aggregation and link failover interfaces. This feature allows multiple network interfaces to be plugged into one or more switches for increased fault tolerance.

See also:

See *LAGG (Link Aggregation)* for more information on configuring link aggregation.

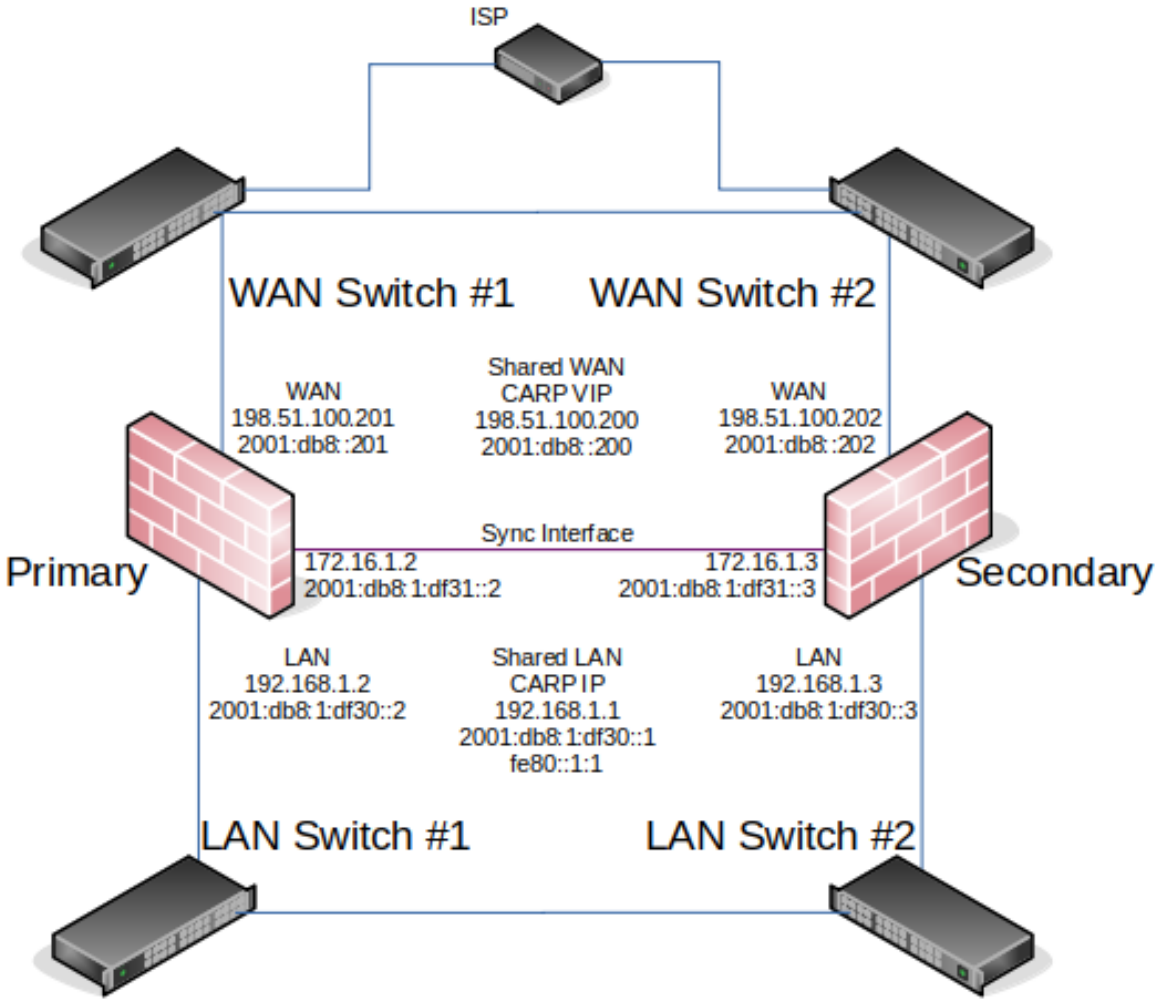


Fig. 4: Diagram of HA with Redundant Switches

27.6.2 Host Redundancy

It is more difficult to obtain host redundancy for critical systems inside the firewall. Each host could have two network cards and a connection to each group of switches using Link Aggregation Control Protocol (LACP) or similar vendor-specific functionality. Servers could also have multiple network connections, and depending on the OS it may be possible to run CARP or a similar protocol on a set of servers so that they would be redundant as well.

Providing host redundancy is more specific to the capabilities of the switches and server operating systems, which is outside the scope of this documentation.

27.6.3 Other Single Points of Failure

When trying to design a fully redundant network, there are many single points of failure that sometimes get missed. Depending on the level of uptime to achieve, there are multiple items to consider beyond a switch failure. Here are a few more examples for redundancy on a wider scale:

- Supply isolated power for each redundant segment
  - Use separate breakers for redundant systems
  - Use multiple UPS banks/generators
  - Use multiple power providers, entering opposite sides of the building where possible
- Even a Multi-WAN configuration is no guarantee of Internet uptime
  - Use multiple Internet connection technologies (Fiber, Cable, DSL, Wireless)
  - If any two carriers use the same pole/tunnel/path, they could both be knocked out at the same time
- Have backup cooling, redundant chillers or a portable/emergency air conditioner
- Consider placing the second set of redundant equipment in another room, another floor, or another building
- Have a duplicate setup in another part of town or another city
- I hear hosting is cheap on Mars, but the latency is killer

27.7 High Availability with Bridging

High availability is not currently compatible with bridging in a native capacity that is considered reliable or worthy of production use. It requires significant manual intervention. The details of the process can be found in *High Availability*.

27.8 Using IP Aliases to Reduce Heartbeat Traffic

If a segment contains a large number of CARP VIPs, the segment can have a lot of multicast traffic. The firewall sends one heartbeat per second per CARP VIP. To reduce this traffic, additional VIPs of the same address family (IPv4 or IPv6) may be "stacked" on top of one CARP VIP of the same family on an interface.

- Pick one CARP VIP to be the "main" VIP for an interface for a given address family (IPv4 or IPv6)
- Edit the other CARP VIPs of the same family in the same subnet
  - Change the type to *IP Alias*
  - Select the "main" CARP VIP as the VIP **Interface**
  - Save

  - Repeat for each additional CARP VIP on the same interface
- Apply Changes

This not only reduces the heartbeats on a given segment, but it also causes all of the IP alias VIPs to change status along with the "main" CARP VIP, reducing the likelihood that a layer 2 issue will cause individual CARP VIPs to not fail over as expected.

IP Alias VIPs do not normally synchronize via XML-RPC configuration synchronization, however, IP alias VIPs set to use CARP interfaces in this manner will synchronize.

- *High Availability Configuration Example without NAT*
- *Troubleshooting High Availability*
- *Troubleshooting High Availability DHCP Failover*
- *Troubleshooting VPN Connectivity to a High Availability Secondary Node*

pfSense® software is one of very few open source solutions offering enterprise-class high availability capabilities with stateful failover, allowing the elimination of the firewall as a single point of failure.

High Availability on pfSense software is achieved through a combination of features:

- CARP for IP address redundancy
- XMLRPC for configuration synchronization
- pfsync for state table synchronization

With this configuration in place nodes act as an "active/passive" cluster with the primary node working as the active node and the secondary node in a backup "hot standby" style role, taking over as needed if the primary node fails.

Two or more redundant firewalls in this configuration are referred to as a "High Availability Cluster" or "HA Cluster".

Warning: This **should not** be called a "CARP Cluster". CARP is only one of several technologies used to achieve High Availability with pfSense software, and in the future CARP could be swapped for a different redundancy protocol.

One interface on each cluster node is dedicated for synchronization tasks. This is typically referred to as the "Sync" interface, and it is used for configuration synchronization, pfsync state synchronization, and some other function-specific synchronization tasks. Any available interface may be used for this role, but the best practice is to use a dedicated interface directly connected between the two nodes.

Warning: This **should not** be called a "CARP" interface as it is not involved with CARP. CARP heartbeats happen on each interface with a CARP VIP; CARP traffic and failover actions do not utilize the Sync interface.

The only supported High Availability cluster configuration consists of exactly two nodes, which is also the most common configuration in practice. While it is possible to have more than two nodes in a cluster, additional nodes do not provide a significant advantage. Configurations with more than two nodes are not officially supported.

It is important to distinguish between the three functions (IP address redundancy, configuration synchronization, and state table synchronization), because they happen in different places. Configuration synchronization and state synchronization happen on the sync interface, directly communicating between firewall nodes. CARP heartbeats are sent on each interface with a CARP VIP. Failover signaling does not happen on the sync interface, but rather it happens on every CARP-enabled interface.

See also:

Hangouts Archive which contains the June 2015 Hangout also covering High Availability.

27.9 CARP Overview

Common Address Redundancy Protocol (CARP) was created by OpenBSD developers as a free, open redundancy solution for sharing IP addresses among a group of network devices. Similar solutions already existed, primarily the IETF standard for Virtual Router Redundancy Protocol (VRRP). However Cisco claims VRRP is covered by its patent on their Hot Standby Router Protocol (HSRP), and told the OpenBSD developers that it would enforce its patent. Hence, the OpenBSD developers created a new free, open protocol to accomplish essentially the same result without infringing on Cisco's patent. CARP became available in October 2003 in OpenBSD, and was later added to FreeBSD.

A CARP type *Virtual IP address* (VIP) is shared between nodes of a cluster. CARP refers to the currently active node as the "master". This node receives traffic sent to the CARP VIP address, and the other nodes sharing the VIP maintain "backup" status and monitor for heartbeats to see if they need to take over the active role. Since only one member of the cluster at a time is using the IP address, there is no IP address conflict between CARP VIPs.

For failover to work properly it is important that inbound traffic coming to the cluster, such as routed upstream traffic, VPNs, NAT, local client gateway, DNS requests, etc., be sent to a CARP VIP and for outgoing traffic such as Outbound NAT to be sent from a CARP VIP. If traffic is addressed to a node directly and not a CARP VIP, then that traffic will not be picked up by other nodes.

CARP works similar to VRRP and HSRP and may even conflict in some cases. Heartbeats are sent out on each interface containing a CARP VIP, one heartbeat per VIP per interface. At the default values for skew and base, each VIP sends out heartbeats about once per second. The skew determines which node is active at a given point in time. Whichever node transmits heartbeats the fastest assumes the active role. A higher skew value causes heartbeats to be transmitted with more delay, so a node with a lower skew will be active unless a network or other issue causes the heartbeats to be delayed or lost.

Note: Never access the firewall GUI, SSH, or other management mechanism using a CARP VIP directly. For management purposes, only use the actual IP address on the interface of each separate node and not the VIP. Otherwise, the client cannot determine beforehand which node it is accessing.

27.9.1 IP Address Requirements for CARP

A High Availability cluster using CARP needs **three** IP addresses in each subnet along with a separate unused subnet for the Sync interface. For WANs, this means that each WAN requires a /29 subnet or larger for an optimal configuration. Each node uses One IP address, plus a shared CARP VIP address for failover. The synchronization interface only requires one IP address per node.

It is technically possible to configure an interface with a CARP VIP as the only IP address in a given subnet, but it is not generally recommended. When used on a WAN, this type of configuration will only allow communication from the primary node to the WAN, which greatly complicates tasks such as updates, package installations, gateway monitoring, or anything that requires external connectivity from the secondary node. It can be a better fit for an internal interface, however internal interfaces do not typically suffer from the same IP address limitations as a WAN, so it is still preferable to configure IP addresses on all nodes.

27.9.2 Switch/Layer 2 Concerns

In the default mode, CARP heartbeats utilize multicast and may require special handling on the switches involved with the cluster. Some switches filter, rate limit, or otherwise interfere with multicast in ways that can cause CARP to fail. Also, some switches employ port security methods which may not work properly with CARP.

At a minimum, to use multicast mode CARP VIPs the switch must:

- Allow Multicast traffic to be sent and received without interference on ports using CARP VIPs.
- Allow traffic to be sent and received using multiple MAC addresses.
- Allow the CARP VIP MAC address to move between ports.

Nearly all problems with CARP failing to properly reflect the expected status are failures of the switch or other layer 2 issues, so be sure the switches are properly configured before continuing.

If multicast mode is not viable, CARP VIPs may be configured in Unicast mode on pfSense Plus software. Unicast mode sends heartbeats to a single defined peer IP address (and vice versa). This mode works across any L3 connectivity through which the heartbeats can be transmitted between the peers without relying on multicast. However, use of unicast mode on traditional infrastructure where multicast is more suitable should be avoided. In unicast mode switches may flood packets for unicast CARP VIPs to all ports, leading to significant security and performance concerns.

VIP Configuration Options

CHAPTER

TWENTYEIGHT

SYSTEM MONITORING

The data and information that pfSense® software collects and displays is every bit as important as the services it provides. Sometimes it seems that commercial routers go out of their way to hide as much information as possible from users, but pfSense software can provide almost as much information as anyone could ever want (and then some).

This chapter contains a variety of methods for finding information about the firewall status, logs, traffic, hardware, and so on.

28.1 Status

These articles cover various ways to check the status of services or features of the firewall, or the firewall itself.

28.1.1 Dashboard

The main page of the firewall GUI is the **Dashboard**. The Dashboard page provides a wealth of information that can be seen at a glance, contained in configurable widgets. These widgets can be added or removed, and dragged around into different positions in multiple columns.

See also:

There are additional options which control dashboard behavior, such as the number of columns for widgets. These options are located at *System > General Setup* and are also available as per-user options in the user manager.

Managing Widgets

Each widget follows basic conventions for controlling its position, size, settings, and so on.

Adding and Removing Widgets

To add widgets, click the  button in the Dashboard controls area of the breadcrumb bar (*Dashboard Controls in the Breadcrumb Bar*.) This button displays the list of available widgets.

Inside the **Available Widgets** panel, click the name of a widget to add it to the Dashboard (See *Available Widgets List*). The dashboard will reload with the new widget displayed in one of its columns.

Fig. 1: Dashboard Controls in the Breadcrumb Bar

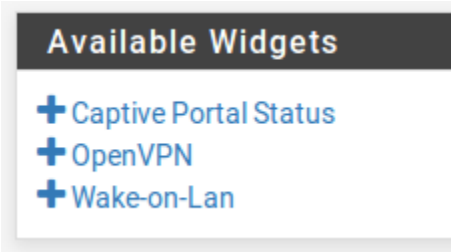

Fig. 2: Available Widgets List

To close and remove a widget from the Dashboard, click the button in its title bar (*Widget Title Bar*), then click in the dashboard controls.

Fig. 3: Widget Title Bar

Rearranging Widgets

Widgets can be rearranged and moved between columns.

To move a widget, click and drag its title bar (Figure *Widget Title Bar*), move the mouse to the desired position, and then release. The widget will "snap" into its new position as it moves, so the new location may be previewed before releasing the mouse button.

After positioning a widget, click in the dashboard controls to store its new location (*Dashboard Controls in the Breadcrumb Bar*).

Minimizing Widgets

To minimize a widget so it hides its content and only shows up as its title bar, click the button in its title bar (*Widget Title Bar*).

To restore the widget to its normal display, click the button.

After changing the widget status, click in the dashboard controls.

Changing Widget Settings

Some widgets have customizable settings which control how they display and update their content.

If a widget supports custom settings, the  button will show up in its title bar as seen in Figure *Widget Title Bar*. Click that button and the settings for the widget will appear. Once the settings have been adjusted, click the **Save** button inside of the widget settings panel.

Available Widgets

Each widget contains a specific set of data, type of information, graph, etc. This section lists each of the currently available widgets along with their settings (if any). These are listed in alphabetical order.

Captive Portal Status

This widget shows the current list of online captive portal users, including their IP address, MAC address, and username.

CARP Status

The CARP Status widget displays a list of all CARP type Virtual IP addresses, along with their status as either MASTER or BACKUP.

Disks

The Disks widget contains information on disk layout and usage. This content was formerly part of the System Information widget, but was moved to its own widget and redesigned.

The widget contains a tree view of the disks in the firewall, entries can be expanded to view details about additional ZFS datasets and mountpoints.

The Disk widget settings allow pinning specific items so they the widget always their status. It also allows changing the usage threshold at which items are always shown, which can help identify disk locations which may need attention.

Dynamic DNS

The Dynamic DNS widget displays a list of all configured Dynamic DNS hostnames, their current address, and status.

Firewall Logs

The **Firewall Logs** widget provides an AJAX-updating view of the firewall log. The number of rows shown by the widget is configurable. As with the normal firewall log view, clicking the action icon next to the log entry will show a window displaying which rule caused the log entry. Clicking the source or destination IP address will copy that value to **Diagnostics > DNS** where the address can be resolved.

Gateways

The Gateways widget lists all of the system gateways along with their current status. The status information consists of the gateway IP address, Round Trip Time (RTT) also known as delay or latency, the amount of packet loss, and the status (Online, Warning, Down, or Gathering Data). The widgets is updated every few seconds via AJAX.

GEOM Mirror Status

This widget will show the status of a gmirror RAID array on the system, if one is configured. The widget will show if the array is online/OK (Complete), rebuilding, or degraded.

Installed Packages

The Installed Packages widget lists all of the packages installed on the system, along with some basic information about them such as the installed version and whether or not an update is available.

When a package has an update available,  is displayed next to the version number. Packages may be updated from this widget by clicking the  button at the end of a package's row.

Packages may also be reinstalled by clicking  or removed by clicking  .

Interface Statistics

This widget shows a grid, with each interface on the system shown in its own column. Various interface statistics are shown in each row, including packet, byte, and error counts.

Interfaces

The **Interfaces** widget differs from the **Interface Statistics** widget in that it displays general information about the interface rather than counters. The **Interfaces** widget shows the type and name of each interface, IPv4 address, IPv6 address, the interface link status (up or down), as well as the link speed when available.

IPsec

The IPsec widget has three tabs:

Overview
: A count of active and inactive tunnels.

Tunnel Status
: Lists each configured IPsec tunnel (P1 and P2) and whether that tunnel is up or down. Each entry has controls to connect or disconnect based on its current status.

Mobile
: Shows online remote access IPsec VPN users, such as those using IKEv2 or Xauth.

Netgate Services and Support

Displays the current support status for this firewall instance from Netgate servers. The widget also includes information about support resources and how to contact support.

NTP Status

The **NTP Status** widget shows the current NTP synchronization source and the server time from that source.

OpenVPN

The **OpenVPN** widget displays the status of each configured OpenVPN instance, for both servers and clients. The status of each instance is shown, but the style and type of information shown varies depending on the type of OpenVPN connection. For example, with SSL/TLS servers in client/server mode the widget shows a list of all connected clients. For peer-to-peer mode instances such as shared key clients and servers, the widget displays an up/down status. In each case it displays the IP address of the connecting client with the name and time of the connection.

Picture

The **Picture** widget, as the name implies, displays a picture chosen by the user. This can either be used functionally, for a network diagram or similar, or it can be for style, displaying a company logo or other image.

To add an image:

- Click  on the Picture widget title bar
- Click **Browse** to locate the picture to upload
- Click **Upload** to upload the picture

The size of the picture will adjust to fit the area of the widget, which can vary depending on the size of the browser and platform.

RSS

The RSS (RDFSite Summary, or as it's often called, Really Simple Syndication) widget will display an arbitrary RSS feed. By default, it shows the Netgate blog RSS feed. Some people choose to show internal company RSS feeds or security site RSS feeds, but it can load any RSS feed.

In addition to defining the RSS feeds to display, the number of stories and size of displayed content are also configurable.

S.M.A.R.T. Status

If S.M.A.R.T. is enabled on a drive in the firewall, this widget will show a brief status of the drive integrity as reported by S.M.A.R.T.

Services Status

This widget provides the same view and control of services that appears under **Status > Services**. Each service is listed along with its description, status (Running, Stopped), and start/restart/stop controls.

System Information

This widget is the main widget, displaying a wide array of information about the running system. The information displayed includes:

Name
The configured fully qualified hostname of the firewall.

User
The user viewing the dashboard and their authentication source.

System
The type of system, if the firewall can identify the environment. Can be a specific hardware model, a type of virtual machine, or similar string.

This section also displays the **Netgate Device ID** (NDI) which is used by Netgate to determine the support status for the firewall.

BIOS
Information about the system BIOS, if it can be read by the firewall. May include the BIOS vendor, version, and release date.

Version
The current running version of pfSense® software. The widget displays the version, architecture, and build time at the top. Beneath that, the widget prints the underlying version of FreeBSD.

At the bottom of this section, the widget prints the result of an automatic update check for a more recent version of pfSense software. This automatic update check can be disabled in the update settings.

CPU Type
The version string for the processor, such as `Intel(R) Atom(TM) CPU C2758 @ 2.40GHz`. The widget also prints the CPU count and package/core layout.

If **powerd** is active and the CPU frequency has been lowered, then the current frequency is shown next to the maximum frequency.

If the CPU contains hardware cryptographic features, such as AES-NI or QAT, the widget also prints the status of those items.

Hardware crypto
If hardware cryptographic acceleration is enabled, the widget displays a list of ciphers which the hardware can accelerate.

Uptime
Time since the firewall was last rebooted.

Current date/time
The current date and time of the firewall, including the time zone. This is useful for comparing the log entries, especially when the time zone on the firewall is different from where the user resides.

DNS Server(s)
A lists of all configured and automatically located DNS Servers used by the firewall.

Last config change
The date of the last configuration change on the firewall.

State table size
A graphical and numerical representation of active connection states and the maximum possible states as configured on the firewall. Underneath the state counts is a link to view the contents of the state table.

MBUF usage
The number of network memory buffer clusters in use, and the maximum the system has available. These network memory buffers are used for network operations, among other tasks. If the number is close to maximum or at the maximum, increase the number of available mbufs as described in *Hardware Tuning and Troubleshooting*.

Temperature
The current temperature as reported by the hardware, if available.

Load Average
A count of active processes on the firewall which are in a running state during the last 5, 10, and 15 minutes. This is typically `0.00` on an idle or lightly loaded system.

CPU usage
A bar chart and percentage of CPU time used by the firewall.

Note: Viewing the dashboard increases the CPU usage, depending on the platform. On slower platforms this is likely to read significantly higher than it would be otherwise.

Memory usage
The current amount of RAM in use by the system. Note that unused RAM is often allocated for caching and other tasks so it is not wasted or idle, so this number may show higher than expected even when the firewall is operating normally.

Swap usage
The amount of swap space in use by the system. If the system runs out of physical RAM, and there is swap space available, lesser used pages of memory will be paged out to the swap file on the hard drive. This indicator only shows when the system has swap space configured.

Thermal Sensors

The **Thermal Sensors** widget displays the temperature from supported sensors when present. For many popular Intel and AMD-based chips, the sensors may be activated by choosing the appropriate sensor type under **System > Advanced** on the **Miscellaneous** tab under **Thermal Sensors**.

The widget displays a bar for each sensor, which typically corresponds to each CPU core. The warning and critical thresholds may be configured in the widget settings.

Traffic Graphs

The Traffic Graphs widget contains a live graph for the traffic on each interface. The interfaces displayed are configurable in the widget settings. The default refresh rate of the graphs is once every 10 seconds, but that may also be adjusted in the settings for this widget. The graphs are drawn the same way as those found under **Status > Traffic Graph**.

Wake On LAN

The Wake on LAN widget shows all of the WOL entries configured under **Services > Wake on LAN**, and offers a quick means to send a WOL magic packet to each system in order to wake it up. The widget also displays the current status of WOL entries, if possible. To wake up a system, click  next to its entry.

ZFS

This widget is available on pfSense Plus software and displays current status of ZFS pools and their component disks.

28.1.2 Interface Status

The page at **Status > Interfaces** displays the status of each assigned network interface on the firewall.

Status Information

The information available for each interface varies depending on the interface type, but may include:

Header Information
The header of each interface contains the following information:

Friendly Name
The name of the interface as designated by the user (e.g. `DMZ`).

Internal Name
The internal name of the interface (e.g. `wan`, `opt1`).

Assigned Interface
The name of the underlying interface which was assigned to this entry (e.g. `ix2`).

Status
The current status of the interface along with an icon which visually represents the status. The status is typically one of:

Up
The interface is up, has a link, and is operating normally.

Associated
A wireless interface is up and associated with an access point.

Down
A dynamic WAN type is not connected or does not have an IP address.

No Carrier
Typically means that the cable is not plugged in or the device on the other end is malfunctioning in some way.

Disabled
The interface is assigned but manually disabled in the configuration.

Dynamic WAN Controls
Dynamic interfaces have a button to manually change their current state.

DHCP, DHCP6
Interfaces obtaining an IP address from DHCP or DHCPv6 have a **Release** button when there is an active lease, and a **Renew** button when there is not.

The DHCP **Release** action has an optional **Relinquish Lease** checkbox. When set, the release action also sends a special message to the DHCP server which relinquishes its current lease.

PPPoE, PPTP, L2TP, PPP
PPP-based connection types like PPPoE have a **Disconnect** button when connected and a **Connect** button when offline.

If a PPP connection is using dial-on-demand it will reconnect itself when triggered even after a manual disconnect action. Disable dial-on-demand if the interface must remain disconnected.

Note: Clicking 'Renew' or 'Connect' will trigger an attempt to take that action, but the attempt may fail if the interface has a problem or the upstream service is not responding.

PPP Uptime
PPP-based interfaces track how long they have been up based on the time the interface last connected to its upstream provider.

Cellular Status
PPP type interfaces connecting through cellular modems (e.g. 5G, LTE, 4G, 3G, etc.) may show additional statistics from the modem. This varies by hardware and type of connection.

Cell Signal (RSSI)
The signal strength from the cellular provider.

Cell Mode
System mode change indicator.

Cell SIM State
SIM card status (e.g. inserted or removed.)

Cell Service
Service mode change indicator.

Cell Upstream
Measured upload speed.

Cell Downstream
Measured download speed.

Cell Current Up
Maximum upload speed.

Cell Current Down
Maximum download speed.

MAC Address
The hardware MAC Address of the interface.

Tip: Installing the NMAP package activates a feature which allows the page to also display the manufacturer associated with the MAC address, if it is known. Note that this is not effective in some cases, such as for virtual machines which use randomly generated MAC addresses or for wireless clients which utilize privacy features that alter their MAC addresses.

IPv4 Address
The current IPv4 address assigned to the interface.

Note: This does not include Virtual IP addresses.

Subnet mask IPv4
The subnet mask for the current IPv4 address.

Gateway IPv4
The IPv4 gateway defined on this interface, if any.

IPv6 Link Local
The IPv6 link-local address for this interface, including the interface scope.

IPv6 Address
The current IPv6 address assigned to the interface.

Subnet mask IPv6
The length of the prefix for the current IPv6 address.

Gateway IPv6
The IPv6 gateway defined on this interface, if any.

DNS Servers
DNS servers obtained from upstream providers on this interface (e.g. DHCP or PPPoE).

MTU
maximum transmission unit (MTU) of this interface, which is the largest packet it can transmit or receive.

Media
The type of media connected to this interface, including the link speed and type. The exact values depend upon the network interface type and what is connected to that interface.

For example, it may be `1000baseT <full-duplex>` for some types of 1Gbit/s copper Ethernet or `10Gbase-SR <full-duplex>` for some types of 10Gbit/s fiber.

SFP Module Information
If the interface uses an SFP module and the operating system can read the data from the module, the page will also include that information. The data may include the following fields:

- Description (**Plugged**)
- Vendor
- Temperature
- Voltage
- Signal levels

Note: Some interfaces capable of using SFP modules, such as combination copper and SFP interfaces, do not expose this module data to the operating system. As such, the page cannot include

module data from these interfaces.

LAGG Information
If this interface is an assigned LAGG interface, the page displays information about the LAGG itself.

LAGG Protocol
The current protocol for LAGG, for example it could be failover, loadbalance, LACP, etc.

The current LAGG hashing method is also in this field, which typically is `l2,l3,l4` which indicates that when load balancing it takes information from OSI layers 2, 3, and 4 into account when deciding which port to use.

LAGG Ports
The underlying interfaces which are a members of this LAGG, along with their current status.

Wireless Information
The page displays additional information specific to wireless interfaces as well, including:

Channel
The wireless channel the interface is using to communicate with peers.

SSID
When acting as an access point, this is the SSID being broadcast to clients.

BSSID
When acting as a wireless client, this is the SSID of the AP to which this interface is connecting.

Rate
When acting as a wireless client, this is the current wireless data transfer rate to the AP.

RSSI
When acting as a wireless client, this is the current signal level to the AP.

In/Out Packets
The number of packets received (in) and transmitted (out) by this interface.

In/Out Packets (Pass)
The number of packets `pf` has passed on this interface.

In/Out Packets (Block)
The number of packets `pf` has blocked on this interface.

In/Out Errors
Input and output errors on the interface. This is a total count and can be from a variety of causes. For example, it could be from a hardware issue or packets lost because they could not be processed due to high load.

Hardware issues are typically physical in nature: cabling or port errors. The most common suspect is cables, and they are easy and cheap to replace.

In many cases, occasional errors are not indicative of a problem, however, if the number is large and/or rapidly increasing, there is cause for concern.

Note: Depending on the interface type, more detail may be available from `sysctl`. For example, an `ix0` interface would have information under `sysctl dev.ix.0`, in particular `dev.ix.0.mac_stats` has several fields detailing different types of error conditions.

Collisions
The number of network collisions experienced by this interface.

In most cases this can only happen on half-duplex networks (i.e. hubs, not switches). If this is non-zero it can also indicate that the interface has not linked at the proper duplex.

See also:

See *Interface Configuration* for more about setting the speed and duplex of an interface.

Bridge Interface
If an interface is a member of a bridge, the title of this field contains the name of the bridge and the content is the current status.

Total Interrupts
For physical interfaces this field may show the total number of hardware interrupts generated by this interface. A rapidly increasing number of interrupts can indicate that an interface is highly loaded, but that does not necessarily mean there is a problem if the load is expected.

Example Status

In the first part of Figure *Interface Status*, the firewall has a DHCP WAN connection and it obtained the IPv4 and IPv6 address, DNS, etc. automatically.

In the lower part of the image, the LAN connection is visible. Since this is a normal interface with a static IP address, only the usual set of items are present.

28.1.3 Service Status

The page at **Status > Services** displays the status of most base system and package service daemons.

The page lists each service with its name, description, and status as seen in Figure *Services Status*. The status is listed as **Running** or **Stopped**.

Normally it is not necessary to control services in this manner, but occasionally there are maintenance or troubleshooting reasons for doing so.

From this view, services can be controlled in various ways:

- Click  to restart a running service

---

Note: Some services will stop and start, others reload the configuration. Check the documentation of each service for details.

- Click  to stop a running service
- Click  to start a stopped service

If available, each entry also contains additional shortcuts which navigate to pages related to the service. See *Quickly Navigate the GUI with Shortcuts* for information about shortcut icons.

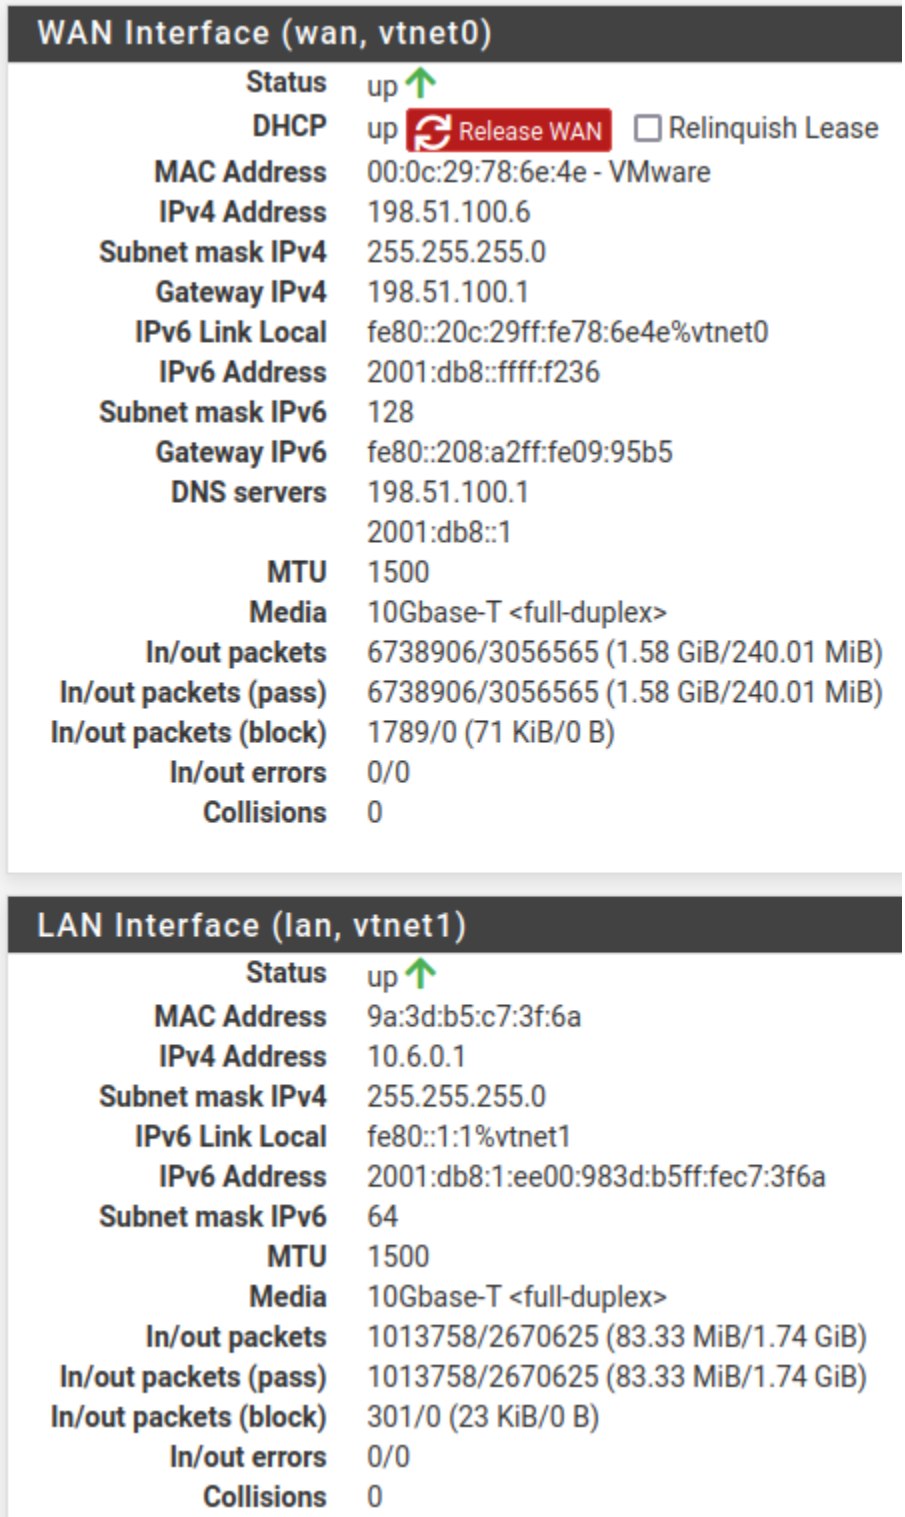

Fig. 4: Interface Status

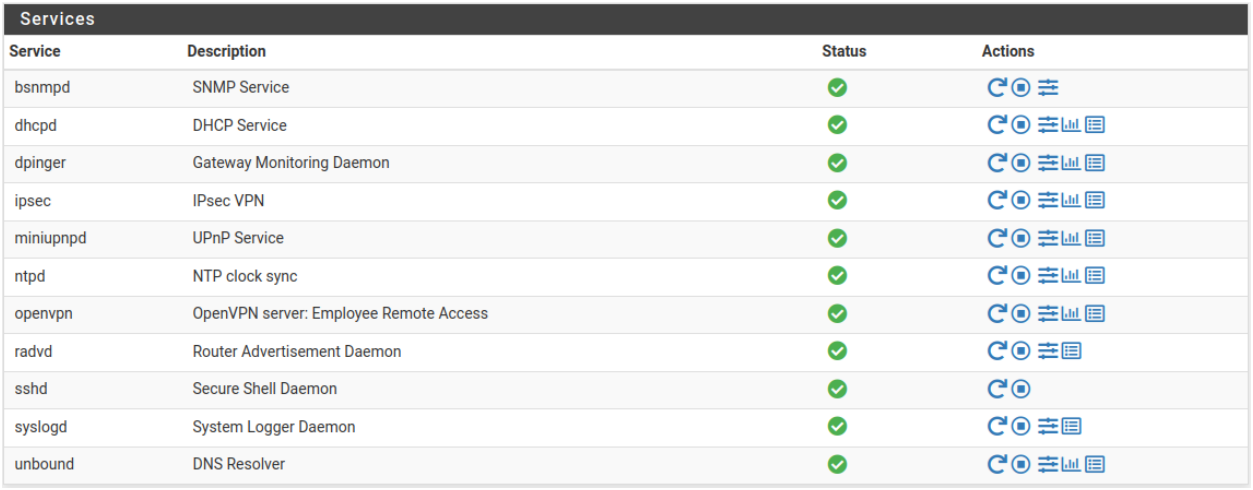

Services

Service	Description	Status	Actions
bsnmpd	SNMP Service		
dhcpd	DHCP Service		
dpinger	Gateway Monitoring Daemon		
ipsec	IPsec VPN		
miniupnpd	UPnP Service		
ntpd	NTP clock sync		
openvpn	OpenVPN server: Employee Remote Access		
radvd	Router Advertisement Daemon		
sshd	Secure Shell Daemon		
syslogd	System Logger Daemon		
unbound	DNS Resolver		

Fig. 5: Services Status

28.1.4 System Activity (Top)

The **Diagnostics > System Activity** page displays several aspects of system activity as reported by `top` which are updated every few seconds. This is equivalent to running the command `top -aSH` at a shell prompt.

The output contains several key types of information:

- The system load average.
- A total count of processes in various states (running, sleeping, waiting, etc.).
- The current CPU usage.
- A breakdown of memory usage in various areas.

  See also:

  See *Memory Management* for details on each area.
- ZFS ARC usage breakdown, if the system contains any active ZFS pools.

  See also:

  See *ZFS Tuning* for information on reducing this if necessary.
- Swap memory usage.
- A list of the active processes running on the firewall.

Using this view it is easy to see processes that consume the most CPU power during a time of high load. For example, if the highest entry is an interrupt processing queue for one of the network cards, and the system isn't passing enough traffic, it could be one sign that the firewall is trying to push more than the hardware can handle in the current configuration. If the top process is a PHP process, it could be that a browser has requested a GUI page that is processing a large amount of data.

Note: Threads that show **idle** in the **COMMAND** column indicate CPU time that is **not** in use (idle). It is normal for these to show 100% if the firewall has little to no load.

28.1.5 pfInfo

The **Diagnostics > pfInfo** page displays statistics and counters for the firewall packet filter which serve as metrics to judge how it is behaving and processing data.

The **Refresh** checkbox at the top of the page controls whether or not the page automatically updates every few seconds with new data. To stop the updates, uncheck the box.

The information shown on the page contains items such as:

Host ID
: The current 32-bit host ID used by pf. This value is randomized each time the filter reloads, and the value is stored on state table entries to indicate which process created the entry.

Bytes In/Out
: Bytes transferred in and out of the firewall.

Packets In/Out
: Packets transferred in or out and passed or blocked counters for each direction.

State Table / Source Tracking Table
: Statistics about the state table and source tracking table (*Firewall States*).

  Current Entries
  : The number of entries in the table

  Searches
  : How many times the table has been searched and the current rate of searches, which roughly corresponds to the number of packets being passed by the firewall on current open connections.

  Inserts
  : The number of new states added to the table, and the rate at which the states are added.

    A high insert rate indicates that there are a lot of new connections being made to or through the firewall.

  Removals
  : The number of old states being removed from the firewall.

Counters
: Statistics and counts for various types of special, unusual or badly formatted packets.

Limit Counters
: Counters that pertain to packets which have reached or exceeded limits configured on firewall rules, such as max states per IP address.

Table Size Limits
: State table max size, source node table size, frag table size, number of allowed tables, and maximum number of table entries.

State Timers
: The current configured timeout values for various connection states for TCP, UDP, and other protocols.

Interface Statistics
: Per-interface packet counters.

28.1.6 S.M.A.R.T. Hard Disk Status

The firewall can monitor the health of hard drives that support Self-Monitoring, Analysis, and Reporting Technology (S.M.A.R.T.). This mechanism is intended to allow drives to test and track their own performance and reliability, with the ultimate goal of identifying a failing drive before it suffers data loss or causes an outage.

Support for S.M.A.R.T. varies by drive and BIOS, but it is fairly well supported in modern SSDs and hard drives. S.M.A.R.T. may need to be enabled in the BIOS and on the drive.

Note: S.M.A.R.T. is not a perfect metric of locating a failed drive; Many drives that have failed still pass a S.M.A.R.T. test, but generally speaking if S.M.A.R.T. does locate a problem, one does exist, so it is useful to identify disk failures.

The **Diagnostics > SMART Status** page obtains and displays information from drives, performs or aborts drive tests, and displays drive logs.

In every section of the page, a **Device** must be selected before choosing an option. This **Device** is the disk to be tested by S.M.A.R.T.

Warning: If a drive is not listed in the **Device** list, it either does not support S.M.A.R.T. or it is connected to a controller that is not supported for this purpose. In the case of RAID controllers, the controller itself may offer similar functionality or reporting via controller-specific utilities in the shell.

Viewing Drive Information

To view information about a drive:

- Navigate to **Diagnostics > SMART Status**
- Locate the **Information** panel on the page
- Select the **Device** to view
- Select the **Information Type**
- Click  **View**

After reviewing the output, click  **Back** to return to the list of options.

The information types are explained in the next subsections.

Device Information

The **Device Information** option shows information about the drive itself, including the make, model, serial number, and other technical information about the drive capabilities, connection, and operation.

```
Model Family:     Intel 53x and Pro 1500/2500 Series SSDs
Device Model:     INTEL SSDSC2BW120A4
Serial Number:    XXXXXXXXXXXX
LU WWN Device Id: 5 5cd2e4 0003ae43c
Firmware Version: DC32
User Capacity:    120,034,123,776 bytes [120 GB]
```

(continues on next page)

(continued from previous page)

```
Sector Size:      512 bytes logical/physical
Rotation Rate:    Solid State Device
TRIM Command:     Available, deterministic
Device is:        In smartctl database [for details use: -P show]
ATA Version is:   ACS-2 (minor revision not indicated)
SATA Version is:  SATA 3.0, 6.0 Gb/s (current: 6.0 Gb/s)
Local Time is:    Wed Feb  9 13:26:15 2022 EST
SMART support is: Available - device has SMART capability.
SMART support is: Enabled
```

Device Health

The **Health** option gives a brief pass/fail status of the drive.

```
SMART overall-health self-assessment test result: PASSED
```

SMART Capabilities

The **SMART Capabilities** choice gives a report about features and tests the drive supports.

```
General SMART Values:
Offline data collection status:  (0x05)      Offline data collection activity
                                     was aborted by an interrupting command from host.
                                     Auto Offline Data Collection: Disabled.
Self-test execution status:      (  33)      The self-test routine was interrupted
                                     by the host with a hard or soft reset.
Total time to complete Offline
data collection:             ( 2930) seconds.
Offline data collection
capabilities:                         (0x7f) SMART execute Offline immediate.
                                     Auto Offline data collection on/off support.
                                     Abort Offline collection upon new
                                     command.
                                     Offline surface scan supported.
                                     Self-test supported.
                                     Conveyance Self-test supported.
                                     Selective Self-test supported.
SMART capabilities:            (0x0003)      Saves SMART data before entering
                                     power-saving mode.
                                     Supports SMART auto save timer.
Error logging capability:        (0x01)      Error logging supported.
                                     General Purpose Logging supported.
Short self-test routine
recommended polling time:     (   1) minutes.
Extended self-test routine
recommended polling time:     (  48) minutes.
Conveyance self-test routine
recommended polling time:     (   2) minutes.
SCT capabilities:           (0x0025) SCT Status supported.
                                     SCT Data Table supported.
```

SMART Attributes

The **SMART Attributes** view is the most useful screen in the majority of cases, but it can also be one of the trickiest to interpret. There are several values displayed but the number and values vary widely by make and model.

The following output is from a 2.5 inch traditional HDD:

```
=== START OF READ SMART DATA SECTION ===
SMART Attributes Data Structure revision number: 16
Vendor Specific SMART Attributes with Thresholds:
ID# ATTRIBUTE_NAME          FLAG     VALUE WORST THRESH TYPE      UPDATED  WHEN_FAILED␣
↪RAW_VALUE
  1 Raw_Read_Error_Rate     0x000b   099   099   062    Pre-fail  Always       -       ␣
↪65537
  2 Throughput_Performance  0x0005   100   100   040    Pre-fail  Offline      -       0

↪36 (Min/Max 19/41)
196 Reallocated_Event_Count 0x0032   100   100   000    Old_age   Always       -       0
197 Current_Pending_Sector  0x0022   100   100   000    Old_age   Always       -       0
198 Offline_Uncorrectable   0x0008   100   100   000    Old_age   Offline      -       0
199 UDMA_CRC_Error_Count    0x000a   200   200   000    Old_age   Always       -       0
223 Load_Retry_Count        0x000a   100   100   000    Old_age   Always       -       0
```

There is a thorough article on Wikipedia for S.M.A.R.T. that includes a guide for interpreting the values. Some values are more obvious than others, for example the counts for reallocated sectors should be at or near zero. Others can be harder such as the Raw Read Error Rate, which on most drives should be low, but there are Seagate and similar drives that output gibberish or a random high number in that field that makes it useless on those disks.

A few of the values are informational, such as the Start/Stop Count, Power Cycle Count, and Power On Hours which give a sense of the overall age and usage for the drive. A high value isn't necessarily bad for those, but if the drive is extraordinarily old, or has been power cycled a great many times, then have a plan prepared to replace the disk in the near future. The drive's Temperature can give an indication of its environment, and if the temperature is too high, it can lead to stability issues.

The Load Cycle Count is a special value for spinning disks, since it indicates the number of times the heads have been parked. Some laptop drives will automatically park the heads after a short time, but an OS like pfSense® software will want to write periodically, which brings the heads out again. The head parking only makes sense in a mobile device that moves a lot so the heads have less chance of impacting the platter; In a server/firewall situation, it's completely unnecessary. Drives are only capable of 100,000-300,000 load cycles in their lifetime, which means the count gets run through quickly if the heads are continually parked and unparked. pfSense software attempts to disable the power management features of hard drives at boot time because otherwise the drive could fail prematurely after running this count up high. This cycling happening is typically audible on drives as a soft clicking noise.

To contrast the above, the following output is from an SSD:

```
=== START OF READ SMART DATA SECTION ===

```

The metrics for an SSD can be significantly different, as seen above. In particular, SSDs can give an estimate of their remaining lifetime, writes of various sizes, errors rates, write failures, and other SSD-specific values in place of the other values that do not apply to an SSD.

All SMART Information

Selecting **All SMART Information** shows all of the information above and also includes the drive logs and self-test results.

All SMART and Non-SMART Information

This choice shows all of the information above, plus more information that can be gathered from the drive. This includes alternate formatting for the attribute list with even greater detail about attribute meanings, a list of available SMART data logs, drive temperature details, additional device statistics, and disk event log content.

Drive Logs

The View Logs section displays the content of various drive logs. These logs contain information and errors, usually related to self-tests and potentially other errors encountered by the disk.

To view drive logs:

- Navigate to **Diagnostics > SMART Status**
- Locate the **View Logs** panel on the page
- Select the **Device** to view
- Select the **Log Type**
- Click  **View**

There are numerous logs available, but some logs are only present on specific types of devices, and some devices may not support certain logs even if they are the correct type.

Summary Error Log
: The **Error** log on a drive contains a record of errors encountered during the drive's operation, such as read errors, uncorrectable errors, CRC errors, and so on. Running an **Offline** test will also make the drive print more errors here if they are found during the test.

Extended Error Log
: Similar to the summary error log but allows for longer and more detailed error messages.

SMART Self-Test Log
: The **Self-test** logs contain a record of several recent self-tests run on the drive. It shows the type of test, the results of the test, and in the case of tests that were stopped prematurely, it shows the percentage of the test remaining.

  If an error is encountered during a test, the first logical block address (LBA) is printed to help determine where in the disk the problem lies.

Extended Self-Test Log
: Similar to the SMART self-test log but allows for longer and more detailed error messages.

Selective Self-Test Log
: Shows the results of recent selective self-tests and the min/max LBA sets which were included in the test.

Log Directory
: Prints the contents of the device log directory, which includes a list of logs and their current sizes.

Device Temperature Log (ATA Only)
The disk temperature information log from the SMART command transport. Prints both the current temperature and a temperature history with an ASCII graph.

Device Statistics (ATA Only)
Values and descriptions of ATA device statistics logged by the drive.

SATA PHY Events (SATA Only)
Values and descriptions of SATA PHY events logged by the drive.

SAS PHY Events (SAS Only)
Values and descriptions of SAS PHY events logged by the drive.

NVMe Log (NVMe Only)
Prints the contents of the NVMe drive log.

SSD Device Statistics (ATA/SCSI)
Prints either the device statistics or a media percentage used endurance indicator.

Drive Self-tests

To perform a test on a drive:

- Navigate to **Diagnostics > SMART Status**
- Locate the **Perform Self-Tests** panel on the page
- Select the **Device** to test
- Select the **Test Type**
- Click  **Test**

The types of tests are described in the following subsections.

Offline

An **Offline** test is called so because it is done while the disk is idle. This test can make accessing the drive slow while it is happening, but if there is a lot of disk activity, the drive may delay the test until the disk becomes idle again. Because of this variability, the exact time the test takes is hard to predict. An estimate of the time to complete an offline test for a given disk is shown in the **S.M.A.R.T. Capabilities**. An offline test will also cause the drive to update several of the S.M.A.R.T. attributes to indicate the results. After running a test and checking the results, review the **S.M.A.R.T. Attributes** again as well as the **Error** log.

Short

The **Short** test takes around ten minutes and checks the drive's mechanics and reading performance. A more accurate estimate of the length the test will take on a drive can be seen in the **S.M.A.R.T. Capabilities**. To see the results of this test, view the **Self-test** Logs. It can be run at any time and it does not typically impact performance.

Long

The **Long** test is similar to the **Short** test but is more thorough. The time taken by the test depends on the size of the disk, but it is much longer than the short test on its own. A more accurate estimate of the length the test will take on a drive can be seen in the **S.M.A.R.T. Capabilities**. As with the short test, the results end up in the **Self-test** Logs.

Conveyance

This test is not supported by all drives. Its primary purpose is to test the drive after it has been physically relocated to determine if any components have been damaged by the move. In most cases it only takes a few minutes to complete. To determine if a drive supports a conveyance test, refer to the **S.M.A.R.T. Capabilities** output.

Canceling Active Tests

To cancel an active test on a drive:

- Navigate to **Diagnostics > SMART Status**
- Locate the **Abort** panel on the page
- Select the **Device** currently running a test
- Click  **Abort**

Any active tests on the drive will be stopped.

28.1.7 Filter Reload Status

The page at **Status > Filter Reload** displays the current status of a filter reload. It also contains controls to perform a manual reload, and a button to force an XMLRPC configuration synchronization attempt.

After making a filter change in the GUI and applying changes, the information box on the page contains a link to this page to monitor the filter reload progress.

Reload Status

This section of the page displays the progress of the reload and it is updated automatically as the process progresses. New messages are placed at the bottom of the output, so scroll down to read the most recent entries.

In most cases updates happen fast enough that `Done.` is the only message shown, indicating that there are no pending changes. With larger configurations, some delays are possible.

Reload Filter

The **Reload Filter** button initiates a manual filter reload. As the process progresses, the page automatically updates with the most recent output.

XMLRPC Synchronization

If this firewall is part of a high availability cluster and has XMLRPC configuration synchronization enabled, the page displays a **Force Config Sync** button.

The **Force Config Sync** button triggers a forced synchronization of the firewall configuration by XMLRPC to the node specified by the *current XMLRPC synchronization configuration*.

As with a typical filter reload, the page updates automatically as the process progresses.

28.1.8 Firewall States

pfSense® software is a *stateful firewall* and uses one state to track each connection to and from the firewall. These states may be viewed in several ways in the GUI and from the console.

Viewing Firewall States in the GUI

The page at **Diagnostics > States** in the GUI contains a listing of the firewall state table contents. Figure *Example States* shows a sample of the output displayed by the GUI.

WAN	tcp	198.51.100.6:37246 -> 162.208.119.39:443	TIME_WAIT:TIME_WAIT	91 / 89	6 KiB / 120 KiB	
LAN	tcp	10.6.0.114:49266 -> 52.88.223.32:443	ESTABLISHED:ESTABLISHED	248 / 244	18 KiB / 20 KiB	
WAN	tcp	198.51.100.6:55087 (10.6.0.114:49266) -> 52.88.223.32:443	ESTABLISHED:ESTABLISHED	248 / 244	18 KiB / 20 KiB	
WAN2	icmp	203.0.113.106:36339 -> 203.0.113.1:36339	0:0	832.827 K / 921	22.26 MiB / 25 KiB	

Fig. 6: Example States

The page displays several columns of information for each state table entry, each with important information:

Interface
: The interface to which the state is bound. This is the interface through which the packet *initially* entered or exited the firewall.

Protocol
: The protocol of the traffic that created the state, such as TCP, UDP, ICMP, or ESP.

Source and Destination
: This column is in two parts, first the source, then an arrow indicating direction, and then the destination.

  The source and destination may also have a port number listed if the protocol in question uses ports.

In cases where NAT is applied (outbound NAT, port forwards, or 1:1 NAT), the address is shown both before and after NAT has been applied. For NAT such as outbound NAT which translates the source, the source section displays the translated source and the original source inside parenthesis. For NAT types that translate the destination, such as port forwards, the destination section shows the translated destination and the original destination in parenthesis.

State
The current status of the connection being tracked by this state entry.

The specific values vary depending on the protocol. For example, TCP has many more state types than UDP or other connectionless protocols. See *Interpreting States* for more detail.

The entry in this column contains two parts separated by a colon. The first part is the connection state for the source side, and the second part is the connection state for the destination side.

Packets
The number of packets the firewall has observed which match the state from the source and destination sides.

Bytes
The total size of packets the firewall has observed which match the state from the source and destination sides.

The  icon at the end of each row removes individual states.

See also:

Firewall Maximum States

Filtering States

The **State Filter** panel enables quick searching of the state table contents to find items of interest.

To search for a state:

- Select a specific **Interface** in the **State Filter** panel or leave it on *all* to match all interfaces.
- Enter a **Filter Expression** which is a simple string of text to match exactly in the entry. This field does not support regular expressions.
- Click  **Filter** to locate the results.

The search process attempts to match text across all columns and it only displays entries matching the search parameters.

Tip: Searching for an IP address or subnet will also present a  **Kill States** button which, when clicked, will remove all states originating from or going to the entered IP address or subnet.

For systems with extraordinarily large state tables, filtering can be a requirement. The **Require State Filter** option on *General Configuration Options* prevents the firewall from displaying state table content until the user filters the state table output. This prevents the page from attempting to display too much data.

Interpreting States

The **State** column for each state table entry provides information necessary to determine exactly what is happening with the connection. Each state entry contains two values with a colon between them, marking which value represents the state of the source (left), and which represents the destination (right).

A few of the most common state types are:

SYN_SENT
: For TCP connections this indicates that the side showing this state sent a TCP SYN packet attempting to start a connection handshake.

CLOSED
: For TCP connections the side with this status considers the connection closed, or the firewall has not received any traffic.

ESTABLISHED
: A TCP connection is considered fully established by this side.

TIME_WAIT/FIN_WAIT
: A TCP connection is in the process of closing and finishing up.

NO_TRAFFIC
: The firewall has not received any packets that match the state from this side.

SINGLE
: The firewall has observed a single packet on this state from this side.

MULTIPLE
: The firewall has observed multiple packets on this state from this side.

Common pairings frequently found in the state table include:

ESTABLISHED:ESTABLISHED
: A fully established two-way TCP connection.

SYN_SENT:CLOSED
: The side showing *SYN_SENT* has sent a TCP SYN packet but no response has been received from the far side. Often this is due to the packet not reaching its destination, or being blocked along the way.

SINGLE:NO_TRAFFIC
: Similar to the above, but for UDP and other connectionless protocols. No response has been received from the destination side.

SINGLE:MULTIPLE
: For UDP and other connectionless protocols, commonly observed with DNS where the client sends one packet but receives a large response in multiple packets.

MULTIPLE:MULTIPLE
: For UDP and other connectionless protocols, there are multiple packets in both directions, which is normal for a fully operational UDP connection.

0:0
: Indicates that there is no state level data. Typically only found on ICMP states, since ICMP does not have state levels like other protocols.

Firewall States Summary

The **State Table Summary**, accessible from **Diagnostics > States Summary**, provides statistics generated by an in-depth analysis of the state table and the connections therein.

The report includes the IP address, a total state count, and breakdowns by protocol and source/destination ports. Hovering over the ports shows a tooltip display of the full port list instead of the total number of ports. Depending on the firewall environment, high values by any metric may be normal.

The report includes the following categories:

By Source IP Address
: States summarized by the source IP address. This is useful for finding a potential source of attack, or a port scan or similar type probe/attack.

By Destination IP Address
: States summarized by the destination IP address of the connection. Useful for finding the target of an attack or identifying servers.

Total per IP Address
: States summarized by all connections to or from an IP address. Useful for finding active hosts using lots of ports, such as bittorrent clients.

By IP Address Pair
: Summarizes states between two IP addresses involved in active connections. Useful for finding specific client/server pairs that have unusually high numbers of connections.

Warning: The **States Summary** can take a long time to process and display, especially if the firewall has an exceptionally large state table or a slow processor. In cases where the state table is extremely large, the page may not display properly or the page may fail with a memory error. In these cases, the summary page cannot be used.

Source Tracking States

When using *Sticky Connections* the firewall maintains a source tracking table which records mappings of internal IP addresses to specific external gateways for connections that were passed by a rule utilizing a Load Balancing gateway group (Multiple gateways on the same tier).

Source tracking associations are displayed by the page at **Diagnostics > States** on the **Source Tracking** tab, which is only visible if the sticky connections option is enabled.

By default these source tracking associations only exist so long as there are active states from the internal IP address. There is a configurable timeout for these source tracking entries to allow them to exist longer if necessary.

See also:

For additional information about sticky connections, see *Sticky Connections*.

The Source Tracking page lists the following information:

Source-to-Destination
: The mapping of a local IP address to a specific load balanced **gateway**.

 # States
: The number of states matching this source IP address to any destination, including traffic that is not load balanced.

 # Connections
: The number of states matching this source IP address which utilize the gateway. For example, connections leaving from this source to an Internet host.

Rate
The rate of packets matching this source tracking entry.

The **Remove** button at the end of each row will remove these associations individually.

Reset State Table / Source Tracking Table

The page at **Diagnostics > States** on the **Reset States** can reset the contents of the state table and source tracking table.

Certain situations call for resetting the state table to force all existing connections to reestablish. The most notable examples are making changes to NAT rules, firewall block rules, or traffic shaping. When these types of changes are made, resetting the state table is the only way to make sure all connections respect the new ruleset or traffic shaping queues.

Warning: Resetting the state table is disruptive but clients may immediately reconnect provided they are still passed by the current firewall rules.

Both the state table and the source tracking table may be reset as follows:

- Navigate to **Diagnostics > States**, **Reset States** tab
- Check **State Table** to clear the contents of the state table
- Check **Source Tracking** to clear the contents of the source tracking table
- Click  **Reset**
- Click **OK** to confirm

After confirming the action the firewall will erase the contents of the state table.

Warning: The browser will appear to lose connection with the firewall when resetting the state table. Once the browser realizes the old connection is invalid, it will reconnect. Close and reopen the browser to reconnect faster.

pfTop

pfTop is available from the GUI and the console menu. It offers live views of the firewall ruleset, state table information, and related statistics.

pfTop in the GUI

The GUI page for pfTop is at **Diagnostics > pfTop**. The GUI offers several options to control the output:

View
Controls the type of output displayed by pfTop. Not all views will contain meaningful information for every firewall configuration.

Default
Shows a balanced amount of information, based around the source and destination of the traffic.

Label
Centered around firewall rule descriptions.

Long
Similar to the default view, but tailored for wider displays with longer rows for more columns of information. Shows the gateway after the destination.

Queue
Shows the ALTQ traffic shaping queues and their usage.

Rules
Shows firewall rules and their usage.

Size
Shows states that have passed the most data.

Speed
Shows states that have high-rate traffic.

State
Shows status of states.

Time
Shows long-lived states.

Filter Expression
An expression used to match groups of states to include in the output.

The expression can include several different types of filtering, such as:

- Filter by protocol: `proto <ip|ip6|ah|carp|esp|icmp|ipv6-icmp|pfsync|tcp|udp>`
- Filter by address: `[src|dst|gw] [host|net|port] <host/network/port>`
- Filter by direction: `[in|out]`

Sort By
Some views can be sorted. When sorting is possible, the following sort methods are available. When selected, the view is sorted by the chosen column in descending order:

None
No sorting, the natural order shown by the chosen view.

Age
The age of the states.

Bytes
The amount of data sent matching the state.

Destination Address
The destination IP address of the state.

Destination Port
The destination port number of the state.

Expiry
The expiration time of the state. This is the countdown timer until the state will be removed if no more data matches the state.

Peak
The peak rate of traffic matching a state in packets per second.

Packet
The number of packets transferred matching a state.

Rate
The current rate of traffic matching a state in packets per second.

Size
The total amount of traffic that has matched a state.

Source Port
The source port number of the state.

Source Address
The source IP address of the state.

Maximum # of States
On views that support sorting, this option limits the number of state entries shown on the page.

pfTop on the Console

To access pfTop from the console or via ssh use option `9` from the menu or run `pftop` from a shell prompt.

While viewing pfTop in this way, there are several methods to alter the view while watching its output.

The most common options are:

- Press `h` to see a help screen that explains the available choices.
- Press `0` through `8` to select different views
- Press `space` for an immediate update
- Press `q` to quit

See the previous section for details on the meaning of the available views and sort orders.

The output is dynamically sized to the terminal width, with wider terminals showing much more information in additional columns.

28.1.9 DHCPv4 Status

The current contents of the DHCPv4 lease database and related information are viewable at **Status > DHCP leases**.

The page contains multiple sections with information about leases. The exact information and layout depends on the selected DHCP backend.

Pool Status (HA/Failover) – ISC DHCP Only

The **Pool Status** section of the page is only present if the firewall is using the ISC DHCP backend and is configured for DHCPv4 failover as a part of a high availability cluster.

This section of the page includes information on DHCP failover pools, including:

Failover Group
The name of the failover group for a given pool, which includes the interface name.

My State
The state of the failover pool from the perspective of this firewall.

Since
The last time the local pool state changed.

Peer State
The state of the failover pool from the perspective of the peer, if known.

Since
The last time the peer pool state changed.

See also:

Troubleshooting High Availability DHCP Failover

DHCPv4 Leases

This section of the page lists client leases and their properties, including:

Status
The first column with no header contains two icons indicating the current status of the lease. Hover over the icon for a tooltip explaining the meaning of the icon.

Lease Type
An icon indicating the type of DHCP lease assigned to this client, which can be one of:

Static
This lease entry is from a static DHCP mapping entry.

Active
A current lease from an active client.

Expired
A lease which has expired because a client did not renew it before its expiration time.

Online
An icon indicating whether or not the device is currently "online" as determined by the contents of the *ARP table*.

If a system shows online, then it has recently tried to communicate to or through this firewall.

A host marked as offline may be powered on and working but it has not attempted communication to or through the firewall recently.

IP Address
IP address assigned to the client by DHCP, or static mapping address.

MAC Address
The client MAC address.

Tip: Installing the NMAP package activates a feature which allows the page to also display the manufacturer associated with the MAC address, if it is known. Note that this is not effective in some cases, such as for virtual machines which use randomly generated MAC addresses or for wireless clients which utilize privacy features that alter their MAC addresses.

Hostname
The hostname (if any) that the client sent as part of its DHCP request.

Description
The description for a host with a DHCP static mapping.

Start/End
The beginning and end times of the DHCP lease.

> **Note:** For static mappings the page prints `n/a` as static mapping leases do not have a start or end time, and they do not expire.

Actions
Icons to take action on this lease. See *Actions* for details.

Search

The search box filters the contents of the **Leases** table based on keyword matching.

Enter a search string or UNIX regular expression into the box and click **Search** to filter the list to only matching records.

By default the search looks at text from all fields in the lease record, but this can be limited to specific fields using the drop-down list.

Actions

Add static mapping

To create a static mapping from a dynamic lease, click  the to the right of the lease. This pre-fills the MAC address of that host into the **Edit static mapping** screen.

Edit static mapping

Entries for existing static mappings have the  icon which takes the user to the page to edit that specific entry.

Wake on LAN Integration

Clicking the  icon to the right of the lease sends a Wake on LAN (WOL) packet to that host.

Click  to create a WOL entry for the MAC address.

See also:

Wake on LAN

Delete a lease

While viewing the leases, an expired or inactive lease may be manually deleted by clicking  at the end of its line. This option is not available for active or static leases, only for offline or expired leases.

Pool Usage Summary

The **Lease Utilization** section summarizes pool usage, giving a count of leases used in each pool configured in the DHCPv4 server.

View inactive leases

By default the page lists active and static leases. Clicking **Show all configured leases** makes the page display all leases, including inactive and expired leases.

To reduce the view back to normal, click **Show active and static leases only**.

Clear All DHCP Leases

The  **Clear all DHCP leases** button stops the DHCP daemon, removes the entire lease database, and then starts the daemon again.

This does not remove static DHCP leases, only dynamic leases.

High Availability Status – Kea DHCP Only

Failover status for Kea DHCP is in a section at the bottom of the DHCP and DHCPv6 Leases pages as in figure *Kea DHCP Failover Status - Primary node, both online*. The failover status works identically for both DHCP and DHCPv6.

High Availability Status

Node Name	Node Type	Node Role	Latest Heartbeat	Node State
ha-primary	local	primary	N/A	hot-standby
ha-secondary	remote	standby	9 seconds ago	hot-standby

Fig. 7: Kea DHCP Failover Status - Primary node, both online

The failover section contains a row for each node with the status of each node using the following fields:

Node Name
An icon indicating the status of a node followed by the configured name for each node.

The possible icons are:

-  : The node is online and has responded recently.
-  : The node is in an interrupted state, indicating it has not responded recently and may be going offline.

-  : The node is in an offline state because it is unresponsive.

Node Type
Indicates whether this entry is local (this node) or remote (the peer).

Node Role
The selected role for this node (primary or standby).

Latest Heartbeat
Elapsed time since this node received a heartbeat from the peer.

Node State
The current state of the node, which may be one of the following:

waiting
The node is waiting for a connection from the peer.

syncing
The node has established a connection with the peer and is synchronizing lease data.

ready
The node has finished synchronizing lease data and is ready to serve clients.

hot-standby
On a primary node this indicates the node is handing out leases for local clients, coordinating lease data with the secondary node, and sending failover heartbeats.

On a standby node this indicates the node is receiving lease data from the primary node, and sending failover heartbeats, but it is not handing out leases.

unavailable
The node is not responding and is considered offline.

partner-down
A standby node has assumed an active role in handing out leases for clients since the primary peer is offline.

28.1.10 DHCPv6 Status

The current contents of the DHCPv6 lease database and related information are viewable at **Status > DHCPv6 leases**.

The page contains multiple sections with information about leases. The exact information and layout depends on the selected DHCP backend.

DHCPv6 Leases

This section of the page lists DHCPv6 client leases and their properties, including:

Status
The first column with no header contains two icons indicating the current status of the lease. Hover over the icon for a tooltip explaining the meaning of the icon.

Lease Type
An icon indicating the type of DHCP lease assigned to this client, which can be one of:

Static
This lease entry is from a static DHCP mapping entry.

Active
A current lease from an active client.

Expired
A lease which has expired because a client did not renew it before its expiration time.

Online
An icon indicating whether or not the device is currently "online" as determined by the contents of the *ARP table*.

If a system shows online, then it has recently tried to communicate to or through this firewall.

A host marked as offline may be powered on and working but it has not attempted communication to or through the firewall recently.

IPv6 Address
IPv6 address assigned to the client by DHCP, or static mapping address.

DHCP Unique Identifier (DUID)**
The **DHCP Unique Identifier** (DUID) of this client.

The DUID is meant to be unique *per device*.

IPv6 hosts are identified by a combination of the IAID and DUID.

Note: Due to variances in DHCPv6 clients between operating systems and manufacturers some DUID values are sized differently than others.

Hostname
The hostname of the client (if known).

Start/End
The beginning and end times of the DHCP lease.

Note: For static mappings the page prints `n/a` as static mapping leases do not have a start or end time, and they do not expire.

Actions
Icons to take action on this lease. See *Actions* for details.

Note: This list only contains information on leases handed out by DHCPv6. If a client assigns itself an address some other way (e.g. SLAAC) it cannot be listed on this page.

Search

The search box filters the contents of the **Leases** table based on keyword matching.

Enter a search string or UNIX regular expression into the box and click **Search** to filter the list to only matching records.

By default the search looks at text from all fields in the lease record, but this can be limited to specific fields using the drop-down list.

Actions

Add static mapping

To create a static mapping from a dynamic lease, click  the to the right of the lease. This pre-fills the DUID of the client into the **Edit static mapping** screen.

See also:

DHCPv6 Static Mappings

Edit static mapping

Entries for existing static mappings have the  icon which takes the user to the page to edit that specific entry.

Wake on LAN Integration

Click  to create a WOL entry for the MAC address.

See also:

Wake on LAN

Delete a lease

While viewing the leases, an expired or inactive lease may be manually deleted by clicking  at the end of its line. This option is not available for active or static leases, only for offline or expired leases.

Delegated Prefixes

When **Prefix Delegation** is enabled, the bottom of the page lists delegated prefixes and their routing.

Entries for each delegated prefix include the following information:

IPv6 Prefix
: The IPv6 prefix and length which the firewall has delegated to a DHCPv6 client.

Routed To
: The IPv6 address to which the firewall is routing the IPv6 prefix.

  The target address will match one of the leases in the list at the top of the screen.

IAID/DUID
: The IAID+DUID combination will match one of the leases in the list at the top of the screen and identifies the host to which the firewall is routing this prefix.

Start/End
: The start and end time of this delegation. If the client renews its delegation request, the times will update accordingly.

State
The status of the delegation, which can be one of:

Active
A current delegation to an active client.

Expired
A delegation which has expired because a client did not renew it before its expiration time.

Pool Usage Summary

The **Lease Utilization** section summarizes pool usage, giving a count of leases used in each pool configured in the DHCPv6 server.

View inactive leases

By default the page lists active and static leases. Clicking **Show all configured leases** makes the page display all leases, including inactive and expired leases.

To reduce the view back to normal, click **Show active and static leases only**.

Clear DHCP Leases

The  **Clear all DHCPv6 leases** button stops the DHCPv6 daemon, removes the entire lease database, and then starts the daemon again.

This does not remove static DHCPv6 mappings, only dynamic leases.

High Availability Status – Kea DHCP Only

Failover status for Kea DHCP is in a section at the bottom of the DHCP and DHCPv6 Leases pages as in figure *Kea DHCP Failover Status - Primary node, both online*. The failover status works identically for both DHCP and DHCPv6, so refer to *High Availability Status – Kea DHCP Only* for details on how the failover status operates.

28.1.11 DNS Resolver Status

The *DNS Resolver* status page at **Status > DNS Resolver** displays the current contents of the DNS resolver infrastructure cache.

The page contains a variety of statistics for DNS servers contacted by the resolver daemon (Unbound), though the type of content varies based on the current *DNS resolver mode*.

Resolver Mode

In resolver mode the status page contains a list of all authoritative DNS servers which Unbound has recently contacted along with the zone for which they were queried.

The page will typically contain entries for root servers (`.` zone), Top Level Domain (TLD) servers (e.g. `.com`, `.org`) and servers for specific domains. When there are multiple servers for the same zone, the statistics tracked in the cache help Unbound decide which server it will use for subsequent queries.

Forwarding Mode

In forwarding mode the status page contains entries for each of the available forwarding DNS servers. These *DNS Servers* are from the list configured on **System > General Setup** as well as from dynamic WAN sources, when present.

The statistics tracked in the cache help Unbound decide which server it will use for subsequent queries. For example, in a multi-WAN environment a server routed through a failed WAN would be marked as unresponsive and skipped. A server connected to a slow or high latency WAN would be skipped unless better sources were unavailable.

28.1.12 Gateway Status

The Gateway Status page at **Status > Gateways** displays the current status of individual gateways as well as gateway groups.

Gateways Tab

The **Gateways** tab displays the status for each gateway on the firewall, including manually defined gateways as well as dynamic gateways.

See also:

- *Gateways*

The status output includes the following information for each entry:

Name
: The name of the gateway.

  If this gateway is currently the default gateway for either IPv4 or IPv6, the page will print `(default)` after the name.

Gateway
: The IP address of the gateway.

Monitor
: The IP address being used by the gateway monitoring system to determine the status of the gateway.

  If the gateway has a custom monitor IP address set, this field will be different than the gateway IP address.

  If monitoring is disabled for this gateway this column contains the string `(unmonitored)`.

RTT
: The round-trip time of the most recent gateway monitoring probes.

RTTsd
: The standard deviation of the round-trip time of recent gateway monitoring probes. This indicates how much variance there is between the fastest and slowest recent responses from the monitoring address.

A high value in this column indicates that the latency on the path to the monitor IP address varies significantly, with large differences between the high and low values. This could be due to load or instability on the link, for example.

A low value indicates that the latency on the circuit is consistent, which can mean it is in good condition, has a light load, or is otherwise operating optimally.

Loss

The amount of packet loss the firewall has experienced recently while probing the monitor IP address. This may indicate that the circuit has a problem somewhere along the path to the monitor IP address.

Some hosts and routers drop or throttle ICMP messages during times of high load. Thus, experiencing packet loss from monitoring probes does not always indicate a problem with the circuit.

Tip: If the circuit appears to be working properly despite showing loss, it's possible that the monitoring probes have been dropped by a router somewhere in between the firewall and the monitor IP address host. In this case the best course of action is to choose a different monitor IP address.

Status

The status field shows the current state of the gateway. The status may be one of: Online, Offline, or Warning.

When in an offline or warning state the field also contains a text description of the problem. For example, it may indicate that the gateway is offline due to packet loss.

Description

The text description of the gateway, either from the manually configured settings or a default string for dynamic gateways.

Action

Selectively kill firewall states using this gateway in various ways.

-  : Kills all firewall states created by policy routing rules using this specific gateway by name.

  This does not include states which used this gateway as a part of a gateway group.

-  : Kills all firewall states created by policy routing rules using this specific gateway by IP address.

  The states must have matched a rule using policy routing with this gateway alone, in a gateway group, or via `reply-to` on a WAN-type interface.

-  : This icon is present only on default gateway entries. It will kill states using the default gateway (`0.0.0.0` for IPv4, `::` for IPv6). This affects states which did not match policy routing rules (e.g. default routing behavior, automatic gateway switching, etc).

  Warning: This can be very disruptive as it may terminate sessions to firewall services and/or on multiple WANs and internal interfaces.

Gateway Groups Tab

The **Gateway Groups** tab shows the status of gateway group members and the groups as a whole.

See also:

- *Gateway Groups*

The status output includes the following information for each entry:

Group Name
The name of the gateway group.

Gateways
A table containing a row for each gateway group member arranged in tiers on different columns.

If all of the gateways on a tier are down, the firewall will use the gateways on the next available tier. For example, if all of the gateways in tier 1 are offline, the firewall will look for gateways in tier 2, then tier 3, and so on.

Description
The text description of the gateway group.

Action
Selectively kill firewall states using this gateway group.

Clicking the  icon kills all firewall states created by policy routing rules using this specific gateway group by name.

This does not affect other uses of the gateway group, such as services bound to a gateway group as their interface.

28.1.13 CARP Status

The CARP status page is a part of the pfSense® software GUI at **Status > CARP (failover)**. This page shows the current status of all configured CARP *Virtual IP addresses*. The page also provides troubleshooting and maintenance controls.

CARP Maintenance Controls

The top section of the page contains buttons to manage the CARP behavior of this node.

> **Warning:** After changing the enable/disable status or maintenance mode, it may take a few moments for a node to completely take over the **MASTER** status on all VIPs.
>
> After clicking one of the buttons the page may refresh before this process is complete. To ensure the status is accurate, wait a few moments and manually reload the page by clicking the page title in the breadcrumb bar.

Enable/Disable CARP

The first button toggles the enable/disable status of CARP temporarily, and will have one of two labels depending on the current status:

Temporarily Disable CARP
When CARP is active this button will temporarily disable CARP and remove the CARP VIP configuration from the operating system.

If this is the primary node, the secondary node will take over the **MASTER** role when the process completes.

This setting is not retained across reboots. If CARP is temporarily disabled and the firewall reboots, CARP will be active after the reboot.

Enable CARP
When CARP is disabled this button will enable CARP and reconfigure the CARP VIPs on the interfaces.

If this is the primary node it will take over the **MASTER** role when the process completes.

Maintenance Mode

The next button toggles CARP maintenance mode. In maintenance mode the VIP configuration remains on the interfaces and a node participating in CARP demotes itself naturally by increasing the advertising frequency skew of its VIPs to the maximum value, `254`. This allows other CARP nodes to take over the **MASTER** role naturally.

For example, the secondary node typically has a skew of `100`. If the primary node enters maintenance mode, the secondary node now has a lower skew (`100` is less than `254`) and the secondary node will assume the **MASTER** role as it will be advertising faster than the demoted primary node.

Maintenance mode persists across reboots so it can ensure that a node does not take back over prematurely before it is ready. This makes it useful for performing upgrades or other maintenance on the primary node.

The button has one of two labels depending on the current status:

Enter Persistent CARP Maintenance Mode
Sets the skew of all VIPs to `254` and sets the maintenance mode flag in the firewall configuration. If this flag is present in the configuration at boot time, the node will remain in maintenance mode.

Leave Persistent CARP Maintenance Mode
Sets the skew of all VIPs to the value specified in the VIP configuration and clears the maintenance mode flag in the firewall configuration.

Warning: If all nodes in a cluster are in maintenance mode, the result is unpredictable as they will all be using the same skew value. Only put one node in a cluster into maintenance mode at a time.

Reset Demotion Status

The system keeps track of a demotion value which can change based on the status of interfaces with CARP VIPs. For example, if an interface with a CARP VIP is down, the system increases the demotion value by `240` and it adds that value internally to the VIP skews. This allows a node to automatically demote itself when it detects a problem. When an interface recovers it decreases the demotion value by the same amount.

When the demotion status is non-zero the status page displays a warning box at the top explaining that the demotion status may be incorrect with a button to reset the value. This **Reset CARP Demotion Status** button resets the demotion value back to the default of `0`.

> **Warning:** Before resetting this value check all interfaces to ensure there is not an ongoing problem that needs resolved first. Resetting the demotion status while there is a problem could result in the demotion status becoming incorrect again when that problem is corrected.
>
> Fixing the underlying problem will naturally correct the demotion value.

In rare cases a node may have a problem properly setting or clearing its own demotion status after processing interface events, and that is the only time the button should be used to return to a working status.

CARP Status

The **CARP Status** table includes entries for each CARP VIP configured on the firewall and also shows IP Alias VIPs which use a CARP VIP as a parent.

Each entry contains the following information:

Interface and VHID
The interface and VHID for a given CARP VIP entry.

For example, a CARP VIP on WAN with a VHID of `11` will be listed as `WAN@11`.

Virtual IP Addresses
The IP addresses associated with the CARP VIP. This includes the CARP VIP itself as well as any IP alias type VIPs which utilize this CARP VIP as a parent.

Status
The **Status** column shows one of the following status strings:

MASTER
Indicates this node is accepting all traffic for this VIP

BACKUP
Indicates this node is monitoring CARP advertisements and not accepting traffic for the VIP.

INIT or blank
Generally indicates a problem with the VIP. Either the VIP is not configured at the OS level, the interface upon which it is configured is down, or the interface has a problem.

When operating normally the primary node should show each VIP in **MASTER** status. On the secondary node each VIP should show **BACKUP** for the status.

If both nodes show **MASTER** there is usually a problem at layer 2 (the switch) preventing the nodes from seeing advertisements from the other node.

See also:

See *Troubleshooting High Availability* for help troubleshooting CARP.

State Synchronization Status / pfsync Nodes

The bottom section of the page contains a list of state creator host IDs.

On current versions of pfSense software the default ID for a host is the last 8 characters of its NDI, but there is an option to set a specfic custom ID (See *Filter Host ID*). On previous versions the default behavior was to generate a randomized value on every filter reload.

When a cluster is configured for state synchronization each node should see states created by IDs from other nodes in this list, indicating that they are properly synchronizing state table data.

There can be some slight differences in the list depending on timing (e.g. when changing the host ID to a custom value) but the list should be nearly identical on all nodes.

Widget

There is a **CARP Status** widget available for the *Dashboard* which shows similar information in a condensed format without the maintenance controls.

28.1.14 Captive Portal Status

The **Captive Portal Status** page is available through the pfSense® software GUI at **Status > Captive Portal**.

The status page defaults to the **Active Users** tab which displays information about active user sessions.

See also:

The other tabs on this page are related to managing voucher rolls and not user sessions. See *Vouchers* for details.

Active Users Tab

The **Active Users** tab lists online users for captive portal zone configurations with and without authentication.

If the captive portal configuration contains more than one zone, the first option presented by the GUI is a drop-down list of zones. To view the sessions for a zone, select it from the **Display Zone** drop-down.

The list of online users contains the following information for each entry:

IP address
: The IP address of the captive portal user.

MAC Address
: The MAC Address of the captive portal user.

  This field may be blank if the zone does not utilize MAC filtering.

Username
: Can be one of several things, depending on the zone configuration:

  - The name of an authenticated captive portal user if they logged in with a username and password.
  - The voucher code if the user authenticated using vouchers.
  - The MAC address of a host if the zone uses **RADIUS** with **MAC Authentication**.
  - The string `unauthenticated` if the zone does not require authentication.

Session Start Time
: The time when the user authenticated their current session.

Actions

A  icon that, if clicked and confirmed, will terminate a captive portal session. The user must authenticate again to get back online.

Active Users Status Examples

These figures are examples of several different user styles that may appear in the list.

For **Local User Manager** or **RADIUS** authentication with username/password, status entries look like Figure *Online Captive Portal Users: User Authentication*:

Fig. 8: Online Captive Portal Users: User Authentication

If a zone allows voucher-based authentication, users that signed on using a voucher look like Figure *Online Captive Portal Users: Vouchers*:

Fig. 9: Online Captive Portal Users: Vouchers

If a zone is set to **No Authentication**, status entries look like Figure *Online Captive Portal Users: No Authentication*:

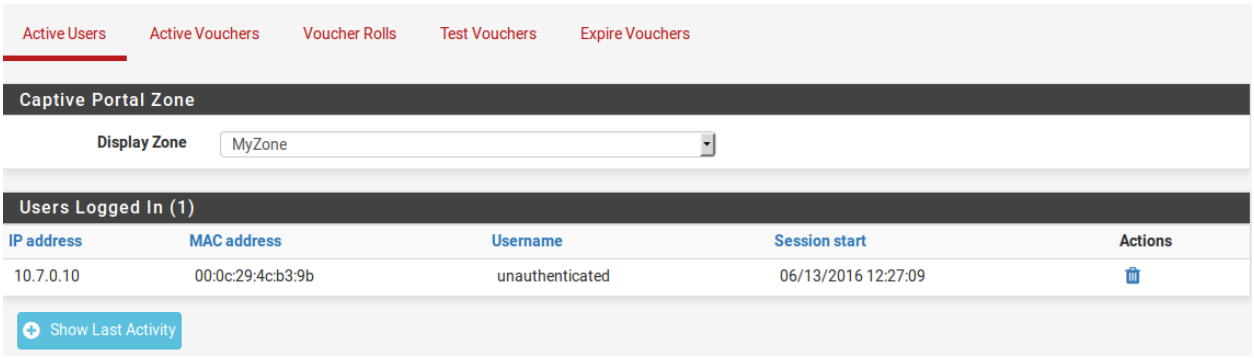

Fig. 10: Online Captive Portal Users: No Authentication

28.1.15 Viewing Active Network Sockets

The **Diagnostics > Sockets** page prints a list of active TCP/IP sockets for both IPv4 and IPv6 *used by the firewall itself*.

Note: The output of this command only shows sockets used by the firewall OS for daemons or other programs on the firewall. It does **not** show connections for traffic passing through the firewall.

This list is useful for determining which IP addresses and ports are in use by various firewall processes and/or packages. The firewall interprets the contents of the page from the output of the FreeBSD command `sockstat`.

By default the page only displays *listening* sockets. Click **Show all socket connections** to also display sockets in use by the firewall for connections to external hosts.

Each row in the output contains the following information:

User
: The operating system user who owns the socket (e.g. `root`)

Command
: The command which holds the socket. This might be a daemon or a program making an outbound connection.

PID
: The process ID of the command holding the socket.

FD
: The file descriptor number of the socket.

Proto
: The transport protocol and address family combined (e.g. TCP4, UDP6, UDP46).

Local
: The local IP address and port number associated with this socket.

Foreign
: The remote IP address and port number associated with this socket.

28.1.16 ARP Table

IPv4 Hosts use ARP (Address Resolution Protocol) to locate IPv4 neighbors by MAC address on a directly connected network.

The ARP table in pfSense® software displays a list of IPv4 hosts on the network which have attempted to talk to or through the firewall within the past few minutes. If a host is up but has not talked to or through the firewall it will not appear in the ARP table.

See also:

For IPv6 hosts, see *NDP Table*.

To view the contents of the ARP table in pfSense software, navigate to **Diagnostics > ARP Table**.

The page contains the following items for each ARP table entry:

Interface
: The interface where the firewall observed the host. If the interface is assigned, this field contains the given name of the interface in pfSense software. Otherwise, the page displays the operating system interface name.

IP Address
The IPv4 address of the host.

MAC Address
The MAC address of the host.

A MAC address listed as **(Incomplete)** indicates that the firewall has attempted to discover the host via ARP but it has not yet received a valid response.

Tip: Installing the NMAP package activates a feature which allows the page to also display the manufacturer associated with the MAC address, if it is known. Note that this is not effective in some cases, such as for virtual machines which use randomly generated MAC addresses or for wireless clients which utilize privacy features that alter their MAC addresses.

Hostname
The fully qualified domain name, or at least the hostname portion, of the host. This can be discovered via DHCP lease database content or by a reverse lookup of the IP address via DNS.

Status
The status of the entry, typically one of two types:

Permanent
A static entry either located on the firewall itself (e.g. interface address, VIP) or a static ARP entry.

Expires in <time>
A dynamic ARP entry which will expire in `<time>` unless the host communicates to or through the firewall again. The default maximum age is `1200` seconds (20 minutes).

Link Type
The type of network link through which this host can be reached (e.g. **Ethernet**).

Actions

Contains the  icon that, if clicked and confirmed, will remove this ARP table entry. This can nudge the firewall to discover a new MAC address for a host if it changes.

The  **Clear ARP Table** button purges the entire contents of the ARP table. Clearing the ARP table is not typically necessary but can help the firewall in situations where multiple hosts have changed MAC addresses and the firewall is still attempting to communicate with the old addresses.

28.1.17 NDP Table

IPv6 Hosts use NDP (Neighbor Discovery Protocol) to locate IPv6 neighbors by MAC address on a directly connected network.

The NDP table in pfSense® software displays a list of IPv6 hosts on the network which have attempted to talk to or through the firewall within the past few minutes. If a host is up but has not talked to or through the firewall it will not appear in the NDP table.

See also:

For IPv4 hosts, see *ARP Table*.

To view the contents of the NDP table in pfSense software, navigate to **Diagnostics > NDP Table**.

The page contains the following items for each NDP table entry:

IPv6 Address
The IPv6 address of the host.

MAC Address
The MAC address of the host.

A MAC address listed as **(Incomplete)** indicates that the firewall has attempted to discover the host via NDP but it has not yet received a valid response.

Tip: Installing the NMAP package activates a feature which allows the page to also display the manufacturer associated with the MAC address, if it is known. Note that this is not effective in some cases, such as for virtual machines which use randomly generated MAC addresses or for wireless clients which utilize privacy features that alter their MAC addresses.

Hostname
The fully qualified domain name, or at least the hostname portion, of the host. This can be discovered using reverse lookup of the IPv6 address via DNS.

Interface
The interface where the firewall observed the host. If the interface is assigned, this field contains the given name of the interface in pfSense software. Otherwise, the page displays the operating system interface name.

Expiration
The expiration status of the entry, typically one of two types:

Permanent
A static entry either located on the firewall itself (e.g. interface address, VIP) or a static NDP entry.

<time>
A dynamic NDP entry which will expire in `<time>` unless the host communicates to or through the firewall again.

Actions

Contains the  icon that, if clicked and confirmed, will remove this NDP table entry. This can nudge the firewall to discover a new MAC address for a host if it changes.

The  **Clear NDP Table** button purges the entire contents of the NDP table. Clearing the NDP table is not typically necessary but can help the firewall in situations where multiple hosts have changed MAC addresses and the firewall is still attempting to communicate with the old addresses.

28.1.18 Hardware Temperature Monitoring

FreeBSD, and thus pfSense® software, supports monitoring hardware temperature on some chipsets. Unfortunately, support for this is limited but growing as hardware is replaced by newer Intel and AMD CPUs that include better monitoring. Where supported, it can be useful.

Widgets and Graphs

The *System Information* dashboard widget contains a single **Temperature** entry on systems with one or more available temperature sensors.

The *Thermal Sensors* widget displays the temperature from every available thermal sensor on the firewall. It also has configurable behavior for warning thresholds and output contents.

When the firewall detects that support for temperature monitoring is available, it also graphs the temperatures over time. See *Monitoring Graphs* for details.

Intel and AMD Temperature Monitoring

There is an option to select either an Intel or AMD temperature monitor module under **System > Advanced** on the **Miscellaneous** tab. These modules work with Intel Core series and later Intel chips, and similarly recent AMD chips, respectively. Support is not universal, but it is common, especially on Intel chips, even Atom-based chips. The temperature can be observed using the Thermal Sensors dashboard widget or by sysctl:

```
# sysctl -a | grep "dev.cpu.*.temperature"
dev.cpu.0.temperature: 46.0C
dev.cpu.1.temperature: 47.0C
dev.cpu.2.temperature: 47.0C
dev.cpu.3.temperature: 47.0C
```

These are typically on-die sensors so they only represent the CPU core temperatures, not other zones in the system.

ACPI Thermal Monitoring

FreeBSD also handles some settings through ACPI. To see if the hardware supports temperature monitoring, try the following command from a shell prompt or **Diagnostics > Command**:

```
sysctl hw.acpi.thermal
```

If the hardware is supported, output similar to the following will be shown:

```
hw.acpi.thermal.min_runtime: 0
hw.acpi.thermal.polling_rate: 10
hw.acpi.thermal.user_override: 0
hw.acpi.thermal.tz0.temperature: 22.5C
hw.acpi.thermal.tz0.active: -1
hw.acpi.thermal.tz0.passive_cooling: 1
hw.acpi.thermal.tz0.thermal_flags: 0
hw.acpi.thermal.tz0._PSV: 85.0C
hw.acpi.thermal.tz0._HOT: -1
hw.acpi.thermal.tz0._CRT: 100.0C
hw.acpi.thermal.tz0._ACx: 85.0C -1 -1 -1 -1 -1 -1 -1 -1 -1
```

In this example, there is only one thermal zone, and its temperature is 22.5C (72.5F).

From the acpi_thermal(4) man page:

```
hw.acpi.thermal.min_runtime
     Number of seconds to continue active cooling once started.  A new
     active cooling level will not be selected until this interval
```

(continues on next page)

(continued from previous page)

```
     expires.

hw.acpi.thermal.polling_rate
     Number of seconds between polling the current temperature.

hw.acpi.thermal.user_override
     If set to 1, allow user override of various setpoints (below).
     The original values for these settings are obtained from the BIOS
     and system overheating and possible damage could occur if
     changed.  Default is 0 (no override).

hw.acpi.thermal.tz%d.active
     Current active cooling system state.  If this is non-negative,
     the appropriate _AC%d object is running.  Set this value to the
     desired active cooling level to force the corresponding fan
     object to the appropriate level.

hw.acpi.thermal.tz%d.passive_cooling
     If set to 1, passive cooling is enabled.  It does cooling without
     fans using cpufreq(4) as the mechanism for controlling CPU speed.
     Default is enabled for tz0 where it is available.

hw.acpi.thermal.tz%d.thermal_flags
     Current thermal zone status.  These are bit-masked values.

hw.acpi.thermal.tz%d.temperature
     Current temperature for this zone.

hw.acpi.thermal.tz%d._PSV
     Temperature to start passive cooling by throttling down CPU, etc.
     This value can be overridden by the user.

hw.acpi.thermal.tz%d._HOT
     Temperature to start critical suspend to disk (S4).  This value
     can be overridden by the user.

hw.acpi.thermal.tz%d._CRT
     Temperature to start critical shutdown (S5).  This value can be
     overridden by the user.

hw.acpi.thermal.tz%d._ACx
     Temperatures at which to switch to the corresponding active cooling
     level.  The lower the _ACx value, the higher the cooling power.

All temperatures are printed in Celsius.  Values can be set in Celsius
(by providing a trailing "C") or Kelvin (by leaving off any trailing letter).
When setting a value by sysctl(8), do not specify a trailing decimal (i.e.,
90C instead of 90.0C).
```

The defaults for these values are taken from the BIOS and some systems will not allow changes. The only way to know is to try. Before attempting to alter any of these values, set this OID:

```
sysctl -w hw.acpi.thermal.user_override=1
```

These values may be set by adding the appropriate lines for the OIDs to **System > Advanced** on the **Tunables** tab. Try setting them at run time:

```
sysctl -w hw.acpi.thermal.tz0._CRT=120C
```

28.1.19 IPsec Status

The IPsec status page at **Status > IPsec** displays the current state of all IPsec tunnels configured on the firewall.

This page is divided into four tabs.

See also:

- *IPsec Logs*
- *IPsec Troubleshooting*

Overview Tab

This tab lists all enabled IPsec tunnels. Each entry contains the tunnel description, links to its settings, outer and inner IP addresses, various properties of the tunnel, counters, and current status.

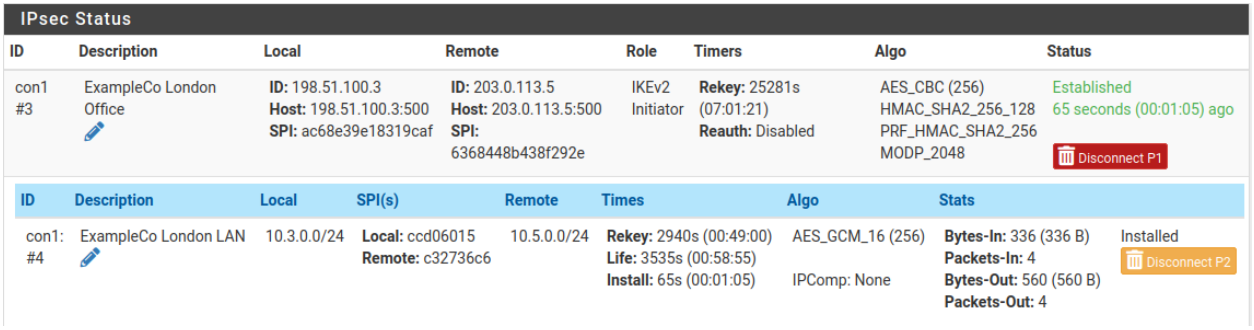

Fig. 11: Connected Tunnel with Child SA List expanded

Connected tunnels are listed first, followed by disconnected tunnels. There are buttons on each row to connect or disconnect entries manually.

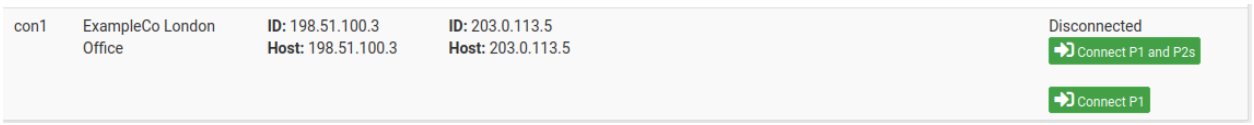

Fig. 12: Disconnected Tunnel

By default only the IKE portion of a tunnel (phase 1) is listed to keep the display compact. Click  **Show child SA entries** to display the child SA (phase 2) entries.

Leases Tab

Lists current usage statistics for mobile IPsec client leases from configured pools. Current and recently connected clients are also listed along with the IP address they were assigned by the firewall.

SAD Tab

Shows the contents of the IPsec Security Association Database (SAD) which contains data about current IKE SA entries and corresponds with active phase 1 entries.

The page contains one entry in the list for each direction between *public peer addresses* of an active IPsec tunnel. For example, one entry for `x.x.x.x` to `y.y.y.y` and a corresponding entry for `y.y.y.y` to `x.x.x.x`.

SPD Tab

Shows the contents of the IPsec Security Policy Database (SPD). These policies define the networks which are interesting to IPsec and corresponds with phase 2 entries.

The page contains one entry for each direction between *private networks* of all IPsec tunnels whether or not they are connected.

28.1.20 OpenVPN Server and Client Status

The OpenVPN status page at **Status > OpenVPN** shows the status of each OpenVPN server and client. The status includes service controls for each separate server and client instance on the status page.

SSL/TLS Client/Server Mode

For OpenVPN servers in SSL/TLS client/server mode (tunnel network larger than `/30`), the status provides a list of connected remote clients along with their usernames or certificate common names and connection data as seen in Figure *OpenVPN status for an SSL/TLS server with one connected client*.

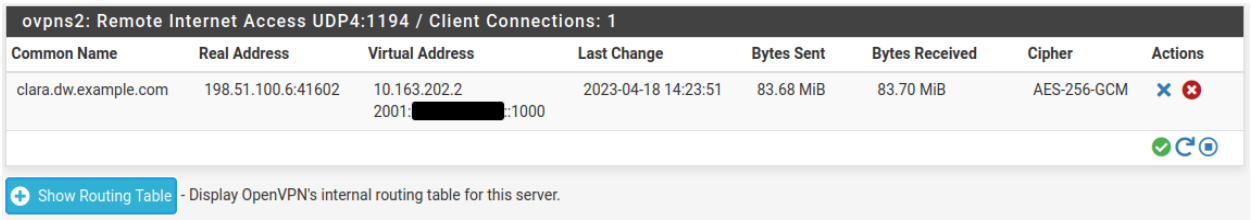

Fig. 13: OpenVPN status for an SSL/TLS server with one connected client

The status of an instance has a header bar which includes the OS interface name (e.g. `ovpns1`), the custom text description of the VPN, its protocol and port, plus a total count of connected clients.

The status output includes the following columns in separate blocks for each server instance in this mode:

Common Name
: The certificate common name and/or username of the client. For VPNs utilizing user authentication, both are printed in this column. The values may differ depending on whether the server has SSL/TLS enabled and whether or not the **Username as Common Name** option is enabled.

Real Address
: The external/public IP address of the client, as it would appear on the WAN.

Virtual Address
The tunnel network IPv4 and/or IPv6 addresses assigned to the client for use inside the VPN.

Connected Since
A timestamp indicating when this client connected to the server or the last status change of the connection.

Bytes Sent
The amount of data the OpenVPN server has sent to this client.

Bytes Received
The amount of data the OpenVPN server has received from this client.

Ciphers
The encryption algorithm in use for this client, which may vary due to cipher negotiation.

Actions
This column includes icons which control the client.

The  icon will appear at the end of each client row if that client authenticated via RADIUS and has firewall rules received from RADIUS. Clicking the icon will open a modal dialog displaying the contents of that user's personal firewall ruleset.

The  icon at the end of each client row clears the client session, which disconnects the client while allowing them to reconnect.

The  icon at the end of each client row sends a command which halts the remote client. If the client honors the request, its process terminates and it will not automatically reconnect without manual intervention. This can be useful for stopping an unattended client from conflicting with a different active session for a user.

The  **Show Routing Table** button under each server's list of clients displays a table of networks and IP addresses connected through each client connected to that server.

Peer-to-Peer Mode

For OpenVPN instances in peer-to-peer mode (shared key or SSL/TLS with a `/30` tunnel network), the output is slightly different. OpenVPN does not report the same amount of information for instances running in peer-to-peer mode, so it cannot offer the same functionality as SSL/TLS client/server mode.

As each instance in this mode is limited to one client per server, the entries are shown in a single table each for clients and servers, with one instance listed per row.

The **Name** colum prints the OS interface name for the VPN (e.g. `ovpns1`) and its configured text description, along with the protocol and port number.

For a server instance the **Status** column indicates whether the instance is running and waiting on connections or if the remote client has connected.

For client instances the **Status** column indicates whether a connection is pending or active.

The status column may display more detailed information if it's available during certain stages of configuration and connection.

Peer to Peer Server Instance Statistics

Name	Status	Last Change	Virtual Address	Remote Host	Bytes Sent	Bytes Received	Service
ovpns5 S2S [redacted] UDP4:1198	Connected (Success)	Mon Apr 17 8:41:48 2023	10.18.105.1	198.51.100.19	3.37 MiB	3.37 MiB	
ovpns6 S2S [redacted] UDP4:1199	Waiting for peer connection	Tue Apr 25 15:42:43 2023			0 B	0 B	

Client Instance Statistics

Name	Status	Last Change	Local Address	Virtual Address	Remote Host	Bytes Sent	Bytes Received	Service
ovpnc6 Client UDP4	Reconnecting (Ping Restart)	Tue Apr 25 15:43:37 2023	(pending)		(pending)	0 B	0 B	

Fig. 14: OpenVPN status showing peer-to-peer instances including a server that is up, a server waiting for a connection, and a client attempting to reconnect

28.1.21 Route Table Contents

The current contents of the firewall route table are displayed by the GUI page at **Diagnostics > Routes**. The CLI can also be display the route table using the command `netstat -rWn`.

Route Table GUI

The GUI route table contents looks like Figure *Route Table Display*.

IPv4 Routes

Destination	Gateway	Flags	Use	Mtu	Netif	Expire
default	198.51.100.1	UGS	1797	1500	igb1	
10.2.0.0/24	link#2	U	0	1500	igb0	
10.2.0.1	link#2	UHS	0	16384	lo0	
127.0.0.1	link#11	UH	204	16384	lo0	
198.51.100.0/24	link#3	U	907	1500	igb1	
198.51.100.1	00:08:a2:09:95:b6	UHS	2519	1500	igb1	
198.51.100.2	link#3	UHS	0	16384	lo0	

Fig. 15: Route Table Display

The route table contents are described in detail *later in this document*.

Routing Table Display Options

The list of routes displayed by the GUI supports pagination and filtering to aid with viewing large routing tables such as those found with a full BGP feed. The top section of the page contains the following options which control the behavior of the page:

Resolve Names
: This option controls whether or not the firewall attempts to resolve items using DNS. The default is unchecked, which disables DNS resolution. When checked, the firewall attempts a DNS lookup to show hostnames rather than IP addresses for route table entries.

> **Warning:** Enabling this feature causes a delay and performance penalty as the page attempts to resolve all of the entries. As the size of the table increases, the delay will also increase and performance will degrade further.

Rows to display
This option controls the number of rows output from each route table. By default the page displays `100` rows. Choose a new value to show more or less rows.

Filter
This text entry box defines a string or pattern which the page uses to search the route table for matching entries. The field supports regular expressions for advanced filtering.

Click  **Update** to redisplay the routing table with the current settings.

Route Table CLI

Viewing the route table in the CLI is similar to the GUI. The *same information* is present, and the labels are similar.

The `netstat -rWn` command can be run from a console or SSH shell:

```
$ netstat -rWn
Routing tables

Internet:
Destination        Gateway            Flags       Use    Mtu      Netif Expire
default            198.51.100.1       UGS         294   1500     vtnet0
127.0.0.1          link#4             UH        20976  16384        lo0
192.168.1.0/24     link#2             U             1   1500     vtnet1
192.168.1.1        link#2             UHS           0  16384        lo0
198.51.100.0/24    link#1             U           116   1500     vtnet0
198.51.100.1       ca:1d:62:6c:c6:9c  UHS         191   1500     vtnet0
198.51.100.103     link#1             UHS           0  16384        lo0
```

Omit the `-n` flag and the command will attempt to use DNS to resolve IP addresses to hostnames where possible.

IPv4 and IPv6 Route Table Content

The route table information output by either the GUI or the CLI contains the following fields:

Destination
The destination network or host for this route.

The default route for the each address family is listed as `default`. Otherwise, hosts are listed as an IP address and networks are listed with an IP address and CIDR mask or prefix.

Gateway
The next hop through which the firewall will route traffic going to the **Destination**.

If this column shows a link, such as `link#1`, then that network is directly reachable by that interface and no special routing is necessary. If a host is visible with a MAC address, then it is a locally reachable host with an entry in the ARP table, and packets are sent there directly.

Flags
Properties of this route. See *Route Table Flags* for the meanings of each flag.

Uses
The total number of packets the firewall has sent via this route.

This is helpful for determining if the firewall is actively using a route as the value will continually increment as packets utilize the route.

MTU
The MTU for packets using this route.

Interface
The interface through which the firewall will route traffic for **Destination**.

Expire
An expiration time for temporary routes, such as those added from ICMP redirects.

Route Table Flags

There are quite a few flags, all of which are covered in the FreeBSD man page for *netstat(1)*. The portion of the content from that document covering flags is reproduced in *Route Table Flags*.

Table 1: Route Table Flags

Letter	Flag	Meaning
1	RTF_PROTO1	Protocol specific routing flag #1
2	RTF_PROTO2	Protocol specific routing flag #2
3	RTF_PROTO3	Protocol specific routing flag #3
B	RTF_BLACKHOLE	Discard packets during updates
b	RTF_BROADCAST	Represents a broadcast address
D	RTF_DYNAMIC	Created dynamically by redirect
G	RTF_GATEWAY	Destination requires forwarding by intermediary
H	RTF_HOST	Host entry (net otherwise)
L	RTF_LLINFO	Valid protocol to link address translation
M	RTF_MODIFIED	Modified dynamically (by redirect)
R	RTF_REJECT	Host or net unreachable
S	RTF_STATIC	Manually added
U	RTF_UP	Route usable
X	RTF_XRESOLVE	External daemon translates proto to link address

For example, a route flagged as `UGS` is a usable route, packets are sent via the gateway listed, and it is a static route.

28.1.22 Wireless Status

The Wireless Status page at **Status > Wireless Status** displays a list of access points within range of the wireless radio along with various statistics about the access points detected.

If a wireless card is acting as an access point the page prints a list of associated clients along with related information.

Note: This page is only available when a wireless interface is detected in the firewall and that interface is enabled.

Access Point/Ad-Hoc Peer Capabilities

Name	Description
WME	Wireless Multimedia Extensions (QoS)
WPA	Wi-Fi Protected Access
WPS	Wi-Fi Protected Setup
RSN	802.11i - Robust Secure Network
HTCAP	802.11n - High Throughput (HT)
ATH	Atheros protocol extensions
VEN	Unknown vendor-specific extensions

Access Point/Ad-Hoc Peer Flags

Flag	Description
E	ESS Mode (Access Point)
I	IBSS Mode (Infrastructure/Client)
c	CF Pollable
C	CF Poll Request
P	Privacy
S	Short Preamble
B	PBCC
A	Channel Agility
s	Short Slot Time
R	RSN
D	DSSSOFDM

Peer Status Flags

Flag	Description
A	Authorized for Data
Q	QoS (WME)
E	Extended Rate (ERP), 802.11g
P	Power Save Mode
H	High Throughput (HT)
H+	HT Compat mode (Setup with vendor OUIs)
W	Wi-Fi Protected Setup (WPS)
N	Transitional Security Network (TSN) association
T	Aggregated MAC Protocol Data Unit (AMPDU) Transmit
R	AMPDU Receive
M	MIMO Power Save
M+	MIMO Power Save with RTS
I	Reduced Interframe Space (RIFS)
S	Short GI in HT40
S+	Short GI in HT40 and HT20
s	Short GI in HT20
t	Aggregated MAC Service Data Unit (AMSDU) Transmit
r	AMSDU Receive

28.1.23 ALTQ Traffic Shaper Queue Monitoring

The page at **Status > Queues** displays ALTQ traffic shaper queue usage. Monitor this page to ensure that traffic shaping is working as intended.

Figure *Basic WAN Queues* shows each queue listed by name, its current usage, and other related statistics.

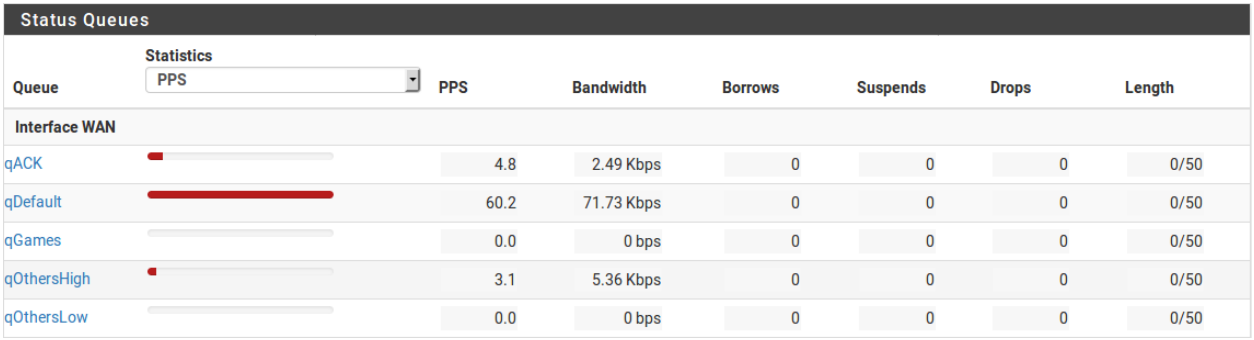

Fig. 16: Basic WAN Queues

Queue Status Columns

Queue
The name of the traffic shaper queue.

Statistics
A graphical bar which shows how "full" this queue is.

PPS
The rate of queued data in packets per second (PPS)

Bandwidth
The rate of queued data in bits per second (e.g. Mbps, Kbps, bps).

Borrows
Borrows happen when a neighboring queue is not full and capacity is borrowed from there.

Suspends
The suspends counter indicates when a delay action happens. The suspends counter is only used with the CBQ scheduler and should be zero when other schedulers are in use.

Drops
Drops happen when traffic in a queue is dropped in favor of higher priority traffic. Drops are normal and this does not mean that a full connection is dropped, only a packet. Usually, one side of the connection will see that a packet was missed and then resend, often slowing down in the process to avoid future drops.

Length
The number of packets in the queue waiting to be transmitted, over the total size of the queue.

Queue Status Options

There are two options on the page which control the output:

Refresh Rate
Controls how frequently the page updates itself automatically. This defaults to 1 second but can be lower (`0.5` seconds) or up to 5 seconds.

Statistics
Controls which data point is used to when generating bar graphs for queue content. This can be *PPS* (Default) or *Bandwidth*.

28.1.24 NTP Daemon Status

The NTP status page at **Status > NTP** shows the status of the NTP daemon. This status includes information on upstream NTP servers as well as other items such as GPS information if such a device is connected and enabled.

An example of the status is shown in Figure *NTP Daemon Status With GPS Output*.

Network Time Protocol Status

Status	Server	Ref ID	Stratum	Type	When	Poll (s)	Reach	Delay (ms)	Offset (ms)	Jitter (ms)
False Ticker	127.127.20.0	.GPS.	0	l	9	16	377	0.000	-127.53	1.879
Pool Placeholder	0.pfsense.pool.ntp.org	.POOL.	16	p	-	64	0	0.000	+0.000	0.004
Pool Placeholder	1.pfsense.pool.ntp.org	.POOL.	16	p	-	64	0	0.000	+0.000	0.004
Pool Placeholder	2.pfsense.pool.ntp.org	.POOL.	16	p	-	64	0	0.000	+0.000	0.004
Active Peer	66.220.9.122	.CDMA.	1	u	38	256	377	50.304	+0.264	1.763
Candidate	162.159.200.123	10.27.8.152	3	u	136	256	377	16.325	-0.033	1.472
Candidate	162.159.200.1	10.27.8.152	3	u	68	256	377	16.051	-0.082	0.213

GPS Information

Clock Latitude	Clock Longitude
38.[redacted] (38°[redacted]N)	-86.[redacted] (86°[redacted]W)
Google Maps Link	

Fig. 17: NTP Daemon Status With GPS Output

The status screen contains one line for every peer, and each entry contains the following items:

Status
The current status of the NTP server entry, which may be one of:

Pool Placeholder
Placeholder entry for pools defined in the configuration. When using a pool, these are the entries in the NTP configuration and the NTP daemon dynamically discovers the servers based on the DNS response for the pool address.

Unreach/Pending
The server is either unreachable or it has not yet responded with sufficient information to determine a better status.

Active Peer
The NTP server with which the daemon is currently synchronizing its clock.

Candidate
A peer which has a high enough quality status to become an active peer.

PPS Peer
A peer utilizing PPS signaling.

Selected
A peer which is included by the combine algorithm.

Excess Peer
An excess peer which is not included because there are too many other viable peers.

False Ticker
A peer which has been rejected by the intersection algorithm.

Outlier
A peer which has been discarded by the cluster algorithm.

See also:

For more information on the algorithms involved in determining status, see the NTP documentation page on Clock Select Algorithm.

Server
The hostname or IP address of the NTP server. For pool placeholders, this is the FQDN of the pool.

Some special sources such as a local NMEA reference clock like a GPS use reserved addresses. A GPS, for example, appear as an address in `127.127.20.x`.

Ref ID
A reference ID indicating how this NTP server is determining its own time.

This is typically a source IP Address for higher stratum servers (2 or higher) which is used by clients to prevent a loop where servers might reference each other which could lead to inaccuracies.

Stratum 1 servers are considered reference clocks. For these servers this reference ID is a four character string indicating the type of reference used to determine the NTP server's own time. There are a handful of pre-defined codes in RFC 5905 but servers can use custom codes as well.

Some commonly observed reference ID codes are:

POOL
This is a pool placeholder entry and not a source.

GPS
This NTP server determines its time based on a GPS device.

PPS
This NTP server determines its time based on a PPS device.

CDMA
This NTP server determines its time based on a CDMA network reference.

Stratum 0 servers are invalid as a time source but offer a four character "Kiss code" indicating a reason why they are not a valid time source at that moment.

See also:

For a full list of pre-defined Kiss and Reference ID codes, see the IANA NTP parameter lists.

Stratum
The stratum of this NTP server, in the following ranges:

Stratum 0
Invalid or unavailable time source.

Stratum 1
Reference clocks which use a non-NTP time source to keep time, such as a GPS, atomic clock, etc.

These servers are highly accurate but should not be used directly by clients. They should be used primarily by servers which will offer NTP service to many of their own local clients.

Stratum 2-14
NTP servers which obtain their own time from other NTP servers on a lower stratum.

These are typically the best sources for clients to use. Though they are potentially not as accurate as stratum 1 servers, in nearly all cases they are accurate enough for the majority of purposes.

Stratum 15
The server is not suitable for synchronizing clients (See the NTP documentation page on Clock Select Algorithm).

Stratum 16
Unsynchronized source.

Type
A code indicating the type of NTP server:

u
Unicast or manycast client

b
Broadcast or multicast client

p
Pool source

l
Local (reference clock)

s
Symmetric (peer)

A
Manycast server

B
Broadcast server

M
Multicast server

When
The amount of time since the NTP daemon last received a packet from this server. The value is - if NTP has not received any packets.

Poll(s)
The interval between polls to this server.

Reach
Reach shift register, displayed in octal.

Delay (ms)
Round trip delay to this NTP server.

Offset (ms)
Clock offset of this NTP server relative to this firewall.

Jitter (ms)
Offset RMS error estimate.

If a serial GPS is connected and configured, the page also prints the coordinates reported by the GPS device along with a link to the coordinates on Google Maps.

Note: The quality of GPS data can vary widely depending on the signal level, the GPS device, and how it is connected. Traditional serial ports are higher quality and better suited to GPS clock usage. USB serial GPS units may be acceptable, but due to how USB functions, the timing of signals cannot be guaranteed the way it can be with a traditional hard-wired serial port.

28.2 Graphs

These articles cover graphs for monitoring pfSense software itself as well as for traffic on interfaces and using additional packages for more detailed monitoring of user throughput/usage.

28.2.1 Monitoring Graphs

pfSense® software has many built-in graphs that monitor different aspects of the system, and they work out-of-the-box with no intervention.

The firewall collects and maintains data about how the system performs, and then stores this data in Round-Robin Database (RRD) files. Graphs created from this data are available under **Status > Monitoring**.

These graphs measure things such as CPU usage, memory usage, state table usage, throughput (in bytes as well as packets), link quality, traffic shaping queue usage, and more.

The graph on that page can be configured to show items from several categories, and a category and graph may be chosen for both the left axis and right axis for easy comparison.

Working with Graphs

The firewall displays a graph showing its CPU usage by default. To view other graphs or to add a second category on another axis, the graph settings must be changed as described in the next section, *Graph Settings*.

Inside the graph, the labels in the top left corner note the sources for the data in the left axis and right axis.

The graph contains a legend at the top right with each of the data sources plotted on the graph. Clicking a data source in the legend will hide it from view.

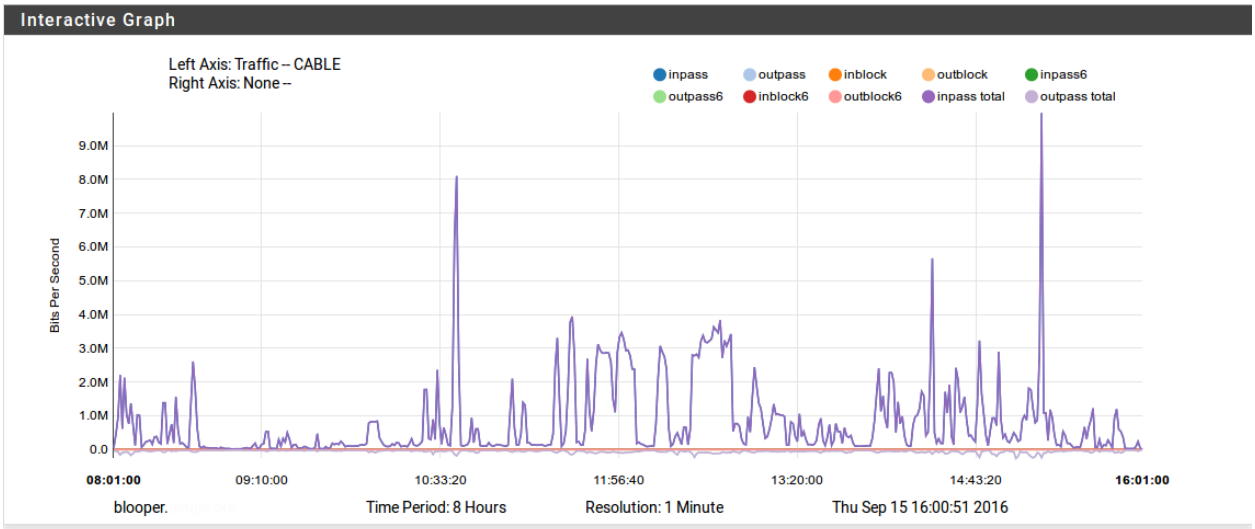
Tip: If a data source has a large spike, click its name in the legend to remove it from the graph. With the larger data source removed, more detail from the other remaining sources will be visible.

The firewall hostname, graph time period, and graph resolution are printed along the bottom of the graph, along with the time the graph was generated.

The firewall prints a table below the graph itself with a summarization of the data. This table contains minimums, averages, maximums, current values, in some cases 95th percentile values. In cases where units are given, hovering the mouse pointer over the unit will display a more detailed description of the unit.

Note: Totals are not displayed because the way data is stored in RRD files, accurate totals are not possible. To see total usage for traffic on network interfaces, install the **Status Traffic Totals** package.

Figure *WAN Traffic Graph* shows an example of an 8-hour graph of traffic on a firewall interface named *CABLE* with inverse enabled. The interface has a maximum utiliztion of 9.96Mbit/s during a 1 minute period.



Data Summary

	Minimum	Average	Maximum	Last	95th Percentile
inpass	16.52 kb/s	817.76 kb/s	9.96 Mb/s	0.00 b/s	3.12 Mb/s
outpass	12.44 kb/s	56.21 kb/s	262.97 kb/s	0.00 b/s	122.66 kb/s
inblock	0.00 b/s	7.27 b/s	676.90 b/s	0.00 b/s	
outblock	0.00 b/s	0.04 b/s	11.54 b/s	0.00 b/s	
inpass6	0.00 b/s	0.00 b/s	0.00 b/s	0.00 b/s	0.00 b/s
outpass6	0.00 b/s	0.00 b/s	0.00 b/s	0.00 b/s	0.00 b/s
inblock6	0.00 b/s	0.00 b/s	0.00 b/s	0.00 b/s	
outblock6	0.00 b/s	0.00 b/s	0.00 b/s	0.00 b/s	
inpass total	16.52 kb/s	817.76 kb/s	9.96 Mb/s	0.00 b/s	3.12 Mb/s
outpass total	12.44 kb/s	56.21 kb/s	262.97 kb/s	0.00 b/s	122.66 kb/s

Fig. 18: WAN Traffic Graph

Graph Settings

To change the graph, click  in the breadcrumb bar to display the graph settings panel.

Tip: The graph settings panel is hidden by default but this behavior can be changed. Navigate to **System > General Setup** and check **Monitoring Settings** to always display the settings panel by default.

The options on the settings panel are:

Left Axis / Right Axis

The options here control the data dispayed on each axis. By default only the **Left Axis** is populated with a value, but both may be utilized to compare areas. First pick a **Category** (or *None*), then pick a **Graph** inside that category. The list of available categories and graphs will vary depending on the firewall configuration.

Category

The general area of the desired graph: System, Traffic, Packets, Quality, Captive Portal, NTP, Queues, QueueDrops, DHCP, Cellular, Wireless, and VPN Users. These are covered in more detail later in this section.

Graph

The specific graph to display from the chosen category.

Options

This section of the settings panel controls how the graph itself looks, including the time span and style.

Time Period

The length of time to show on the graph. The default ranges cover from 1 hour up to 4 years, or a *Custom* period may be chosen. Selecting *Custom* displays the **Custom Period** controls. All of the periods are displayed even if there is no data in a graph database going back that far. The graph will be empty for times when graphing was not active.

Resolution

The smallest slice of time for which data is available on this graph. Over time, data is consolodated over longer periods so resolution is lost. For example, on a 1-hour graph it is possible to see data from one minute intervals, but on a graph including older data, it is not possible to show data that accurately since it has been averaged out. Depending on the time period of the graph it may contain *1 Minute*, *5 Minute*, *1 Hour*, or *1 Day* averages for data. Resolutions which are not possible for the given time period cannot be selected.

Inverse

Used on graphs such as the traffic graph, to separate incoming and outgoing data. For example, with **Inverse** set to *On*, outbound data is represented as a negative value to more easily differentiate it from inbound data.

Custom Period

When **Time Period** is set to *Custom*, the GUI displays this section to configure the custom time period for the graph.

Start Date

The start date for the graph. Clicking in the field will show a calendar date picking control. Only today, or days in the past, may be selected.

Start Hour

The hour of the day to start the graph using 24-hour style (`0`-`23`).

End Date

The end date for the graph.

End Hour

The end hour for the graph, exclusive. The chosen hour is not included in the graph. For example, on a graph starting at hour `10` to hour `12`, the graph covers 10:00am to 12:00pm.

Settings

Click  **Show Advanced** to display additional advanced controls not typically required for average use.

Export as CSV
Click this button to download the data from the graph as a `.csv` (Comma Separated Values) spreadsheet file, which can then be imported into another program for analysis.

Save as Defaults
Click this button to store the current graph settings as the default configuration so this specific graph will be displayed by default on future visits to this page.

Disable/Enable Graphing
This toggle will disable or enable the collection of graph data. Graphing is enabled by default. Normally this would only be disabled for diagnostic purposes or if all required graphing is handled externally.

Reset Graphing Data
Clicking this button will erase all graph database files and create new, empty files.

Click  **Update Graphs** to change the graph to the selected view.

Graph Category List

There are a several different categories of graph data that the firewall can plot. Each category is covered here, but not all categories will be visible on every firewall. Some graphs must be enabled separately or will only be present if a specific feature or piece of hardware is enabled.

System Graphs

The graphs under the *System* category show a general overview of the system utilization, including CPU usage, memory usage, and firewall states.

Mbuf Clusters

The **Mbuf Clusters** graph plots the network memory buffer cluster usage of the firewall. Firewalls with many interfaces, or many CPU cores and NICs that use one interface queue per core, can consume a large number of network memory buffers. In most cases, this usage will be fairly flat, but depending on various circumstances, such as unusually high load, the values may increase. If the usage approaches the configured maximum, increase the number of buffers.

See also:

Refer to *Hardware Tuning and Troubleshooting* for information on how to increase the amount of mbufs available to the OS.

The **Mbuf Clusters** graph contains the following data sources:

Current
The current number of consumed mbuf clusters

Cache
The number of cached mbuf clusters

Total
The total of Current and Cache

Max
The maximum allowed number of mbuf clusters

Memory Graph

The **Memory** graph shows the system RAM usage broken down into multiple areas. These areas are described in detail at *Memory Management*.

Active
Active (in use) memory pages referenced by userland (non-kernel).

Inactive
Memory pages which were in use but have not been referenced recently.

Free
Memory available for immediate use.

Cache
Memory used by the operating system for caching. On systems using ZFS, this is the ZFS ARC cache (23.05+). On UFS systems, it is the UFS directory hash.

See also:

ZFS Tuning.

Wire
Memory allocated by the kernel, including the kernel itself, which cannot be paged/swapped and cannot be freed until explicitly released.

Note: In the OS, the ZFS ARC cache and UFS buffers sizes are included in wired memory. In the graphs on pfSense Plus software version 23.05 and later, however, these values are removed from the Wired total and graphed separately. ZFS ARC usage is graphed under Cache and UFS buffers are graphed under Buffers.

UserWire
Similar to Wired, but memory wired by user processes, not the kernel.

Laundry
Memory pages which are considered “dirty” and are due to be “cleaned”.

Buffers
Memory used for UFS buffers.

Processor Graph

The processor graph shows CPU usage for the firewall using the following data sources:

User Utilization
The amount of processor time consumed by user processes.

Nice Utilization
The amount of processor time consumed by processes with a high priority.

System Utilization
The amount of processor time consumed by the operating system and kernel.

Interrupts
The amount of processor time consumed by interrupt handling, which is processing hardware input and output, including network interfaces.

Processes
The number of running processes.

States Graph

The states graph shows the number of system states but also breaks down the value in several ways.

State Changes
The number of state changes per second, or "churn". A high value from this source would indicate a rapid number of new or expiring connections.

Filter States
The total number of state entries in the states table.

NAT States
The total number of state entries involving NAT (e.g. outbound NAT, port forwards, 1:1 NAT, etc).

Source Addresses
The number of active unique source IP addresses.

Destination Addresses
The number of active unique destination IP addresses.

Traffic Graphs

Traffic graphs shows the amount of bandwidth used on each available interface in *bits per second* notation. The **Graph** list contains entries for each assigned interface, as well as IPsec and individual OpenVPN clients and servers.

The traffic graph is broken down into several data sources. Aside from the total, each has an IPv4 and IPv6 equivalent. The IPv6 data sources have `6` appended to the name.

inpass
The rate of traffic entering this interface that was *passed* into the firewall.

outpass
The rate of traffic leaving from this interface that was *passed* out of the firewall.

inblock
The rate of traffic attempting to reach this interface that was *blocked* from entering the firewall.

outblock
The rate of traffic attempting to leave this interface that was *blocked* from leaving the fiewall.

inpass total
The total rate of traffic (IPv4 and IPv6) that was passed inbound.

outpass total
The total rate of traffic (IPv4 and IPv6) that was passed outbound.

Note: The terms "inbound" and "outbound" on these graphs are from the perspective of the firewall itself. On an external interface such as a WAN, "inbound" traffic is traffic arriving at the firewall from the Internet and "outbound" traffic is traffic leaving the firewall going to a destination on the Internet. For an internal interface, such as LAN,

"inbound" traffic is traffic arriving at the firewall from a host on the LAN, likely destined for a location on the Internet and "outbound" traffic is traffic leaving the firewall going to a host on the LAN.

Packet Graphs

The packet graphs work much like the traffic graphs and have the same names for the data sources, except instead of reporting based on bandwidth used, it reports the number of *packets per second* (pps) passed. The **Graph** list contains entries for each assigned interface, as well as IPsec and individual OpenVPN clients and servers.

Packets Per Second (pps) is a better metric for judging hardware performance than Traffic throguhput as it more accurately reflects how well the hardware handles packets of any size. A circuit may be sold on a certain level of bandwidth, but hardware is more likely to be bottlenecked by an inability to handle a large volume of small packets. In situations where the hardware is the limiting factor, the **Packets** graph may show a high plateau or spikes while the traffic graph shows usage under the rated speed of the line.

Quality Graphs

The **Quality** category contains **Graph** entries that track the quality of WAN or WAN-like interfaces such as interfaces with a gateway specified or those using DHCP or PPPoE. The firewall contains one **Graph** entry per gateway, including gateways that were configured previously, but no longer exist. Graph data files for old gateways are not automatically removed so that historical data is available for future reference.

The following data sources are used to track gateway reliability:

Packet Loss
: The percentage of attempted pings to the monitor IP address that were lost. Loss on the graph indicates connectivity issues or times of excessive bandwidth use where pings were dropped.

Delay Average
: The average delay (Round-trip time, RTT) on pings sent to the monitor IP address. A high RTT means that traffic is taking a long time to make the round trip from the firewall to the monitor IP address and back. A high RTT could be from a problem on the circuit or from high utilization.

Delay Standard Deviation
: The standard deviation on the RTT values. The standard deviation gives an impression of the variability of the RTT during a given calculation period. A low standard deviation indicates that the connection is relatively stable. A high standard deviation means that the RTT is fluctuating up and down over a large range of values, which could mean that the connection is unstable or very busy.

Captive Portal

The **Captive Portal** category contains **Graph** entries for each Captive Portal zone, past and present. Graph data files for old zones are not automatically removed.

Concurrent
: The *Concurrent* graph choice shows how many users are logged in at a given point in time. As users log out or their sessions expire, this count will go down. A large number of concurrent users will not necessarily cause a strain on the portal, but it can be useful for judging overall capacity and bandwidth needs.

Logged In
: The *Logged In* graph shows the number of login events that occur during each polling interval. This is useful for judging how busy the captive portal daemon is at a given point in time. A large number

of users logging in around the same time will put more stress on the portal daemon compared to logins that are spread out over the course of a day.

NTP

The **NTP** graph displays statistics about the NTP service and clock quality. This graph is disabled by default because it is not relevant for most use cases. The graph can be enabled at **Services > NTP**. On that page, check **Enable RRD Graphs of NTP statistics**.

See also:

For more information about these values, see the NTP Configuration Manual, NTP Query Manual, and the NTPv4 Specification.

Offset
Combined clock difference between from server relative to this host.

System Jitter (sjit)
Combined system jitter, which is an estimate of the error in determining the offset.

Clock Jitter (cjit)
Jitter computed by the clock discipline module.

Clock Wander (wander)
Clock frequency stability expressed in parts per million (PPM)

Frequency Offset (freq)
Offset relative to hardware clock (In PPM)

Root Dispersion (disp)
Total difference between the local clock and the primary reference clock across the network.

Queue/Queuedrops Graphs

The queue graphs are a composite of each traffic shaper queue. Each individual queue is shown, represented by a unique color.

The **Queues** category shows individual queue usage in bytes.

The **QueueDrops** category shows a count of packet drops from each queue.

DHCP

The **DHCP** category contains a graph for each interface with a DHCP server enabled. The data sources shown for DHCP are:

Leases
The number of leases in use out of the configured DHCP range for the interface.

Static Leases
The number of static mapping leases configured for the interface.

DHCP Range
The total size of the DHCP pool available for use on the interface.

If the **Leases** count approaches the **Range** value, then a larger pool may be required for the interface. Static mappings exist outside the range, so they do not factor into the amount of leases consumed in the pool.

Cellular

On select 3G/4G devices, the firewall is able to collect signal strength data for the **Cellular** graph. The signal strength is the only value plotted on the graph.

Wireless

The **Wireless** category is present on systems containing an 802.11 wireless network device that is enabled and in-use as a client (Infrastructure, BSS mode). The following data sources are collected and displayed when acting as a wireless client:

SNR
: The signal-to-noise ratio for the AP the client is connected to.

Channel
: The wireless channel number used to reach the AP.

Rate
: The wireless data rate to the AP.

VPN Users

The **VPN Users** category shows the number of OpenVPN users logged in concurrently for each individual OpenVPN server.

28.2.2 Traffic Graphs

Real time traffic graphs drawn with JavaScript using NVD3 are available which update continually. These graphs can be viewed at **Status > Traffic Graph**, and an example of the graph can be found in Figure *Example LAN Graph*.

These traffic graphs show interface traffic as it happens, and give a clear view of what is happening "now" rather than relying on averaged data from the RRD graphs which are better for long-term views.

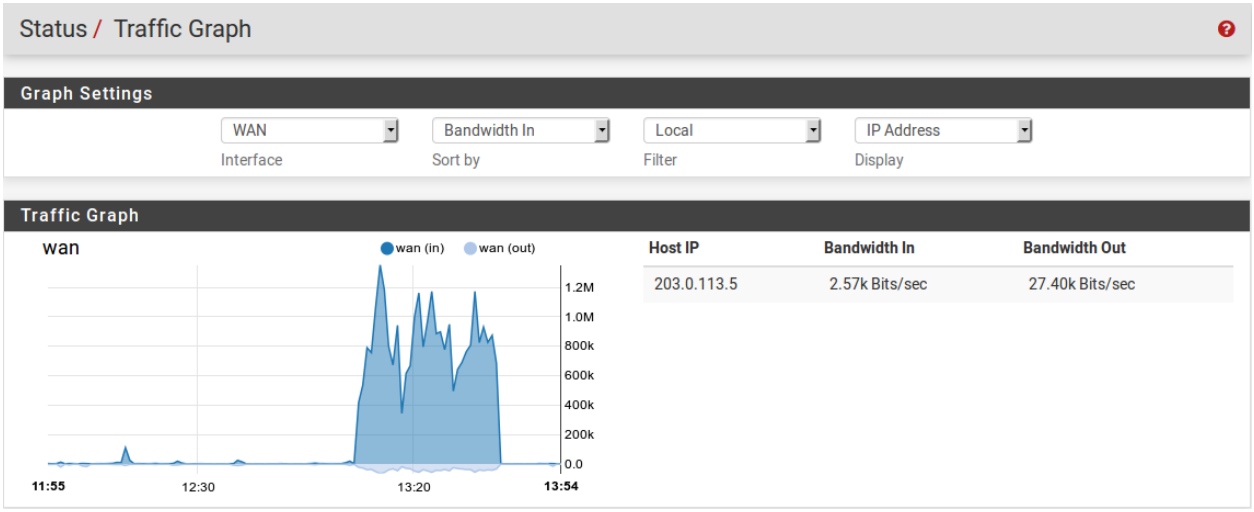


Fig. 19: Example LAN Graph

Only one interface is visible at a time, and this interface can be changed using the **Interface** drop-down list. Once an interface is chosen, the page will automatically refresh and start displaying the new graph.

Similar style traffic graphs can also be viewed on the Dashboard by adding the **Traffic Graphs** widget. Using the widget, multiple traffic graphs can be displayed simultaneously.

See also:

For more about the Dashboard, see *Dashboard*.

A table containing momentary glimpses of data being transferring from specific IP addresses is also displayed next to the traffic graph. These are limited to only displaying briefly, so ongoing transfers are more likely to show up than quick connections. Also, only connection from within that interface's primary subnet will be shown.

The display of the graph and table can be controlled using the following options:

Interface
The firewall interface to use as the traffic source for the graph and the table.

Sort By
Selects the sort order of the graph, either *Bandwidth In* or *Bandwidth Out*.

Filter
Selects which type of hosts to display in the table

Local
Shows only IP addresses within the interface network

Remote
Shows only IP addresses that are not within the interface network

All
Shows all IP addresses, inside and outside the interface network

Display
Controls the display of the **Host IP** column using one of the following choices:

IP Address
The IP address of the host.

Host Name
The short hostname that corresponds to the IP address, as listed in DHCP static mappings, DNS Resolver host overrides, or DNS Forwarder host overrides.

Description
The description that corresponds to the IP address, as listed in DHCP static mappings, DNS Resolver host overrides, or DNS Forwarder host overrides.

FQDN
The fully qualified domain name that corresponds to the IP address, as listed in DHCP static mappings, DNS Resolver host overrides, or DNS Forwarder host overrides.

28.2.3 Monitoring Bandwidth Usage

With pfSense® software, there are several methods for monitoring bandwidth usage, with different levels of granularity.

pftop

If a connection is currently active, connect to the firewall console (physical access or ssh) and watch the traffic flow with pftop (Option `9`).

The output can be changed to show several views (press `0`-`8` or `v` to cycle) and may be sorted in various ways. Press `?` for a list of available command keys while running pftop.

iftop

Run `iftop` from the shell (console or SSH) as follows:

```
iftop -nNpPi em0
```

Change `em0` to an appropriate interface to monitor.

In the above example, `-nNpP` tells iftop to not resolve hostnames (`n`) or port numbers (`N`), and to run in promiscuous mode (`p`) and also display ports in the output (`P`).

Press `t` to cycle through various views.

trafshow

Another option for viewing real time throughput is trafshow, which can be installed from the CLI with `pkg install trafshow` followed by `rehash`.

Once installed, run it at an SSH command prompt:

```
trafshow
```

Then select the interface.

Built-in Graphs

If overall per-interface usage is all that is required, there are built-in RRD graphs in pfSense software, which can be found under **Status > Monitoring**.

BandwidthD

If more detail is required, such as by client IP on the LAN interface, there is a package for bandwidthd that can be installed under **System > Packages**. Once installed, it appears under **Services > BandwidthD**.

Darkstat

Darkstat is also available in **System > Packages**. Once installed, it appears under **Services > darkstat**. It also offers bandwidth graphs for an interface, as well as traffic to/from specific IP addresses.

ntopng

If even more detail is required, the ntopng package, which can also be found under **System > Packages**, can help. It can break down detail by IP, protocol, and so on. Once installed, it appears under **Diagnostics > ntopng**. It will even track where connections were made by local PCs, and how much bandwidth was used on individual connections.

Note: Due to the resource requirements of ntopng, it is not suited for with low CPU or RAM.

Monitoring on Multiple Interfaces

The **bandwidthd** package cannot listen on multiple interfaces.

The **darkstat** and **ntopng** packages can listen on multiple interfaces.

Netflow

Netflow is another option for bandwidth usage analysis. Netflow is a standard means of traffic accounting supported by many routers and firewalls. Netflow collector running on a host inside the network is required to collect the data. pfSense software can export Netflow data to the collector using the *softflowd* package.

Traffic Totals

Traffic Totals is another bandwidth monitoring tool available to install as a package. See *Status Traffic Totals* for more information.

See also:

- *Exporting NetFlow with softflowd*

28.3 Logs

Logs in pfSense software contain recent events and messages from daemons. These messages can be stored locally on a limited basis, or forwarded to a central logging server for long-term storage, better reporting, alerting, and so on.

28.3.1 System Logs

pfSense® software logs a lot of data by default, but does so in a manner that attempts to avoid overflowing the storage on the firewall. The GUI has pages which display and manage logs under **Status > System Logs** and the log files themselves are under `/var/log/` on the file system.

Some services, such as DHCP and IPsec, generate enough logs that they have their own log files and tabs in the GUI. This reduces clutter in the main system log and makes it easier to troubleshoot these individual services. To view other logs in the GUI, click the tab for the subsystem to view. Certain areas, such as **System**, and **VPN**, have sub-tabs with additional related options.

Log Format

pfSense® Plus software version 21.02 and pfSense CE software version 2.5.0 use plain text log files. The firewall periodically rotates these log files to keep their size in check. The rotation behavior is controlled by the log settings (*Log Rotation Settings*).

For each separate log, the firewall has is one main log file plus a number of rotated log files. The firewall compresses rotated log files by default on most installations, but this compression is disabled for systems running ZFS as ZFS already compresses this data. The GUI understands each compression option and displays and searches contents of rotated log files in addition to the main log file. This adds processing time but vastly increases the amount of log data available to the GUI.

pfSense® software versions older than 21.02/2.5.0 used a binary circular log format known as `clog` to maintain a constant log size without the need for rotation. As `syslogd` wrote new entries to a `clog` file, it removed older entries automatically. As such, the older data was lost.

Though there were multiple benefits to binary circular logs, such as restricting log file sizes, the downsides were too significant on modern systems. Among other reasons, binary circular logs were not very flexible, could not be used directly by shell utilities, were susceptible to corruption, and could not reliably store larger amounts of log data. Furthermore, the original justification for size restrictions were primarily based on hardware choices from over a decade ago. Hardware, even embedded system hardware, is much more capable now.

Tip: If log retention is an issue for an organization, the logs can be copied to another server with syslog where they may be permanently retained or rotated with less frequency. See *Remote Logging with Syslog* later in this chapter for information about syslog.

On normal installations where logs are kept on disk, they are retained across reboots. When `/var` is in a RAM disk, the system attempts to backup the logs at shutdown and restore them when booting. If the system does not shut down cleanly, the logs will reset.

Viewing System Logs

The GUI interface to view system logs is located at **Status > System Logs**, on the **System** tab. This includes log entries generated by the host itself in addition to those created by services and packages which do not have their logs redirected to other tabs/log files.

As shown by the example entries in *Example System Log Entries*, there are log entries from several different areas in the main system log. Many other subsystems will log here, but most will not overload the logs at any one time. Typically services which generate a significant volume of log entries have their own tab and log file.

Filtering Log Entries

The GUI can search and filter every log to find entries matching specific patterns. This is useful for tracking down log entries from a single service or log messages containing a specific username, IP address, and so on.

To search for log entries:

- Navigate to **Status > System Logs**
- Click the tab for the log to search
- Click  in the breadcrumb bar to open the **Advanced Log Filter** panel
- Enter the search criteria, for example, enter text or a regular expression in the **Message** field

2021-12-27 01:01:17.556514-05:00	php	26665	rc.dyndns.update: phpDynDNS: Not updating clara [redacted] A record because the IP address has not changed.

Fig. 20: Example System Log Entries

- Click  **Apply Filter**

The filtering fields vary by log tab, but may include:

Message
: The body of the log message itself. A word or phrase may be entered to match exactly, or use regular expressions to match complex patterns.

Time
: The timestamp of the log message. Uses month names abbreviated to three letters.

Process
: The *name* of the process or daemon generating the log messages, such as `sshd` or `check_reload_status`.

PID
: The process ID number of a running command or daemon. In cases where there are multiple copies of a daemon running, such as `openvpn`, use this field to isolate messages from a single instance.

Quantity
: The number of matches to return in filter results. Setting this value higher than the number of log entries in the log file will have no effect, but setting it higher than the current display value will temporarily show more log messages.

The **Firewall** log tab has a different set of filtering fields:

Source IP Address
: The source IP address listed in the log entry.

Destination IP Address
: The destination IP address listed in the log entry.

Pass
: Check this option to only match log entries that passed traffic.

Block
: Check this option to only match log entries that blocked traffic.

Interface
The friendly description name of the interface to match (e.g. `WAN`, `LAN`, `OPT2`, `DMZ`.)

Source Port
The source port of the log entry to match, if the protocol uses ports.

Destination Port
The destination port of the log entry to match, if the protocol uses ports.

Protocol
The protocol to match, such as TCP, UDP, or ICMP.

Protocol Flags
For TCP, this field matches the TCP flags on the log entry, such as `SA` (SYN+ACK) or `FA` (FIN+ACK)

Tip: The filter pane is hidden by default, but the **Log Filter** setting under **System > General Setup** can alter this behavior. When set, the GUI expands the filter pane on the log pages at all times.

28.3.2 Log Settings

Log settings on pfSense® software may be adjusted in two different ways:

- Globally at **Status > System Logs** on the **Settings** tab
- On each log tab where settings can override the global defaults

To change these settings click  in the breadcrumb bar while viewing a log.

Each of these methods will be explained in detail in this section.

The global options area contains more options than the per-log settings. Only differences will be covered in detail for the per-log settings.

Global Log Settings

The global log options under **Status > System Logs** on the **Settings** tab include:

In the GUI, the **Settings** tab under **Status > System Logs** controls how the logging system behaves.

Log Message Format
The format of messages logged by the system log daemon (`syslogd`) for local and remote logs. Both formats are handled the same way locally, but remote syslog servers may prefer one format or the other. Check the documentation of the syslog server for details.

BSD (RFC 3164, default)
The default log format used by previous versions of pfSense software and natively used by FreeBSD.

syslog (RFC 5424, with RFC 3339 microsecond-precision timestamps
A modern syslog message format with more precise timestamps. Also includes the hostname.

Forward/Reverse Display
By default the logs are displayed in their natural order with the oldest entries at the top and the newest entries at the bottom. Some administrators prefer to see the newest entries at the top, which can be accomplished by checking this box to flip the order.

GUI Log Entries
The number of log entries to display in the log tabs of the GUI by default. This does not limit the number of entries in the file, only what is shown on the page at the time. The default value is `50`. The actual log files may contain much more than the number of lines to display, depending on the **Log File Size**.

Raw Logs
When checked, this setting disables log parsing, displaying the raw contents of the logs instead. The raw logs contain more detail, but they are much more difficult to read. For many logs it also stops the GUI from showing separate columns for the process and PID, leaving all of that information contained in the **Message** column.

See also:

For more information on raw firewall logs, see *Raw Filter Log Format*.

Show Rule Descriptions
Controls if, and where, the firewall log display will show descriptions for the rules that triggered entries. Displaying the rule descriptions causes extra processing overhead that can slow down the log display, especially in cases where the view is set to show a large number of entries.

Don't load descriptions
When selected this choice will not display any rule descriptions. The description may still be viewed by clicking the action column icon in the firewall log view (e.g.  or ).

Display as column
The default for new installations. Adds the rule description in a separate column. This works best if the descriptions are short, or the display is wide.

Display as second row
Adds a second row to each firewall log entry containing the rule description. This choice is better for long rule descriptions or narrow displays.

Tip: If the firewall logs display slowly with rule descriptions enabled, select *Don't load descriptions* for faster performance.

Local Logging
When checked, local logs are not retained. They are not written to disk nor are they kept in memory. While this saves on disk writes, it necessitates the use of remote logging so that information is not lost. This is not a best practice, as having local logs is vital for the vast majority of use cases.

Reset Log Files
This button clears the data from all log files and reinitialize them as new, empty logs. This can be used to clear out irrelevant/old information from logs if necessary.

> **Warning:** Resetting the log files will not save the other options on the page. If options on this page have been changed, click **Save** before attempting to reset the log files.

Logging Preferences

These options control whether or not certain items create log entries. Administrators may wish to disable some of these options to reduce logging or perform custom logging using other methods.

Default Firewall "block" Rules
: Checked by default. When enabled, the default deny rules, which block traffic not matched by other rules, will log entries to the firewall log.

  Typically these log entries are beneficial, but in certain rare use cases they may produce undesirable log entries that are made redundant by custom block rules with logging enabled.

Default Firewall "pass" Rules
: Unchecked by default. When set, the firewall will create log entries for packets matching the default outbound pass rules on interfaces.

  This option will generate a large amount of log data for connections outbound from the firewall. The best practice is to only enable this for brief periods of time while performing troubleshooting or diagnostics.

Default "Bogon Networks" Block Rules
: Checked by default. When checked, if an interface has **Block Bogon Networks** active, the firewall will log packets matching those rules. Uncheck to disable this logging.

Default "Private Networks" Block Rules
: Checked by default. When checked, if an interface has **Block Private Networks** active, the firewall will log packets matching those rules. Uncheck to disable this logging.

Default "IPv4 link-local" Block Rules
: Checked by default. When checked, the firewall will log packets blocked by the default internal rules which block IPv6 link-local packets which should never traverse a firewall or router. Uncheck to disable this logging.

  See also:

  Allow APIPA

Hosts blocked by IDS
: Checked by default. When checked, the firewall will log packets blocked by IDS software, such as Snort or Suricata.

  While these logs are a best practice for security, they can be very high volume.

Web Server
: Checked by default. When checked, the firewall will log messages from the Web GUI and Captive Portal web server processes (`nginx`).

  On occasion, especially with Captive Portal active, these messages can be frequent but irrelevant and clutter the log contents.

Configuration Changes
: Checked by default. When checked, the firewall creates a log entry any time a configuration change occurs. The log message includes the description of the configuration change when possible.

Click **Save** to store the new settings. The remaining options on this screen are discussed in *Remote Logging with Syslog*.

Log Rotation Settings

Starting with pfSense Plus software version 21.02 and pfSense CE software version 2.5.0, the system logs are kept in a plain text format and periodically rotated. The options in this section control how the firewall handles log rotation.

Note: The options in this section of the page are global only, and cannot be changed for individual logs.

Log Rotation Size (Bytes)
This field controls the size at which the firewall rotates logs. The default size is `500` KiB per log file. There are nearly 20 log files, so plan space accordingly.

This **does not** account for space used by rotated log files.

Note: Increasing this value allows every log file to grow to the specified size, so disk usage can increase significantly. The firewall checks log file sizes once per minute to determine if rotation is necessary, so a rapidly growing log file may exceed this value.

Log Compression
The type of compression the firewall uses when rotating log files. Compressing rotated log files saves disk space, and the compressed logs remain available for display and searching in the GUI. Though processing large compressed files can be time consuming, most use cases will not notice significant slowness.

The types of compression available are `bzip2` (default), `gzip`, `xz`, `zstd`, and `none` (disables compression). All of the options which use compression are reasonably fast and offer good compression rates. Some may compress better than others, others are slightly faster, but ultimately the decision is up to the environment and the administrators.

Warning: The type of compression used by all log files must be identical. When changing this value, the firewall must remove all previously rotated compressed log files.

On certain systems, disabling compression (set to `none`) is the best course of action. Examples include:

- Firewalls using large log file sizes, which may take too long to compress
- Slower firewalls which may take too long to compress or search the log files even at default sizes
- Firewalls using ZFS which by default will already compress disk contents

Log Retention Count
The number of rotated log files to keep before the oldest copy is removed. Keeping more log files will consume more disk space, but compressed logs files do not consume nearly as much space as decompressed logs.

Per-Log Settings

To change per-log settings, visit the log tab to change and then click  in the breadcrumb bar to expand the settings panel.

On this panel, several options are displayed. Most of the options will show the global default value or have a **General Logging Options Settings** choice which will use the global value and not the per-log value.

The per-log settings panel for each tab only displays options relevant to that log. For example, the options to log default block or pass rules are displayed only when viewing the **Firewall** log tab.

Each per-log settings panel has at least the following options: **Forward/Reverse Display**, **GUI Log Entries**, and **Formatted/Raw Display**. For each of these, a value which will only apply to this log may be set.

See also:

For more information on how these options work, see *Global Log Settings* above.

Click **Save** to store the new log settings.

See also:

- *Remote Logging with Syslog*
- *Accessing Firewall Services over IPsec*
- *Working with Log Files*
- *Adjusting the Size of Log Files*

28.3.3 Remote Logging with Syslog

The **Remote Logging** options under **Status > System Logs** on the **Settings** tab enable `syslog` to copy log entries to a remote server.

The logs kept by pfSense® software on the firewall itself are of a finite size. Copying these entries to a syslog server can aid troubleshooting and allow for long-term monitoring. Having a remote copy can also help diagnose events that occur before a firewall restarts or after they would have otherwise been lost due to clearing of the logs or when older entries are cycled out of the log, and in cases when local storage has failed but the network remains active.

Warning: Corporate or local legislative policies may dictate the length of time an organization must retain log data from firewalls and similar devices. If an organization requires long-term log retention for their own or government purposes, a remote syslog server is required to receive and retain these logs.

Warning: Logs sent using this method are delivered in the clear (not encrypted) unless the logs are sent through a VPN or using a mechanism such as *Stunnel package*. As an alternative, consider using the **syslog-ng** package which supports encrypted syslog.

The following options are available for remote logging:

Source Address
: Controls where the `syslog` daemon binds for sending out messages. In most cases, the default (*Any*) is the best option, so the firewall will use the address nearest the target. If the destination server is across a tunnel mode IPsec VPN, however, choosing an interface or Virtual IP address inside the local Phase 2 network will allow the log messages to flow properly over a tunnel.

IP Protocol
When choosing an interface for the **Source Address**, this option gives the `syslog` daemon a preference for either using IPv4 or IPv6, depending on which is available. If there is no matching address for the selected type, the other type is used instead.

Remote Log Servers
Enter up to three remote servers using the boxes contained in this section. Each remote server can use either an IP address or hostname, and an optional UDP port number. If the port is not specified, the default *syslogd* port, `514`, is assumed.

A syslog server is typically a server that is directly reachable from the firewall on a local interface. Logging can also be sent to a server across a VPN.

> **Warning:** Do not send log data directly across any WAN connection or unencrypted site-to-site link, as it is plain text and could contain sensitive information.

Note: The syslog daemon only supports sending messages over UDP. To send syslog messages over TCP, consider using the **syslog-ng** package.

Remote Syslog Contents
The options in this section control which log messages will be sent to the remote log server.

Everything
When set, all log messages from all areas are sent to the server.

System Events
Main system log messages that do not fall into other categories.

Firewall Events
Firewall log messages in raw format. The format of the raw log is covered in *Raw Filter Log Format*.

DNS Events
Messages from the DNS Resolver (`unbound`), DNS Forwarder (`dnsmasq`), and from the `filterdns` daemon which periodically resolves hostnames in aliases.

DHCP Events
Messages from the IPv4 and IPv6 DHCP daemons, relay agents, and clients.

PPP Events
Messages from PPP WAN clients (PPPoE, L2TP, PPTP)

General Authentication Events
Log messages about authentication events, such as for the GUI or certain types of VPNs.

Captive Portal Events
Messages from the Captive Portal system, typically authentication messages and errors.

VPN Events
Messages from VPN daemons such as IPsec and OpenVPN, as well as the L2TP server and PPPoE server.

Gateway Monitor Events
Messages from the gateway monitoring daemon, `dpinger`

Routing Daemon Events
Routing-related messages such as UPnP IGD & PCP, IPv6 routing advertisements, and routing daemons from packages like OSPF, BGP, and RIP.

Network Time Protocol Events
Messages from the NTP daemon and client.

Wireless Events
Messages from the Wireless AP daemon, `hostapd`.

To start logging remotely:

- Navigate to **Status > System Logs** on the **Settings** tab
- Check **Send log messages to remote syslog server**
- Configure the options as described above
- Click Save to store the changes.

If a syslog server is not already available, it is fairly easy to set one up. Almost any UNIX or UNIX-like system can be used as a syslog server. FreeBSD is described in the following section, but others may be similar.

Setup Syslog on the Logging Host

FreeBSD

First, configure the syslog server to accept remote connections which means running it with the `-a <subnet>` or similar flag.

On FreeBSD, edit `/etc/rc.conf` and add this line:

```
syslogd_flags=" -a 192.168.1.1 "
```

Where `192.168.1.1` is the IP address of the pfSense firewall.

More complex allow rules for syslog are also possible, like so:

```
syslogd_flags=" -a 10.0.10.0/24:*"
```

Using that parameter, syslog will accept from any IP address in the 10.0.10.0 subnet (mask 255.255.255.0) and the messages may come from any UDP port.

Now, edit `/etc/syslog.conf` and add a block at the bottom:

```
!*
+*

+pfsense
*.*                /var/log/pfsense.log
```

Where `pfSense` is the hostname of the pfSense firewall. An entry may also need to be added in **/etc/hosts** for that system, depending on the DNS setup. Logs may be split separate files. Use the **/etc/syslog.conf** file on the pfSense firewall for more details on which logging facilities are used for specific items.

```
192.168.1.1            pfsense     pfsense.example.com
```

The log file may also need to be created manually with proper permissions:

```
touch /var/log/pfsense.log
chmod 640 /var/log/pfsense.log
```

Now restart syslog:

```
/etc/rc.d/syslogd restart
```

Windows

Setting this up on Windows entirely depends on which syslog server is being used. Consult the documentation for more information on configuration.

There is a free multi-purpose utility that can act as a syslog server, which can be found here: http://tftpd32.jounin.net/

Kiwi Syslog Server is free for up to 5 devices. https://www.solarwinds.com/free-tools/kiwi-free-syslog-server

Linux

Configuration of the system logger on Linux depends on the distribution. Consult the distribution's documentation on how to change the behavior of **syslogd**. It should be similar in many cases to the alterations in the FreeBSD section.

OpenBSD

The configuration for OpenBSD is similar to FreeBSD, with the following notes:

1. The option to accept remote syslog events is `-u`.
2. This option may be enabled using *rcctl(8)*:

```
rcctl set syslogd flags -u
```

1. To restart the syslogd service:

```
rcctl restart syslogd
```

Other Logging Servers

Other log systems or styles such as Splunk, ELSA (Enterprise Log Search and Archive), Graylog, ELK (Elasticsearch, Logstash, and Kibana), or OpenSearch (open source fork of ELK components) may also be used but the methods for implementing them are beyond the scope of this document. If such a system is syslog-compatible, then the pfSense software side should be fairly simple to setup as it would be for any other syslog system.

28.3.4 Adjusting the Size of Log Files

pfSense® software manages log files automatically and attempts to limit their size. The default size is 500 KiB per log file, and there are around 20 log files.

When increasing log sizes, keep disk space in mind. There is a disk space indicator for the filesystem containing the logs under the **Log Rotation Size (Bytes)** text description on *Log Settings*.

Tip: These log files are held in `/var/log` which may optionally be a RAM disk.

Recent versions of pfSense software (pfSense Plus software version 21.02, pfSense CE software version 2.5.0) and later use plain text log files and log rotation keeps the size in check. Space for rotated log files is **in addition to** the default log size limit.

For example, the firewall will keep multiple rotated copies of the log by default, but rotation is triggered by the size of the main log file. If the firewall keeps 7 rotated log files in addition to the main log, and has disabled compression for rotated log files, then the actual consumed space for logs could be up to 8 times the rotation size. The GUI displays a "worst case" disk usage amount under the **Log Rotation Size (Bytes)** text description on *Log Settings*.

See also:

Log rotation settings are covered in *Log Rotation Settings*.

The GUI only shows 50 lines per log by default but the files contain many more entries. See *Log Settings* for more information on that setting.

Short Version

To change the log file sizes:

- Navigate to **Status > System Logs**, **Settings** tab
- Enter a new value in **Log Rotation Size (Bytes)**, being careful not to overfill the disk containing the logs.
- Click **Save**

Details

The rotation settings in *Log Rotation Settings* cover this topic thoroughly.

The default size for a log file is `512000` (500KiB) which can generally hold between 2000-3000 log entries but varies by entry size. The time span covered by logs depends entirely on how much data is logged. A quiet log file could contain months or even years of information, a busy log file may only contain minutes.

Underneath the text for **Log Rotation Size (Bytes)** the current and available disk space is displayed based on the current log file sizes and their location. For example:

```
Disk space currently used by log files: 4.3M
Worst case disk usage for base system logs based on current global settings: 58.11 MiB
Remaining disk space for log files: 9.3G
```

There are approximately 20 log files affected by the size control. The value entered in **Log Rotation Size (Bytes)** is for a single log file, so the actual usage will be approximately **20 times** that value, not including rotated log files. Increasing this value allows every log file to grow to the specified size, so disk usage can increase significantly. The firewall checks log file sizes once per minute to determine if rotation is necessary, so a rapidly growing log file may exceed this value.

As shown above, with the default value of `512000`, the firewall could consume up to around 10MB of total log space for the main log files, plus extra for the rotated copies. If the size of the logs is increased to `1024000` (1MB), then nearly 20MB could be used for logs. Be certain before changing the **Log Rotation Size (Bytes)** value that the disk has enough space to hold all of the log files.

Warning: Do not increase the log file size to huge values in an attempt to retain log data on the firewall long term. Not only does that consume large amounts of disk space and make it more difficult for the firewall to display and manage logs, but it is unreliable compared to properly storing log files on a remote syslog server dedicated to that purpose.

28.3.5 Working with Log Files

The format of log files is described in *Log Format*, read that section before proceeding.

pfSense® Plus software version 21.02, pfSense CE software version 2.5.0, and later versions utilize plain text log files which can be used by a variety of traditional shell utilities. There are also utilities compatible with the various types of compressed rotated log files.

pfSense® software versions older than 21.02/2.5.0 use a binary circular log format known as `clog` to maintain a constant log size without the need for rotation. As `syslogd` writes new entries to a `clog` file, it removes older entries automatically. As such, the older data is lost. These binary log files cannot be processed directly by shell utilities and must first be unwrapped with the `clog` utility.

Viewing Log Contents (21.02/2.5.0 and later)

To view the contents of a log, use common shell utilities, such as `cat`, `grep`, and so on:

```
cat /var/log/filter.log
grep -i "error" /var/log/system.log
```

To follow the contents of a log file in real time, use `tail -f` or `tail -F`. The latter form follows the log to a new file after rotation.

```
tail -F /var/log/filter.log
```

In addition to the main log file, the rotated log files can be viewed and searched by passing them through utilities specific to the format with which they are compressed. For example, the default compression type is `bzip2`, so use `bzcat`, or `bzgrep`:

```
bzcat /var/log/filter.log.0.bz2
bzgrep -i "error" /var/log/system.log.0.bz2
```

Additional utilities can be utilized by piping the output.

The following list contains the different compression options and a sample of utilities which can parse their contents:

bzip2 (`*.log.<number>.bz2`)
: `bzcat`, `bzgrep`, `bzless`.

gzip (`*.log.<number>.gz`)
: `zcat`, `zgrep`, `zless`.

xz (`*.log.<number>.xz`)
: `xzcat`, `xzgrep`, `xzless`.

zstd (`*.log.<number>.zst`)
: `zstdcat`, `zstdgrep`, `zstdless`.

none (`*.log.<number>`)
: `cat`, `grep`, `less`, plus anything else capable of parsing text files.

Viewing Log Contents (< 21.02/2.5.0, clog)

On versions of pfSense software before 21.02/2.5.0, the contents of binary circular log files can only be read using the `clog` command:

```
clog /var/log/filter.log
```

The output of that command may then be piped to tools like `grep`:

```
clog /var/log/system.log | grep -i "error"
```

To follow the log files in a manner like `tail -f`, use `clog -f`:

```
clog -f /var/log/filter.log
```

The command prints the entire contents of the log file to the console, and then prints new entries as they are written.

28.3.6 Viewing the Firewall Log

The firewall creates log entries for each rule configured to log and for various other internal rules such as default deny rules. There are several ways to view these log entries, each with varying levels of detail. There is no particular best method as it depends on preferences and skill level of the firewall administrators, though using the GUI is the easiest method.

Tip: The logging behavior of the default deny rules and other internal rules can be controlled using the **Settings** tab under **Status > System Logs**. See *Logging Preferences* for details.

Like other logs, the firewall log only retains a certain number of entries. If the needs of an organization require a permanent record of firewall logs for a longer period of time, see *Remote Logging with Syslog* for information on copying these log entries to a syslog server as they happen.

See also:

- *Troubleshooting Blocked Log Entries for Legitimate Connection Packets*
- *Working with Log Files*
- *Log Settings*
- *Logging Preferences*
- *Filtering Log Entries*

Viewing in the GUI

To view firewall logs in the GUI, navigate to **Status > System Logs**, **Firewall** tab.

By default, this page parses and renders firewall log entries in an easy-to-read format.

See also:

Several aspects of firewall log display behavior are controlled by options on the **Settings** tab. See *Log Settings* for information on how to view and change these log settings.

The parsed GUI logs, shown in Figure *Example Log Entries Viewed From The GUI*, are in multiple columns:

Action	Time	Interface	Rule	Source	Destination	Protocol
✕	Dec 15 05:02:22	WAN2	Default deny rule IPv4 (1000000103)	203.0.113.1:30069	203.0.113.129:68	UDP
✕	Dec 15 06:02:21	WAN2	Default deny rule IPv4 (1000000103)	203.0.113.1:30069	203.0.113.129:68	UDP
✕	Dec 15 07:02:22	WAN2	Default deny rule IPv4 (1000000103)	203.0.113.1:30069	203.0.113.129:68	UDP
✕	Dec 15 08:02:23	WAN2	Default deny rule IPv4 (1000000103)	203.0.113.1:30069	203.0.113.129:68	UDP
✕	Dec 15 09:02:23	WAN2	Default deny rule IPv4 (1000000103)	203.0.113.1:30069	203.0.113.129:68	UDP
✕	Dec 15 10:02:23	WAN2	Default deny rule IPv4 (1000000103)	203.0.113.1:30069	203.0.113.129:68	UDP

Fig. 21: Example Log Entries Viewed From The GUI

Action
Icon representing the firewall rule action which resulted in the log entry (e.g. pass or block).

Hovering the mouse over the action icon displays several details about the log entry in a popup, including which rule triggered the log entry. These details can be useful when troubleshooting rule issues.

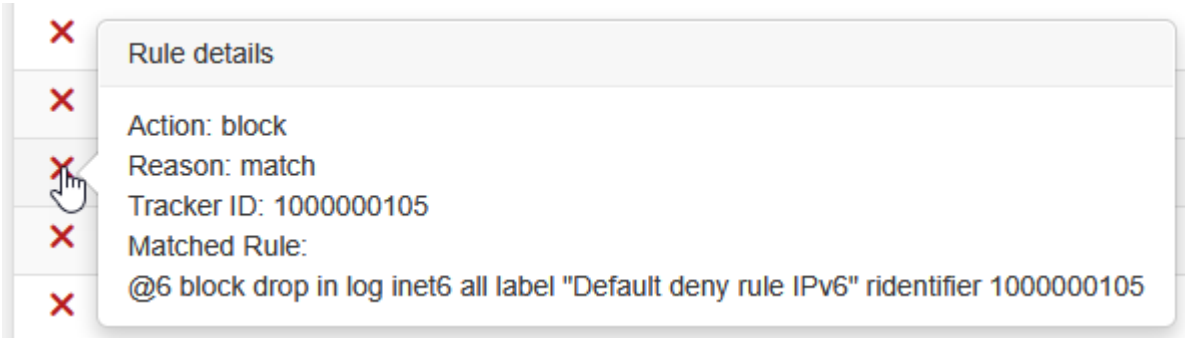

Fig. 22: Firewall Log Entry Detail

The details displayed by this view include:

Action
Full text of the firewall rule action which triggered this log entry (e.g. Pass, Block, etc.)

Reason
The reason the log entry was generated, e.g. `match`. There are several possible reason strings which are typically self-explanatory based on the text, such as `match` being from a packet matching a rule. Reasons can also include things like state mismatches, checksum mismatches, time mismatches, hitting state limitations, or even the presence of IP options.

Tracker ID
The firewall *Rule Tracking ID* which uniquely identifies this rule.

Matched Rule
The rule which matched this packet, if the firewall was able to locate the rule.

Associated Rules
A list of rules with the same tracking ID as the rule which generated the log entry. This can help narrow down which rule may have triggered a log entry when the firewall could not locate an exact match.

Time
The time that the packet arrived.

Interface
Where the packet entered the firewall.

The GUI prints a ▶ character next to the interface if a rule matched a packet in the *outbound* direction. The vast majority of rules match in the inbound direction, so the direction is omitted in that case.

Rule
The firewall rule description and *rule tracking ID* which generated the log entry, if available. This column only appears when rule descriptions are configured to appear in a separate column. They may also be shown in a separate row, or disabled entirely.

See also:

- *Log Settings*
- *Rule Tracking ID*

Source
The source IP address and port.

Clicking the  icon next to the source and destination IP addresses makes the firewall perform a DNS lookup on the IP address. If the address has a valid hostname, the page will display it underneath the IP address in all instances of that address on the page.

Clicking the  icon next to the source IP address or the  icon next to the destination IP address will add firewall rules based on those addresses using EasyRule.

See also:

Using EasyRule to Manage Firewall Rules

Destination
The destination IP address and port.

Protocol
The protocol of the packet, e.g. ICMP, TCP, UDP, etc.

Log entries for TCP packets have extra information appended to the protocol field displaying TCP flags present in the packet. These flags indicate various connection states or packet attributes.

See also:

TCP Flags

The GUI can also filter log output to find specific entries, so long as they exist in log files on the device. Click  to display the filtering options. See *Filtering Log Entries* for more information.

Viewing from the Console Menu

Option `10` from the console menu views and follows the `filter.log` in real time. An easy example is a log entry like that seen above in Figure *Example Log Entries Viewed From The GUI*:

```
Aug  3 08:59:02 master filterlog: 5,16777216,,1000000103,igb1,match,block,in,4,0x10,,128,
↪0,0,
none,17,udp,328,198.51.100.1,198.51.100.2,67,68,308
```

This single line shows that the log entry was triggered by rule id `1000000103`, which resulted in a block action on the `igb1` interface. The source and destination IP addresses are shown near the end of the log entry, followed by the source and destination port. Packets from other protocols may show significantly more data.

See also:

See *Raw Filter Log Format* for details on the format of the filter log file.

Viewing from the Shell

When using the shell, either from SSH or from the console, there are numerous options available to view the filter logs.

When directly viewing the contents of the log file, the log entries can be quite complex and verbose.

For information on viewing logs from the shell, see *Working with Log Files*.

Viewing parsed log output in the shell

There is a simple log parser written in PHP which can be used from the shell to produce reduced output instead of the full raw log. To view the parsed contents of the current log, run:

```
# cat /var/log/filter.log | filterparser.php
```

The script prints the log entries one per line, with simplified output:

```
Aug  3 08:59:02 block igb1 UDP 198.51.100.1:67 198.51.100.2:68
```

Finding the rule which caused a log entry

When viewing one of the raw log formats, the log includes the *Rule Tracking ID* for an entry. This tracking ID can be used to find the rule which caused the match.

The following example locates the rule with a tracking ID of `1000000103`:

```
# pfctl -vvsr | grep 1000000103
@4 block drop in log inet all label "Default deny rule IPv4" ridentifier 1000000103
```

As shown in the above output, this was the default deny rule for IPv4.

28.3.7 Raw Filter Log Format

The raw filter log output format generated by pfSense software for its internal filter log, and the log output transmitted over syslog to remote hosts, is a single line containing comma-separated values.

Plain text layout

This section describes the content of the raw log in general terms.

See also:

For a more technical representation with greater detail, see *BNF / Grammar*.

Note: The hostname is not included in log messages the firewall forwards to remote log hosts with the default **BSD** log message format, but it is included in the optional **syslog** (RFC5424) format. See *Log Settings* for details.

```
<Timestamp> <Hostname> filterlog: <CSV data>
```

CSV Data has many common fields and some that vary by protocol:

Common fields:

- Rule Number
- Sub rule number
- Anchor
- Tracker - unique *Rule Tracking ID* per rule, stored with the rule in `config.xml` for user added rules, or check `/tmp/rules.debug`
- Real interface (e.g. `em0`)
- Reason for the log entry (e.g. `match`)
- Action taken that resulted in the log entry (e.g. `block`, `pass`)
- Direction of the traffic (`in`/`out`)
- IP version (`4` for IPv4, `6` for IPv6)

IPv4:

- TOS
- ECN
- TTL
- ID
- Offset
- Flags
- Protocol ID
- Protocol text (tcp, udp, etc)

IPv6:

- Class
- Flow Label
- Hop Limit
- Protocol
- Protocol ID

IPv4 or IPv6:

- Length
- Source IP
- Destination IP

For TCP and UDP (Proto ID 6 or 17) on IPv4 or IPv6

- Source Port
- Destination Port
- Data Length

TCP Only:

- TCP Flags
- Sequence Number
- ACK
- Window
- URG
- Options

ICMP:

- ICMP Type, used to choose between the following possibilities

ICMP Echo Request/Reply

- ICMP ID
- ICMP Sequence

ICMP Protocol Unreachable

- ICMP Destination IP
- ICMP Protocol ID

ICMP Port Unreachable

- ICMP Destination IP
- ICMP Protocol ID
- ICMP Port Number

ICMP unreachable (other), time exceeded, parameter problem, redirect, mask reply:

- ICMP Description

ICMP Need Frag

- ICMP Destination IP
- ICMP MTU

ICMP tstamp

- ICMP ID
- ICMP Sequence

ICMP tstamp reply

- ICMP ID

- ICMP Sequence
- ICMP otime
- ICMP rtime
- ICMP ttime

ICMP default:

- ICMP Description

CARP (Protocol ID 112):

- Type
- TTL
- VHID
- Version
- Advskew
- Advbase

BNF / Grammar

For more technical purposes, this is a BNF format representation of the log output. It is not a 100% complete BNF as the exact contents of many of the fields are beyond the scope of this document as they aren't generally relevant to typical logging, but they are included in the log entries for completeness. Consult a reference on IP packet headers for more information.

```
<log-entry> ::= <time-stamp> <host-name> "filterlog:" <log-data>

<log-data> ::= <rule-number>,<sub-rule-number>,<anchor>,<tracker>,<real-interface>,
↪<reason>,<action>,<direction>,<ip-version>[,<ip-specific-data>]

<rule-number> ::= <integer> -- Rule number in the pf Ruleset
<sub-rule-number> ::= <integer> -- Sub rule number in the pf Ruleset (not typically␣
↪significant for general use)
<anchor> ::= <text> -- Anchor name in which the rule exists
<tracker> ::= <integer> -- Unique rule tracking ID per rule, stored with the rule in␣
↪config.xml for user added rules, or check /tmp/rules.debug
<real-interface> ::= <text> -- Real interface for the log entry (e.g. em0)
<reason> ::= <text> | "unkn(%u)" -- Reason for the log entry (typically "match")
<action> ::= "pass" | "block" | "unkn(%u)" -- Action taken that resulted in the log entry
<direction> ::= "in" | "out" | "unkn(%u)" -- Direction of the logged traffic
<ip-version> ::= "4" | "6" -- IPv4 or IPv6
<ip-specific-data> ::= (<ipv4-specific-data>|<ipv6-specific-data>),<ip-data>[,<protocol-
↪specific-data>]

<ipv4-specific-data> ::= <tos>,<ecn>,<ttl>,<id>,<offset>,<flags>,<protocol-id>,<protocol-
↪text>

<tos> ::= <empty> | <hex> -- Type of Service identification
<ecn> ::= <empty> | -- Explicit Congestion Notification
<ttl> ::= <integer> -- Time To Live (TTL) of the packet
<id> ::= <integer> -- ID of the packet
```

(continues on next page)

(continued from previous page)

```
<offset> ::= <integer> -- Fragment offset
<flags> ::= "none" | <text> -- IP Flags (NOT TCP flags -- those are later)
<protocol-id> ::= <integer> -- IP protocol ID (e.g. 6 for TCP, 17 for UDP)
<protocol-text> ::= "tcp" | "udp" | "icmp" | <text> -- IP protocol text (examples given)
<ipv6-specific-data> ::= <class>,<flow-label>,<hop-limit>,<protocol-text>,<protocol-id>

<class> ::= <hex> -- ToS traffic class
<flow-label> ::= <data> -- Flow label
<hop-limit> ::= <integer> -- Hop Limit (similar to IPv4 TTL)
<protocol-text> ::= "tcp" | "udp" | "icmp" | <text> -- IP protocol text (examples given)
<protocol-id> ::= <integer> -- IP protocol ID (e.g. 6 for TCP, 17 for UDP)
<ip-data> ::= <length>,<source-address>,<destination-address>

<length> ::= <integer> -- Length of the packet in bytes
<source-address> ::= <ip-address> -- The source IP address of the logged traffic
<destination-address> ::= <ip-address> -- The destination IP address of the logged␣
↪traffic
<protocol-specific-data> ::= <tcp-data> | <udp-data> | <icmp-data> | <carp-data>

<tcp-data> ::= <source-port>,<destination-port>,<data-length>,<tcp-flags>,<sequence-
↪number>,<ack-number>,<tcp-window>,<urg>,<tcp-options>

<source-port> ::= <integer> -- Source port number
<destination-port> ::= <integer> -- Destination port number
<data-length> ::= <integer> -- Data/payload length
<tcp-flags> ::= [S][A][.][F][R][P][U][E][W] -- TCP Flags
<sequence-number> ::= <integer> -- TCP Sequence ID
<ack-number> ::= <integer> -- ACK number
<tcp-window> ::= <integer> -- Windows size
<urg> ::= <data> -- Urgent pointer data
<tcp-options> ::= <data> -- TCP Options
<udp-data> ::= <source-port>,<destination-port>,<data-length>

<icmp-data> ::= <icmp-type>,(<echo-data> | <unreachproto-data> | <unreachport-data> |
↪<other-unreachable-data> | <needfrag-data> | <tstamp-data> | <tstampreply-data> |
↪<icmp-default-data>)

<advbase> ::= <integer> -- Advertisement base timer interval (seconds)
<advskew> ::= <integer> -- Advertisement skew (1/256 of a second)
```

28.3.8 Gateway Logs

The gateway logs can be found through the pfSense® software GUI under **Status > System Logs** on the **System/Gateways** sub-tab.

This log contains entries from the gateway monitoring daemon, *dpinger*, which can generate a significant amount of logging with many gateways to monitor.

The entries found here will record events such as when a gateway is down, or in an alarm state, or has returned to an online state.

Interpreting Gateway Logs

The gateway logs contain several types of messages that some users may find initially confusing. The most common log messages are:

Monitoring startup
: These messages are logged when gateway monitoring starts or restarts, one line per gateway.

Note: These logs are normal and **do not** indicate a problem.

```
dpinger[34996]: send_interval 500ms  loss_interval 2000ms  time_period 60000ms
  report_interval 0ms  data_len 1  alert_interval 1 000ms  latency_alarm 500ms
  loss_alarm 20%  dest_addr 198.51.100.1 bind_addr 198.51.100.10 identifier "WAN_GW"
```

Gateway Alarm
This type of message indicates that a gateway entered an "Alarm" state. For example, due to connectivity loss between the firewall and the monitor address.

```
dpinger[11000]: WAN_GW 198.51.100.1: Alarm latency 4807us stddev 1790us loss 21%
```

Gateway Recovery
This type of log message indicates a gateway is recovering from an Alarm state and is now available for use.

```
dpinger[11000]: WAN_GW 198.51.100.1: Clear latency 4464us stddev 1028us loss 5%
```

28.3.9 NTP Logs

The NTP daemon Log contains logs generated by the *Network Time Protocol daemon* and other time-related actions.

28.3.10 Package Logs

This tab contains messages from packages which support logging to this central location.

Tip: If logs from a specific package are not present, contact the package maintainer to see if the package can be updated to support this mechanism.

Some packages will log to the main system log or a related tab inside the system logs (**Status > System Logs**). Others may keep their own logs in a separate location. Some packages, such as Snort, offer configuration options to control where and how logs are made. Some logs may need to be viewed outside the GUI or via **Diagnostics > Command**.

28.3.11 PPP Logs

The **PPP** logs tab displays any events from the PPP system for WAN type connections, not locally-hosted servers. This would be for WANs that connect using PPPoE, L2TP, Cellular networks, and so on.

28.3.12 Resolver Logs

The Resolver logs are located at **Status > System Logs** on the **System/DNS Resolver** tab.

This log contains entries from DNS-related processes. These include the DNS Resolver (Unbound), DNS Forwarder (`dnsmasq`) , the `filterdns` process that monitors for updates in hostnames for Aliases/IPsec/etc., and the BIND package.

28.3.13 Routing Logs

The Routing logs are located at **Status > System Logs** on the **System/Routing** tab.

This log contains entries from routing-related processes for both IPv4 and IPv6, including:

- `radvd` (IPv6 Router Advertisements)
- `zebra` (FRR)
- `ospfd` (FRR)
- `bgpd` (FRR)

- `bfdd` (FRR)
- `pimd` (PIMD)
- `igmpproxy` (IGMP Proxy)
- `miniupnpd` (UPnP IGD & PCP)

28.3.14 IPsec Logs

The IPsec log shows output from strongSwan components such as the IPsec daemon `charon`. This log contains output for successful connections, normal ongoing activity such as DPD checks, and errors.

Troubleshooting IPsec VPNs contains example entries and guidance for interpreting the meaning of log messages.

28.3.15 OpenVPN Logs

Logs for OpenVPN are located in the GUI under **Status > System Logs** on the **OpenVPN** tab.

These logs include output from the OpenVPN daemon(s) in use, both clients and servers. Log messages include entries for successful connections as well as failures and errors.

If there are no log entries for a server after the process starts, traffic likely is not reaching the OpenVPN daemon. Check the WAN-side firewall rules and the address/port used by the client.

See also:

Troubleshooting OpenVPN.

28.3.16 Captive Portal Authentication Logs

The Captive Portal Authentication Logs are available through the GUI at **Status > System Logs**, on the **Portal Auth** tab. The logs list login information from the **Captive Portal** system.

28.3.17 Wireless Logs

The Wireless logs can be found in the GUI under **Status > System Logs** on the **System/Wireless** tab.

These logs contain entries from the `hostapd` daemon which handles wireless access point connections. This process can be overly verbose when handling client traffic, logging rekeys and other information that can otherwise clutter the main system log.

28.3.18 L2TP Logs

A record of login and logout events is kept on **Status > System Logs**, on the **VPN** tab, under **L2TP Logins**.

Each login and logout is recorded with a timestamp and username, and each login will also show the IP address assigned to the L2TP client. The full log can be found on the **L2TP Raw** tab.

28.3.19 DHCP Logs

The DHCP log view at **Status > System Logs** on the **DHCP** Tab, displays messages and events from the DHCP Daemon and the DHCP client for WANs.

Each DHCP request and reply from DHCP clients is shown here, along with events and errors. IP addresses, MAC addresses, and client-supplied hostnames are all visible in the logs.

TWENTYNINE

DIAGNOSTICS

These documents cover functions found under the **Diagnostics** menu in pfSense® software.

29.1 DNS Lookup

Diagnostics > DNS Lookup performs simple forward and reverse DNS queries. These queries obtain information about an IP address or hostname and also test the DNS servers configured on the firewall (*DNS Server Settings*).

To perform a DNS Lookup:

- Navigate to **Diagnostics > DNS Lookup**
- Enter a **Hostname** or IP address to query
- Click  **Lookup**

The page displays the results of the DNS query along with supporting information and options.

29.1.1 DNS servers included in testing

The page will query a specific set of DNS servers. This set depends upon the *DNS Server Settings* under **System > General**.

The page will test against `127.0.0.1` if the DNS Resolver or DNS Forwarder are active and the *DNS Resolution Behavior* setting is not set to ignore local DNS.

The page will test each of the *DNS Servers* from the list at **System > General**.

The page will also test DNS servers from dynamic WANs if **DNS Server Override** is set and the firewall has obtained servers from dynamic sources.

Note: The *DNS Resolver mode* does not impact the behavior of this test. Even in resolver mode the individual DNS servers are tested as described above.

29.1.2 Results

The **Results** panel contains addresses returned by the DNS query along with the record type.

Underneath the results is a table containing the resolution **Timings** per server. This shows how fast each of the configured DNS servers responded to the specified query, or if they never responded.

The **More Information** panel contains links to ping and traceroute functions on the firewall for this host.

29.1.3 Aliases

The GUI can also create a *firewall alias* from the results of the DNS Lookup query.

Click  **Add alias** to create an alias containing the results of the query.

The name of the alias is the text entered for the DNS query but with `.` characters replaced by `_`. For example, a DNS lookup for `example.com` results in an alias named `example_com`.

If an alias already exists with that name, the button is labeled **Update Alias** instead. That version of the button will replace the contents of the existing alias with the current results of the DNS lookup.

29.2 Editing Files on the Firewall

Diagnostics > Edit File contains a file editor that allows editing and creating files on the filesystem of a device running pfSense® software.

> **Warning:** Be careful when choosing a file to edit! It is very easy to render the firewall unusable by editing the wrong file or introducing errors into the source code.
>
> Do not use this except under guidance of support or when there is sufficient knowledge to use it without causing unintended side effects.

29.2.1 Edit an Existing file

- Enter the full path of the filename to edit in **Save / Load from path** or click **Browse** and locate the file
- Click **Load**
- Edit the text
- Click **Save** to store the new content in the file

29.2.2 Create a new File

- Enter the new path and filename in **Save / Load from path**
- Enter the new contents of the file
- Click **Save** to create the new file with the given content

29.3 Command Prompt

The command prompt, available at **Diagnostics > Command Prompt**, executes shell commands, PHP code, and can download or upload whole files.

> **Warning:** Exercise caution using any of these utilities. Executing commands and PHP code improperly can render the firewall unusable. Use of this tool is not recommended except under the guidance of a support representative or if there is sufficient knowledge on the part of the user.

29.3.1 Execute Shell Commands

To execute a shell command:

- Navigate to **Diagnostics > Command Prompt**
- Enter the command into the **Command** box under **Execute Shell command**
- Click **Execute**

Commands are executed as if they were run from a console command line, and the page prints the results when the command terminates.

> **Warning: Commands must run and then stop or return**.
>
> Commands that run indefinitely, such as `ping` without a count or `tcpdump` without a limit set will never stop or return output, and will be left running indefinitely in the background until they are manually killed.
>
> Interactive commands, such as `vi` will fail similarly, or may exit due to other issues with the terminal being non-interactive.

Previously used commands from this session can be recalled with the  and  buttons. The browser will forget the previous command list once it leaves the page.

29.3.2 Download

To download a file from the firewall filesystem:

- Navigate to **Diagnostics > Command Prompt**
- Enter the full path name in **File to download**
- Click  **Download**

29.3.3 Upload

To upload a file:

- Navigate to **Diagnostics > Command Prompt**
- Click **Browse**
- Locate and select the file on the local client computer
- Click  **Upload**

Note: Uploaded files are placed in `/tmp/` and can then be moved to alternate locations by other functions (such as the **Execute Shell Command** feature).

29.3.4 PHP Execute

This page can also execute PHP code.

- Navigate to **Diagnostics > Command Prompt**
- Type or paste PHP code into the **Execute PHP Commands** text area
- Click **Execute**

The GUI displays the output from the PHP code above the text area, or an error if the it could not run the code.

29.4 Ping Host

The firewall can send ICMP echo reqests, also known as "pings", to hosts over the network. These diagnostic packets test if the target host responds and measures latency between the firewall and target host. A basic ping test can be performed at the console, and a more detailed test is available in the GUI at **Diagnostics > Ping**.

29.4.1 Ping Options

When performing a ping test from the GUI, the following options are available:

Hostname
: A hostname or IP address to which the firewall will send ping requests.

IP Protocol
: The address type to ping when a hostname is entered that has both A (*IPv4*) and AAAA (*IPv6*) records.

Source Address
: The IP address on the firewall from which the ping request will be sent. This is especially important when testing LAN-to-LAN VPN connectivity. The default choice allows the operating system to automatically select the closest address to the target, based on the routing table.

Maximum Number of Pings
: The number of ping requests the firewall will send during this test. A higher count will take longer to complete and display results, especially if the target is down. Default is 3.

Seconds Between Pings
The number of seconds to wait between sending ping requests. Default is 1 second.

29.4.2 Ping from the GUI

To perform a ping test from the GUI:

- Navigate to **Diagnostics > Ping**
- Fill in the *Ping Options*

Note: At a minimum the **Hostname** is required.

- Click  **Ping** to start the test
- Wait for the GUI to display the test results

The GUI will display the results of the test automatically once complete. Do not navigate away from the page while the test is running.

29.4.3 Ping from the Console

A simple ping test may also be performed at the console menu, but without the additional options mentioned earlier. See *Ping host* for more information.

- Access the console menu locally or via SSH with an admin-level account (`admin`, `root`, or another privileged account using `sudo`).
- Enter the menu option which corresponds with **Ping Host** (e.g. `7`)
- Press `Enter`
- Enter the IP address or hostname to ping
- Press `Enter` to start the test
- Wait for the test to complete.

  The console outputs the test results in real time, and pauses afterward.
- Press `Enter` to return to the menu

29.5 Halting and Powering Off the Firewall

The firewall can be shut down safely by the **Halt** function available at **Diagnostics > Halt System** or from the console menu.

Warning: The best practice is to **never** cut power from a running system. Halting before removing power is always the safest procedure.

Aafter the operating system halts, the device power will also be turned off if that feature is supported by the hardware.

29.5.1 Halt from the GUI

To halt the operating system from the GUI:

- Navigate to **Diagnostics > Halt System**
- Click  **Halt**
- Click **OK** to confirm the action and start the halt process

29.5.2 Halt from the Console

- Access the console menu locally or via SSH with an admin-level account (`admin`, `root`, or another privileged account using `sudo`).
- Enter the menu option which corresponds with **Halt system** (e.g. `6`)
- Press `Enter`
- Enter the `y` to confirm the action
- Press `Enter` to start the halt process

29.6 Rebooting the Firewall

pfSense® software can be rebooted safely and returned to an operational state using the page at **Diagnostics > Reboot System** or the console.

29.6.1 Reboot Methods

The following reboot methods are possible, but available options may be limited depending on the platform and installation options.

Reboot normally
: Performs a normal reboot in the traditional way. This method is always available.

Reroot
: Performs a "reroot" style reboot, which is faster than a traditional reboot but does not restart the entire operating system. All running processes are killed, all filesystems are remounted, and then the system startup sequence is run again. This type of restart is much faster as it does not reset the hardware, reload the kernel, or need to go through the hardware detection process.

Reboot into Single User Mode
: Restarts the firewall into single user mode for diagnostic purposes. The firewall cannot automatically recover from this state, console access is required to use single user mode and reboot the firewall.

  This option is not compatible with ARM-based systems.

> **Warning:** Using this option with ZFS will not automatically return to a normal boot and requires manual intervention at the console. See *Re-mount ZFS Volumes as Read/Write*.

> **Warning:** In single user mode the root filesystem defaults to read-only and other filesystems are not mounted. The firewall also does not have an active network connection. This option must only be used under the guidance of a support representative or a FreeBSD user with advanced knowledge.

Reboot and run a filesystem check
Reboots the firewall and forces a filesystem check using `fsck`, run five times. This operation can often correct issues with the filesystem on the firewall.

This option is not compatible with ARM-based systems or ZFS.

29.6.2 Reboot from the GUI

To reboot from the GUI:

- Navigate to **Diagnostics > Reboot System**
- Select the *Reboot Method*
- Click  **Submit** to reboot the system immediately

29.6.3 Reboot from the Console

To reboot from the console:

- Access the console menu locally or via SSH with an admin-level account (`admin`, `root`, or another privileged account using `sudo`).
- Enter the menu option which corresponds with **Reboot system** (e.g. `5`)
- Press `Enter`
- Enter the letter which corresponds with the desired *Reboot Method*
- Press `Enter`

Note: The single user mode and filesystem check options require an uppercase letter to be entered to confirm the action. This is necessary to avoid activating the options accidentally. The reboot and reroot options may be entered in upper or lower case.

29.7 Testing a TCP Port

The **Diagnostics > Test Port** page performs a simple TCP port connection test to check if the firewall can communicate with another host. This tests if a host is up and accepting connections on a given port, at least from the perspective of the firewall.

No data is transmitted to the remote host by this test. The test only attempts to open a connection and optionally displays the data sent back from the server.

In the default mode the test attempts a simple TCP handshake (SYN, SYN+ACK, ACK), and if the attempt succeeds, it reports the result.

Note: This test does not function for UDP since there is no way to reliably determine if a UDP port accepts connections in this manner.

To perform a test:

- Navigate to **Diagnostics > Test Port**
- Fill in the fields on the page. The **Hostname** and **Port** fields are required, the rest are optional.
- Click  **Test**.

The following options are available on this page:

Hostname
The IP address or hostname of the target system.

This is a required field.

Port
The TCP port on the target used by the test.

This is a required field and must be a valid port number, meaning an integer between `1` and `65535`.

Source Port
An optional specific source port for the query. This is unnecessary in most cases.

Remote Text
If checked, this option shows the text given by the server when connecting to the port. The server is given 10 seconds to respond, and this page will display all of the text sent back by the server in those 10 seconds. As such, the test will run for a minimum of 10 seconds when performing this check.

Note: Not all daemons will output text to the user on connect, so this may be blank even if the service is working properly. For example, an SMTP server will respond with a welcome message, as will FTP, but an HTTP daemon will not send any text.

Source Address
A specific source IP address or IP Alias/CARP Virtual IP from which the query will be sent. The service being tested may require a specific source IP address, network, etc, in order to make a connection.

IP Protocol
This option selects either *IPv4* or *IPv6* to control which type of IP address is used when testing a hostname. If the connection is forced to IPv4 or IPv6 and the hostname does not contain a result using that protocol, the test will produce an error. For example if forced to IPv4 and given a hostname that only returns an IPv6 IP address (AAAA record), the test will fail.

29.7.1 Troubleshooting

```
nc: bind failed: Address already in use
```

The test produces this error if the **Source Port** field is set to a port currently in use by a local daemon on the firewall. Leave **Source Port** blank or pick another unused port.

See also:

To view a list of *ports currently in use*, visit **Diagnostics > Sockets**.

29.8 Traceroute

The traceroute page, located at **Diagnostics > Traceroute**, works like the *traceroute* command found on many platforms. It sends special packets which, as the name implies, trace a route across the network from this firewall to a remote host.

The results include a list of hops between hosts along with response times, as long as the intervening hosts support (or do not filter) traffic required for traceroute to work.

This document also includes a detailed explanation of how traceroute functions.

29.8.1 Traceroute Options

The GUI page to perform a traceroute contains the following options which control the behavior of the test:

Host
A hostname or IP address to which the firewall will trace the route.

IP Protocol
The address type the firewall will use when a hostname has both A (*IPv4*) and AAAA (*IPv6*) records.

Source Address
The IP address from which the firewall will send the trace.

This is especially important when testing LAN-to-LAN VPN connectivity.

Maximum number of hops
The maximum length of the path to trace.

The trace will stop if the path cannot be traced completely after this number of hops.

Reverse Address Lookup
When checked, traceroute will attempt to perform a PTR lookup to locate hostnames for hops along the path.

This option slows down the process as it has to wait for DNS replies.

Use ICMP
By default, traceroute uses UDP but that may be blocked by some routers. Check this box to use ICMP instead, which may succeed.

The page will display output once the trace is complete. Press the **Stop** button at any time to see the current output of the trace if it is still running or stalled.

29.8.2 How Traceroute Works

Every IP packet contains a time-to-live (TTL) value. When a router passes a packet it decrements the TTL by one. When a router receives a packet with a TTL of 1 and the destination is not a locally attached network, the router returns an ICMP error message "Time-to-live exceeded" and drops the packet. This limits the impact of routing loops, which otherwise would cause each packet to loop indefinitely.

Traceroute uses this TTL to its advantage to map the path to a specific network destination. It starts by sending the first packet with a TTL of 1. The first router (usually the default gateway) will send back an ICMP time-to-live exceeded error. The program outputs the time between sending the packet and receiving the ICMP error along with the IP address that sent the error and its reverse DNS, if any. After sending three packets with a TTL of 1 and displaying their response times it increments the TTL to 2 and sends three more packets. It outputs the same types of information for the second hop. Traceroute increments the TTL and repeats the process until it reaches the specified destination or exceeds the maximum number of hops.

Traceroute functions slightly differently on Windows and Unix-like operating systems (BSD, Linux, macOS, Unix, etc.). Windows uses ICMP echo request packets (pings) while Unix-like systems use UDP packets by default. ICMP and UDP are layer 4 protocols, and traceroute is done at layer 3, so the protocol is largely irrelevant except when considering firewall rules and policy routing configurations. Traceroute from Windows clients will be policy routed based on rules which permit ICMP echo requests, while Unix-like clients will be policy routed by rules matching UDP.

In this example, `traceroute` is used to view the route to `www.google.com`:

```
# traceroute www.google.com
traceroute: Warning: www.google.com has multiple addresses; using 74.125.95.99
traceroute to www.l.google.com (74.125.95.99), 64 hops max, 40 byte packets
 1  core (172.17.23.1)  1.450 ms  1.901 ms  2.213 ms
 2  172.17.25.21 (172.17.25.21)  4.852 ms  3.698 ms  3.120 ms
 3  bb1-g4-0-2.ipltin.ameritech.net (151.164.42.156)  3.275 ms  3.210 ms  3.215 ms
 4  151.164.93.49 (151.164.93.49)  8.791 ms  8.593 ms  8.891 ms
 5  74.125.48.117 (74.125.48.117)  8.460 ms  39.941 ms  8.551 ms
 6  209.85.254.120 (209.85.254.120)  10.376 ms  8.904 ms  8.765 ms
 7  209.85.241.22 (209.85.241.22)  19.479 ms  20.058 ms  19.550 ms
 8  209.85.241.29 (209.85.241.29)  20.547 ms  19.761 ms
    209.85.241.27 (209.85.241.27)  20.131 ms
 9  209.85.240.49 (209.85.240.49)  30.184 ms
    72.14.239.189 (72.14.239.189)  21.337 ms  21.756 ms
10  iw-in-f99.google.com (74.125.95.99)  19.793 ms  19.665 ms  20.603 ms
```

The output shows that it took 10 hops to reach the destination and the latency generally increased with each hop, which is expected.

Note: When utilizing policy routing, such as with Multi-WAN, the firewall itself may not appear as a hop in traceroute. When policy routing is employed, `pf` does not decrement the TTL when forwarding packets, so traceroute cannot detect the firewall as an intermediate router.

29.9 Packet Capturing

29.9.1 Selecting the Proper Interface

To perform a packet capture, first determine the location from which to take the capture. A packet capture looks different depending upon the chosen interface and in certain scenarios it is better to capture on one specific interface, and in others, running multiple simultaneous captures on different interfaces is preferable.

Using `tcpdump` at the command line requires the "real" interface names that go with the friendly names shown in the firewall GUI. Visit **Interfaces > Assignments** and make a note of which OS interfaces (e.g. `igb1`), correspond with the friendly interfaces names on the firewall (e.g. `WAN`). *Real Interfaces vs. Friendly Names* lists common additional unassigned interface names that are present in many firewalls, depending on their configuration.

Table 1: Real Interfaces vs. Friendly Names

Real/Physical Name	Friendly Name
`enc0`, `ipsecX`	IPsec, encrypted traffic
`ovpncX`, `ovpnsX`	OpenVPN, encrypted traffic (Clients, Servers)
`pppoeX`, `poesX`	PPPoE WAN, PPPoE Server
`l2tpX`, `l2tpsX`	L2TP WAN, L2TP Server
`lo0`	Loopback Interface
`pfsync0`	pfsync interface – used internally
`pflog0`	pf logging – used internally

When selecting an interface, start with where the traffic flows into the firewall. For example, if a user is having trouble connecting to a port forward from outside the network, start with the WAN interface since that is where the traffic originates. If a client PC cannot reach the Internet, start with the LAN interface. When in doubt, try multiple interfaces and filter for the IP addresses or ports in question, keeping in mind when NAT will be applied.

29.9.2 Limiting capture volume

When capturing packets, limiting the volume of packets captured is important. Set limits on the capture so that it captures enough relevant traffic to troubleshoot the problem. If the limit is too low, the capture may be missing important details. If the limit is too high, there may be too much noise to sort through to find the problem.

Note: Capture files also consume disk space, which can be a factor on systems with smaller drives. Large captures will also take more time to download, which can be a concern on remote systems with slow WAN upload capacity.

When capturing without filtering on most networks, even for short time frame, huge amounts of data will end up in the capture to dig through when attempting to locate the problem. Display filters in Wireshark can limit which parts of an existing capture file are shown, but filtering appropriately at the time of capture is preferable to keep the capture file size down and to reduce processing time. Filters are discussed later in this chapter.

With an appropriate filter and packet count, capture files can be manageable and contain useful information.

29.9.3 Packet Capture GUI

The pfSense® software GUI offers an easy-to-use front end to `tcpdump` that performs packet captures which can then be viewed in the GUI or downloaded for deeper analysis using utilities such as Wireshark.

This feature is located at **Diagnostics > Packet Capture**.

See also:

If the options available in the GUI are too limiting, skip ahead to *Using tcpdump on the command line*.

Packet Capture Options

Interface
The network interface from which `tcpdump` will capture packets. Each assigned and unassigned interface on the firewall appears in the list, excluding special interfaces such as `pfsync0` and `pflog0`.

Packet Capture Filter
Selects a filter option or preset for the packet capture. Selecting a preset filter will hide the *Custom Filter Options* section.

Custom Filter
Enter custom values to limit captures.

Everything
Will capture any packet.

Only Untagged
Will exclusively capture any packets which are *not* VLAN-tagged.

Only Tagged
Will exclusively capture any packets which are VLAN-tagged.

Packet Count
Determines the total number of packets to capture before the capture stops automatically.

Captures may be "noisy" if they are not limited in some way. To get a usable result in these cases, increase this value beyond the default of `1000` to a much higher amount such as `10000`.

Packet Length
Sets the portion, in bytes, of each packet to capture.

In most cases the best practice is to capture the full packet (`0`), but for captures run over longer periods of time where the headers matter more than the payload of the packets, limiting this to `64` bytes or so will result in a much smaller capture file that may still have adequate data for troubleshooting purposes.

Promiscuous Mode
When checked, a capture includes all traffic arriving on the network interface for any destination MAC Address.

Without promiscuous mode the capture can only include traffic to/from the firewall itself as well as broadcast and multicast traffic.

> **Warning:** Some interface drivers and chipsets do not handle promiscuous mode well.

View Detail
Selects the amount of detail to display in the GUI when viewing a capture.

Note: View options (including `Name Lookup`) **do not** affect the packet capture file itself, and may be changed before or after the packet capture. Change the value and click  **View** to display the capture with the new view option.

View Type
Force the captured traffic to be interpreted as the specified type when viewed. This is particularly helpful when viewing CARP traffic.

Name Lookup
Causes `tcpdump` to perform a name lookup for the port and host address, including the MAC OUI.

Warning: Avoid using this option when possible as it will delay the output due to the extra time taken by reverse DNS lookups. Also, it is typically easier to troubleshoot when viewing IP addresses instead of hostnames, and reverse DNS can be inaccurate.

Custom Filter Options

Filter Sections

Filter options are separated into two sections, untagged and tagged. Each section may be individually included or excluded in the packet capture. This is useful in the case where both untagged and some other tagged traffic need to be captured. The available filter sections are:

Untagged Filter
Values entered in this section will only apply to packets which *do not* have a VLAN tag.

Tagged Filter
Values entered in this section will only apply to packets which have a VLAN tag set.

Multiple Values and Filter Operators

All input fields accept multiple **space-separated** values. When multiple values are specified, the drop-down menu for each option has an operator which defines the behavior:

all of
Captures only packets that match **all** of the values specified in this single filter option.

any of
Captures packets that match **any** of the values specified in this single filter option.

none of
Captures packets that **do not** match the values specified in this single filter option.

OR <type>
Places a logocal "or" between multiple separate filter options (e.g. a given host IP address **or** a given MAC address)

Filter Options

The following fields are available for filtering in the Untagged and/or Tagged filter option groups:

Include/Exclude
Defines how the GUI handles packets and options in a section (untagged, tagged):

Include any of
Enables the filter options for this section and includes packets of this type provided they match the defined criteria.

Exclude all
Disables the filter options for this section and excludes all packets of this type.

VLAN Tag
Match traffic that is tagged with the specified VLAN tags. This is particularly useful when capturing on a trunk interface and not all VLANs need to be captured.

VLAN Tag Level
Which VLAN tag stack level to apply the filter to. This is useful when filtering QinQ traffic.

Host Address or Subnet
Filters traffic going to or from specific IP addresses (`x.x.x.x`) or CIDR-masked subnets (`x.x.x.x/yy`).

Host MAC Address
Filters traffic going to or from specific MAC addresses.

Enter MAC addresses in colon-separated format, such as `xx:xx:xx:xx:xx:xx`. To match a partial address, use one (`xx`), two (`xx:xx`), or four (`xx:xx:xx:xx`) segments in the same colon-separated format.

Protocol
Limits the capture to packets for specific protocols. The drop-down option in the GUI includes common protocols such as TCP, UDP, ICMP, ICMP6, CARP, but any protocols may be specified manually by number or name.

Port Number
Limits the capture to packets with the specified source or destination port. Only effective on protocols which have ports (TCP, UDP).

Ethertype
May be used to limit the capture to only IPv4, IPv6, or ARP traffic. This is useful when not filtering by IP address (e.g. by port number or MAC address).

Performing a Packet Capture

To make a packet capture in the GUI:

- Navigate to **Diagnostics > Packet Capture**
- Configure the options on the page as described in *Packet Capture Options*
- Click  **Start** to begin capturing packets.

  The page will display a live preview of the captured packets which refreshes every few seconds. The resulting `tcpdump` command is also shown, along with the message "Running packet capture" indicating the capture is in process.

- Click  **Stop** to manually end the capture and view the output.

  If the capture has a maximum packet **Count** set it will stop automatically when it reaches that count. In this case the capture does not need a manual stop action unless it must be stopped before reaching that count.

Viewing the Captured Data

The capture output can be viewed in the GUI or downloaded for later viewing in a program such as Wireshark.

- Navigate to **Diagnostics > Packet Capture**
- Set the **View Options** (*Packet Capture Options*) to control how the GUI displays the contents of the capture.
- Click  **View**

  The page displays the output in a field titled **Packet Capture Output** in standard `tcpdump` format.

  Note: If the **View** button is not visible on the page, there is no existing capture data to view. Perform a new capture first.

- Click  **Download** to download this file for later viewing (Optional).

  See also:

  For more detail on using Wireshark to view a capture file, see *Viewing a Packet Capture File*.

29.9.4 Using tcpdump on the command line

The `tcpdump` program is a command line packet capture utility provided with most UNIX and UNIX-like operating system distributions, including FreeBSD. It is included in pfSense® software and is usable from a shell on the console or over SSH.

The `tcpdump` program is an exceptionally powerful tool, but that also makes it daunting to the uninitiated user. The `tcpdump` binary in FreeBSD supports over 50 different command line flags, limitless possibilities with filter expressions, and its man page, providing only a brief overview of all its options, is nearly 1200 lines long and 67k.

After learning to use `tcpdump`, knowledge of how to interpret the data it provides is also necessary, which can require an in-depth understanding of networking protocols.

This section is intended to provide an introduction to this topic and leave the reader with enough knowledge for basic troubleshooting. A comprehensive review of packet capturing and interpretation of the results is outside the scope of this documentation.

See also:

For those with a thirst for more than basic knowledge in this area, see *Additional References* for more resources.

Common tcpdump flags

The following table shows the most common command line flags for `tcpdump`. This section contains information on each of these flags.

Table 2: Commonly Used tcpdump Flags

Flag	Description
`-i <interface>`	Listen on `<interface>`, .e.g. `-i igb0`
`-n`	Do not perform reverse DNS resolution on IP addresses
`-w <filename>`	Save capture in pcap format to `<filename>`, e.g. `-w /tmp/wan.pcap`
`-s <bytes>`	Snap length: Amount of data to be captured from each frame
`-c <packets>`	Exit after receiving a specific number of packets
`-p`	Do not put the interface in promiscuous mode
`-v`	Verbose output
`-e`	Print link-layer header on each line

-i flag

The `-i` flag specifies the interface on which `tcpdump` will listen. Use FreeBSD interface names here, such as `igb0`, `em0`, `vmx0`, etc.

-n flag

Do not resolve IP addresses using reverse DNS. When this option is *not* specified, `tcpdump` will perform a reverse DNS (PTR) lookup for each IP address. This generates a significant amount of DNS traffic in captures displaying large volumes of traffic. Disable this to avoid adding load to DNS servers.

The best practice is to always use `-n` because it eliminates the delay caused by performing the reverse lookup between when `tcpdump` captures a packet and when it can display the content. Also, IP addresses are typically easier to read and understand than their PTR records. That is a matter of personal preference, though, and in familiar environments where the PTR records are known to provide the actual host names of the devices, captures may be run without `-n` to show the hostnames.

Another reason to use `-n`, is to be "sneaky." One means of detecting packet capturing is looking for spikes and patterns in DNS PTR lookups. Skipping the DNS lookup will not cause any extra traffic to be generated in the process.

-w flag

`tcpdump` can save capture files in pcap format for later analysis or analysis on another system. This is commonly done from command line only devices like those running pfSense software so the file can be copied to a host running Wireshark or another graphical network protocol analyzer and reviewed there. When saving to a file using `-w`, the frames will not be displayed in the terminal as they otherwise are.

See also:

See *Using Wireshark* for more information about using Wireshark with pfSense software.

-s flag

By default `tcpdump` only saves the first `64` bytes of each frame when capturing to a file. This is enough to contain the IP and protocol header for most protocols, but limits the usability of capture files. By using the `-s` flag, `tcpdump` can be told how much of the frame to capture, in bytes. This is called the snap length.

Table 3: Example Uses of tcpdump -s

Flag	Description
`-s 500`	Capture the first 500 bytes of each frame
`-s 0`	Capture each frame in its entirety

In most cases, using `-s 0` is the best practice when capturing to a file for analysis on another system. The only exception to this is scenarios where a significant amount of traffic must be captured over a longer period of time. If the information being sought is known to be in the header, the default `64` bytes of each frame may be used to get the required information while significantly reducing the size of the resulting capture file.

-c flag

To capture a certain number of frames and then exit, use the `-c` flag. Example usage: `tcpdump` will exit after capturing 100 frames by specifying `-c 100`.

-p flag

Normally when capturing traffic with `tcpdump`, it puts the network interface into promiscuous mode. When not running in promiscuous mode, the interface only receives frames destined for its own MAC address as well as broadcast and multicast addresses. When switched into promiscuous mode, the interface shows every frame on the wire that arrives at the network interface. In a switched network, this generally has little impact on the capture. In networks where the device is connected to a vswitch also in promiscuous mode, or a hub, using `-p` can significantly limit noise in the capture when the only traffic of interest is to and from the system performing the capture.

-v flag

The `-v` flag controls the detail, or verbosity, of the output. Using more `v` options yields more detail, so use `-v`, `-vv`, or `-vvv` to view even more detail in the output printed to the console. This option does not affect the detail stored in a capture file when using the `-w` switch, but will instead cause the process to report the number of packets captured every `10` seconds.

-e flag

Normally `tcpdump` does not show any link layer information. Specify `-e` to display the source and destination MAC addresses, and VLAN tag information for any traffic tagged with 802.1q VLANs.

Example capture without -e

This capture shows the default output, containing no link layer information:

```
# tcpdump -ni igb1 -c 5
tcpdump: verbose output suppressed, use -v or -vv for full protocol decode
listening on igb1, link-type EN10MB (Ethernet), capture size 96 bytes
23:18:15.830706 IP 10.0.64.210.22 > 10.0.64.15.1395: P 2023587125:2023587241(116)
   ack 2091089207 win 65535
23:18:15.830851 IP 10.0.64.210.22 > 10.0.64.15.1395: P 116:232(116) ack 1 win 65535
23:18:15.831256 IP 10.0.64.15.1395 > 10.0.64.210.22: . ack 116 win 65299
23:18:15.839834 IP 10.0.64.3 > 224.0.0.18: VRRPv2, Advertisement, vrid 4, prio 0,
   authtype none, intvl 1s, length 36
23:18:16.006407 IP 10.0.64.15.1395 > 10.0.64.210.22: . ack 232 win 65183
5 packets captured
```

Example capture using -e

Here the link layer information is included by using `-e`. Note the source and destination MAC addresses in addition to the source and destination IP addresses:

```
# tcpdump -ni igb1 -e -c 5
tcpdump: verbose output suppressed, use -v or -vv for full protocol decode
listening on igb1, link-type EN10MB (Ethernet), capture size 96 bytes
23:30:05.914958 00:0c:29:0b:c3:ed > 00:13:d4:f7:73:d2, ethertype IPv4 (0x0800), length␣
↪170:
   10.0.64.210.22 > 10.0.64.15.1395: P 2023592509:2023592625(116) ack 2091091355 win␣
↪65535
23:30:05.915110 00:0c:29:0b:c3:ed > 00:13:d4:f7:73:d2, ethertype IPv4 (0x0800), length␣
↪170:
   10.0.64.210.22 > 10.0.64.15.1395: P 116:232(116) ack 1 win 65535
23:30:05.915396 00:13:d4:f7:73:d2 > 00:0c:29:0b:c3:ed, ethertype IPv4 (0x0800), length␣
↪60:
   10.0.64.15.1395 > 10.0.64.210.22: . ack 116 win 65299
23:30:05.973359 00:00:5e:00:01:04 > 01:00:5e:00:00:12, ethertype IPv4 (0x0800), length␣
↪70:
   10.0.64.3 > 224.0.0.18: VRRPv2, Advertisement, vrid 4, prio 0, authtype none, intvl␣
↪1s,
   length 36
23:30:06.065200 00:13:d4:f7:73:d2 > 00:0c:29:0b:c3:ed, ethertype IPv4 (0x0800), length␣
↪60:
   10.0.64.15.1395 > 10.0.64.210.22: . ack 232 win 65183
5 packets captured
```

tcpdump Filters

Running `tcpdump` without filters on most firewalls will produce so much output that it is extremely difficult to find traffic of interest. There are numerous filtering expressions available that limit traffic display and capture.

Host filters

To filter for a specific host, append `host` and the IP address to the `tcpdump` command.

To filter for host `192.168.1.100` use the following command:

```
# tcpdump -ni igb1 host 192.168.1.100
```

The previous command captures all traffic to and from the given host. To only capture traffic being *initiated* by that host, use the `src` directive:

```
# tcpdump -ni igb1 src host 192.168.1.100
```

Similarly, filtering for traffic *destined* to that IP address is possible by specifying `dst`:

```
# tcpdump -ni igb1 dst host 192.168.1.100
```

Network filters

Network filters narrow the capture to a specific subnet using the `net` expression. Following `net`, specify a CIDR-masked network (`192.168.1.0/24`), dotted quad (`192.168.1.1`), dotted triple (`192.168.1`), dotted pair (`192.168`) or simply a number (`192`). A dotted quad is equivalent to specifying `host`, a dotted triple uses a subnet mask of `255.255.255.0`, a dotted pair uses `255.255.0.0`, and a number alone uses `255.0.0.0`.

The best practice for filtering by network is to use a CIDR masked subnet prefix specification as an argument to `net`:

```
# tcpdump -ni igb1 src net 172.16.0.0/12
```

Alternately, omit parts of an address to use the assumed masks mentioned previously.

The following command displays traffic to or from any host with a `192.168.1.x` IP address:

```
# tcpdump -ni igb1 net 192.168.1
```

The next command will capture traffic to or from any host with a `10.x.x.x` IP address:

```
# tcpdump -ni igb1 net 10
```

Those examples will capture all traffic to or from the specified network. The `src` or `dst` keywords may be used the same as with `host` filters to capture only traffic initiated by or destined to the specified network:

```
# tcpdump -ni igb1 src net 10
```

Protocol and port filters

Narrowing down by host or network can be inadequate to eliminate unnecessary traffic from a capture. Or the source or destination of traffic may not be significant, and all traffic of a certain type should be captured. In other cases, filtering out all traffic of a specific type can reduce noise.

TCP and UDP port filters

To filter on TCP and UDP ports, use the `port` directive. This captures both TCP and UDP traffic using the specified port either as a source or destination port. It can be combined with `tcp` or `udp` to specify the protocol, and `src` or `dst` to specify a source or destination port.

Capture all HTTP traffic

```
# tcpdump -ni igb1 tcp port 80
```

Capture all DNS traffic

Capture all DNS traffic (Queries can use both UDP and TCP):

```
# tcpdump -ni igb1 port 53
```

Protocol filters

Specific protocols can be filtered using the `proto` directive or by using the protocol name directly. Parameters passed to the `proto` directive can be specified using the IP protocol number or one of the names `icmp`, `igmp`, `igrp`, `pim`, `ah`, `esp`, `carp`, `vrrp`, `udp`, or `tcp`. Because the normal protocol names are reserved words, they must be escaped with one or two backslashes when used with the `proto` directive, depending on the shell. The default shell available in pfSense software requires two backslashes to escape these protocol names. If the command returns a syntax error, check that the protocol name is properly escaped.

The following capture will show all ICMP traffic on the `igb1` interface:

```
# tcpdump -ni igb1 proto \\icmp
```

Specifying `carp` for the protocol will capture CARP traffic but it also needs `-T carp` in order to interpret the CARP packets correctly when viewing the output using `tcpdump`. The GUI makes this adjustment automatically when capturing CARP.

The following capture will show all CARP traffic on the `igb1` interface, which can be useful to ensure CARP traffic is being sent and received on the specified interface. It also omits the `proto` keyword, showing that it works on its own:

```
# tcpdump -i igb1 -T carp carp
```

Negating a filter match

In addition to matching specific parameters, a filter match can be negated by specifying `not` in front of the filter expression. When troubleshooting something other than CARP, and its multicast heartbeats are cluttering the capture output, exclude it as follows:

```
# tcpdump -ni igb1 not proto \\carp
```

Combining filters

Any of the aforementioned filters can be combined using `and` or `or`. The following sections provide some examples.

Display all HTTP traffic to and from a host

Display all HTTP traffic to or from `192.168.1.11`:

```
# tcpdump -ni igb1 host 192.168.1.11 and tcp port 80
```

Display all HTTP traffic to and from multiple hosts

Display all HTTP traffic from either `192.168.1.11` or `192.168.1.15`:

```
# tcpdump -ni igb1 host 192.168.1.11 or host 192.168.1.15 and tcp port 80
```

Filter expression usage

Filter expressions must come after every command line flag used. Adding any flags after a filter expression will result in a syntax error.

Incorrect ordering

```
# tcpdump -ni igb1 -T carp carp -c 2
tcpdump: syntax error
```

Correct ordering

```
# tcpdump -ni igb1 -T carp -c 2 carp
tcpdump: verbose output suppressed, use -v or -vv for full protocol decode
listening on igb1, link-type EN10MB (Ethernet), capture size 65535 bytes
14:50:07.426993 IP 198.51.100.12 > 224.0.0.18: CARPv2-advertise 36: vhid=11 advbase=1
   advskew=0 authlen=7 counter=5449924379588860810
14:50:08.436849 IP 198.51.100.12 > 224.0.0.18: CARPv2-advertise 36: vhid=11 advbase=1
   advskew=0 authlen=7 counter=5449924379588860810
2 packets captured
78 packets received by filter
0 packets dropped by kernel
```

More on Filters

This section covered the most commonly used `tcpdump` filter expressions, and probably covers all the syntax most users will need. However this barely scratches the surface of the possibilities. There are many documents on the web that cover `tcpdump` in general and filtering specifically. See *Additional References* at the end of this chapter for links to more resources.

Practical Troubleshooting Examples

This section details best practice approaches for troubleshooting a few specific problems. There are multiple ways to approach any problem, but packet capturing can rarely be beat for its effectiveness. Examining the traffic on the wire provides a level of visibility into what is actually happening on the network

Port forward not working

In this example, a new port forward is failing to respond to a request from a host on the Internet. The troubleshooting steps outlined in *Troubleshooting NAT Port Forwards* offers one way to approach this, but sometimes packet capturing is the only or easiest way to find the source of the problem.

Start from WAN

First, make sure the traffic is getting to the WAN interface. Start a `tcpdump` session on the WAN interface, and watch for the traffic:

```
# tcpdump -ni igb1 tcp port 5900
tcpdump: verbose output suppressed, use -v or -vv for full protocol decode
listening on igb1, link-type EN10MB (Ethernet), capture size 96 bytes
11:14:02.444006 IP 172.17.11.9.37219 > 10.0.73.5.5900: S 3863112259:3863112259(0)
   win 65535 <mss 1260,nop,nop,sackOK>
```

In this case, a packet comes in from the WAN, so it is making it that far. Note that the first part of the TCP handshake, a packet with only SYN set (the `S` shown), is reaching the firewall. If the port forward was working, a SYN ACK (`S.`) packet would be shown in reply to the SYN. With no return traffic visible, it could be a firewall rule or the target system may be unreachable – turned off, not listening on the specified port, host firewall blocking the traffic, etc.

Check Internal Interface

The next step would be to run a `tcpdump` session on the internal interface associated with the port forward:

```
# tcpdump -ni igb0 tcp port 5900
tcpdump: verbose output suppressed, use -v or -vv for full protocol decode
listening on igb0, link-type EN10MB (Ethernet), capture size 96 bytes
11:14:38.339926 IP 172.17.11.9.2302 > 192.168.30.5.5900: S 1481321921:1481321921(0)
   win 65535 <mss 1260,nop,nop,sackOK>
```

Looking at the internal traffic, the connection left the inside interface and the local IP address was translated correctly. If this local address matches what was expected, then both the port forward and the firewall rule are working properly, and connectivity to the local PC must be confirmed by other means. If no output was displayed, then there is a problem with the firewall rule or the port forward may have been incorrectly defined. For this example, the target system was unplugged.

IPsec tunnel will not connect

tcpdump has some awareness of the protocols being used, which can be very helpful in figuring out problems with IPsec tunnels. The next few examples will show how certain error conditions may present themselves when monitoring with tcpdump. The IPsec logs are usually more helpful, but this can confirm what is actually being seen by the firewall. For encrypted traffic such as IPsec, packet capturing of the traffic is of less value as the payload of the captured packets cannot be examined without additional parameters, but it is helpful to determine if traffic from the remote end is reaching the firewall and which phases complete.

This first tunnel has an unreachable peer:

```
# tcpdump -ni igb1 host 192.168.10.6
tcpdump: verbose output suppressed, use -v or -vv for full protocol decode
listening on igb1, link-type EN10MB (Ethernet), capture size 96 bytes

19:11:11.542976 IP 192.168.10.5.500 > 192.168.10.6.500: isakmp: phase 1 I agg
19:11:21.544644 IP 192.168.10.5.500 > 192.168.10.6.500: isakmp: phase 1 I agg
```

This tunnel attempt has a mismatched PSK, notice how it attempts to move to phase 2, but then stops:

```
# tcpdump -ni igb1 host 192.168.10.6
tcpdump: verbose output suppressed, use -v or -vv for full protocol decode
listening on igb1, link-type EN10MB (Ethernet), capture size 96 bytes
19:15:05.566352 IP 192.168.10.5.500 > 192.168.10.6.500: isakmp: phase 1 I agg
19:15:05.623288 IP 192.168.10.6.500 > 192.168.10.5.500: isakmp: phase 1 R agg
19:15:05.653504 IP 192.168.10.5.500 > 192.168.10.6.500: isakmp: phase 2/others I inf[E]
```

Now Phase 1 is OK but there is a mismatch in the Phase 2 information. It will repeatedly attempt phase 2 traffic but there will not be any traffic in the tunnel:

```
# tcpdump -ni igb1 host 192.168.10.6
tcpdump: verbose output suppressed, use -v or -vv for full protocol decode
listening on igb1, link-type EN10MB (Ethernet), capture size 96 bytes
19:17:18.447952 IP 192.168.10.5.500 > 192.168.10.6.500: isakmp: phase 1 I agg
19:17:18.490278 IP 192.168.10.6.500 > 192.168.10.5.500: isakmp: phase 1 R agg
19:17:18.520149 IP 192.168.10.5.500 > 192.168.10.6.500: isakmp: phase 1 I agg
19:17:18.520761 IP 192.168.10.6.500 > 192.168.10.5.500: isakmp: phase 2/others R inf[E]
19:17:18.525474 IP 192.168.10.5.500 > 192.168.10.6.500: isakmp: phase 2/others I inf[E]
19:17:19.527962 IP 192.168.10.5.500 > 192.168.10.6.500: isakmp: phase 2/others I oakley-
↪quick[E]
```

Finally, a fully working tunnel with two-way traffic after Phase 1 and Phase 2 have completed!:

```
#  tcpdump -ni igb1 host 192.168.10.6
tcpdump: verbose output suppressed, use -v or -vv for full protocol decode
listening on igb1, link-type EN10MB (Ethernet), capture size 96 bytes
21:50:11.238263 IP 192.168.10.5.500 > 192.168.10.6.500: isakmp: phase 1 I agg
21:50:11.713364 IP 192.168.10.6.500 > 192.168.10.5.500: isakmp: phase 1 R agg
21:50:11.799162 IP 192.168.10.5.500 > 192.168.10.6.500: isakmp: phase 1 I agg
21:50:11.801706 IP 192.168.10.5.500 > 192.168.10.6.500: isakmp: phase 2/others I inf[E]
21:50:11.812809 IP 192.168.10.6.500 > 192.168.10.5.500: isakmp: phase 2/others R inf[E]
21:50:12.820191 IP 192.168.10.5.500 > 192.168.10.6.500: isakmp: phase 2/others I oakley-
↪quick[E]
21:50:12.836478 IP 192.168.10.6.500 > 192.168.10.5.500: isakmp: phase 2/others R oakley-
```

(continues on next page)

21:50:15.189349 IP 192.168.10.5 > 192.168.10.6: ESP(spi=0x09bf945f,seq=0x3), length 132
21:50:15.191756 IP 192.168.10.6 > 192.168.10.5: ESP(spi=0x0a6f9257,seq=0x3), length 132
```

Traffic traversing an IPsec tunnel

Traffic can also be observed traversing IPsec tunnels by capturing on the `enc0` interface. This can help determine if traffic is attempting to reach the far end by using the tunnel. All traffic for all IPsec tunnels appears on the `enc0` interface.

In the following example, a host on one side of the tunnel is successfully sending an ICMP echo request (ping) to the far side, and receiving replies:

```
# tcpdump -ni enc0
tcpdump: WARNING: enc0: no IPv4 address assigned
tcpdump: verbose output suppressed, use -v or -vv for full protocol decode
listening on enc0, link-type ENC (OpenBSD encapsulated IP), capture size 65535 bytes
15:52:46.151098 (authentic,confidential): SPI 0xcd77e085: IP 10.3.0.1 > 10.7.0.1:
   ICMP echo request, id 44640, seq 0, length 64
15:52:46.151814 (authentic,confidential): SPI 0xc0afb14d: IP 10.7.0.1 > 10.3.0.1:
   ICMP echo reply, id 44640, seq 0, length 64
15:52:47.154243 (authentic,confidential): SPI 0xcd77e085: IP 10.3.0.1 > 10.7.0.1:
   ICMP echo request, id 44640, seq 1, length 64
15:52:47.154843 (authentic,confidential): SPI 0xc0afb14d: IP 10.7.0.1 > 10.3.0.1:
   ICMP echo reply, id 44640, seq 1, length 64
```

If traffic was not properly entering the tunnel, no output would be shown. If there is a firewall or internal routing issue on the far side, traffic will appear leaving but nothing will show returning.

Troubleshooting Outbound NAT

For complex environments where Manual Outbound NAT is needed, `tcpdump` can be of great assistance in troubleshooting the Outbound NAT configuration. One good capture to use is to look for traffic with private IP addresses on the WAN interface, as everything on WAN should be have NAT applied and appear to be a public IP address. The following capture will display any traffic with RFC 1918 IP addresses as the source or destination. This will show any traffic that is not matching one of the outbound NAT rules, providing information to help review the Outbound NAT configuration to find the problem:

```
# tcpdump -ni igb1 net 10 or net 192.168 or net 172.16.0.0/12
```

29.9.5 Using Wireshark

Wireshark is a GUI protocol analysis and packet capture tool that can view and capture traffic much like `tcpdump`. Wireshark is Open Source software, freely available at http://www.wireshark.org/. Wireshark can analyze capture files generated by the pfSense® software GUI, `tcpdump`, Wireshark, or any other software that writes files in the standard `pcap` file format.

Before proceeding, download and install Wireshark onto a client computer.

Viewing a Packet Capture File

To view a capture file in Wireshark, use one of the following methods:

Manually Open File
The basic way to open a file manually is:

- Start Wireshark
- Navigate to **File > Open**
- Locate the capture file and click it
- Click the **Open** button

Double Click
A file with a `.pcap` extension can be opened by double clicking on it in Windows, macOS, and many Linux distributions. This action is typically performed in a file manager such as File Explorer, Finder, Nemo, Dolphin, or similar programs.

Download and Open
Browsers may often to open a downloaded capture file directly in Wireshark. This may be an option on a file download prompt, or an option from the list of downloaded files.

Once the file is open Wireshark displays a screen similar to Figure *Wireshark Capture View* which contains data from the capture file.

This view in Wireshark has a list summarizing the packets in the capture file in the top pane, with one packet per line. If there are too many packets, the results can be filtered using the **Filter** box on the toolbar.

Select a packet by clicking it in the list and the lower frames show the details of what is contained within the packet payload. The first lower pane shows a break-down of the packet structure, and each of these items can be expanded for more detail. If the packet is part of a protocol known to Wireshark, in some cases it can interpret the data and show even more details. The bottom pane shows a hexadecimal and ASCII representation of the data contained in the packet.

Viewing the capture this way makes it easy to see the flow of traffic with as much or as little detail as needed.

Wireshark Analysis Tools

While some problems will require considerable knowledge of how the underlying protocols function, the analysis tools built into Wireshark helps lessen that need for many protocols. The **Analyze** and **Statistics** menus have a few options that automate some of the analysis and provide summarized views of capture content. The **Expert Info** options under the **Analyze** menu show a list of errors, warnings, notes and network conversations contained in the capture.

Wireshark may note errors for incorrect checksums. This is because most network interfaces handle checksums in hardware directly before putting it on the wire. This is the only exception to the earlier note saying what is shown in a packet capture is what is on the wire. Traffic sent from the system where the capture is taken will have incorrect checksums where they are performed in hardware, though traffic coming in from a remote system should always have correct checksums. Checksum offloading can be turned off to ensure traffic is shown exactly as the host is putting it on

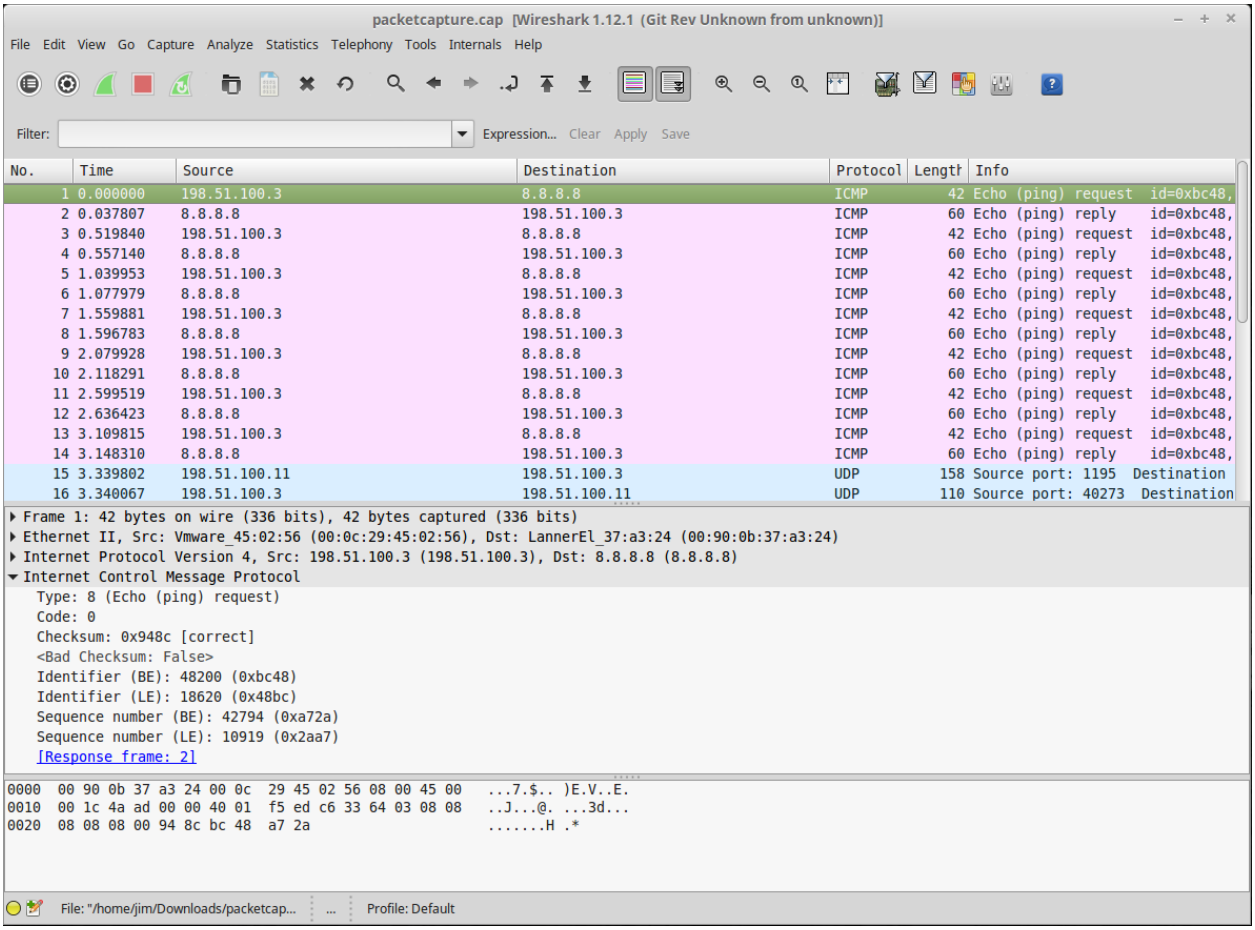

Fig. 1: Wireshark Capture View

the wire, though usually this is safe to ignore. To verify checksums, capture traffic from another system using a network tap or switch span port.

Tip: Span ports can also be setup on bridges in pfSense software, see *Span Port* for more information.

The **Telephony** menu is one example of automated analysis Wireshark can perform. These functions make it easy to diagnose VoIP problems. In the example shown in Figure *Wireshark RTP Analysis*, VoIP traffic was traversing an MPLS WAN circuit with the provider's routers attached to an OPT interface of pfSense software on both sides. A capture from the OPT interface on the initiating end showed no loss, indicating the traffic was being sent to the provider router, but the OPT interface on the opposite end showed considerable packet loss in one direction when multiple simultaneous calls were active. These packet captures helped convince the provider of a problem on their network, and they found and fixed a QoS configuration problem on their side.

Src IP addr	Src port	Dest IP addr	Dest port	SSRC	Payload	Packets	Lost	Max Delta (ms)	Max Jitter (ms)	Mean Jitter (ms)	Pb?
10	13114	192	2244	0x63B69143	ITU-T G.711 PCMU	2103	0 (0.0%)	20.07	0.12	0.01	X
192.1	2244	1	13114	0x6F1D173B	ITU-T G.711 PCMU	1646	477 (22.5%)	179.89	51.24	1.84	X
10	11224	192	2268	0x2247C8D8	ITU-T G.711 PCMU	1321	0 (0.0%)	99.99	5.03	0.07	X
192.1	2268	1	11224	0x6C5B26A1	ITU-T G.711 PCMU	879	460 (34.4%)	340.79	49.96	2.67	X
10	17924	192	2242	0x393CBA89	ITU-T G.711 PCMU	480	0 (0.0%)	20.04	0.15	0.01	X
192.1	2242	1	17924	0x6177246E	ITU-T G.711 PCMU	133	366 (73.3%)	339.79	71.38	9.17	X

Fig. 2: Wireshark RTP Analysis

When viewing a packet capture containing RTP traffic, click **Telephony > RTP > Show all streams** to see this screen.

Remote Real-time Capture

From a UNIX host that has Wireshark available, real-time remote capture is possible by redirecting the output from an SSH session. This has been tested and known to work on FreeBSD and Ubuntu-based Linux distributions.

In order to use this technique, SSH must be enabled on pfSense software and an SSH key is required (see *Secure Shell (SSH)*). The key must first be loaded into `ssh-agent` or generated without a passphrase because the redirection will not allow the user to enter a password or passphrase.

Warning: Using `ssh-agent` is the best practice as any key without a passphrase is highly insecure.

Before attempting this technique, check that the user can connect to the firewall running pfSense software using an SSH key without needing to type the passphrase. The first time the user connects, they are prompted to save the host key, so that must also be done before trying to start Wireshark. `ssh-agent` may also be started from a terminal window or shell like so:

```
# eval ssh-agent
Agent pid 29047
# ssh-add
Enter passphrase for /home/jimp/.ssh/id_rsa:
Identity added: /home/jimp/.ssh/id_rsa (/home/jimp/.ssh/id_rsa)
```

Then start an SSH session as usual:

```
# ssh root@192.168.1.1
The authenticity of host '192.168.1.1 (192.168.1.1)' can't be established.
DSA key fingerprint is 9e:c0:b0:5a:b9:9b:f4:ec:7f:1d:8a:2d:4a:49:01:1b.
```

(continues on next page)

(continued from previous page)

```
Are you sure you want to continue connecting (yes/no)? yes
Warning: Permanently added '192.168.1.1' (DSA) to the list of known hosts.

*** Welcome to pfSense ***
[...]
```

After confirming the SSH connection works, start the remote capture as follows:

```
# wireshark -k -i <(ssh root@192.168.1.1 tcpdump -i igb1 -U -w - not tcp port 22)
```

Replace `192.168.1.1` with the IP address of the firewall running pfSense software. The `not tcp port 22` filter excludes traffic from the SSH session, which will otherwise clog the capture output. The above is written in BASH style syntax, but may work with other shells. Adjust the `tcpdump` arguments for the interface, and add additional expressions. The `-U` and `-w -` are necessary so that it writes the output to `stdout`, and writes each packet as it arrives.

See also:

The Capture Setup/Pipes page on the Wireshark wiki contains other related techniques.

29.9.6 Additional References

This chapter only scratches the surface of the possibilities with packet captures. Packet capturing is a powerful means of troubleshooting network connectivity issues, and troubleshooting skills are greatly improved when the possibilities are learned in more depth. The following links are related resources with deeper knowledge beyond the scope of this documentation.

- Computer Networking: Internet Protocols in Action by Jeanna Matthews
- Tcpdump Filters by Jamie French
- Tcpdump Advanced Filters by Sebastien Wains
- Tcpdump Filters by Marios Iliofotou
- FreeBSD Man Page for tcpdump

Capturing packets is the most effective means of troubleshooting problems with network connectivity. Packet capturing, also known as "sniffing", shows packets "on the wire" coming in and going out of an interface. Observing how traffic is sent and received by the firewall is a great help in narrowing down problems with firewall rules, NAT entries, and other networking issues. pfSense® software includes a GUI page that captures packets using `tcpdump` in an easy manner. The `tcpdump` utility can also be used at the command line in a shell, and alternately, packet capturing can be performed by Wireshark.

29.9.7 Capture frame of reference

Keep in mind that packet captures show exactly what is on the wire. A packet capture is the first process to see traffic when an interface receives a packet and it is the last to see traffic when an interface sends a packet as it flows through the firewall. It sees traffic before firewall rule, NAT rule, and all other processing on the firewall happens for traffic coming into that interface, and after all that processing occurs for traffic leaving that interface. For incoming traffic, captures shows traffic that arrives on an interface on the firewall regardless of whether that traffic will be blocked by the firewall configuration. Figure *Stack Processing Order* illustrates where `tcpdump` packet captures tie into the processing order.

See also:

Ordering of NAT and Firewall Processing explains how the firewall processes connections in greater detail.

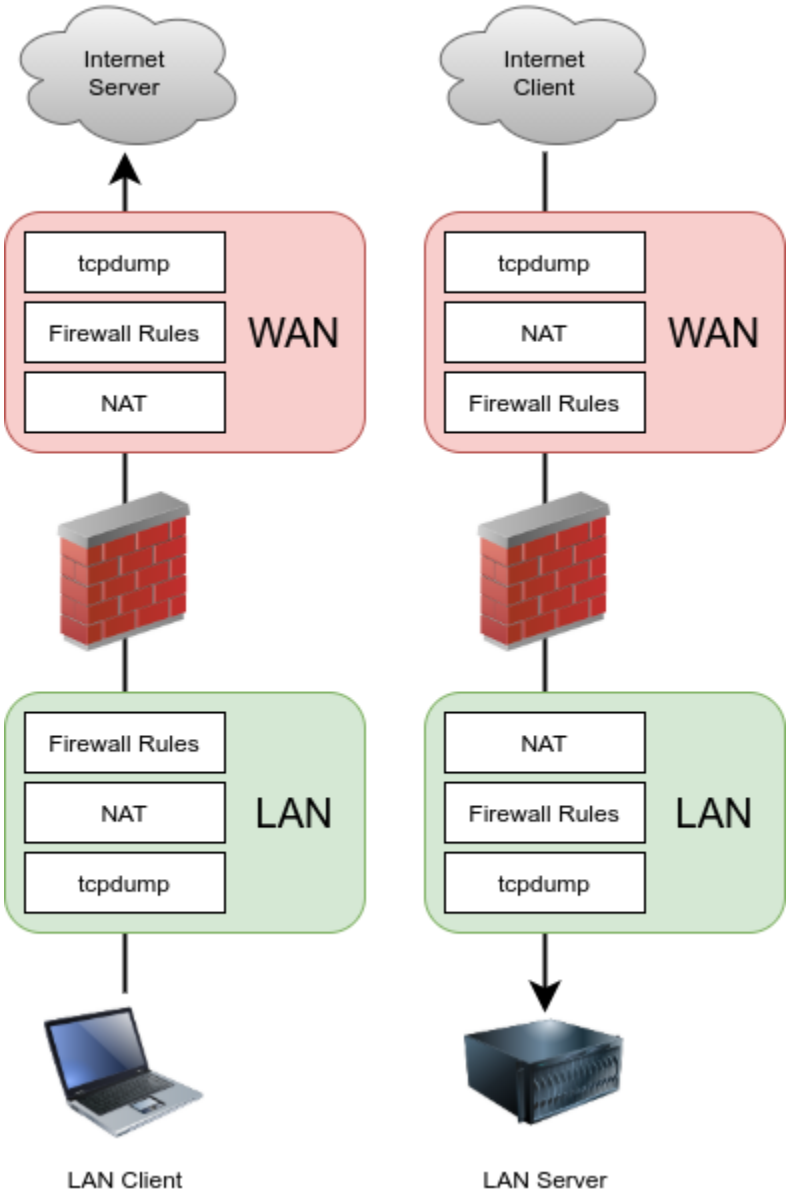

Fig. 3: Stack Processing Order

CHAPTER

THIRTY

PACKAGES

30.1 Package Manager

Packages are managed at **System > Packages** (Figure *Package Listing*). The listings there, presented in alphabetical order, show all of the information about a package.

See also:

pfSense® software uses similar mechanisms to handle base system upgrades. For more information on that process, see *Upgrade Guide*.

Name
The name of the package. This is a unique, and typically short, name used to identify the package. On some packages, the name is a link to more information about the package.

Version
The version number of the package. This number is specific to the package on pfSense, and is not necessarily related to the version of the underlying software (if there is any). The version number is also a link to recent changes for the package.

Description
Longer text describing the package, its purpose, and so on. If the package depends upon other packages, the GUI lists them here denoted by  .

Warning: For security reasons, keep the installed packages to the bare minimum required for a deployment.

See also:

- *Troubleshooting Upgrades* (Packages and Updates use the same backend)
- *Troubleshooting DNS Resolution Issues*
- *Troubleshooting Routes*
- *Troubleshooting a Broken pkg Database*

Fig. 1: Package Listing

30.1.1 Installing Packages

Packages are installed as follows:

- Navigate to **System > Packages**, **Available Packages** tab
- Locate the package to install in the list

Tip: Search for a package by entering a value in the **Search term** box and clicking **Search**

- Click **Install** to the right of the package entry
- Click **Confirm** to proceed with the package installation

After confirming the installation, the GUI displays the package installation screen containing the install progress (Figure *Post-Install Package Screen*).

30.1.2 Reinstalling and Updating Packages

Packages are reinstalled and updated the same way they are installed:

- Navigate to **System > Packages**, **Installed Packages** tab

  The list will look like Figure *Installed Package List*
- Locate the package to reinstall or update in the list

  If there is a newer version available than is installed, the **Package Version** column will state the old and new versions with special highlighted text
- Click to update or to reinstall the package
- Click **Confirm** to proceed with the package reinstallation

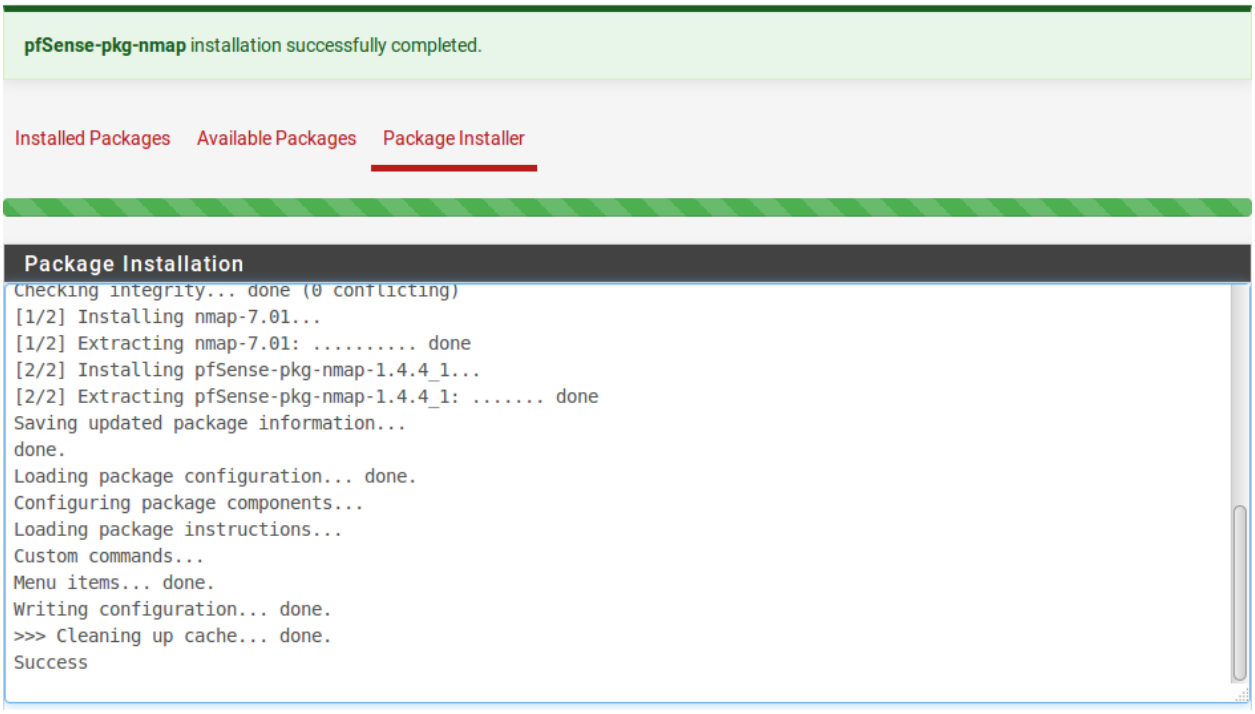

Fig. 2: Post-Install Package Screen

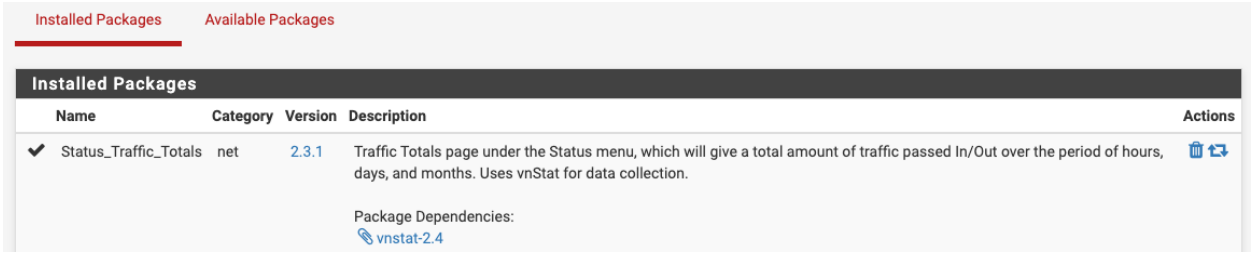

Fig. 3: Installed Package List

30.1.3 Uninstalling Packages

To uninstall a package:

- Navigate to **System > Packages**, **Installed Packages** tab
- Locate the package to uninstall in the list
- Click  to remove the package
- Click  **Confirm** to proceed with the package removal

30.2 Package List

The following packages are available from the pfSense® software package repository.

Warning: Packages availability can change over time. Check **System > Package Manager > Available Packages** for an always up-to-date list of packages.

Tip: The package name in the list below links to documentation for the package, if it exists.

ACME
: The Automated Certificate Management Environment (ACME) package manages certificates from ACME providers such as Let's Encrypt.

  See also:

  ACME package

arping
: Broadcasts a `who-has` ARP packet on the network and prints answers.

  See also:

  Arping Package

arpwatch
: Monitors devices on directly attached networks and notifies when it detects new MAC addresses.

apcupsd
: Controls all APC UPS models. It can monitor and log the current power and battery status, perform automatic shutdown, and can run in network mode to power down other hosts over the network.

aws-wizard **(pfSense Plus Only)**
: AWS VPC VPN Connection Wizard. Automatically creates a VPN tunnel and BGP configuration to communicate with an Amazon AWS VPC.

Avahi
: Facilitates service discovery on a local network via the mDNS/DNS-SD protocol suite. This enables clients to plug a laptop or computer into a network and instantly be able to view other people who they can chat with, find printers to print to or find files being shared. In addition it supports mDNS reflection across LAN segments. Compatible technology is found in Apple macOS (branded Bonjour and sometimes Zeroconf).

See also:

Avahi package

Backup
Backs up and restores arbitrary files and directories.

See also:

Backup Files and Directories with the Backup Package

bandwidthd
Tracks TCP/IP network usage and creates graphs of data consumption for individual IP addresses.

BIND
Provides a GUI for BIND DNS server.

cellular
Provides a GUI for cellular cards (e.g. 3G/4G/LTE), it currently supports certain Huawei models.

Cron
Manages scheduled commands run periodically by the firewall.

Darkstat
A network statistics gatherer that offers bandwidth graphs for interfaces, as well as traffic to/from specific IP addresses. Once installed, it appears under **Services > darkstat**.

filer
Stores custom files persistently in the configuration.

FreeRADIUS
A free implementation of the RADIUS protocol, used for Authentication, Authorization, and Accounting (AAA).

See also:

FreeRADIUS package

FRR
A GUI for the FRR routing daemon which supports BGP, OSPF, and OSPF6.

FTP Client Proxy
A basic FTP client proxy using `ftp-proxy` from FreeBSD.

HAproxy
A reliable, high performance TCP/HTTP(S) load balancer. This package implements the TCP, HTTP and HTTPS balancing features from haproxy and supports ACLs for smart backend switching. A good replacement when relayd is incapable of handling load balancing needs. Requires SSD/HDD.

See also:

HAProxy

HAproxy-devel
The development package for *HAproxy*.

iperf
A tool for testing network throughput, loss, and jitter. Can act as a client or a server.

See also:

iperf package

ipsec-profile-wizard **(pfSense Plus Only)**
Creates IPsec configuration profiles for Apple devices (iOS and macOS) and IPsec import script bundles for Windows devices.

LADVD
Sends and decodes link layer advertisements.

Supports LLDP (Link Layer Discovery Protocol), CDP (Cisco Discovery Protocol), EDP (Extreme Discovery Protocol) and NDP (Nortel Discovery Protocol).

See also:

Using LLDP on pfSense software

LCDproc
LCD display drivers and service.

Lightsquid

> **Danger:** The add-on packages Squid, SquidGuard and Lightsquid are deprecated in pfSense Plus and pfSense CE software due to a large number of unfixed upstream security vulnerabilities. Netgate **STRONGLY** recommends that users uninstall these packages. The packages will no longer function in the next major release of pfSense Plus and pfSense CE software.

A high performance web proxy reporting tool. Includes realtime proxy statistics (SQStat). Requires the **Squid** package. Requires SSD/HDD.

lldpd
Provides support for the 802.1ab Link Layer Discovery Protocol (LLDP), as well as support for several proprietary discovery protocols including Cisco Discovery Protocol (CDP), Extreme Discovery Protocol (EDP), Foundry Discovery Protocol (FDP), and Nortel Discovery Protocol (NDP / SONMP).

Similar to LADVD but a more modern implementation.

Mailreport
Manages periodic e-mail reports containing command output and log file contents.

MTR
An enhanced traceroute replacement. `mtr` combines the functionality of the traceroute and ping programs in a single network diagnostic tool.

Netgate Firmware Upgrade **(pfSense Plus Only)**
Provides a mechanism to update firmware on certain Netgate hardware models. Varies by hardware and may be Coreboot, Blinkboot, or other types of firmware.

net-snmp
The NET-SNMP implementation of SNMP. More extensible than the built-in SNMP daemon (bsnmpd), and supports SNMPv3 authentication and TLS encryption.

nmap
A utility for network exploration and security auditing. It supports scanning to determine active hosts, many port scanning techniques to determine services offered by hosts, version detection to determine what application/service is running on a port, and TCP/IP fingerprinting to identify the OS on remote hosts. It also offers flexible target and port specification, decoy/stealth scanning, SunRPC scanning, and more.

See also:

Nmap package

node_exporter
Prometheus exporter for machine metrics.

Notes
Maintains a list of noteworthy items for the system.

NRPE
Provides a GUI for Nagios NRPE. It execute Nagios plugins on remote hosts and report the results to the main Nagios server.

It also allows Nagios to execute plugins like `check_disk`, `check_procs`, etc. on remote hosts.

ntopng
A network probe that shows network usage in a way similar to what top does for processes. In interactive mode, it displays the network status on the user's terminal. In Web mode it acts as a Web server, creating an HTML dump of the network status. It sports a NetFlow/sFlow emitter/collector, an HTTP-based client interface for creating ntop-centric monitoring applications, and RRD for persistently storing traffic statistics. Requires SSD/HDD.

Network UPS Tools (NUT)
Provides support for monitoring of Uninterruptible Power Supplies. It supports UPS units attached locally via USB or serial, and remote units via the SNMP protocol, the APCUPSD protocol or the NUT protocol.

See also:

Nut package

Open-VM-Tools
A suite of open source utilities which enhance the performance of VMware virtual machine guest operating systems and improve management of virtual machines.

See also:

Open VM Tools package

OpenVPN Client Export
Generates pre-configured OpenVPN configuration files for clients, Windows Client installers with configurations bundled, and macOS Viscosity configuration bundles, among others.

See also:

OpenVPN Client Export Package

OpenVPN Client Import **(pfSense Plus Only)**
Imports a unified OpenVPN client configuration file as exported by an OpenVPN server, allowing clients to be easily configured without creating a client instance and adding settings manually.

pfBlockerNG
Utility for controlling connections through the firewall based on more general criteria than firewall rules (e.g. by country, by domain name, etc). Manages IPv4/v6 List Sources into 'Deny, Permit or Match' formats. GeoIP database by MaxMind Inc. (GeoLite2 Free version). De-Duplication, Suppression, and Reputation enhancements. Provision to download from diverse List formats. Advanced Integration for Proofpoint ET IQRisk IP Reputation Threat Sources. Domain Name (DNSBL) blocking via Unbound DNS Resolver.

See also:

pfBlocker-NG Package

pfBlockerNG-devel
The development version of pfBlockerNG

See also:

pfBlocker-NG Package

PIMD
A GUI for `pimd`, a multicast routing daemon. Primarily replaces the role of the built-in IGMP Proxy function to allow routing multicast traffic across multiple interfaces. Not a replacement for Avahi.

RRD Summary
Gives a total amount of traffic passed In/Out during this and the previous month. Set to be replaced by the **Traffic totals** package.

Service Watchdog
Monitors for stopped services and restarts them.

Shellcmd
Manages boot-time commands.

See also:

Executing Commands at Boot

Siproxd
A proxy for handling multiple SIP devices using a single public IP address.

See also:

Siproxd package

snmptt
SNMP Trap Translator for use with the Net-SNMP. Easy to setup and use.

Snort
An open source network intrusion detection and prevention system (IDS/IPS). Combining the benefits of signature, protocol, and anomaly-based inspection. SSD/HDD is strongly recommended.

See also:

IDS / IPS

Softflowd
A flow-based network traffic analyzer capable of Cisco NetFlow data export. Tracks traffic flows and reports via NetFlow to a collecting host.

See also:

- *Firewall Packet Flow Data* (Plus only)
- *Exporting NetFlow with softflowd*

Squid

> **Danger:** The add-on packages Squid, SquidGuard and Lightsquid are deprecated in pfSense Plus and pfSense CE software due to a large number of unfixed upstream security vulnerabilities. Netgate **STRONGLY** recommends that users uninstall these packages. The packages will no longer function in the next major release of pfSense Plus and pfSense CE software.

A high performance web proxy cache. It combines Squid as a proxy server with its capabilities of acting as a HTTP/HTTPS reverse proxy. It includes an Exchange-Web-Access (OWA) Assistant, SSL filtering and antivirus integration via C-ICAP. SSD/HDD recommended.

See also:

Squid

SquidGuard

> **Danger:** The add-on packages Squid, SquidGuard and Lightsquid are deprecated in pfSense Plus and pfSense CE software due to a large number of unfixed upstream security vulnerabilities. Netgate **STRONGLY** recommends that users uninstall these packages. The packages will no longer function in the next major release of pfSense Plus and pfSense CE software.

A high performance web proxy URL filter. SSD/HDD recommended.

See also:

Configuring the SquidGuard Package

Status Traffic Totals
Calculates a total amount of traffic passed In/Out over the period of hours, days, and months. Uses vnStat for data collection. It shows up in the menu under **Status > Traffic Totals**.

See also:

Status Traffic Totals

Stunnel
A TLS encryption wrapper between a remote client and local or remote servers.

See also:

Stunnel package

Sudo
Delegates privileges to users in the shell so commands can be run as other users, such as `root`.

See also:

Sudo Package

Suricata
A high performance network IDS/IPS and security monitoring engine by OISF. SSD/HDD strongly recommended.

Syslog-ng
A modern syslog server which supports TCP and TLS encryption, among other features.

Note: This service is not intended to replace the default syslog server on the firewall but rather acts as an independent syslog server.

System Patches
Manages custom code patches to be applied and maintained to the system. These can be commits from Github, manual diffs, or loaded from URLs.

See also:

System Patches Package

Telegraf
An agent written in Go for collecting, processing, aggregating, and writing metrics.

TFTPD
GUI for a TFTP server, using the versatile **tftp-hpa** daemon.

Tinc
A Virtual Private Network (VPN) daemon that uses tunneling and encryption to create a secure private network between hosts on the Internet. A single tinc daemon can accept more than one connection at a time, thus making it possible to create larger virtual networks, because some limitations are circumvented. Instead of most other

VPN implementations, tinc encapsulates each network packet in its own UDP packet, instead of encapsulating all into one TCP or even PPP over TCP stream. This results in lower latency, less overhead, and in general better responsiveness and throughput.

UDP Broadcast Relay
A GUI for UDP Broadcast Relay. This program listens for UDP broadcast packets and retransmits them on additional interfaces.

WireGuard®
WireGuard is a new VPN Layer 3 protocol designed for speed and simplicity. It performs nearly as fast as hardware-accelerated IPsec and has only a small number of options in its configuration.

Zabbix-agent
Zabbix Monitoring agent. The agent gathers operational information locally and reports data to Zabbix server for further processing. The agent can also generate alerts in case of failures. Available in multiple versions.

Zabbix-proxy
Zabbix Agent proxy. Collects performance and availability data on behalf of the Zabbix server, lowering the burden on the server. Available in multiple versions.

The package system in pfSense® software provides the ability to extend the functionality of the software without adding bloat and potential security vulnerabilities to the base distribution. To see the packages available for the current firewall platform being utilized, browse to **System > Packages**, on the **Available Packages** tab.

Some packages have been written by the pfSense community, and others directly developed by Netgate. The available packages vary quite widely, and some are more mature and well-maintained than others. There are packages which install and provide a GUI interface for third-party software, such as HAProxy, and others which extend the functionality of pfSense software, like the OpenVPN Client Export Utility package which automatically creates OpenVPN configuration files.

Some other examples of available packages are:

- Additional filtering functionality (pfBlockerNG)
- IDS/IPS software (Snort and Suricata)
- Additional VPN technologies (WireGuard, Tinc)
- Bandwidth monitors that show traffic by IP address such as ntopng, and Darkstat.
- Extra services such as FreeRADIUS and BIND.
- Reverse proxies for HTTP and HTTPS such as HAProxy
- Proxies for other services such as SIP and FTP
- System utilities such as NUT for monitoring a UPS.
- Popular third-party utilities such as nmap, iperf, and arping.
- BGP Routing, OSPF routing, Cron editing, Zabbix agent, and many others.
- Features that were formerly in the base system but were moved to packages, such as RIP (routed)

As of this writing there are more than 60 different packages available; too many to cover them all in this documentation! The full list of packages that can be installed on a particular system is available from within the GUI at **System > Packages** on the **Available Packages** tab.

The packages screen takes longer to load than other pages in the web interface because the firewall fetches package information from the Netgate package repository servers before the page is rendered to provide the most up-to-date information. If the firewall does not have a functional Internet connection including DNS resolution, this will fail. This is usually caused by a missing or incorrect DNS server configuration, or a missing default gateway.

30.3 ACME package

Let's Encrypt is an open, free, and completely automated Certificate Authority from the non-profit Internet Security Research Group (ISRG). The goal of Let's Encrypt is to encrypt the web by removing the cost barrier and some of the technical barriers that discourage server administrators and organizations from obtaining certificates for use on Internet servers, primarily web servers. Most browsers trust certificates from Let's Encrypt. These certificates can be used for web servers (HTTPS), SMTP servers, IMAP/POP3 servers, and other similar roles which utilize the same type of certificates.

The ACME Package for pfSense® software interfaces with Let's Encrypt to handle the certificate generation, validation, and renewal processes.

Certificates from Let's Encrypt are domain validated, and this validation ensures that the system requesting the certificate has authority over the domain in question. This validation can be performed in a number of ways, such as by proving ownership of the domain's DNS records or hosting a file on a web server for the domain.

By using a certificate from Let's Encrypt for a web server, including a firewall running pfSense software, the browser will trust the certificate and show a green check mark, padlock, or similar indication. The connection will be encrypted without the need for a client to manually trust an invalid or self-signed certificate.

Let's Encrypt certificates are valid for a period of 90 days, so they must be renewed periodically. The ACME package automates this renewal by using a cron job to check once per day to see if a certificate needs to be renewed.

30.3.1 ACME Overview

Rate Limits

Let's Encrypt enforces rate limitations when using the production validation system, such as:

- Five validation failures per account, per hostname, per hour
- Each certificate may have at most 100 SAN entries
- Only 50 certificates may be created per domain per week

A testing validation system exists for developers who are programming clients or administrators testing their settings. The test system has higher limits, which aid testing and development, but the test system does not produce certificates which are trusted publicly.

Security Limitations

When validating using a method such as webroot or standalone the service must be available to the Internet on its standard port: 80 for HTTP or 443 for TLS-ALPN. This is a security limitation to prevent a user from running an alternate web server on a high- numbered port and obtaining a certificate for a server they do not normally control.

Validation Process

When creating a certificate, one or more fully qualified domain names (FQDNs) are listed on the certificate in the SAN list. Let's Encrypt will query each of these domain names in DNS in different ways depending on the validation method.

When a validation method starts, the client obtains an authorization value from the server (authz).

For DNS-based methods, Let's Encrypt checks for a TXT record in the form of `_acme-challenge.<domain name>` which must contain the authorization value. This proves that the person or system requesting the certificate controls DNS records for the domain.

For File-based methods such as webroot or standalone, Let's Encrypt connects to an IP address obtained by resolving the A record for the FQDN and requests a file from the web server at `.well-known/acme-challenge/` underneath the webroot directory. This file contains the authorization value. This proves that the person or system requesting the certificate controls web server for the domain name.

30.3.2 Obtaining a Certificate

These instructions cover the general process of obtaining a certificate. Specific settings will vary by deployment, and each section below links to the settings for each area.

Generate an Account Key

Before a certificate can be created by the firewall, the firewall must first obtain an account key. This key is typically unique for each server, but can be shared.

For users unfamiliar with Let's Encrypt, the first key should be for the staging system which has no rate limits but is not valid for public use. Once a certificate is successfully issued by the staging system, create an account key for the production system and then issue the certificate again using that key.

To create and register an account key:

- Navigate to **Services > ACME Certificates**, **Account Keys** tab
- Click  **Add**
- Fill in the info as described in *Account Key Settings*
- Click  **Create new account key**
- Click  **Register ACME account key**
- Click **Save**

Create a certificate

The next step is to create a certificate entry.

- Navigate to **Services > ACME Certificates**, **Certificates** tab
- Click  **Add**
- Fill in the info as described in *Certificate Settings*
- Add one or more **Domain SAN List entries** (*Certificate Settings*) with appropriate validation settings (*Validation Methods*)
- Add one or more **Actions list** entries (*Certificate Settings*)
- Click **Save**

Configure General Settings

The last step is to enable at least the **Cron Entry** to ensure that the ACME package will automatically renew certificates before they expire. See *General Settings* for detailed descriptions of the options.

- Navigate to **Services > ACME Certificates**, **General Settings** tab
- Check **Cron Entry**
- Check **Write Certificates** (optional)
- Click **Save**

30.3.3 ACME Package Settings

These sections describe the settings for each tab in the ACME package.

Account Key Settings

An ACME account key has the following settings:

Name
A short name for the key

Description
A longer string describing the key

ACME Server
The ACME server to which this key will be registered by the package.

Currently supported options are:

Let's Encrypt Staging ACMEv2
Use this server when testing the certificate validation process. Does not produce publicly trusted certificates.

Let's Encrypt Production ACMEv2
Use this server for trusted production certificates.

BuyPass Production ACMEv2
An alternative service for ACME certificates

E-Mail Address
An e-mail address which Let's Encrypt will use to send certificate expiration notices if certificates are not renewed in a timely manner.

Account Key

The RSA private key for this entry. To create a new key, click  Create new account key.

Certificate Settings

Certificate entries have the following settings:

Name
A short name for the certificate

Description
A longer string describing the certificate

Status
Whether or not this entry is active

Active
This entry will be processed manually and by the Cron job (*General Settings*)

Disabled
This entry will be ignored

Acme Account
The account key ACME will use when requesting the certificate (see *Generate an Account Key*)

Private Key
The key length of the private key for this certificate. May be either RSA or ECDSA in several predefined sizes. Select *Custom* to manually enter a private key generated elsewhere

2048-bit RSA is an acceptable default choice, but larger keys are more secure

OCSP Must Staple
When set, ACME will configure the certificate request for OCSP Stapling

> **Warning:** Do not enable this option unless all consumers of the certificate support OCSP Stapling.

Domain SAN List
A list of all domain names which will be included in this certificate as Subject Alternative Name (SAN) entries.

Note: A certificate can contain up to 100 SAN entries, and they can use the same or different update methods. Each SAN must be individually validated by Let's Encrypt before a certificate will be issued.

Mode
Whether or not this SAN is active in the certificate

Domain Name
The domain name for a SAN entry in this certificate (e.g. `www.example.com`)

Method
The method used by ACME to validate ownership of this domain. Method settings are described in (*Validation Methods*)

Click  **Add** for additional SAN entries

DNS Providers also have some common settings which appear for all types:

DNS Alias
An alternative domain name used by the validation process. Instead of updating the DNS record for **Domain Name** directly, the package uses this domain name is used instead. See *DNS Alias Mode* for details.

DNS Alias Mode
When set, controls whether or not the DNS alias mode used is Challenge Alias (Unchecked, Default) or Domain Alias (Checked). See *DNS Alias Mode* for details.

DNS-Sleep
The amount of time the ACME validation process will wait after making DNS changes before attempting to validate. Some DNS services take a few minutes to propagate entries after making backend changes.

The default settings are typically sufficient, but slower providers may require a longer sleep time.

Actions List
Commands to run after the package renews a certificate.

Mode
Whether or not this action is active

Command
Full path to command and arguments, service name, or name of script

Method
Defines how the **Command** is executed by the package

Shell Command
The **Command** is a full path to a shell command and its arguments

PHP Command Script
The **Command** value is run as PHP code

Restart Local Service
The name of a local service to restart

Restart Remote Service
The name of a remote service to restart via XMLRPC. This utilizes the system *XMLRPC sync configuration*

The GUI includes several examples of common actions

Certificate Renewal After
When the package will attempt a renewal for the certificate. Default is `60` days (2 months). Certificates are valid for a maximum of `90` days.

Validation Methods

ACME providers can validate by checking the contents of a TXT record in DNS, or by fetching a file in a known location from a web server.

The ACME package support validating directly with standalone methods or webroot, but those options are less secure than DNS-based options. The ACME package also supports numerous methods to update various DNS providers. Wildcard certificates can only be obtained through DNS-based methods (*Wildcard Certificates*)

Tip: DNS-based update methods are the best practice as they do not require external inbound access. They can be used for internal systems that do not allow or cannot receive Internet traffic.

The following list is only a portion of the validation methods supported by the package.

See also:

DNS methods also have a common option for DNS Alias mode. See *Certificate Settings* and *DNS Alias Mode* for details.

nsupdate

The `nsupdate` method uses RFC 2136 style DNS updates to populate a TXT record in DNS.

Before starting, an appropriate DNS key and settings must be in place in the DNS infrastructure for the domain to allow the host to update a TXT DNS record for `_acme-challenge.<domain name>`.

This method has the following options:

Server
: The IP address or hostname of the DNS server to which the client sends updates

Key Name
: The name of the update key

  Leave this blank unless it is different than `_acme-challenge.<domain name>`

Key Algorithm
: The algorithm used for the key, which must match the key and the server

Key
: The update key for this record

Zone
: Sets the zone name the package sends to the DNS server in the update request

DNS-Manual

The manual DNS method can be utilized when a firewall cannot receive inbound traffic and it does not have access to any automatic DNS-based method.

The **manual** in the name indicates that the process **must be performed by hand** both initially and when it is time to renew the certificate. The firewall obtains the authorization value and then the TXT record must be manually created or updated with this value.

Warning: Avoid using this method unless no other method is available.

To use this method:

- Add an entry to the **Domain SAN list**
- **Mode**: Enabled
- Enter domain name (e.g. `myhost.example.com`)
- Set **Method** to *DNS-Manual*
- Click **Save**
- Click **Issue**
- Locate the record info in the output:

```
[Mon Feb 6 14:49:23 EST 2017] Add the following TXT record:
[Mon Feb 6 14:49:23 EST 2017] Domain: '_acme-challenge.www.example.com'
[Mon Feb 6 14:49:23 EST 2017] TXT value: 'xPrykHSri5epT5yrJJWyY536Z1T51r_Ef4LkWJry-
↪iw'
[Mon Feb 6 14:49:23 EST 2017] Please be aware that you prepend _acme-challenge.␣
↪before your domain
[Mon Feb 6 14:49:23 EST 2017] so the resulting subdomain will be: _acme-challenge.
↪www.example.com
[Mon Feb 6 14:49:23 EST 2017] Please add the TXT records to the domains, and retry␣
↪again.
```

- Add or update the TXT record in the domain's DNS server for `_acme-challenge.<domain name>` with the TXT value from the output
- Wait approximately 2 minutes, or longer, for DNS to propagate
- Click **Renew**

Namecheap API

For certain accounts with Namecheap, API access may be obtained that allows remote manipulation of DNS records. This can be used with the ACME package to validate certificates for domains with DNS hosted at Namecheap using their BasicDNS servers.

> **Warning:** The Namecheap DNS API requires that the client read all records and then write them all back when making any change. This is potentially dangerous. Take a backup of all DNS records on the domain before attempting to use the API.

The first step is to request API access:

- Login to a Namecheap account
- Navigate to **Profile > Tools** under the account
- Look for **Namecheap API Access** under **Business & Dev Tools**
- If the status does not say **On**, then click **Manage** and change the slider to **On**.

> **Note:** API access must be approved by Namecheap. There are qualifications to meet, such as a specific number of domains or a balance on the account. Check the Namecheap API documentation for more information. The

process is documented as taking 2 days, but may take longer. If API access is not enabled after several days, contact Namecheap support.

Once the API is enabled, then perform the following steps:

- Login to a Namecheap account
- Navigate to **Profile > Tools** under the account
- Look for **Namecheap API Access** under **Business & Dev Tools**
- Click **Manage**
- Note the API key for use in the ACME package
- Click **Edit** and add whitelisted IP addresses that can contact the API using this API key.

Now setup the account in the ACME package:

- Add an entry to the **Domain SAN list**
- **Mode**: Enabled
- Enter domain name (e.g. `myhost.example.com`)
- Set **Method** to *DNS-Namecheap*
- Click + to expand the method-specific settings
- Fill in the info

  API Key
  The API Key displayed in the Namecheap API Access manager, as described previously.

  Username
  The Namecheap account username associated with the API Key.
- Ensure the other options are set properly, per *Create a certificate*.
- Click **Save**
- Click **Issue/Renew**

Other DNS Methods

The package contains several additional DNS-based methods for other providers. These work similar to the nsupdate method above, but have configuration values specific to each provider. Contact the DNS provider or server administrator to obtain the necessary settings or credentials.

FTP Webroot

The **FTP webroot** method is useful when the firewall is performing NAT (port forward or 1:1) or reverse proxy duty for handling traffic for the domain. The firewall can use SFTP or FTPS to store the domain validation files on a web server behind the firewall so it does not have to host the files itself.

This method has the following options:

Server
The server where the package will send the challenge response files, e.g. `sftp://x.x.x.x`

Note: This method supports `sftp://` and `ftps://` servers.

Username/password
Credentials for the SFTP/FTPS account

Folder
Full path to the target directory including `/.well-known/acme-challenge` at the end

Warning: Make sure the specified user has write permissions to the directory!

Webroot Local Folder

This method works similar to FTP Webroot but with the files hosted on the firewall itself. This method cannot be utilized by the GUI web server as that would mean exposing the GUI to the Internet, which is a major security issue.

This method can, however, be used in conjunction with the HAProxy package to host the files on the firewall itself in some circumstances. See https://forum.netgate.com/post/677786 for details.

Standalone (HTTP/TLS-ALPN)

The **Standalone** methods for HTTP and TLS-ALPN run a small web server natively that is active only while the validation process is running. The TLS-ALPN method is more secure as it encrypts communication with the ACME provider.

Warning: These methods are not best practices as they expose a service on the firewall to the Internet. Only use these methods if no other method is available.

Warning: The service **must** be accessible using port `80` (HTTP) or `443` (TLS-ALPN)!

If the firewall is using port `80` (HTTP) or `443` (TLS-ALPN) for another service, such as the firewall GUI or its redirect, then this method may not be viable. If the service on the port is public, then it cannot be used. If the service is private, then it may be possible to relocate the existing service or bind the update method to an alternate port, then port forward on the WAN interface.

A firewall rule must allow traffic to the target port at all times, it cannot be automatically enabled and disabled in the current package.

Note: The standalone binding should only be changed if the port is forwarded via NAT to a different port (e.g. 80 forwarded to 8080)

Standalone HTTP

Standalone HTTP Server has the following options:

Port
Port to which the package will bind listening for HTTP requests with a stand-alone server. Must be `80` or port `80` must be forwarded to this port on the default gateway WAN.

> **Warning:** If port `80` is used by the standalone service, the GUI redirect must be disabled on **System > Advanced** using the **Disable webConfigurator redirect rule** option. If the redirect is active when standalone mode attempts to use the port, it will print an error message stating that `socat` is unable to bind to the port.

Bind to IPv6 instead of IPv4
If the domain name for the firewall has both an A and AAAA DNS record, check this option so that validation can occur over IPv6.

Standalone TLS-ALPN

Standalone TLS-ALPN Server has the following options:

Port
Port to which the package will bind listening for TLS-ALPN requests with a stand-alone server. Must be `443` or port `443` must be forwarded to this port on the default gateway WAN.

> **Warning:** If port `443` is used by the standalone service, the GUI must be moved to an alternate port on **System > Advanced** using the **TCP Port** option for the GUI. If the redirect is active when standalone mode attempts to use the port, the standalone service will fail.

DNS Alias Mode

DNS Alias mode allows a DNS update method to update an alternate domain name instead of updating a record for the domain name directly.

If the main DNS provider does not support updating TXT records, a CNAME record can point to an alternative domain which does.

Challenge Alias

In Challenge Alias mode (default), the ACME package still automatically prepends `_acme-challenge.` to both the **Domain Name** and the **DNS Alias** domain.

In the certificate entry, set:

Domain Name
`company.example` which does not support automatic updates

DNS Alias Domain
`dynamic.example` which is the alternative domain in a dynamic zone

DNS Domain Alias mode
Leave unchecked

On the DNS server, add a CNAME record pointing to the **DNS Alias** hostname with `_acme-challenge.` prepended:

```
_acme-challenge.company.example      IN      CNAME   _acme-challenge.dynamic.example.
```

When updating, the package will update `_acme-challenge.dynamic.example` in DNS while sending `company.example` in the certificate request to the ACME provider.

Domain Alias

Domain Alias mode works similar to Challenge Alias mode but it **does not** prepend `_acme-challenge.` to the **DNS Alias** domain. Some administrators prefer this when using many hostnames in a single dynamic zone, or for working around limitations in DNS providers or platforms.

In the certificate entry, set:

Domain Name
`company.example` which does not support automatic updates

DNS Alias Domain
`checkme.dynamic.example` which is the alternative domain in a dynamic zone

DNS Domain Alias mode
Checked

On the DNS server, add a CNAME record pointing directly to the **DNS Alias** hostname:

```
_acme-challenge.company.example      IN      CNAME   checkme.dynamic.example.
```

When updating, the package will update `checkme.dynamic.example` in DNS while sending `company.example` in the certificate request to the ACME provider.

General Settings

These settings control the general behavior of the ACME package and are not specific to any single certificate or key.

Cron Entry
A checkbox which enables the ACME renewal cron job. When set, the ACME package will check all certificates each night and if any are up for renewal, it will attempt to renew them.

Write Certificates
When set, the ACME package will write the certificate files out in `/conf/acme`. From there, other scripts or processes which do not support GUI integration can pick up the certificate.

30.3.4 Wildcard Certificates

Let's Encrypt supports wildcard certificates (e.g. `*.example.com`) with their ACMEv2 infrastructure. A wildcard certificate will work for any hostname inside a given domain, which helps with handling certificates for multiple domains.

Note: Unrelated to ACME, but wildcard certificates in general: A wildcard only helps for **one level** of subdomains. For example, `*.example.com` will work for `host.example.com` but will NOT work for `host.sub.example.com`. If hosts are structured in this way, a wildcard certificate is required for each sub zone, e.g. `*.sub.example.com`.

Wildcard validation **requires a DNS-based method** and works similar to validating a regular domain. For example, to get a certificate for `*.example.com`, the package updates a TXT record in DNS the same as it would for `example.com`, which means the DNS record (and potentially key name) would be for `_acme-challenge.example.com`.

To obtain a wildcard certificate, follow the same procedures as other DNS validation methods, with the following differences:

- The **Account Key** must be registered with an ACME v2 server (staging for testing, or production)
- The **Domain SAN list** should contain entries for the base domain (e.g. `example.com` and the wildcard version of the same domain (e.g. `*.example.com`. The settings will be the same for both entries.
- For *DNS-NSupdate / RFC 2136*: Set the **Key Name** to the base domain (`example.com`) for both entries.

30.4 Arping Package

arping is a utility to test the reachability and responsiveness of hosts to ARP. It is effectively like ICMP ping, except using ARP instead. This is beneficial in circumstances where the host has a firewall enabled (every host even firewalled will respond to ARP), or there is no layer 3 connectivity on the IP subnet of the host and hence cannot ping, but do have layer 2 connectivity.

The **arping** package can be very useful when trying to pick an unused IP address for a subnet to which there is not yet a route or link, but is connected at Layer 2.

See also:

Visit the arping website for more information.

30.4.1 Package Support

This package is currently supported by Netgate TAC to those with an active support subscription.

30.5 Avahi package

The Avahi package used in pfSense® software is a system which facilitates service discovery on a local network. This means that a laptop or computer may be connected into a network and instantly be able to view other people to chat with, find printers to print to or find files being shared.

This kind of technology is already found in Apple macOS (branded Rendezvous, Bonjour, and sometimes Zeroconf) and is very convenient. Avahi is mainly based on Lennart Poettering's flexmdns mDNS implementation for Linux which has been discontinued in favour of Avahi.

30.5.1 Known issues

See also:

The pfSense software issue tracker contains a list of known issues with this package.

30.5.2 Package Support

This package is currently supported by Netgate TAC to those with an active support subscription.

30.6 AWS VPC Wizard

This guide explains how to use the AWS VPC Wizard, available in pfSense Plus software, to simplify the configuration of a VPN to a remote VPC. The administrator is asked for the minimum amount of basic information required to establish the VPN. The configurations, both on the AWS VPC side and on the pfSense Plus software side are then automatically created. When the wizard is finished executing, a functioning VPN connection to a VPC should be established.

30.6.1 AWS Access Keys

In order to connect to the AWS API to make certain required configuration changes, the AWS VPC Wizard requires Access Keys to retrieve and modify VPC configurations.

See also:

Find more information about AWS Security Credential, including Access Keys by reading AWS Security Credentials.

Access keys consist of two parts:

1. An access key ID
    - For example, `AKIAIOSFODNN7EXAMPLE`.
2. A secret access key
    - For example, `wJalrXUtnFEMI/K7MDENG/bPxRfiCYEXAMPLEKEY`.

Access keys are like a username/password and needed for programmatic requests to AWS, including the AWS VPC Wizard. Use both the access key ID and secret access key together to authenticate requests.

Important: Manage access keys as securely as a user name and password.

Managing Access Keys

To create, modify, or delete IAM user access keys, do the following:

1. Sign in to the IAM console.
2. In the navigation bar on the upper right, choose a user name, and then choose **My Security Credentials**.
3. On the **AWS IAM Credentials** tab, in the **Access keys for CLI, SDK, and API access** section, choose **Create access key**.
4. Choose **Download .csv file** to save the access key ID and secret access key to a .csv file on the client computer. Store the file in a secure location. There is no access to the secret access key again after this dialog box closes. After the .csv file has been downloaded, choose **Close**. When an access key is created, the key pair is active by default, and the pair can be used right away.
    - To disable an active access key, choose **Make inactive**.
    - To reenable an inactive access key, choose **Make active**.

- To delete an access key, choose its **X** button at the far right of the row. Then choose **Delete** to confirm. When an access key is deleted, it's gone forever and cannot be retrieved. However, new keys can always be created.

To create, modify, or delete another IAM user's access keys, do the following:

1. Sign in to the IAM console.
2. In the navigation pane, choose **Users**.
3. Choose the name of the user whose access keys to manage, and then choose the **Security credentials** tab.
4. In the **Access keys** section, choose **Create access key**.
5. Choose **Download .csv file** to save the access key ID and secret access key to a CSV file on your computer.

Rotating Access Keys

As a security best practice, regularly rotate (change) IAM user access keys. Rotating access keys can be done from the AWS Management Console.

To rotate access keys for an IAM user without interrupting the applications (console), create a second access key while the first access key is still active:

1. Sign in to the IAM console.
2. In the navigation pane, choose **Users**.
3. Choose the name of the user whose access keys to manage, and then choose the **Security credentials** tab.
4. In the **Access keys** section, choose **Create access key**.
5. Choose **Download .csv file** to save the access key ID and secret access key to a CSV file on the client computer.
6. The new access key is active by default. At this point, the user has two active access keys.

After waiting some period of time to ensure that all applications and tools have been updated, delete the first access key:

1. Sign in to the IAM console.
2. In the navigation pane, choose **Users**.
3. Choose the name of the user whose access keys to manage, and then choose the **Security credentials** tab.
4. Locate the access key to delete and choose its **X** button at the far right of the row. Then choose **Delete** to confirm.

Determining When Access Keys Need Rotating

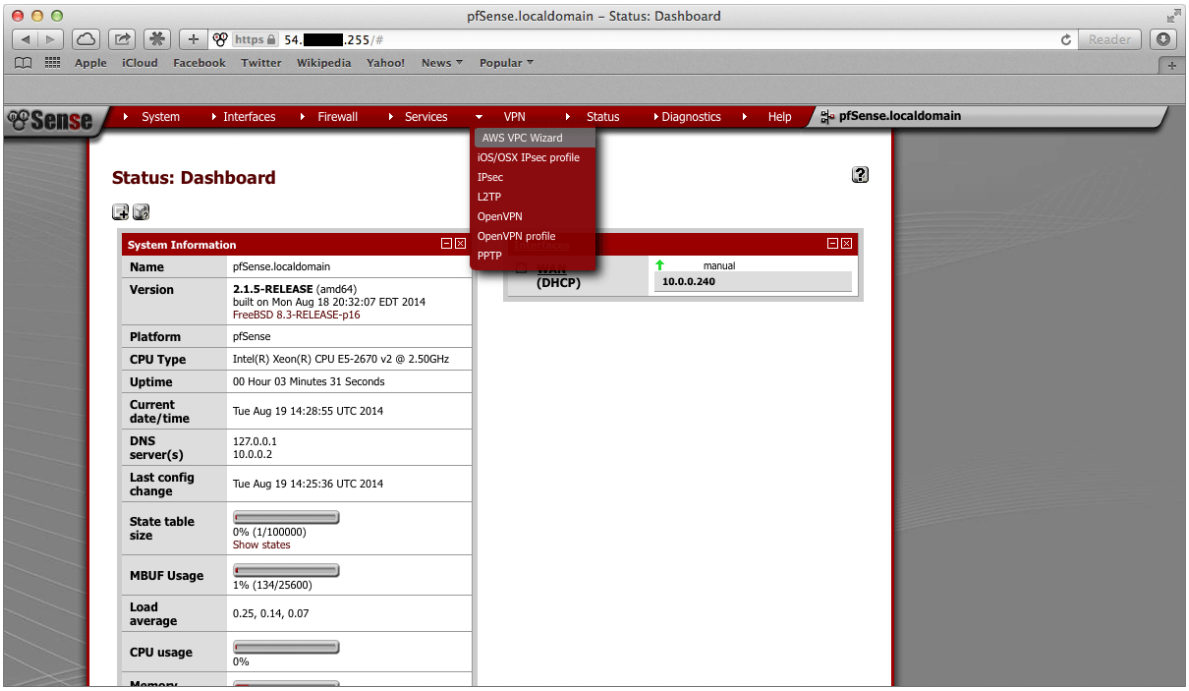
To determine when access keys need rotating (console), do the following:

1. Sign in to the IAM console.
2. In the navigation pane, choose **Users**.
3. If necessary, add the **Access key age** column to the users table by completing the following steps:
    1. Above the table on the far right, click the settings icon.
    2. In **Manage columns**, select **Access key age**.
    3. Choose **Close** to return to the list of users.

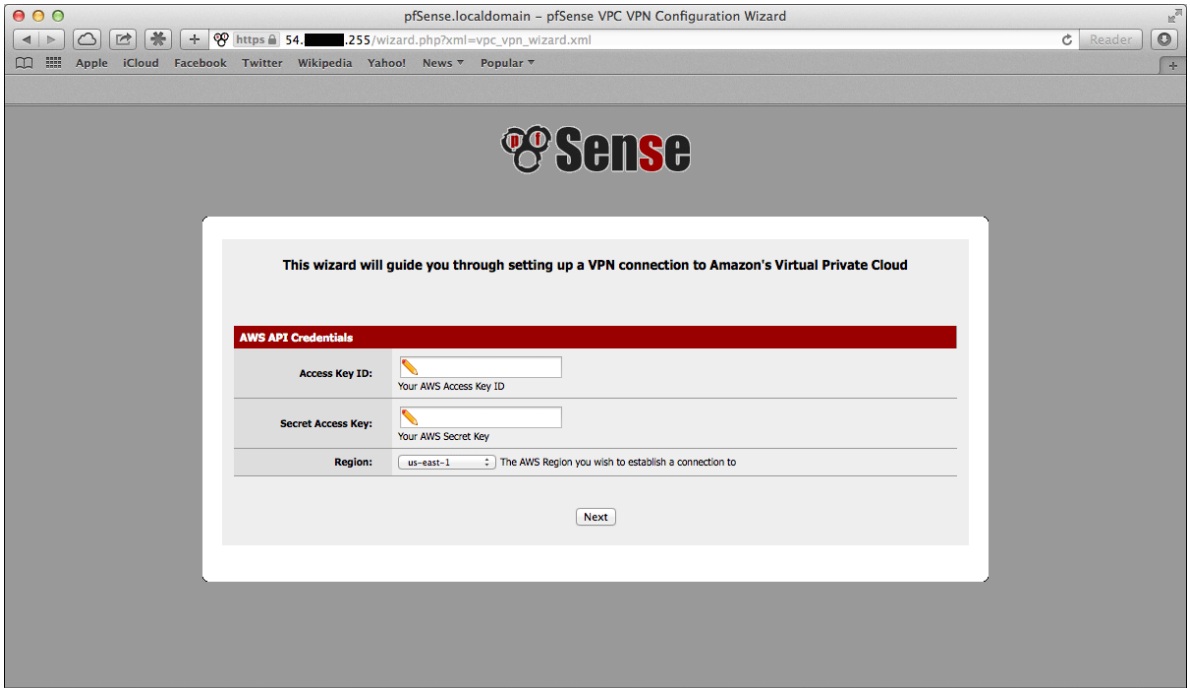
4. The **Access key age** column shows the number of days since the oldest active access key was created. Use this information to find users with access keys that need rotating. The column displays **None** for users with no access key.

30.6.2 Using the Wizard

1. Gather the **AWS Access Key ID** and **Secret Key**.
2. Navigate to **VPN > AWS VPC Wizard** in the main menu in the Netgate® pfSense Plus WebGUI.



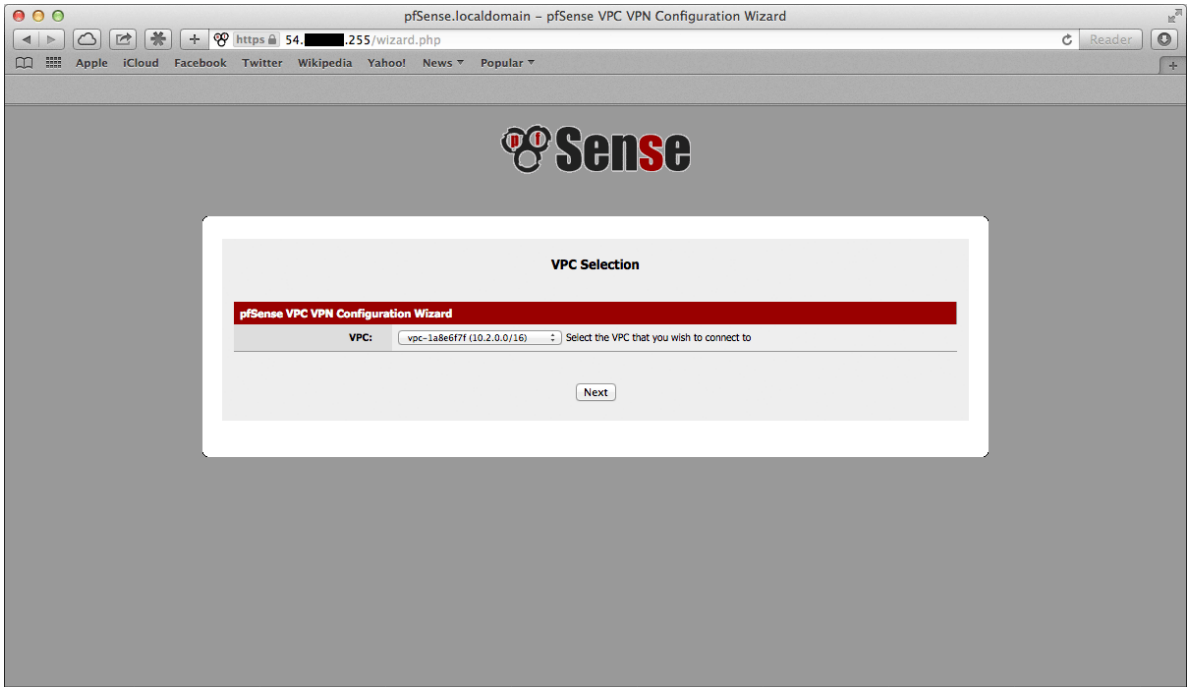
3. The first screen of the wizard prompts for the AWS Credentials. Enter the **Access Key ID** and **Secret Access Key** in the appropriate text fields and select the **Region** to connect to in the dropdown menu, then click **Next**.



The wizard will then query the AWS API using those credentials to find which VPC's exist in the selected region. If the credentials were rejected, an error message will be displayed and return to the first screen.

4. The next screen will prompt to select from the available VPC's in the selected region. Select the one to connect to from the dropdown menu. The wizard will not create a new VPC, it will only connect to an existing VPC.

   Click **Next** after selecting the desired VPC.

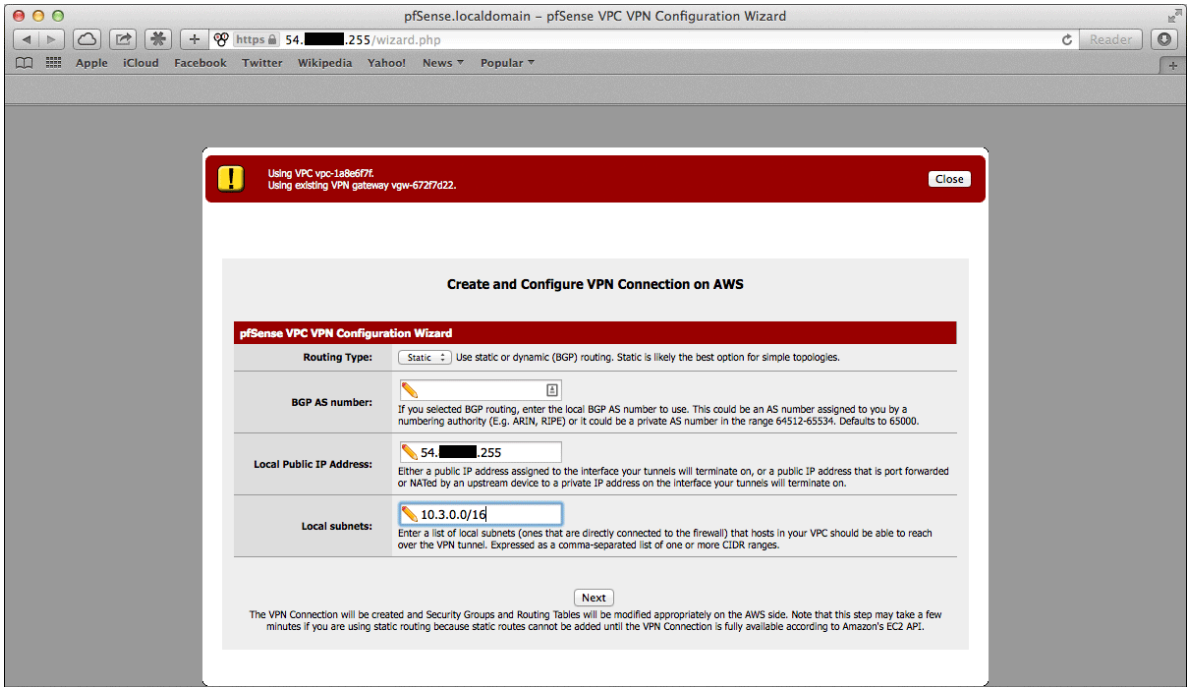


Note: If the desired VPC's to connect to isn't available, create one via the **AWS Management Console** and try

again.

The wizard will then query the AWS API to check whether there is a VPN Gateway attached to the selected VPC. If none exists, one will be created via the API. Then the next screen will be displayed.

5. On the next screen, specify routing and network data.



A description of what should be entered for each of these fields follows.

Routing Type
: AWS offers either **static** routing or **BGP** routing. Select the appropriate type from the dropdown menu. If unsure, static routing is likely to be adequate.

BGP AS Number
: If static routing was chosen, leave this field blank. Otherwise it is possible to specify an AS number to use. If left blank, the value will default to `65000`.

Local Public IP Address
: On an AWS Netgate appliance instance, this should be the public IP address of the Elastic IP associated with the instance. If configuring a hardware device running pfSense Plus, this could be the public address assigned to the WAN (or other) interface of the device.

Local subnets
: The subnets connected to the pfSense Plus instance that should be routed over the tunnel from hosts in the remote VPC. As an example, if connecting a pfSense Plus instance to a remote VPC in the AWS **us-east-1** region, enter the subnets (or a single subnet) that are local to the pfSense Plus instance and when hosts in your VPC in **us-east-1** attempted to reach addresses within those subnets, the traffic will be sent through the VPN tunnel that is being configured.

Note: When selecting static routing as the routing type, there will be a delay that is typically between 2-5 minutes before the next screen is displayed. This is because static routes must be added to the VPN Connection via the AWS API. This operation fails until the VPN Connection reaches the "available" state. This can take a few minutes to occur.

Click **Next** when done.

The wizard will then query the AWS API to find whether a Customer Gateway is configured with the selected Public IP Address. If none exists, one will be created. If one already exists, the ID will be retrieved and it will be used.

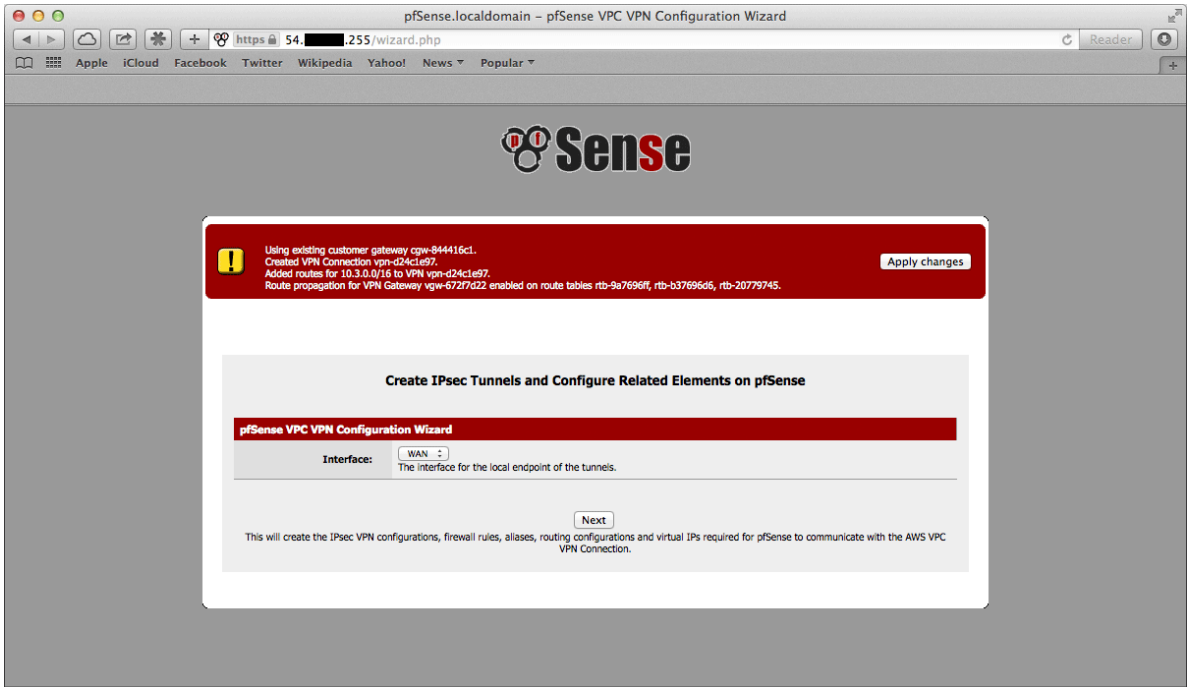
The wizard will then query the AWS API to see if a VPC Connection already exists that matches the data entered. If one exists, it will be used. Otherwise one will be created.

If static routing was selected, static routes will be added to the VPN Connection for the Local subnets entered.

Route propagation will be enabled for the VPN Gateway in each of the Route Tables that are associated with the VPC. All of these configurations are carried out in the AWS API, nothing has been changed in the pfSense Plus VPN configurations yet.

> **Warning:** **Important Note on Billing:** Once this step is carried out and the VPN Connection is created, AWS will start billing the AWS account the hourly rate for a VPN Connection. This is $0.05 as of this writing, and that is a charge that goes entirely to AWS itself. They will do this until the VPN Connection is deleted via the **VPC Management Console**.
>
> Nothing in pfSense Plus will ever cause AWS to stop billing for this VPN Connection. Whether it works or not, whether the pfSense Plus instance is up or down, whether the IPsec tunnels have been deleted or reconfigured, AWS will continue to bill the hourly fee for a VPN Connection if the creation of it succeeds until it is deleted through their web interface.
>
> The wizard helps establish an initial configuration that works and configures the appropriate elements in AWS's API to facilitate this.
>
> The account holder is responsible for understanding billable charges and disabling any functions, including VPN Connections, that are no longer necessary.

6. If the operations of the previous step succeeded, the next screen will appear.



Select an **Interface** to act as the local endpoint of the VPN tunnels that will be created. In most cases, this should

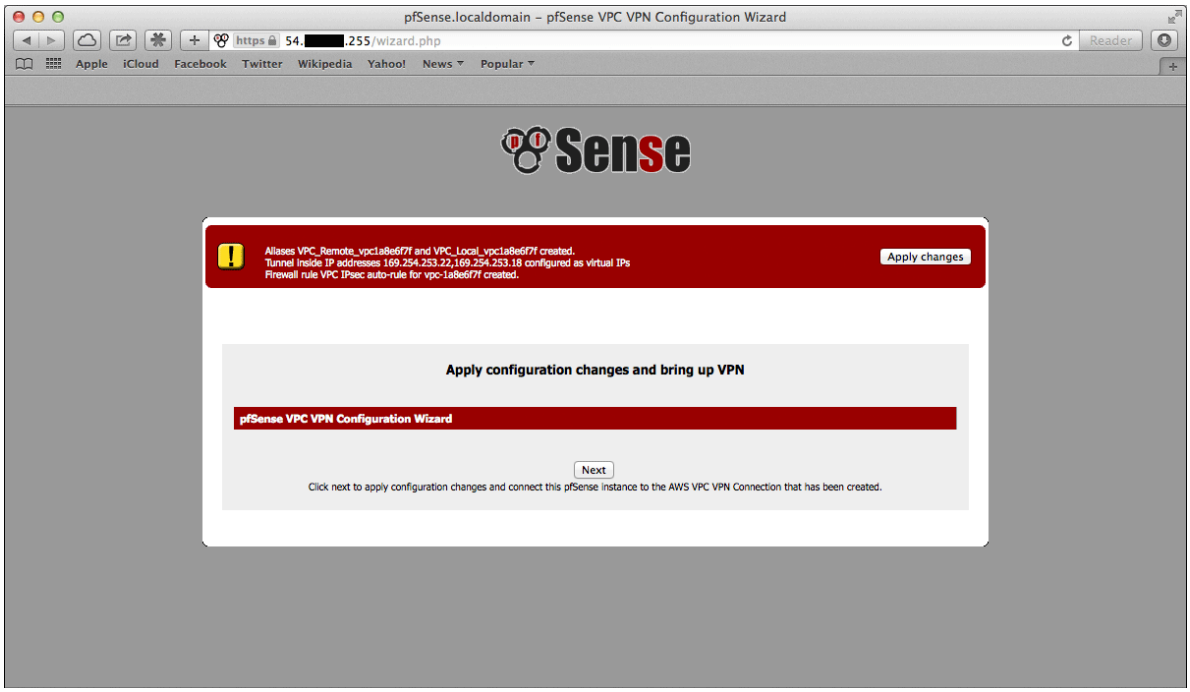
be the WAN interface. It should generally be whatever interface is associated with the Local Public IP Address entered in the previous step.

On an AWS Netgate pfSense Plus instance, this will be whatever interface the Elastic IP is associated with. On a hardware device running pfSense Plus that has the Local Public IP Address directly configured on an interface, this will be the interface that the Local Public IP Address is configured on.

After clicking **Next**, the wizard will configure the VPN and associated settings within pfSense Plus itself using data returned by the AWS API in the previous step.

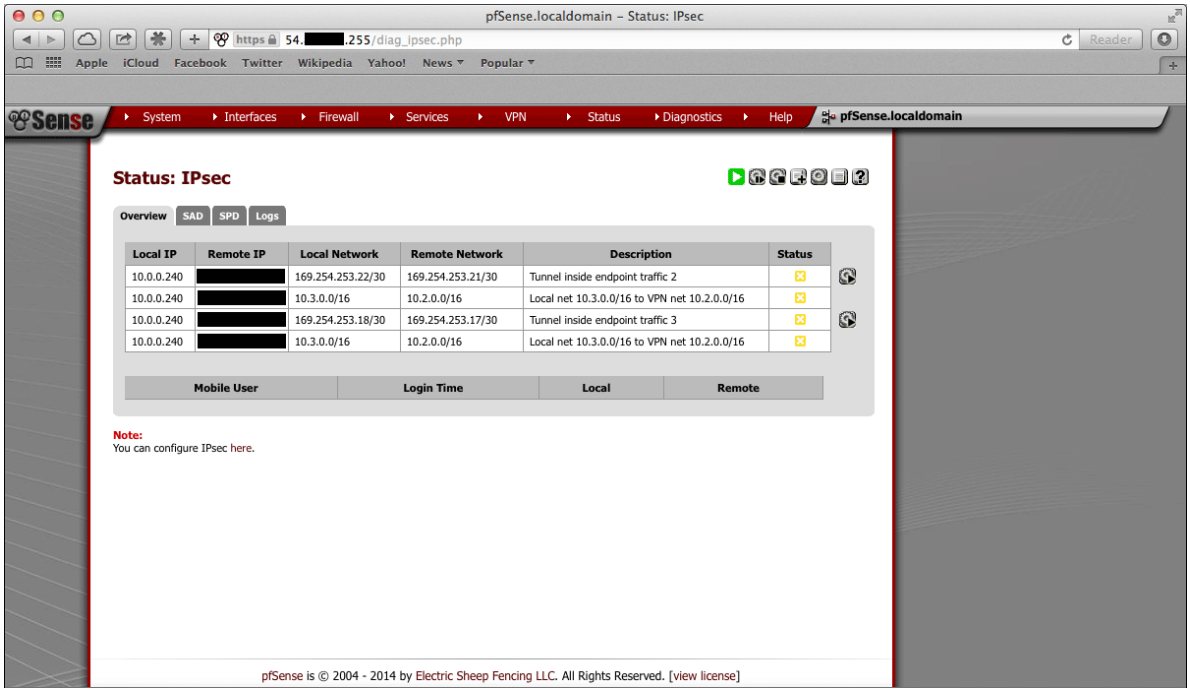
It will configure 2 IPsec tunnels, a firewall rule, 2 Aliases (referenced by the firewall rule), and 2 Virtual IP Addresses. If **BGP** was selected as the **Routing Type** in the previous step, it will install the **FRR** package automatically and configure it appropriately.

7. The next screen will appear and prompt to apply the configuration changes that have been made.



After clicking **Next**, all the configuration changes that were made will be applied.

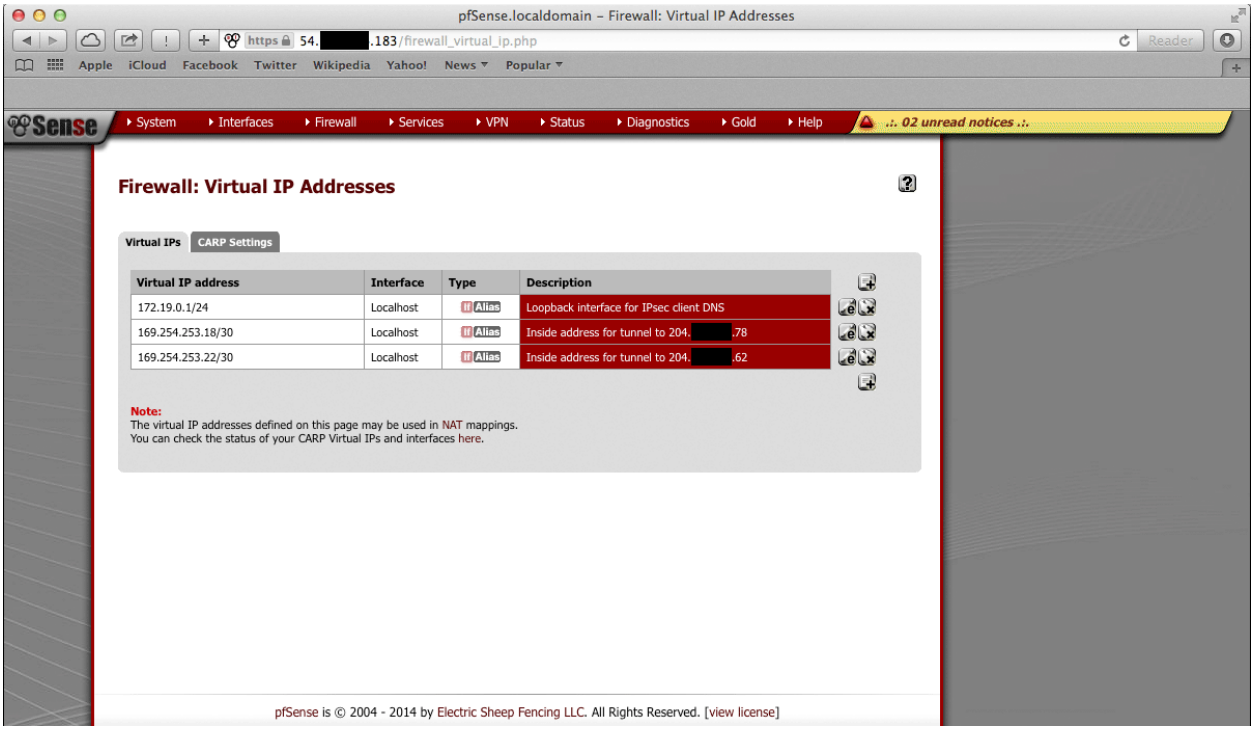
8. The wizard will be completed and the browser will be redirected to the IPsec status page. The VPN to the VPC should now be fully configured.



Note: Sometimes there is a delay of 5-10 minutes before the tunnels are fully functional and passing traffic. This has been observed particularly often during the setup of tunnels using BGP routing.

30.6.3 Testing Connectivity

Verify that the IPsec tunnels are functioning by attempting to ping the "inside tunnel addresses" of the VPC side of the tunnel by navigating to **Firewall > Virtual IP**. There should be two virtual IP addresses configured that have Descriptions like "Inside address for tunnel to <remote IP address>".



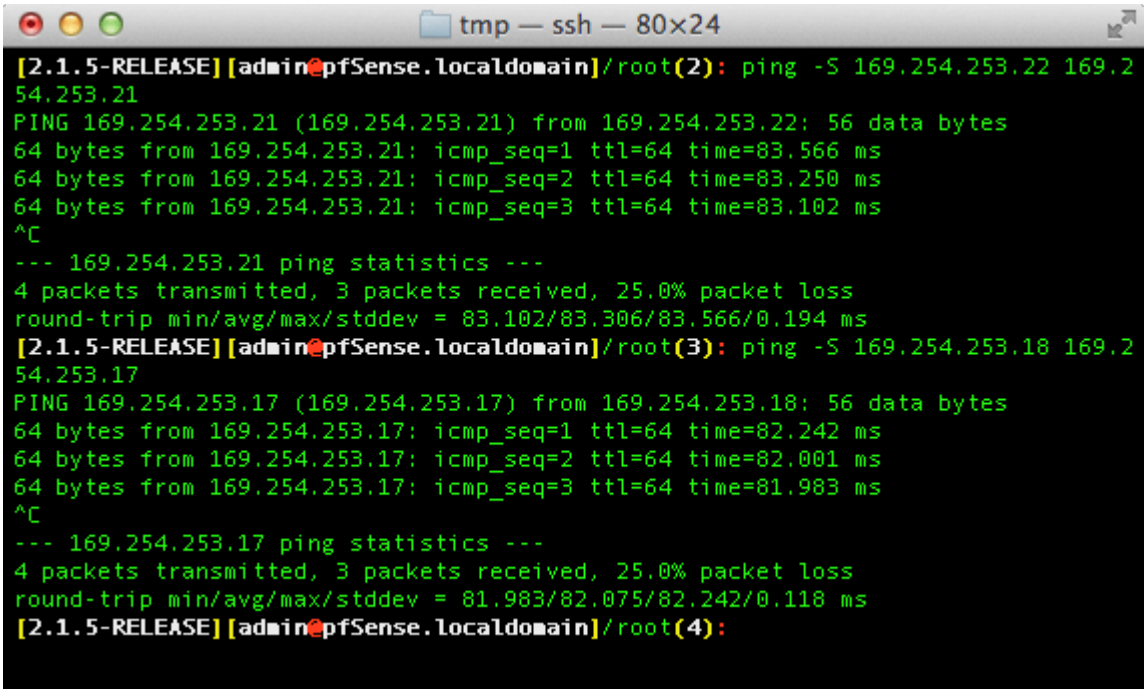
Amazon provides inside addresses for each end of the tunnel in a `/30` subnet in IPv4 link local address space (`169.254.x.y`). Typically, the first usable address in the `/30` is the inside address for the VPC end of the tunnel and the other usable address is the inside address for the local end of the tunnel. Ping from one of the virtual IP addresses configured on the pfSense Plus instance to the IP address that is one less (for example, if the virtual IP address were `169.254.253.22`, ping from `169.254.253.22` to `169.254.253.21`), that checks whether the other end of the tunnel is responding and whether the tunnel is functioning properly.

Note: It sometimes takes a few minutes for the tunnels to begin working after the configuration wizard completes.

To ping, log into the pfSense Plus instance via SSH and execute `ping` from a shell prompt. For the previous example of `169.254.253.22`, the proper syntax is:

```
ping -S 169.254.253.22 169.254.253.21
```

When pinging from a shell prompt, it is possible leave the command running indefinitely and interrupt it there is a response.



It is also possible to ping via the **Diagnostics > Ping** page by selecting the appropriate source address and entering the remote tunnel inside address in the **Host** field. This will only send a limited number of ping packets, so it may be necessary to repeat this a few times.

30.6.4 VPC Configuration Details

The AWS documentation for connecting a hardware device to a VPC provides a great amount of detail on configuring VPN Connections to VPC.

The main configuration elements that exist in Amazon's data model are the Virtual Private Gateway, the Customer Gateway, and the VPN Connection. In order to configure a VPN connection to a VPC, all 3 of these need to exist. The Virtual Private Gateway is the VPN endpoint on Amazon's side. The customer gateway is the VPN endpoint on the Netgate® pfSense Plus instance/device being configured. The VPN Connection is the IPsec VPN between Amazon and the pfSense Plus instance/device.

A Virtual Private Gateway needs to exist and be associated to the VPC. A particular VPN Gateway can only be associated to one VPC at a time. Once the VPC to connect to has been selected, the wizard invokes the AWS API call **DescribeVpnGateways** to determine if a VPN Gateway already exists that is attached to the VPC. If none exists, it creates one with the **CreateVpnGateway** API call and attaches it to the VPC with the **AttachVpnGateway** call.

A Customer Gateway needs to be created for the public IP address of the device or virtual machine that will be used to connect to the VPC. The wizard invokes the AWS API call **DescribeCustomerGateways** to determine if a Customer Gateway already exists. If none exists, one is created with the **CreateCustomerGateway** API call.

The VPN Connection connects the Virtual Private Gateway and Customer Gateway. The wizard checks to see if there is an existing VPN Connection configured that connects those endpoints by invoking the AWS API call **DescribeVpnConnections**. If none exists, one is created using the **CreateVpnConnection** call. One of the fields returned by this call is a block of XML configuration data that contains configuration data assigned by AWS for use with configuring the VPN Connection. This data is stored and used in subsequent steps to make the required configuration changes within pfSense Plus.

Any objects created through API calls by the wizard will be tagged with names like `auto-created by pfSense VPC <your_VPC_ID>`. This is accomplished by calling the AWS API call **CreateTags** and using `Name` as the key for the

tag.

In addition to creation of the items mentioned above, required adjustments are made to Security Groups and Route Tables to facilitate communication over the VPN. The Security Groups associated with the VPC are updated to allow inbound access from the local subnets on the pfSense Plus end of the VPN. They are checked first via the **DescribeSecurityGroups** AWS API call to determine if the access is already allowed. Any of the subnets that is not already allowed has inbound access added via the **AuthorizeSecurityGroupIngress** AWS API call.

Route Tables associated with the VPC are updated to receive routes from the VPN Gateway used by the VPN Connection. They are checked first via the **DescribeRouteTables** AWS API call. If the VPN Gateway ID is not included in the list of VPN Gateways propagating routes, route propagation for the VPN Gateway is enabled on that table using the **EnableVgwRoutePropagation** AWS API call.

For VPN Connections using static routing, static routes for the specified subnets are added to the VPN Connection. This is done via the **CreateVpnConnectionRoute** AWS API call.

30.6.5 pfSense Plus Software Configuration Details

On the pfSense Plus software side, there are numerous configurations added to support the VPN to the VPC.

Aliases

First, aliases are created for use in a firewall rule. These aliases are intended to contain the subnets that traffic should be allowed to ingress over the IPsec tunnel. One alias represents the local subnets on the pfSense Plus side and is given a name like **VPC_Local_vpc_12345678** and the other represents the remote subnets on the VPC side and is given a name like **VPC_Remote_vpc_12345678**.

Virtual IP addresses

Next, virtual IP addresses are added on the `lo0` (loopback) interface. These virtual IP addresses are the local "inside addresses" of the IPsec tunnels. These addresses are used as the local address for BGP communication when BGP routing is selected. These addresses are IPv4 link local addresses (see RFC 3297). AWS assigns `/30` subnets out of the network `169.254.0.0/16` for this purpose.

Note: These addresses are also useful as a ping target to execute a basic test of whether the tunnel is functioning properly. Executing a ping from a source address of one of these IP addresses to the corresponding inside address of the other end of the tunnel helps determine whether the tunnel negotiation is completing properly.

Firewall rules

Next, a firewall rule is added on the IPsec interface that allows traffic from the VPC networks to the local subnets. This rule uses the previously created Aliases as source/destination targets.

IPsec

Then, IPsec phase 1 and phase 2 associations are set up. Most of the settings required are extracted from a block of XML data that was returned by the **CreateVpnConnection** call made during the AWS configuration step. This includes parameters like endpoint IP addresses, encryption ciphers, timer values, etc.

If BGP routing was selected, the configurations for the FRR BGP daemon are established. The required settings are determined using the AS number entered into the wizard and the parameters returned by the **CreateVpnConnection** call made during the AWS configuration step.

30.6.6 Tested Configurations

Various topologies may be possible to establish using the AWS VPC Configuration Wizard. This section enumerates some of the configurations that were successfully tested.

Platforms

- Various hardware platforms.
- 64-bit virtual machines in VMware vSphere/ESX.
- Amazon EC2 instances (Xen virtual machines) of the Netgate® pfSense Plus Router/Firewall/VPN AWS AMI.

Local network/routing configurations

- pfSense Plus with a public address configured on the WAN interface.
- pfSense Plus with a private address configured on the WAN interface behind a 1:1 NAT.
- pfSense Plus with a private address configured on the WAN interface behind a PAT (1:many NAT).

VPC Topologies

- pfSense Plus connected to a single VPC.
- pfSense Plus connected to multiple VPCs in different regions.
- Amazon EC2 instance of the Netgate pfSense Plus Router/Firewall/VPN AWS AMI connected to a VPC belonging to the same AWS account in a different region.
- Amazon EC2 instance of the Netgate pfSense Plus Router/Firewall/VPN AWS AMI connected to a VPC belonging to a different AWS account in the same region.

The configuration recommended for the greatest amount of stability is to have a public IPv4 address directly configured on the WAN interface of the firewall, but VPNs have been successfully established under all of the conditions listed above.

Whether any of these solutions is appropriate should be evaluated in the context of personal needs and existing infrastructure. Other configurations not listed above may be possible as well.

30.6.7 AWS VPC Wizard FAQ

1. What level of redundancy is provided by the two tunnels?

Amazon provides two tunnel endpoints that will allow traffic to be sent between local networks and the remote VPC to which the firewall connects. The IPsec daemon in pfSense Plus is only capable of establishing an active phase 2 association for a particular source/destination pair on a single tunnel.

Phase 2 associations between the local subnets and the remote VPC subnet are configured in the pfSense Plus software GUI for both tunnels, but IPsec will only actually establish an association for the first tunnel. This means that the IPsec daemon will only ever try to send traffic destined for the remote VPC subnet over the first tunnel.

If that tunnel goes down, the second tunnel may be up and inbound traffic from the remote VPC may be sent to the local networks over that tunnel automatically. But outbound traffic to the remote VPC would not automatically fail over to the second tunnel. To send outbound traffic over the second tunnel, disable the phase 2 associations for the first tunnel and apply the changes.

2. I quit the wizard before finishing. Now what?

To finish setting up the VPN, go back to the wizard and run through it again. It should reuse any partial configurations that were generated before it was stopped and create the new elements that are required.

3. What are the AWS charges for this?

AWS determines their own pricing and provides details for EC2 pricing and VPC pricing. There are many types of charges that may be incurred for operating instances on AWS (e.g. charges related to running an instance, bandwidth, storage, elastic IPs, etc).

The charge of specific interest in this case is the hourly charge for a VPN Connection. As of this writing, it costs $0.05 (USD) per hour in most regions to have a VPN Connection configured and available. AWS will charge whether the VPN Connection is being used or not as long as it is configured. This will be configured by the third step of the wizard and will never be removed by pfSense Plus software.

If the VPN Connection is no longer needed and billing for it needs to be stopped, visit the AWS **VPC Management Console** and delete the VPN Connection manually.

4. Can I use the wizard to connect to the GovCloud region?

This hasn't been officially tested, but at least one user has reported that they were able to successfully connect to the GovCloud region. They manually added the region **us-gov-west-1** to the list of regions in the first step of the wizard and were able to successfully connect to their VPC in that region. This may be supported in a future build, but to try without official support, do the following:

1. Under the **System > Advanced** menu, make sure the **Enable Secure Shell** box is checked. This is already done by default on AWS instances, but is off by default on Netgate hardware devices with pfSense Plus software.
2. Log into the instance via SSH.
3. Make sure the root filesystem is mounted as read/write. On an AWS instance or a hardware device running on an SSD, this should be true. On a hardware device using Compact Flash or an SD card for storage, it will probably be necessary to remount the root filesystem in read/write mode by running:

```
mount -uw /
```

4. Edit the file `/usr/local/www/wizards/vpc_vpn_wizard.xml` using `vi`. Look for a section of the file that looks like this:

```
<option>
    <name>sa-east-1</name>
    <value>sa-east-1</value>
</option>
```

That should appear directly after several similar `<option>` specifications containing all of the other available regions. Right underneath that section, add the following:

```
<option>
    <name>us-gov-west-1</name>
    <value>us-gov-west-1</value>
</option>
```

Then save the file and exit vi.

5. If the filesystem had to be remounted in read/write mode earlier, remount it in read-only mode by running:

```
mount -ur /
```

The GovCloud region should now appear as a choice in the first step of the wizard.

30.7 Backup Files and Directories with the Backup Package

The **Backup** package allows any given set of files/folders on the system to be backed up and restored. For most, this is not necessary, but it can be useful for backing up RRD data or for packages that may have customized files that are not kept in config.xml.

To install the package:

- Navigate to **System > Packages**
- Locate **Backup** in the list
- Click **Install** at the end of its entry
- Click **Confirm** to begin the installation

Once installed, the package is available at **Diagnostics > Backup Files/Dir**. It is fairly simple to use, as shown in the following example.

30.7.1 Backing up RRD Data

Using this Backup package it is quite easy to make a backup of RRD graph data outside of the config.xml method.

See also:

Monitoring Graphs

- Navigate to **Diagnostics > Backup Files/Dir**
- Click **Add** to add a new location to the backup set
- Enter `RRD Files` in the **Name** field

- Enter `/var/db/rrd` in the **Path** field
- Set **Enabled** to *True*
- Enter `RRD Graph Data Files` in the **Description**
- Click **Save**
- Click the **Backup** button to download the backup archive, which contains the configured files and directories for the backup set.
- Save the file in a safe location and consider keeping multiple copies if the data is important.

30.7.2 Restoring RRD Data

- Navigate to **Diagnostics > Backup Files/Dir**
- Click **Browse**
- Locate and select the backup archive file downloaded previously
- Click **Upload** to restore the files

For this example, because the RRD files are only touched when updated once every 60 seconds, it is not necessary to reboot or restart any services once the files are restored.

30.8 Cache / Proxy

Proxies are intermediaries that sit between clients and servers. A client connects to a proxy, and then the proxy decides if the client can receive content from a server. If so, the proxy makes its own connection to the server and then passes back data to the client.

There are two major types of proxies:

Forward Proxy
: Typically sits between local clients and remote Internet servers. It can be used to control which web sites that clients are allowed to load, or log servers and URLs clients are visiting. These mostly work with HTTP, but in special cases can also work with HTTPS.

Reverse Proxy
: Typically sits between remote clients and local servers. These allow for load balancing, failover, or other intelligent connection routing for public services such as web servers.

30.8.1 Squid

Danger: The add-on packages Squid, SquidGuard and Lightsquid are deprecated in pfSense Plus and pfSense CE software due to a large number of unfixed upstream security vulnerabilities. Netgate **STRONGLY** recommends that users uninstall these packages. The packages will no longer function in the next major release of pfSense Plus and pfSense CE software.

Squid is primarily a forward proxy used for client access control. It can, however, be used in a reverse proxy role if needed. The reverse proxy capabilities are inferior to HAProxy, however.

Tuning the Squid Package

Danger: The add-on packages Squid, SquidGuard and Lightsquid are deprecated in pfSense Plus and pfSense CE software due to a large number of unfixed upstream security vulnerabilities. Netgate **STRONGLY** recommends that users uninstall these packages. The packages will no longer function in the next major release of pfSense Plus and pfSense CE software.

Performance Tweaks

Some users have reported better performance by using the *ufs* cache filesystem setting. When using *ufs* filesystem, `vfs.read_max=32` may be increased to `vfs.read_max=128` in **System > Advanced**, **Sytem Tunables** tab.

Compact swap.state

Squid keeps a cache index journal called `swap.state` in the top level of the squid cache folder, typically `/var/squid/cache/swap.sate`. **This file can grow very large and consume all hard drive space**. To ensure this does not happen, set a **Log Rotate** value in the squid configuration.

By setting a number of days to retain the logs, the squid package will activate a nightly cron job which runs:

```
squid -k rotate
```

Part of this rotation process includes compacting the `swap.state` file, keeping it from getting too large.

If this file is too large and needs to be removed, this may be done while squid is running. After the file is removed, run:

```
squid -k rotate
```

This will cause it to be written out again (but compacted). Alternately, tell squid to perform a clean shutdown with:

```
squid -k shutdown
```

This will also write the `swap.state` file out again, but squid will stop after this and must be restarted, so it is a less desirable option.

If the `swap.state` file is removed while squid is *not* running, it will have to completely rescan the cache folder to rebuild it once squid restarts. This can be a lengthy and time consuming process. It may be better to remove the contents of the existing cache folder, and rebuild the structure again by running:

```
squid -z
```

See the Squid FAQ entry for more details.

Random Tips/Tricks

Warning: There could be any number of reasons not to do the following things. Be careful, and test any changes.

Caching Windows Updates

Warning: These settings could break things, but when it works it works beautifully!

If there are a bunch of local PCs that need Windows Updates, but a WSUS server is not an option, squid can cache them.

- On the **General Settings** tab of the squid configuration (**Services > Proxy Server**), place the following patterns recommended by Squid in the **Custom Options** box at the bottom:

```
refresh_pattern -i windowsupdate.com/.*\.
↪(cab|exe|ms[i|u|f|p]|[ap]sf|wm[v|a]|dat|zip|psf) 43200 80% 129600 reload-into-ims
refresh_pattern -i microsoft.com/.*\.
↪(cab|exe|ms[i|u|f|p]|[ap]sf|wm[v|a]|dat|zip|psf) 43200 80% 129600 reload-into-ims
refresh_pattern -i windows.com/.*\.(cab|exe|ms[i|u|f|p]|[ap]sf|wm[v|a]|dat|zip|psf)␣
↪43200 80% 129600 reload-into-ims
refresh_pattern -i microsoft.com.akadns.net/.*\.
↪(cab|exe|ms[i|u|f|p]|[ap]sf|wm[v|a]|dat|zip|psf) 43200 80% 129600 reload-into-ims
refresh_pattern -i deploy.akamaitechnologies.com/.*\.
↪(cab|exe|ms[i|u|f|p]|[ap]sf|wm[v|a]|dat|zip|psf) 43200 80% 129600 reload-into-ims
range_offset_limit none
```

- Click **Save**
- On the **Cache Management** tab of the Squid configuration:
  - Change **Hard Disk Cache size** to something large, say `3000` or `4000` (3GB or 4GB), to accommodate the updates.
  - Change the **Maximum object size** to something big, such as `512000` for 512MB. Going bigger may be needed if any updates larger than that size are released.
- Click **Save**

Caching Mac Updates

```
refresh_pattern ([^.]+.|)(download|adcdownload).(apple.|)com/.*\.(pkg|dmg) 4320 100%␣
↪43200 reload-into-ims
```

Caching AVG and other Updates

As above, but add this before the other options. The same warnings apply:

```
refresh_pattern ([^.]+.|)avg.com/.*\.(bin) 4320 100% 43200 reload-into-ims
refresh_pattern ([^.]+.|)spywareblaster.net/.*\.(dtb) 4320 100% 64800 reload-into-ims
refresh_pattern ([^.]+.|)symantecliveupdate.com/.*\.(zip|exe) 43200 100% 43200 reload-
↪into-ims
refresh_pattern ([^.]+.|)avast.com/.*\.(vpu|vpaa) 4320 100% 43200 reload-into-ims
```

Tweaking Update Caching / Squid seems to download on its own

Change This:

```
range_offset_limit none
```

To:

```
range_offset_limit 0
```

As an alternative, also try:

```
quick_abort_min 0 KB
quick_abort_max 0 KB
```

Or:

```
quick_abort_pct 70
```

To ensure that a file is only downloaded if a user actually receives 70% or more of it. Otherwise if a user requests a file and then aborts, it will download the whole file.

Note: If `range_offset_limit` is set to `-1` the quick abort options will NOT work

---

Parent proxy

Setting parent proxy available at the **Proxy server: Upstream proxy settings** tab. In most cases, these settings work if the parent proxy also squid.

To use a parent proxy on another server (not squid), it is necessary to disable **Upstream proxy settings**, and use the **Custom options** in the **Proxy server: General settings** tab.

Configuring the SquidGuard Package

Danger: The add-on packages Squid, SquidGuard and Lightsquid are deprecated in pfSense Plus and pfSense CE software due to a large number of unfixed upstream security vulnerabilities. Netgate **STRONGLY** recommends that users uninstall these packages. The packages will no longer function in the next major release of pfSense Plus and pfSense CE software.

squidGuard is a URL redirector used to integrate blacklists with the Squid proxy software. There are two big advantages to squidGuard: it is fast and it is free. squidGuard is published under the GNU Public License.

squidGuard can be used to:

- Limit the web access for some users to a list of accepted/well known web servers and/or URLs only.
- Block access to some listed or blacklisted web servers and/or URLs for some users.
- Block access to URLs matching a list of regular expressions or words for some users.
- Enforce the use of domain names/prohibit the use of IP addresses in URLs.
- Redirect blocked URLs to an info page.
- Redirect banners to an empty GIF.
- Have different access rules based on time of day, day of the week, date etc.

Installing Squid and squidGuard

1. From the pfSense® webGUI, navigate to **System > Packages**, **Available Packages** tab
2. Install the **Squid** package if it is not already installed.
3. Install the **squidGuard** package
4. Configure **Squid** package.
5. Configure **squidGuard** package.

Configure the squidGuard Package

Basic configuration

Here describes how to enable and configure squidGuard, and common users access.

1. Open **General settings** tab.
    1. Check the **Enable** box to activate the package.
    2. Set **Blacklist** options to use blacklist categories. (See above, optional)
    3. Click **Save** button.
2. Open **Common ACL** page.
    1. Click **Target Rules List** to show defined blacklists and target categories
        1. Define default user access: select **Default access [all]** as *allow* or *deny*.
        2. Define other category actions:

1. Select **—**, to ignore a category.
2. Select **allow**, to allow this category for clients.
3. Select **deny**, to deny this category for clients.
4. Select **white**, to allow this category without any restrictions. This option is used for exceptions to prohibited categories.

3. To prohibit clients from using IP addresses in URLs, check **Do Not Allow IP Addresses in URL**.
4. Select **Redirect mode**:
   1. *Int error page*: Use the built-in error page. A custom message may be entered in the **Redirect info** box below.
   2. *Int blank page*: Redirect to a blank page
   3. The other options are various redirects to external error pages, and a URL must be entered in the **Redirect info** box if they are chosen.
5. **Use safe search engine**: Protect customers from unwanted search results. It is supported by *Google, Yandex, Yahoo, MSN, Live Search*. Make sure that these search engines are available. If this protection should be strictly enforced, disable access to all other search engines.

3. After settings are complete, return to the **General Settings** tab and press **Apply**.

Blacklist

Blacklists are optional, but often useful for allowing access to certain types of sites.

squidGuard comes with a small blacklist basically for testing purposes. They should not be used in production. A better way is to start with one of the blacklist collections recommended by squidGuard.

Downloading blacklists:

1. Open **General Settings** tab in squidGuard package GUI, found at **Services > Proxy Filter**.
2. Check **Blacklist** to enable the use of blacklists.
3. Enter blacklist URL in the field **Blacklist URL**.
4. If the firewall is itself behind a proxy, enter the proxy information in **Blacklist proxy** (this step is not necessary for most people).
5. Click **Save**.
6. Navigate to the **Blacklist** tab inside of squidGuard.
7. Click the **Download** button.
8. Wait while blacklist will downloaded and prepared to use (10-35 min). Progress will be displayed on that page as the list is downloaded and processed.

How-Tos

Exclude domain/URL from blacklist

In the squidGuard GUI (**Services > Proxy Filter**):

1. Open the **Target categories** page
2. Click  to add a new item
3. Enter a name for the category - `myWhitelist` for example.
4. Add domains and/or URLs to the lists as needed. Entries should be separated by a space. The examples on the page show how entries should be formatted.
5. As with the Common ACL discussed previously, redirect and logging options specific to this category may be set.
6. Click **Save**.
7. Open **Common ACL** or **Groups ACL** page (whichever should have an exclusion).
8. Click **Target Rule List** to expand the list of categories. The newly created category should show alphabetically in the list, above any blacklist categories. Find the **MyWhiteList** entry in the list and select **whitelist**.
9. Click **Save**.
10. Return to the **General Settings** tab and press **Apply**.

Block download by Extension

In the squidGuard GUI (**Services > Proxy Filter**):

1. Open the **Target categories** page.
2. Click  to add a new item.
3. Enter a name for the category - `myBlockExt` for example.
4. Add Expressions (for example for asf, zip, exe and etc files):

```
(.*\/.*\.(asf|wm|wma|wmv|zip|rar|cab|mp3|avi|mpg|swf|exe|mpeg|mp.|mpv|mp3|wm.|vpu))
```

5. Click **Save**.
6. Open **Common ACL** or **Groups ACL** page (whichever should have an exclusion).
7. Click **Target Rule List** to expand the list of categories. The newly created category should show alphabetically in the list, above any blacklist categories. Find the **myBlockExt** entry in the list and select **deny**.
8. Click **Save**.
9. Return to the **General Settings** tab and press **Apply**.

Troubleshooting

Netflix

If Netflix will not load while squidGuard is active, it is likely because Netflix requires accessing URLs by IP address. Ensure that ACLs matching clients allowed to reach Netflix also have **Do not allow IP-Addresses in URL** unchecked.

Service Does Not Start

If the squidGuard service will not start, there are a few possible explanations:

- On all versions of Squid, if **only** blacklists have been configured, then at startup some important files/directories may not be set properly.
  - Add at least one **Custom Target Category** with a site to pass or block and use it along with the blacklist entries to work around the problem.
- On squid 3.x, the squidGuard service will only start when traffic requires it to run, so it can appear to be stopped even when working properly.
  - Only worry about the service if it appears to not work, don't count on the service status alone.

Known issues

See also:

The pfSense software issue tracker contains a list of known issues with this package.

Package Support

This package is currently supported by Netgate TAC to those with an active support subscription.

30.8.2 HAProxy

HAProxy is a powerful reverse proxy that can handle many different types of tasks and scales well for large deployments.

- *HAProxy package*
- *Troubleshooting the HAProxy Package*

30.9 FreeRADIUS package

FreeRADIUS is a free implementation of the RADIUS protocol. Supports MySQL, PostgreSQL, LDAP, Kerberos.

Refer to the following articles for more information on the listed topics:

30.9.1 Testing the FreeRADIUS Package

Testing the *FreeRADIUS Package* on a firewall running pfSense® software.

Test Configuration

At a minimum, testing FreeRADIUS requires A **User**, an **Interface**, and a **NAS/Client**.

- Add a **User** with the following configuration:

  Username
  `testuser`

  Password
  `testpassword`

- Add a **Client/NAS** with the following configuration:

  IP Address
  `127.0.0.1`

  Shared Secret
  `testing123`

- Add an **Interface** with the following configuration:

  IP Address
  `127.0.0.1`

  Interface Type
  Auth

  Port
  `1812`

GUI Test

The easiest way to test is by using **Diagnostics > Authentication** in the GUI.

First, add a RADIUS server entry to the user manager as described in *Authentication Servers*.

- Navigate to **System > User Manager**, **Authentication Servers** tab
- Fill in the settings to match the entry in FreeRADIUS:

  Descriptive Name
  `FreeRADIUS`

  Type
  RADIUS

  Hostname or IP Address
  `127.0.0.1`

Shared Secret
`testing123`

Services Offered
Authentication

Authentication Port
`1812`

- Click **Save**

Next, perform the GUI test:

- Navigate to **Diagnostics > Authentication**
- Set **Authentication Server** to the RADIUS server in the user manager
- Fill in the **Username** and **Password**
- Click  **Test**

If the test succeeds, the GUI prints a success message:

User testuser authenticated successfully.

The system log will also contain a message indicating a successful login:

```
radiusd[44793]: Login OK: [testuser/testpassword] (from client testing port 0)
```

If the test fails, the GUI prints a failure message:

Authentication failed.

The system log will also contain a message indicating failure:

```
radiusd[44793]: Login incorrect: [testser/testpassword] (from client testing port 0)
```

CLI Test

FreeRADIUS offers an easy to use command line tool to check if the server is running and listening to incoming requests.

SSH to the firewall, start a shell, and type in the following command:

```
radtest testuser testpassword 127.0.0.1:1812 0 testing123
```

The following output will appear if the test succeeds:

```
: radtest testuser testpassword 127.0.0.1:1812 10 testing123
Sending Access-Request of id 1 to 127.0.0.1 port 1812
       User-Name = "testuser"
       User-Password = "testpassword"
       NAS-IP-Address = 192.168.0.22
       NAS-Port = 10
       Message-Authenticator = 0x00000000000000000000000000000000
rad_recv: Access-Accept packet from host 127.0.0.1 port 1812, id=1, length=20
```

The `Access-Accept` portion of the output is the most relevant.

Check the system log for the following output:

```
radiusd[44793]: Login OK: [testuser/testpassword] (from client testing port 10)
```

If a part of the test fails, such as incorrect username, then the test command output will look like the following:

```
: radtest testser testpassword 127.0.0.1:1812 10 testing123
Sending Access-Request of id 104 to 127.0.0.1 port 1812
       User-Name = "testser"
       User-Password = "testpassword"
       NAS-IP-Address = 192.168.0.22
       NAS-Port = 10
       Message-Authenticator = 0x00000000000000000000000000000000
rad_recv: Access-Reject packet from host 127.0.0.1 port 1812, id=104, length=20
```

The `Accesss-Reject` packet indicates that the server rejected the attempt, and the system log will contain the following output:

```
radiusd[44793]: Login incorrect: [testser/testpassword] (from client testing port 10)
```

30.9.2 Features

- Authentication with Captive-Portal
- Pre-defined user attributes and custom check-items and reply-items
- NAS/Clients running on IPv4 and IPv6
- Interfaces can listen on IPv4 and IPv6
- OpenVPN + Username + RADIUS and OpenVPN + Username + Cert + RADIUS
- Auth with PAP, CHAP, MSCHAP, MSCHAPv2
- Auth with EAP-MD5 + dynamic VLAN assignment
- Auth with PEAP + dynamic VLAN assignment
- Auth with EAP-TLS/EAP-TTLS + dynamic VLAN assignment

```
radiusd[3206]: Login OK: [testuser/<via Auth-Type = EAP>] (from client pfsense
   port 0 cli 00-04-23-5C-9D-19)
radiusd[3206]: Login OK: [testuser/<via Auth-Type = EAP>] (from client pfsense
   port 0 cli 00-04-23-5C-9D-19)
radiusd[3206]: Login OK: [testuser/<via Auth-Type = EAP>] (from client pfsense
   port 0 via TLS tunnel)
radiusd[3206]: Login OK: [testuser/<via Auth-Type = EAP>] (from client pfsense
   port 0 via TLS tunnel)
```

- Simultaneous-Use - The following will be present in the system log

```
radiusd[3206]: Multiple logins (max 1) : [testuser/testpw] (from client testing␣
↪port 10)
```

- A certain amount of time per day/week/month/forever (`CHECK-ITEM: Max-Daily-Session := 60`) The user will be disconnected and cannot re-login after the amount of time is reached:

```
radiusd[3206]: Invalid user (rlm_counter: Maximum daily usage time reached):
   [testuser/<via Auth-Type = EAP>] (from client pfsense port 0 cli 00-04-23-5C-9D-
↪19)
```

- A certain amount of traffic per day/week/month/forever. The user will be disconnected and cannot re-login after the amount of traffic is reached. The syslog output looks like this:

```
root: FreeRADIUS: Used amount of daily upload and download traffic by testuser is 0␣
↪of
   100 MB! The user was accepted!!!
root: FreeRADIUS: Credentials are probably correct but the user testuser has␣
↪reached the
   daily amount of upload and download traffic which is 243 of 100 MB! The user was␣
↪rejected!!!
```

- MySQL
- LDAP/ActiveDirectory (connecting to MS AD with PAP)
- One-Time-Password

30.9.3 Installation and Configuration

- Navigate to **System > Packages**, **Available Packages** tab.
- Click  at the end of the row for **freeradius3**.
- Confirm the installation.
- Monitor the progress as it installs.

After Installation, the service may be configured at **Services > FreeRADIUS**.

- Configure the **Interface(s)** on which the RADIUS server should listen.
- Configure the **NAS / Client(s)** from which the RADIUS server should accept packets.
- Add the **User(s)** who should have access.

After this, have a look at the system log. There should be the following:

```
radiusd[16634]: Ready to process requests.
radiusd[16627]: Loaded virtual server
```

30.9.4 Troubleshooting RADIUS Authentication

When attempting to authenticate against a RADIUS server, errors may be encountered that prevent it from working properly. Here are some errors found in the logs and how to resolve them:

```
mpd: [pt0] RADIUS: RadiusSendRequest: rad_init_send_request failed: -1
```

- This appears to happen when the RADIUS shared secret contains special characters. Try again with an alphanumeric shared secret.

30.9.5 Get FreeRADIUS Status Server Updates

The status server provides detailed information about the FreeRADIUS server. The status data includes Accounting-Packets, dropped packets and much more.

To enable status server:

- Setup an interface with **Interface-Type**: *status* and a free port.

  The default port for RADIUS status is `18121`.

- Setup a NAS/Client with **IP-Address**: `127.0.0.1` and a password if one does not already exist.

  This example uses a password of `testing123`.

To request information from the status server:

- SSH to the firewall and enter the following command on the command line:

```
$ echo "Message-Authenticator = 0x00, FreeRADIUS-Statistics-Type = All" | \
  radclient -x localhost:18121 status testing123
```

The output should look like this:

```
Received response ID 223, code 3, length = 140
       FreeRADIUS-Total-Access-Requests = 1
       FreeRADIUS-Total-Access-Accepts = 0
       FreeRADIUS-Total-Access-Rejects = 14
       FreeRADIUS-Total-Access-Challenges = 0
       FreeRADIUS-Total-Auth-Responses = 14
       FreeRADIUS-Total-Auth-Duplicate-Requests = 0
       FreeRADIUS-Total-Auth-Malformed-Requests = 0
       FreeRADIUS-Total-Auth-Invalid-Requests = 0
       FreeRADIUS-Total-Auth-Dropped-Requests = 0
       FreeRADIUS-Total-Auth-Unknown-Types = 0
       [...]
```

To request specific subsets of the status data, replace `All` in `FreeRADIUS-Statistics-Type = All` from the command above with another valid name or value.

A few common names and values are:

- Authentication packets: `Authentication` / `1`
- Accounting packets: `Accounting` / `2`
- Internal server statistics: `Internal` / `0x10`

Tip: The status server accepts either the name **or** its corresponding value a parameter.

More name/value pairs for `FreeRADIUS-Statistics-Type` are listed in the FreeRADIUS dictionary file on the firewall:

```
/usr/local/share/freeradius/dictionary.freeradius
```

30.10 FRR Package

The FRR package manages dynamic routing for the firewall. Dynamic routing refers to routes that are capable of changing, generally due to routing protocols exchanging routing information with neighboring routers.

Unlike static routes, dynamic routing does not require remote network destinations and gateways to be hardcoded in the configuration. Routes and gateways are automatically determined by the protocol instead.

Currently the FRR package supports the following dynamic routing protocols:

Border Gateway Protocol (BGP)
: BGP routes between autonomous systems, connecting to defined neighbors to exchange routing and path information. BGP supports IPv4 and IPv6.

Open Shortest Path First v2 (OSPF)
: OSPF is a link-state routing protocol capable of automatically locating neighboring IPv4 routers within an autonomous system, typically with multicast, and exchanges routing information for networks reachable through each neighbor. OSPF v2 only supports IPv4.

Open Shortest Path First v3 (OSPF6)
: Similar to OSPF v2, but for IPv6 networks.

30.10.1 FRR Global Settings

The **Global Settings** area in FRR defines options which control the behavior of FRR in general, options which can be utilizied by multiple routing protocols, and options which are not specific to a routing protocol.

These options include **Access Lists**, **Prefix Lists**, and **Route Maps**. These mechanisms allow for fine-tuning dynamic routing behavior.

The options here primarily govern the bahvior of the `zebra` and `staticd` daemons in FRR.

FRR Global Settings Configuration

Configuration of FRR Global Settings is performed at **Services > FRR Global/Zebra**, on the **Global Settings** tab in FRR. From other areas of FRR, these settings can also be reached by the **[Global Settings]** tab.

General Options

Enable
Master enable option for FRR. When unchecked, all of FRR is disabled, including individual routing daemons.

Default Router ID
The **Router ID** is an IPv4-address formatted string which uniquely identifies this router. Typically it is set to the LAN address of a router or another unique interface address.

This default router ID is used by FRR when a per-protocol router ID is not set.

Master Password
The password used by FRR for accessing the management daemons internally. This is not typically used by humans interacting with the daemons in the shell (e.g. via `vtysh`) but only internally in FRR.

Encrypt Password
When set, encrypts passwords in output from FRR.

Ignore IPsec Restart
When checked, IPsec restarts cause no action to be taken by FRR. When unchecked, IPsec VTI interfaces will be reset in FRR when IPsec restarts. This reset can prevent routes from becoming inactive in the routing table after IPsec VTI interface events.

CARP Status IP
Used to determine the CARP status when using FRR with certain high availability setups. When the selected CARP vhid is in BACKUP status, FRR will not be started. This check is also made when a CARP VIP transitions to a new status, and the FRR daemons will be stopped or started appropriately to match the VIP status.

Logging

The dynamic routing manager daemon can send log messages to a file, via syslog, or both.

Syslog Logging
Instructs FRR to send its log messages to syslog.

Package Logging Level
Controls the verboseness of FRR package scripts

Normal
Typical log messages.

Extended
Detailed log messages, which may include debugging information.

Modules

The **Enable SNMP AgentX** option in this section controls whether or not data from FRR will be available through the NET-SNMP package.

Note: This feature is not compatible with the `bsnmp` daemon included with the firewall, only the NET-SNMP package.

Route Handling

The options in this section influence FRR global routing behavior. For example, it can setup special automatic lists to control route acceptance and also to setup FRR-based static routes (e.g. `staticd`). These are different than static routes managed in the firewall GUI directly (*Static Routes*).

Do Not Accept
When set, routes matching the **Subnet** exactly will not be accepted from routing protocols.

Null Route
When set, traffic from hosts inside the defined **Subnet** will never be routed. The traffic will be dropped when it arrives at the firewall.

This option takes precedence over other routing options.

Subnet
An IPv4 subnet or IPv6 prefix for this entry.

Static Route Target
A list of available system gateways, BGP neighbors, and interfaces which can be used as a destination for this route entry. Selecting an entry from the drop-down turns this entry into an FRR static route.

Force Service Restart

By default, FRR attempts to stay running and enact changes in a dynamic way so that there is no loss of service when possible.

Certain changes may necessitate a full restart of FRR, which can be done with the **Force Service Restart** button in this section.

Access Lists

Access list entries determine if networks are allowed or denied in specific contexts used in various routing daemons. For example, an access list may be used to determine if a route is accepted or rejected, or for limiting routes distributed to neighbors.

Access lists are managed on the **Access Lists** tab under **Services > FRR Global/Zebra**.

Access List Configuration

To create a new access list, click  **Add** from the **Access Lists** tab.

The top section of the page sets data about the access list itself:

Type
The type of access list, can be one of:

Standard
A standard access list can match source addresses only.

Extended
An extended access list can match source or destination addresses.

Zebra
A Zebra access list is similar to an **Extended** list, but supports IPv6.

IP Version
The IP version to match using this access list, either `IPv4` or `IPv6`.

Name
The name of this access list, which will be visible in drop-down lists throughout FRR where access lists can be selected.

The allowed names depend upon the chosen type, and are limited to:

- `1-99` or `1300-1999` for standard access lists.
- `100-199` or `2000-2699` for extended access lists.
- Text names for zebra access lists.

Description
A text comment to describe this access list.

Access List Entries

The **Access list entries** list contains rules which govern the behavior of the list. An access list can have multiple rules.

To add more entries to the list, click  **Add**.

Sequence
The order of entries inside access lists is important, and the order is determined by this sequence number.

Each rule in an access list must have a unique sequence number. Best practice is to leave gaps in the sequence to allow for adding rules in the future. For example, use `10`, `20`, `30`, rather than `1`, `2`, `3`.

> **Warning:** The order of rules displayed in the GUI may be different than the order set by the **sequence** numbers. The **sequence** number order is the true order in which rules are evaluated.

Action
The action to take for this rule, either `permit` or `deny`.

Source Network
The source IP prefix to match for this rule, given in network/prefix notation. For example, `192.168.0.0/16`.

Source Any
When set, the **Source Network** is ignored and any source will match the rule.

Destination Network
The destination IP prefix to match for this rule, given in network/prefix notation. For example, `192.168.0.0/16`.

Destination Any
When set, the **Destination Network** is ignored and any destination will match the rule.

Exact
Will only match if a network prefix matches exactly, rather than matching networks contained within the specified prefix.

Prefix Lists

Prefix List entries determine parts of networks which can be allowed or denied in specific contexts used in routing daemons. For example, a prefix list may be used to match specific routes in a route map.

Prefix lists are managed on the **Prefix Lists** tab under **Services > FRR Global/Zebra**.

Prefix List Configuration

To create a new prefix list, click  **Add** from the **Prefix Lists** tab.

The top section of the page sets data about the prefix list itself:

IP Type
The IP version to match using this access list, either `IPv4` or `IPv6`.

Name
The name of this prefix list, which will be visible in drop-down lists throughout FRR where prefix lists can be selected.

Description
A text comment to describe this prefix list.

Prefix List Entries

The **Prefix list entries** list contains rules which govern the behavior of the list. A prefix list can have multiple rules.

To add more entries to the list, click  **Add**.

Sequence
The order of entries inside prefix lists is important, and this order is determined by a sequence number.

Each rule in a prefix list must have a unique sequence number. Best practice is to leave gaps in the sequence to allow for adding rules in the future. For example, use `10`, `20`, `30`, rather than `1`, `2`, `3`.

> **Warning:** The order of rules displayed in the GUI may be different than the order set by the **sequence** numbers. The **sequence** number order is the true order in which rules are evaluated.

Action
The action to take for this rule, either `permit` or `deny`.

Network
The network prefix to match. This may optionally be bound by **Minimum Prefix** (lower bound) or **Maximum Prefix** (upper bound) size limit. When no upper or lower bound is set, the prefix will be matched only exactly as given. Setting bounds allows a prefix list to also match more specific routes which are a contained within the given prefix.

Any
When set, matches any prefix.

Minimum Prefix
Also known as `ge`. Sets a lower bound for the prefix length. This must be greater than the prefix length given in **Network**, and less than or equal to the value of **Maximum Prefix**, if present.

Maximum Prefix
Also known as `le`. Sets an upper bound for the prefix length. This must be greater than the prefix length given in **Network**, and greater than or equal to the value of **Minimum Prefix**, if present.

Prefix List Examples

For example, the following prefix list will match any of the RFC1918 networks:

- Sequence: 10, Action: Permit, Network: `10.0.0.0/8`, Maximum Prefix: `32`
- Sequence: 20, Action: Permit, Network: `172.16.0.0/12`, Maximum Prefix: `32`
- Sequence: 30, Action: Permit, Network: `192.168.0.0/16`, Maximum Prefix: `32`

For each of these entries, the prefix list will match based on the bits specified in the prefix. A match will occur for any network included in the specified range. For example, `10.0.0.0/8` with a **Maximum Prefix** of `32` means a route for any smaller network inside `10.0.0.0/8` will also match, so long as the prefix length is less than `32`. So `10.2.0.0/16` will also match this entry, as will `10.34.157.82/32`. Taken as a whole, this prefix list will match not only the list of RFC1918 networks exactly, but any smaller network wholly contained inside.

As another example, consider this rule instead:

- Sequence: 10, Action: Deny, Network: `10.0.0.0/8`, Minimum Prefix: `24`, Maximum Prefix: `32`

This matches routes for networks inside of `10.0.0.0/8` with a prefix length greater than or equal to `24` but less than or equal to `32`. Meaning it will **not** match larger networks such as `10.2.0.0/16` but it will match more specific networks such as `10.2.56.128/29` anywhere inside the `10.0.0.0/8` address space. This type of rule can be used to exclude small prefixes from being matched by a route map, for example.

Dynamic Routing Route Maps

Route maps are a powerful mechanism which can match or set various values for use by routing daemons, especially BGP. A route map can match based on criteria such as those set by *Access Lists* and *Prefix Lists*, among others. Route maps can control, for example, whether or not specific routes are accepted from neighbors, or whether or not specific routes are distributed to neighbors. They can also adjust various properties of routes, which largely depends upon the context in which they are used, such as for BGP or OSPF.

Route maps are managed on the **Route Maps** tab under **Services > FRR Global/Zebra**.

Route map entries are complex, and multiple entries can be combined by using the same name on more than one entry, but with different sequence numbers to control the order in which the route map entries are processed by FRR.

Route Map Configuration

To create a new route map, click  **Add** from the **Route Maps** tab.

The **General Options** section of the page sets data about this route map entry:

Name
The name of this route map entry.

Note: The same name can be used for multiple entries, but each entry using the same name must use a unique sequence number.

Description
A text description of this route map

Action
The action taken by this route map, either `permit` or `deny`.

permit
When an entry is matched and permitted, the "set" actions of a route map are carried out, if present, and then *Logic Control* entries, if present, are performed. The route will be allowed unless the control flow ultimately prevents that from happening.

deny
When an entry is matched and denied, the route is not allowed.

Sequence
The sequence number of this route map. Must be in the range `1-65535`.

The order of entries inside route maps is important, and this order is determined by a sequence number.

Each entry in a route map must have a unique sequence number. Best practice is to leave gaps in the sequence to allow for adding entries in the future. For example, use `10`, `20`, `30`, rather than `1`, `2`, `3`.

Warning: The order of entries displayed in the GUI may be different than the order set by the **sequence** numbers. The **sequence** number order is the true order in which rules are evaluated.

Route Map Contents

The remaining sections on the page control what this route map entry will do. There are numerous options available, from control and logic flow, to matching, setting, and altering routes.

Generally speaking, when an option in the remainder of the page is set to *None*, it will be ignored or have no effect.

Due to complexity, these options are broken up until multiple sections.

Logic Control

Call Route Map
Will immediately process the selected route map. If the called route map returns `deny`, then processing is stopped and the route is denied.

Exit Action

next
Proceeds to the next rule in the route-map

<sequence> number
Skips to the rule with the given sequence number in this route map.

Access Lists

Sets an *Access List* used to match this route map entry.

Prefix Lists

Sets a *Prefix List* used to match this route map entry.

Next Hop

Controls operations matching or setting the next hop for a route.

Next Hop Action
Chooses between actions to take for the next hop of a route.

Match Peer
Matches a specific next hop peer (e.g. BGP Neighbor).

Match ACL
Matches based on a specific *Access List*.

Match Prefix List
Matches based on a specific *Prefix List*.

Set (Peer Only)
Changes the next hop on a route to the specified peer (e.g. BGP Neighbor).

Peer
Specifies a peer for **Next Hop Action** when it is set to **Match Peer** or **Set (Peer Only)**.

Local (match only)
Matches a route when its next hop is this firewall.

Unchanged (set only)
Leaves the next hop unchanged.

Peer Address (set only)
For inbound IPv4 routes received from a neighbor, sets the next-hop to the address of the neighbor. For outgoing routes this is the local address used to establish an adjacency with the neighbor.

<Neighbor>
A list of available peers fills out the list. Selecting an entry uses that specific peer to match or set.

ACL
Specifies an *Access List* used to match the next hop value when **Next Hop Action** is set to **Match ACL**.

Prefix List
Specifies an *Prefix List* used to match the next hop value when **Next Hop Action** is set to **Match Prefix List**.

Metric

Match or set the metric of a route.

Metric Action
Chooses between actions to take for the metric of a route.

Match
Matches the given metric value.

Set
Sets the MED value for routes. When this router has multiple links to the same AS, the MED value influences which path the router will prefer. The router will prefer to use links with a lower MED value. Adding a + before the metric value will result in a relative adjustment instead of setting an absolute value.

Set OSPF6 External Type 1 Metric
Similar to above, but only operates on the OSPF6 External Type 1 Metric.

Set OSPF6 External Type 2 Metric
Similar to above, but only operates on the OSPF6 External Type 2 Metric.

Metric Value
The metric value to match or apply. When setting a metric, the value may be `+rtt`, `-rtt`, + or - value offset, or a specific metric.

Weight

Sets the weight of the route to the supplied value. When a remote AS is reachable via multiple paths through other intermediate AS neighbors, the router will prefer to use a higher weight path to reach it.

Local Preference

The options in this section will either match or set the BGP local preference value of a route using the given **Local Preference** value.

BGP AS Paths

Matches or sets a *BGP AS Path*.

AS Path Action

Match AS Path
Match based on the *BGP AS Paths* selected in **Match AS Path** below.

Set Exclude
Excludes the AS numbers specified in **Set AS List** from the path of the route.

Set Prepend
Prepends the AS numbers specified in **Set AS List** to the AS path.

Set Prepend Last-AS
Prepends the last AS the number of times specified in **Set AS List** to the leftmost end of the path.

> **Warning:** Do not select `Set Prepend Last-AS` in an outbound route-map. The `set` statement would be executed *before* the local AS number is prepended to the AS-path.

Match AS Path
The specific *BGP AS Path* to match.

Set AS List
A list of *BGP AS Path* entries to apply to the route.

BGP Communities

Matches or sets *BGP community* values in routes.

Community Action

Match
Match based on community value in **Match Community**.

Match Exact
Match, but only if the community value matches exactly, rather than being part of a list.

Set
Sets the BGP community value to the list in **Set Community**.

Match Community

internet, no-export, no-advertise, local-as
Match one of the well-known communities.

<Community Name>
Match a community defined at *BGP Community Lists*.

Set Community
When setting a community, this is a **space-separated** list of communities in `AS:VAL` format, or a well-known community: `internet`, `no-export`, `no-advertise`, or `local-as`. Can also be set to `none` to remove BGP community values entirely.

Additive
Adds the specified community value to the route without replacing the existing values.

Origin

Origin Action
Match or set based on the origin (source) of the route.

Origin Name

Remote EGP
Routes from Exterior Gateway Protocols (e.g. BGP).

Local IGP
Routes from Interior Gateway Protocols (e.g. OSPF).

Unknown Heritage (Incomplete)
Routes from unknown sources.

Source Protocol

Matched based on a specific route source protocol from a list of possible options.

Note: Not all options in the list are supported by the FRR package currently.

Tags

Tag Action

Match
Match a tag value set by another route map rule.

Set
Set a tag value to be matched by another route map rule.

Tag Value
The specific tag value to match or set. This value is an integer from `1-4294967295`.

RPKI

Matches based on the RPKI state.

Prefix Not Found
The prefix is not present in the configuration.

Invalid Prefix
The prefix is known but failed validation.

Valid Prefix
The prefix is known and passed validation.

Route Map Examples

This example creates a route map to control which routes will be sent to peers via BGP. The first rule prevents any route from sending if it matches entries in the `RFC1918` prefix list. The second rule allows routes that match networks listed in the `MY-ROUTES` prefix list. This ensures that even if other mechanisms would try to export routes to peers, that no routes to private networks are leaked.

- Name: EBGP-OUT, Sequence: 10, Action: Deny, Match Prefix List: RFC1918
- Name: EBGP-OUT, Sequence: 20, Action: Permit, Match Prefix List: MY-ROUTES

FRR Status

The status page for FRR can be found at **Status > FRR** or on the **Status** tab.

Accessing the **Status** tab from **Global Settings** shows an overview of FRR and basic information from all active routing protocols.

The protocol and daemon-specific tabs (Zebra, BGP, OSPF, OSPF6, BFD) display more detailed information related to each area.

The **Configuration** tab shows the current configuration file (`frr.conf`).

See also:

- *BGP Status*
- *OSPF Status*

Output Limits and Filtering

Most sections on the status page limit the amount of data shown to ensure that the GUI does not get overwhelmed when dealing with large amounts of data, such as from full BGP feeds.

There are two options which govern the output shown in each area of the status page:

Display XX of YY items
This option controls the number of items the GUI will display for that area. There are several values to choose from as well as an **all** selection which displays everything.

> **Warning:** Do not select **all** when using full BGP feeds or other sources of large routing data. Attempting to display that much data will cause the status page to fail, or will drastically reduce performance.

Filter expression
This option filters the output so it only includes lines which match the given expression. This can be a simple string to match or a regular expression pattern.

Zebra Status

The `zebra` daemon orchestrates all of the other protocol and related daemons in FRR. As such, it has general information about the operation of FRR in general, plus information which spans across multiple routing protocols.

Zebra Routes
The complete IPv4 routing table known to `zebra`, including notations for routes sent from and received through each protocol.

The first column of output contains codes which are explained in the output header. These codes can also explain which routes are associated with each type of :ref:`dynamicrouting-protocol-lists`.

Note: The output here may differ from the OS routing table visible at **Diagnostics > Routes** as not every route in FRR may be set to be active there.

Example entries:

- `B>* 10.7.0.0/16 [20/0] via 10.6.106.2, ipsec4000, weight 1, 4d01h00m`
  - This route was received from BGP (`B`), selected for use (>) and is in the firewall routing table (FIB, *).
- `O 10.3.0.0/24 [110/10] is directly connected, vmx1, weight 1, 5d15h55m`
  - This route is being advertised to OSPF neighbors (`O`, but directly connected).
- `O>* 10.20.0.0/16 [110/20] via 10.3.111.2, ipsec4000 onlink, weight 1, 4d01h39m`
  - This route was received from OSPF (`O`), selected for use (>) and is in the firewall routing table (FIB, *).

Zebra IPv6 Routes
Same as **Zebra Routes** but for IPv6 routes.

Zebra CPU
CPU usage statistics for the `zebra` daemon and its various threads.

Zebra Interfaces
Information about system interfaces as seen by `zebra`. This may also include information relevant to interface participation in specific routing protocols.

Zebra Memory
Memory usage statistics for various data used by `zebra`.

30.10.2 Border Gateway Protocol

Border Gateway Protocol (BGP) is a dynamic routing protocol used between network hosts. BGP routes between autonomous systems, connecting to defined neighbors to exchange routing information.

BGP can be used for exterior routing (ebgp) or interior routing (ibgp), routing across Internet circuits, private links, or segments of local networks.

BGP Required Information

Before starting, take the time to gather all of the information required to form a BGP adjacency to a neighbor. At a minimum, FRR will need to know these items:

Local AS Number
: The autonomous system (AS) number for this firewall. This is typically assigned by an upstream source, an RIR, or mutually agreed upon by internal neighbors.

Local Router ID
: Typically the highest numbered local address on the firewall. This is also frequently set as the internal or LAN side IP address of a router. It does not matter what this ID is, so long as it is given in IPv4 address notation and does not conflict with any neighbors.

Local Network(s)
: The list of networks that are advertised over BGP as belonging to the Local AS. For external BGP, this is typically the IP address block allocated by the RIR. For internal BGP, this may be a list of local networks or a summarized block.

Neighbor AS Number
: The autonomous system number of the neighbor.

Neighbor IP Address
: The IP address of the neighboring router.

The example in this section uses the following values:

Table 1: Example BGP Configuration

Item	Value
Local AS Number	65014
Local Router ID	10.14.0.1
Local Network(s)	10.14.0.0/16
Neighbor AS Number	65002
Neighbor IP Address	203.0.113.2

BGP Example Configuration

The following example configures a BGP adjacency to a neighbor using the settings from *Example BGP Configuration*.

Assumptions

This example makes a few assumptions for brevity and to keep the example simple, including:

- The remote peer is already configured for BGP with equivalent settings.
- Transit to the peer across a directly attached shared network is already configured, for example over a VPN, shared network segment, or peer-to-peer link.
- Firewall rules pass BGP traffic on TCP port 179 between the peers.

Example Configuration

Route Map for Peer Filtering

Before configuring BGP, add a route map to match any routes so it can be used by FRR to allow exchanging all routes with the peer.

Warning: This basic example replicates previous FRR behavior which allowed any routes to be exchanged with a peer. This is convenient, but not secure. For increased security, create a set of route map entries which ensure that only expected routes are sent and received where possible.

- Navigate to **Services > FRR Global/Zebra**, **Route Maps** tab
- Click  **Add**
- Set the following options:

  Name
  `ALLOW-ALL`

  Description
  Match any route

  Action
  Permit

  Sequence
  100

FRR BGP Configuration

- Navigate to **Services > FRR BGP**
- Set the following options:

  Enable
  Checked

  Local AS
  `65014`

  Router ID
  `10.14.0.1`

  Networks to Distribute
  `10.14.0.0/16`

- Click **Save**
- Navigate to the **Neighbors** tab
- Click  **Add**
- Set the following options:

  Name/Address
  `203.0.113.2`

Remote AS
`65002`

Route Map Filters
Set both **Inbound** and **Outbound** to `ALLOW-ALL`

FRR Global Configuration

- Navigate to the **[Global Settings]** tab
- Set the following options:

  Enable
  Checked

  Master Password
  Create a random string to use

- Click **Save**
- Navigate to the **Status** tab
- Confirm that the BGP neighbor is present and its routes are in the table

FRR BGP Configuration

The FRR BGP service contains numerous methods to configure and fine-tune BGP routing behavior. Due to this complexity, the topic has been split into several sections. Read through each section before attempting to create a new BGP configuration.

BGP Tab Configuration

BGP Router Options

Enable
Master enable switch for BGP routing. When checked, FRR will start the BGP routing daemon and attempt to use the BGP settings in this section.

Log Adjacency Changes
When set, BGP neighbor adjacency changes will be written via syslog.

Local AS
Required. The autonomous system (AS) number for this firewall. This is typically assigned by an upstream source, an RIR, or mutually agreed upon by internal neighbors.

Router ID
Typically the highest numbered local address on the firewall. This is also frequently set as the internal or LAN side IP address of a router. It does not matter what this ID is, so long as it is given in IPv4 address notation and does not conflict with any neighbors.

Timers

Keep Alive Interval
Configures the intervals between keep alive messages.

Hold Time
How long to wait for a response before considering the peer unreachable.

Update Delay
Keeps BGP in a read-only mode for the specified time after the daemon restarts or peers are cleared.

Peer Wait
The amount of time to wait for peers to reach an established state. This starts the same time as the **Update Delay** and allows FRR to end the update delay early if peers are available within the given time period.

Disable Default IPv4 Unicast
When unchecked, FRR assumes the peer supports IPv4 unicast in all cases, even when the neighbor is connected over IPv6.

Modules

Enable SNMP AgentX
Enable agentx support for accessing FRR BGP data via SNMP with the net-snmp package.

Enable BGP RPKI
Enable BGP Resource Public Key Infrastructure.

Global Neighbor Shutdown

Global Neighbor Shutdown
When checked, **all** neighbors are placed into an administratively shutdown state.

Message
An optional message sent to BGP peers when in this shutdown state.

Graceful Restart/Shutdown

Disable BGP Graceful Restart
Globally disable graceful restart functionality in both restart and helper mode.

Preserve FW State
If checked, sets the forwarding state (F) bit indication that the FIB is preserved while performing a graceful restart.

Timers

Stale Path Time
The time (in seconds) FRR will to retain stale paths from a restarting peer.

Restart Time
The time (in seconds) to wait before deleting stale routes unless a BGP open message is received.

Select Defer Time
The time (in seconds) FRR defers the route selection process after it restarts.

RIB Stale Time
The time (in seconds) stale routes are retained in the RIB.

Enable BGP Graceful Shutdown
When set, BGP graceful shutdown is enabled.

RPKI Timers

Configures timers for *BGP RPKI*.

Polling Period
The time (in seconds) FRR waits until it queries the cache for updated data.

Expire Interval
The time (in seconds) after which FRR will expire RPKI cache data.

Retry Interval
The time (in seconds) at which FRR will retry connecting to an RPKI cache server after a connection failure.

Network Distribution

These options control networks for which FRR will distribute or redistribute routes to peers. Peers will be informed to reach these networks through this router.

Redistribute Option Choices
Each option in this section may be set to one of the following choices:

No
Does not distribute routes from this source.

IPv4
Distributes only IPv4 routes from this source.

IPv6
Distributes only IPv6 routes from this source.

IPv4+IPv6
Distributes both IPv4 and IPv6 routes from this source.

<Route Map Name>
Filters distribution of routes by use of the named *route map*.

Redistribute Local
These networks are considered local to the router.

Redistribute Connected Networks
Redistributes routes for networks which are attached to and present on interfaces of this firewall.

Redistribute FRR Static Routes
Redistributes routes for networks defined as *FRR static routes* in **Global Settings**.

Redistribute Kernel Routing Table
Redistributes routes for other networks found in the kernel routing table. This includes static routes defined in pfSense (*Static Routes*), as well as automatic static routes setup for other purposes.

Redistribute OSPF
These networks can be reached through OSPF neighbors, not directly on this firewall.

Redistribute OSPF Routes to BGP Neighbors
Redistributes routes for networks reachable through IPv4 OSPF neighbors.

Redistribute OSPFv3 Routes to BGP Neighbors
Redistributes routes for networks reachable through IPv6 OSPF6 (OSPFv3) neighbors.

Networks To Distribute
A manual list of networks that are advertised over BGP as belonging to the Local AS. For external BGP, this is typically the IP address block allocated by the RIR. For internal BGP, this may be a list of local networks or a summarized block.

Subnet to Route
An IPv4 subnet or IPv6 prefix to advertise to peers.

Note: If this subnet is not in the routing table (e.g. it is a summary or aggregation) then the **Network Import Check** option in *Advanced BGP Configuration* must be *unchecked*.

Route Map
A route map to apply to messages advertising this network.

BGP Neighbor Configuration

BGP Neighbors are managed at **Services > FRR BGP** on the **Neighbors** tab.

The **Neighbors** tab contains a list of current neighbors, if any, and controls to manage the entries (e.g. edit, delete).

The  **Add** button creates a new neighbor.

The remaining sections on this page cover the various options available when creating or editing a neighbor entry.

General Options

Name/Address
The name of a peer group or IP address of a neighbor.

Enter a text name to define a Peer Group. Enter an IP Address to define a Peer.

Peer groups allow common options to be defined which may then be applied to multiple neighbors without manually placing the options on each neighbor.

Description
A text description about this neighbor.

Peer Group
A list of existing peer groups to which this neighbor can be added. Can only be used when defining a neighbor by IP address.

Password
Sets a password used to secure communication with this neighbor using TCP MD5.

The operating system of the neighbor and its BGP support may restrict which of the password types can be used.

FRR and setkey Bidirectional
Configures the password in FRR and at the operating system level in security policies for both inbound and outbound packets.

This is the best option to use when possible as it fully implements TCP MD5 at the operating system level and in FRR. Use this when both neighbors fully support TCP MD5 for both sending and receiving.

FRR and setkey Outbound
Configures the password in FRR and at the operating system level in security policies, but only in the outbound direction.

This option does not validate TCP MD5 on inbound packets, but will add TCP MD5 information to packets sent to the neighbor. Use this if the neighbor is unable to properly send TCP MD5 which can be validated by this firewall.

FRR Only
Configures the password only in FRR, not at the operating system level.

setkey Only Outbound
Configures the password only at the operating system level in security policies, but only in the outbound direction.

setkey Only Bidirectional
Configures the password at the operating system level in security policies for both inbound and outbound packets, but not in FRR.

Shutdown

Neighbor Administrative Shutdown
When checked, the neighbor will be put into, and kept in, an administratively shutdown state.

Shutdown Message
A text message sent to the neighbor while it is administratively shut down.

Auto-Shutdown

RTT
If the round-trip time to the neighbor exceeds this value it will be automatically shut down.

Keep alive Count
If the neighbor fails to respond to this number of keep alive messages, it will be automatically shut down.

Basic Options

Remote AS
Autonomous System (AS) Number for this neighbor. May be an integer from `1-4294967295`, `external`, or `internal`.

Update Source
These options control how FRR will communicate with the neighbor.

IP Type
Sets the address family of the IP address to which FRR will bind for communicating to this neighbor, either IPv4 or IPv6.

Local Source
Sets the specific IP address to use when communicating with the neighbor. This can be an interface address, an IP alias VIP, or a CARP VIP.

Address Family
When set, the neighbor is allowed to advertise routes for both IPv4 and IPv6. Otherwise, the type of routes will be restricted to whichever IP type is set for the **Update Source**.

Default Originate
These options control whether or not FRR will advertise itself as the default route for this neighbor.

Originate Default to Neighbor
Sets the address family for which a default route will be sent to the neighbor, either IPv4, IPv6, or both.

Route Map
A route map used to restrict default origination.

Send Community
Sends the community attribute to this peer, limited to the specified types.

Next Hop Self
Disables next hop calculation for this neighbor and uses the address of this router instead.

Enabled
Uses the address of this router as the next hop in routes announced to this peer if they are learned via eBGP.

Force
When set, also sets the next hop to the address of this router on reflected routes.

Inbound Soft Reconfiguration
Allows the peer to send requests for soft reconfiguration, to apply changes to routes or new attributes without the need for a session reset.

Timers

Keep Alive Interval
Configures the interval between keep alive messages to wait for a response from this neighbor before considering the peer unreachable. This overrides the default values set on the BGP server itself.

Hold Time
Configures how long to wait for a response from this neighbor before considering the peer unreachable. This overrides the default values set on the BGP server itself.

Connect Timer
The amount of time, in seconds from `1-65535`, in which a connection to this peer must be established or else it is considered unsuccessful.

Peer Filtering

These options control which routes may be sent to, or received from, this neighbor.

Note: The current FRR package does not exchange routes with BGP peers by default without being explicitly allowed to do so by a filter. This is secure behavior but requires manually specifying a filter to allow routes to be exchanged.

To replicate the behavior of older FRR versions, add a *route map* to permit all routes (Name: `allow-all`, Action: *Permit*, Sequence: `100`), then set that route map on BGP neighbors for inbound and outbound peer filtering. For increased security, utilize route maps which filter incoming and outgoing routes so they match more strictly.

Distribute List Filter
Defines an *access list* which is used by BGP to filter route updates for this peer, in either the inbound or outbound direction.

Prefix List Filter
Defines a prefix list which is used by BGP to filter route updates for this peer, in either the inbound or outbound direction.

AS Path Filter
Defines an *AS path list* which is used by BGP to filter route updates by AS path in either the inbound or outbound direction.

Route Map Filters
Defines a route map which is used by BGP to filter route updates for this peer, in either the inbound or outbound direction.

Unsuppress Route Map
Configures a route map which BGP can use to unsuppress routes that would otherwise be suppressed by other configuration settings.

BFD

Configures *Bidirectional Forwarding Detection* (BFD) options for this peer.

BFD Enable
Listen for BFD events registered on the same target as this BGP neighbor.

BFD Check Control Plane Failure
Allow FRR to write CBIT independence in outgoing BFD packets. Also allow FRR to read both the CBIT value of BFD and lookup BGP peer status. This option allows BFD to ignore down events during a graceful restart of the remote peer if graceful restarts are enabled in BGP. When enabled, if BFD catches a down event it first checks if the BGP peer has requested that local the BGP daemon keep the remote BGP entries marked as stale. In that case it can safely ignore the event to allow the restart to happen gracefully (RFC 4724).

BFD Peer
Selects a *BFD peer* to associate with this neighbor.

Graceful Restart

Graceful restart mode for this neighbor, may be one of:

Default
Will use the default value for BGP graceful restart from *Graceful Restart/Shutdown*.

Restart
Enables BGP graceful restart functionality for this peer.

Helper
Enables BGP graceful restart helper only functionality for this peer.

Disable
Disables all BGP graceful restart functionality for this peer.

Advanced Options

Weight
Applies the given weight to routes received from this peer.

Passive
When set, this router will not issue open requests to the neighbor on its own. The BGP daemon will only respond to remote open requests from this neighbor.

Path Advertise

All Paths
Advertise all known paths to this peer, instead of only advertising the base path.

Best Path
Advertise only the best known base paths for each AS.

Advertisement Interval
Minimal time (in seconds) between sending BGP routing updates to this neighbor.

Allow AS Inbound
Allows routes to be received from this peer which are from the same AS of this router, but through a different path.

Enabled
Always allow.

Only if Origin
Accept the AS of this router in an AS path if the route originated in the AS of this router.

Allow <number>x
Allowed number of AS occurrences, from `1-10`.

AS Override
Override ASNs in outbound updates to this peer if the AS path is identical to the remote AS.

Attribute Unchanged
Propagates route attributes to this peer unchanged. This behavior can be optionally restricted to only specific attributes.

Advertise Capability
Advertises the selected capabilities to this neighbor, may be one of:

Dynamic
Enables negotiation of the `dynamic` capability with this neighbor or peer group.

Extended Next-Hop
Enables negotiation of the `extended-nexthop` capability with this neighbor or peer group. This capability can set IPv6 next-hops for IPv4 routes when peering with IPv6 neighbors on interfaces without IPv4 connectivity. This is automatically enabled when peering with IPv6 link-local addresses.

ORF
Advertise outbound route filtering capability to this peer.

Disable Capability Negotiation
Disables dynamic capability negotiation with the peer. When set, the router does not advertise capabilities, nor does it accept them. This results in using only locally configured capabilities.

Override Capability Negotiation
Ignores capabilities sent by the peer during negotiation and uses locally configured capabilities instead.

TTL Security Hops
Sets a specific hop count at which neighbors must be reached, rather than the maximum value set by **eBGP multi-hop**.

This cannot be set if **eBGP multi-hop** is set.

Disable Connected Check
Disables a check that normally prevents peering with eBGP neighbors which are not directly connected. This enables using loopback interfaces to establish adjacency with peers.

eBGP Multi-Hop
The maximum allowed hops between this router and the neighbor, in the range `1-255`. When enabled without a specific value, the default is `1`.

This value cannot be set if **TTL Security Hops** is set.

Enforce eBGP Multi-Hop
When set, enforces that neighbors perform multi-hop.

Local AS

Local AS Number
Sets the local AS number sent to this neighbor, which replaces the AS number configured on the BGP server itself. By default, this value is prepended to the AS path for routes received from this neighbor or peer group, and is added to the AS path for routes sent to this neighbor or peer group after the AS number from the BGP sever.

Do not prepend eBGP
Suppresses prepending this AS number to the AS path for received routes from eBGP.

Do not prepend iBGP
Suppresses prepending this AS number to the AS path for received routes from iBGP.

Maximum Prefix
Defines the maximum number of prefixes this router will accept from the peer before tearing down the BGP session.

Note: This action is considered harsh and the best practice is to filter received prefixes by other mechanisms such as a `prefix-list` rather than to abruptly break contact in this way.

Maximum Prefix
The maximum number of prefixes to allow from the peer, from `1-4294967295`.

Warn Percentage
Warning message threshold, from `1-100` percent.

Warn Only
Warn the peer when the limit is exceeded, rather than disconnecting.

Restart Interval
Restarts the connection after warning limits are exceeded. The restart is performed at the defined interval, in minutes, from `1-65535`.

Maximum Prefix Out
Limits the number of prefixes which will be sent to the neighbor by FRR.

Remove Private AS

Remove Outbound
Prevents the BGP daemon from sending routes with private AS numbers to this peer.

Apply to All
When present, this action applies to all ASNs.

Replace with Local
When present, replaces private AS numbers with the AS number of this router.

Route Client

Route Reflector Client
Configures this peer as a route reflector client. This allows routes received from peers in the same AS or using iBGP to be reflected to other peers, avoiding the need for a full mesh configuration between all routing peers.

Route Server Client
Configures this peer as a route server client. This enables transparent mode, which retains attributes unmodified, and maintains a local RIB for this peer.

Solo Peer
Instructs the router to prevent reflection of routes received from this neighbor back to this neighbor. This option is not useful in peer groups with multiple members.

Advanced BGP Configuration

Advanced Options

Default Local Preference
Configure default Local Preference value (0-4294967295, higher=more preferred)

Table Map
Uses the specified route map to control how routes received from BGP peers are passed to the dynamic routing manager process, and thus, into routing tables.

Advanced Timers

Coalesce Timer
Configures the Subgroup coalesce timer, in milliseconds (`1-4294967295`).

Route Map Delay
Time to wait (in seconds) before processing route map changes. A value of `0` disables the timer and stops route updates from happening when route maps change.

Dampening
BGP route flap dampening (RFC 2439) prevents unstable routers from adversely affecting routing behavior.

Time Penalty Half Life
The time duration during which the stability value will be reduced by half if the route is unreachable.

When to Reuse a Route
Stability threshold that must be crossed for a route to be reused.

Start Suppressing Route
Stability threshold that, when crossed, a route will be suppressed.

Max Time to Suppress
Maximum time to suppress a route considered stable.

Advanced Routing Behavior

Disable Fast External Failover
Do not immediately reset session if a link to a directly connected external peer goes down.

Network Import Check
Checks if a BGP network route exists in IGP before creating BGP table entries.

Note: This should be disabled if this router wants to advertise manually summarized routes that do not exist in the routing table, such as collecting all local routes into a larger network in which they can be contained (e.g. `10.14.0.0/16`).

Reject AS_SET/AS_CONFED_SET Routes
Reject incoming and outgoing routes with AS_SET or AS_CONFED_SET type.

Route Reflecting

Route Reflector Outbound
Allows attributes modified by route maps to be reflected.

Cluster ID
Route reflector cluster ID.

Disable Client-to-Client
Disables reflection of routes from one client to another client.

Aggregate Behavior

Configures route aggregation using a list of prefixes. More specific routes contained within the specified prefixes will be aggregated into the larger prefix, minimizing the set of networks advertised to peers.

Aggregate Address
The prefix to aggregate.

Generate AS Set
When present, routes for the specified prefix will include an AS set. An AS set is a collection of AS numbers for which routes have been aggregated. This allows peers to detect routing loops, duplicate routes, and so on.

Summary Only
When present, aggregated routes for this prefix will not be announced, so peers only see the aggregate prefix and not the component networks.

Multi-Exit Discriminator

Deterministic MED
Determine route selection locally, even when MED values are present. Picks the best MED path from neighbor advertisements.

Always Compare MED
Instructs the BGP daemon to always consult MED values in routes, no matter which AS the routes were received through.

Max MED

Administratively applied max MED (Indefinite)
Sends a MED value of `4294967294` at all times.

Definite admin max MED
Sends this value at all times instead of the default `4294967294`.

Time Period for Max MED on startup
Sends a MED value of `4294967294` at startup for this number of seconds.

Max MED used during startup
Sends this value at startup instead of the default `4294967294`.

Confederation

AS Confederation
Configures an AS number for the entire group of iBGP routers participating in confederation.

Confederation Peers
Configures the sub-AS number for the subset of peers inside a group of iBGP routers participating in confederation.

Distance

Administrative Distance
Manually configures the administrative distance for a given prefix

Define
The administrative distance for this prefix, from `1-255`.

IP Source Prefix
The IP prefix to which this distance will be applied.

Access List
An access list which can be used to apply the distance to only a subset of the configured prefix.

BGP Distance
Configures distance values which control how BGP will treat routes based on the length of their AS path.

AS External Routes
The distance at which routes are considered external, from `1-255`.

AS Internal Routes
The distance at which routes are considered internal, from `1-255`.

Local Routes
The distance at which routes are considered local, from `1-255`.

Best Path Selection

Controls how the BGP daemon determines the best path to a destination.

Compare Path with Confederation
Considers the length of confederation path sets and sequences.

Ignore AS Path
Ignores AS path lengths when computing the route to a destination.

Multipath Relax

Allow Load Sharing
Consider paths of equal length when choosing between multiple paths to a destination, rather than looking for an exact match. This allows load sharing across different AS paths, so long as they are of equal length.

Generate an AS_SET
Adds AS set information for aggregate routes.

Compare Router ID
Uses the router ID of peers (or originator ID, if present) to break ties when computing paths to a destination based on other information. A lower router ID will win in a tie.

MED Confederation

Compare MED among confederation paths
Compare confederation path MEDs

Treat missing MED as least preferred path
If a route is missing MED information, it will be considered least preferred.

eBGP

eBGP Nexthop Connected
Disable checking if nexthop is an eBGP session.

Enforce First AS
Enforce the first AS for eBGP routes

Disable eBGP Require Policy
Disable the requirement to apply incoming and outgoing filter to eBGP sessions.

Networking Behavior

Subgroup Packet Queue
Maximum size of the subgroup packet queue.

Write Quanta
Controls the size of peer update transmissions.

BGP AS Paths

AS Path access lists entries determine if networks are allowed or denied in specific BGP configuration contexts. They are primarily used in BGP route maps, but also can be used in other areas of BGP configuration which accept AS Path lists as parameters.

The order of entries inside an AS Path list is important, and this order is determined by a sequence number. As with other access lists, AS Path access lists implicitly deny anything not matched.

AS Path lists are managed at **Services > FRR BGP** on the **AS Paths** tab.

The order of entries inside an AS Path list is important, and this order is determined by a sequence number.

BGP AS Path Configuration

The **AS Paths** tab contains a list of current AS Path lists, if any, and controls to manage the entires (e.g. edit, delete).

The  **Add** button creates a new AS Path list.

When creating or editing an AS Path list, the following options are available:

Name
The name of this BGP AS Path list.

Description
A text description of this list (e.g. its purpose)

AS Path Entries

A list of AS paths to match in this list. Click  **Add** to create additional rules on the same list.

Sequence
The sequence number for this rule, which controls the order in which rules are matched inside this AS Path list. Each rule must have a unique sequence number. Best practice is to leave gaps in the sequence to allow for adding rules in the future. For example, use `10`, `20`, `30`, rather than `1`, `2`, `3`.

Action
The action taken when this AS Path rule is matched, either *permit* or *deny*.

Regular Expression
A regular expression pattern which will match on the AS number.

Regular expression patterns support common pattern special characters for matching, but also a special _ character. The _ character matches common AS delimiters such as start of line, end of line, space, comma, braces, and parenthesis. The _ character can be used on either side of an AS number to match it exactly, such as `_65534_`.

BGP Community Lists

A BGP community, as defined in RFC 1997, is a group of destinations which share common properties. Community Lists define sets of community attributes which the BGP daemon can use to match or set community values in routing updates. BGP communities determine AS membership and priority values in BGP-specific contexts such as route-maps.

BGP community lists are managed at **Services > FRR BGP** on the **Communities** tab.

The order of entries inside a community list is important, and this order is determined by a sequence number.

BGP Well-Known Communities

There are several "well-known" communities available for use in Community Lists. Each of these communities have special meanings:

internet
: A community value of `0`, indicating the Internet as a destination.

no-export
: Routes received carrying this attribute value must not be exported to routers outside of the current confederation.

no-advertise
: Routes received carrying this attribute value must not be advertised to any other BGP peer.

local-as
: Also known as "No Export Subconfed". Routes received carrying this attribute value must not be advertised to any external BGP peer, even those in the same confederation.

blackhole
: Routes received carrying this attribute should not be routed (e.g. null routed).

graceful-shutdown
: Indicates support for RFC 8326 Graceful Shutdown, which allows BGP routers to indicate to peers that specific paths can be gracefully shut down rather than abruptly terminated when performing an intentional shutdown.

no-peer
: Indicates that routes with this community value should not be readvertised to peers (RFC 3765).

BGP Community List Configuration

The **Communities** tab contains a list of current community lists, if any, and controls to manage the entires (e.g. edit, delete). The  **Add** button creates a new community list.

When creating or editing a community list, the following options are available:

Name
: The name of this BGP community list.

Description
: A text description of this list (e.g. its purpose)

Community List Type
: The type of community list to use for this entry, which controls how values are matched.

Standard
Matches based on specific values for community attributes, either AS:Value pairs or names of *well-known communities*.

Expanded
Matches based on an ordered list using a regular expression. Due to the use of regular expression evaluation, these lists incur a performance penalty.

Community List Entries

A list of rules for this community list. Click  **Add** to create additional rules on the same list.

Sequence
The sequence number for this rule, which controls the order in which rules are matched inside this community list. Each rule must have a unique sequence number. Best practice is to leave gaps in the sequence to allow for adding rules in the future. For example, use `10`, `20`, `30`, rather than `1`, `2`, `3`.

Action
The action taken when this Community List rule is matched, either *permit* or *deny*.

Community
The value of the community to match.

Standard Community Lists
This is a space-separated list of communities in AS:Value format, or from the *well-known communities* list.

Expanded Community Lists
A string containing a regular expression to match against.

Regular expression patterns support common pattern special characters for matching, but also a special _ character. The _ character matches common AS delimiters such as start of line, end of line, space, comma, braces, and parenthesis.

BGP RPKI Cache Servers

Resource Public Key Infrastructure (RPKI) is a means by which FRR can enact Prefix Origin Validation (POV) to ensure that it is talking to the correct origin for a given AS.

This validation is **not** performed by FRR or other routers directly, but by trusted servers which cache the information.

Note: For more details, see RFC 6810 for the protocol and RFC 6811 for validation.

RPKI happens over a plain TCP connection but FRR can protect this by performing the validation over SSH.

Route maps can be used to filter routes based on a validated origin.

RPKI Cache Servers are managed at **Services > FRR BGP** on the **RPKI Cache Servers** tab.

RPKI Cache Server Configuration

The **RPKI Cache Servers** tab contains a list of current RPKI Cache Servers, if any, and controls to manage the entires (e.g. edit, delete). The  **Add** button creates a new RPKI Cache Server.

When creating or editing an RPKI Cache Server, the following options are available:

Address
: **Required**. The IP **Address** or hostname of the RPKI Cache Server, and the **Port** number upon which the service is listening.

Preference
: **Required**. A preference value FRR can use to decide between multiple RPKI Cache Servers.

SSH Options
: The best practice is to encrypt communication with the RPKI Cache Server using SSH. The remaining options setup an SSH session, and all are optional.

  Username
  : The username to use when connecting to the server via SSH.

  Private Key Path
  : Full filesystem path to the private key for this router.

  > **Warning:** This must not have a passphrase as there is no way to securely store and use a passphrase. Protect the private key file appropriately, but it must also be accessible to FRR.

  Public Key Path
  : Full filesystem path to the public key for this router.

  Known hosts Path
  : Full filesystem path to a file containing valid public keys for RPKI Cache Servers in SSH `known_hosts` format.

BGP Status

The status page for BGP can be found at **Status > FRR**, **BGP** tab. It can also be accessed by visiting the **Status** tab while configuring BGP options.

See also:

For general FRR status information, see *FRR Status*.

BGP Routes
: A list of routes being advertised to BGP and received from BGP. The list includes information about the status of the route, its origin, AS path, and metrics.

BGP IPv6 Routes
: Same as **BGP Routes** but for IPv6 routes.

BGP Summary
: A high-level overview of BGP operations, including a brief list of neighbors and a summary of their activity and statistics.

BGP Neighbors
Detailed information about BGP peers and their status, including the state of the neighbor (e.g. `Established`), its capabilities, and much more.

BGP Peer Groups
Information about BGP Peer Groups, if any are in use.

BGP Next Hops
A list of known route targets kept in a cache by FRR.

BGP Memory
A summary of memory (RAM) consumed by BGP.

30.10.3 Open Shortest Path First v2 (OSPF)

Open Shortest Path First v2 (OSPF) is a link-state routing protocol defined by RFC 2328. OSPF automatically locates neighboring IPv4 routers within an autonomous system, typically with multicast, and exchanges IPv4 routing information for networks reachable through each neighbor.

OSPF is an interior routing protocol (IGP), and facilitates routing between private links or segments of local networks.

OSPF Terminology

OSPF has common terms used throughout this section which can be confusing for those unfamiliar with the protocol.

Area
A collection of routers inside an AS, each sharing the same area ID. An Area ID is typically formatted like an IP address in dotted quad notation, `nnn.nnn.nnn.nnn`, but can also be expressed as an unsigned 32-bit integer.

Area Border Router (ABR)
A router connected to multiple areas.

Autonomous System Boundary Router (ASBR)
A router connected to external networks (outside the area).

Backbone
The central area of an AS, typically area `0.0.0.0`. All areas in the AS connect to the backbone through ABRs.

Cost
A numeric value assigned to a link between networks, used by OSPF to calculate optimal paths to a destination. Typically higher bandwidth or higher quality circuits will be assigned a low cost, while circuits that are undesirable will be given a high cost. OSPF will prefer to use a route when it has the lowest total cost from a source to a destination.

Designated Router (DR)
In a network with multiple routers, one of them will be elected as a designated router (DR) using `Hello` messages. The DR takes on the task of generating LSA messages for the network, among other special duties.

Flooding
The mechanism by which OSPF routers distribute link state database information to neighbors.

Hello
Special OSPF messages which introduce neighbors to each other. Using these messages, neighbors can discover each other and begin to form routing relationships.

Interior Gateway Protocol (IGP)
A routing protocol, such as OSPF, which exchanges information about how to reach networks *inside* an autonomous system.

Link State Advertisement (LSA)
Messages sent by OSPF routers which describe the state of network links, or the router itself, including information about its interfaces and other neighbors.

Link State Database (LSDB)
A database containing the collected LSA messages of all routers and networks in the domain.

Link State Advertisement Message Types

LSA messages each have a type, indicating the information carried within. These types may be referenced throughout this section when describing routing behaviors.

Type 1 - Router LSA
Sent by every router in an area. Contains a description of all links on the router, including their state and costs.

Type 2 - Network LSA
Sent by the DR for a network. Contains a description of every router attached to the network, including the DR.

Type 3 - Network Summary-LSA
Sent by ABRs. Contains a description of destinations outside the current area (inter-area) when the destination is an IP network.

Type 4 - ASBR Summary-LSA
Similar to Type 3, but when sent when the destination is an ASBR.

Type 5 - AS-external LSA
Sent by ASBRs. Contains a description of destinations outside of this AS. Typically each message only contains information about a single destination.

Type 6 - Multicast Group Membership LSA
Not used.

Type 7 - NSSA External Link-State Advertisements
Similar to Type 5, but are only exchanged inside an NSSA.

Type 8 - External attribute LSA
Carry information from external routing protocols, such as BGP, when such destinations are announced with Type 5 LSAs.

Type 9 - Link Scope Opaque LSA
Carries information intended for uses other than OSPF, such as available bandwidth. It is carried through to other routers without being processed by OSPF itself. Type 9 messages are for other routers on the same link.

Type 10 - Area Scope Opaque LSA
Similar to Type 9, but flooded to all routers in an area.

Type 11 - AS Scope Opaque LSA
Similar to Type 9, but flooded to all routers throughout the AS, except for special areas such as stubs.

Area Types

OSPF Areas can be one of several types which alter their behavior in important ways.

Normal
A typical area in which all routers know all possible routes.

Stub Area
An area with no external connections. Since traffic passing out of a stub area must pass through an ABR, it only needs to know about routes to the ABR, not beyond the ABR. Routers in a stub area do not receive Type 5 LSAs.

Totally Stub Area
Similar to a stub area, but routers also do not receive summary LSA messages except for default route information. As such, they do not receive LSA messages of type 3, 4, or 5.

Not-so-Stubby-Area (NSSA)
Similar to a Stub area but it may contain static routes to non-OSPF networks. Routers in an NSSA exchange external routing information in Type 7 LSAs instead of Type 5.

NSSA Totally Stub Area
Similar to both NSSA and a Totally Stub area. As such, they do not receive LSA messages of type 3, 4, or 5.

Metric Types

Type 1 or E1
A Type 1 external metric, also known as E1, uses a similar cost calculation to typical link states, where internal and external costs are added together to find the total cost.

Type 2 or E2
A Type 2 external metric, also known as E2, only considers external costs and ignores internal costs.

OSPF Required Information

Before starting, take the time to gather all of the information required to form an OSPF adjacency to a neighbor. At a minimum, FRR will need to know these items:

Local Router ID
Typically the highest numbered local address on the firewall. This is also frequently set as the internal or LAN side IP address of a router. It does not matter what this ID is, so long as it is given in IPv4 address notation and does not conflict with any neighbors.

Local OSPF Area
A designation for the set of networks to which this router belongs. Can be any number capable of being expressed in dotted quad notation (IPv4 address) or as a 32-bit unsigned integer.

In typical OSPF configurations such as this example, `0.0.0.0` is the backbone area between all routers and each local network has its own area. For simpler deployments, the only area may be `0.0.0.0` on every router and interface. Using a single area disables some features such as route summarization.

OSPF Active Interfaces
The interfaces on this router upon which the OSPF daemon will advertise itself and look for neighbors. These interfaces are connected to network segments with other routers. They may be connected to local networks or remote point-to-point links. These interfaces must be configured with IP addresses.

OSPF Active Interface Cost Values
OSPF calculates the most efficient way to route between networks based on the total cost of a path from source to destination. Less desirable links (e.g. wireless) can be given a higher cost so that paths over faster networks will be used by traffic unless the preferred path is unavailable. For single connections to other networks, this value is not necessary and may be omitted or set to a simple default such as `5` or `10`.

OSPF Passive Interfaces
These interfaces contain networks which should be advertised as reachable through this router, but do not contain other routers.

Summary Routes
A list of networks to advertise instead of using networks from directly attached interfaces. This allows many similar routes to be summarized as one larger route if they can all be contained within a larger subnet.

This can only be done when connecting to an ABR in a configuration with multiple areas.

Note: This is optional, but without this in place, every network which must be advertised to neighbors must be attached to this firewall and the interfaces must be added as passive interfaces in OSPF. Using a summary route is cleaner in that it advertises less (one large subnet vs many small subnets) and that it requires less ongoing configuration.

The example in this section uses the following values:

Table 2: Example OSPF Configuration

Item	Value
Local Router ID	10.2.0.1
OSPF Backbone Area	0.0.0.0
Local OSPF Area	0.0.0.2
Active Interfaces (Cost)	OPT1 (10)
Passive Interfaces	LAN
Summary Routes	10.2.0.0/16

OSPF Example Configuration

This example configuration implements a multi-area OSPF setup using the required information from *Example OSPF Configuration*.

Assumptions

This example makes a few assumptions for brevity and to keep the example simple, including:

- The remote peer is already configured for OSPF with equivalent settings.
- Transit to the peer across a directly attached shared network is already configured, for example over a VPN, shared network segment, or peer-to-peer link.
- The link to the peer is capable of handling multicast traffic.
- Firewall rules pass OSPF traffic, which is protocol `89`. It is not TCP or UDP. Firewall rules must allow multicast traffic destinations for OSPF, and it cannot be restricted to specific sources and destinations in this example.

Example Configuration

The OSPF configuration must be done in the following order initially. Later changes may be made in any order. This is because a valid OSPF configuration requires **Interface** tab entries which must exist before the main OSPF settings can be saved.

OSPF Area Configuration

- Navigate to **Services > FRR OSPF**, **Areas** tab
- Click  **Add** to create a new area
- Set the following options:

  Area
  `0.0.0.0`

  Description
  `Backbone`

- Click **Save**
- Click  **Add** to create a new area
- Set the following options:

  Area
  `0.0.0.23`

  Description
  `Local Area`

  Area Type
  Stub Area (stub)

  Summary Range
  `10.2.0.0/16`

- Click **Save**

OSPF Interface Configuration

- Navigate to **Services > FRR OSPF**, **Interfaces** tab
- Click  **Add** to create a new interface
- Set the following options:

  Interface
  LAN

  Interface is Passive
  Checked

  Area
  `0.0.0.23`

- Click **Save**
- Click  **Add** to create a new interface
- Set the following options:

  Interface
  OPT1

  Ignore MTU
  Checked

  Metric
  `10`

  Area
  `0.0.0.0`

- Click **Save**

OSPF Configuration

- Navigate to **Services > FRR OSPF**, **OSPF** tab
- Set the following options:

  Enable
  Checked

  Router ID
  `10.2.0.1`

  Default Area
  `0.0.0.0`

- Click **Save**

FRR Global Configuration

- Navigate to the **[Global Settings]** tab
- Set the following options:

  Enable
  Checked

  Master Password
  Create a random string to use

- Click **Save**
- Navigate to the **Status** tab
- Confirm that the OSPF neighbor is present and its routes are in the table

OSPF Configuration

OSPF FRR configuration, as shown in the example, can be fairly straightforward. That said, there are a number of ways to fine-tune the behavior and create complex OSPF routing configurations.

Read through each section before attempting to create a new OSPF configuration.

Note: Though the documentations covers OSPF in *tab* order, OSPF interfaces must be configured before the general OSPF options.

OSPF Tab Configuration

The options on this page configure the general behavior of OSPF in FRR, including various default values used when more specific options are not available.

> **Warning:** When creating an initial OSPF configuration, configure the *interfaces to be used with OSPF* first. The interface configuration must exist before these general OSPF settings can be saved.

General Options

Enable
Master enable switch for OSPF routing. When checked, FRR will start the OSPF routing daemon and attempt to use the OSPF settings in this section.

Log Adjacency Changes
When set, instructs the OSPF daemon to log changes in neighbor adjacencies. This is useful for tracking changes to neighbor relationships, especially during initial configuration.

Router ID
Typically the highest numbered local address on the firewall. This is also frequently set as the internal or LAN side IP address of a router. It does not matter what this ID is, so long as it is given in IPv4 address notation and does not conflict with any neighbors.

SPF Hold Time
SPF timers determine when the router will make SPF routing decisions. Lowest time allowed between SPF calculations. Specified in milliseconds from `0-600000`, with a default value of `1000`.

The maximum time is calculated as 10x this value.

SPF calculations are adaptive, and if a new event occurs which would otherwise trigger a calculation before the hold timer expires, then the hold is increased by the **SPF Hold Time** value, up to the maximum. This avoids excessive consecutive recalculations.

SPF Delay
Controls timers that determine when the router will make SPF routing decisions. Minimum time after an event occurs before allowing SPF calculation. Lower values will react faster to changes, but can be less stable. Specified in milliseconds from `0-600000`, with a default value of `200`.

Modules

Enable SNMP AgentX
Enable agentx support for accessing FRR OSPF data via SNMP with the net-snmp package.

Default Area

Default Area
Default OSPF area for this instance of OSPF. Used when an area is required but not defined elsewhere. See *OSPF Area Configuration* for details.

Default Area Type
Sets the type for the **Default Area**. See *Area Types* and *OSPF Area Configuration* for details.

OSPF Networks

> **Warning:** This section is **deprecated** and will not be covered here. Define *areas* and use areas on *interfaces* instead. Use summary routes instead, or use route-maps and distribute lists to limit distributed networks.

Route Redistribution

This section controls which, if any, IPv4 routes are redistributed to OSPF neighbors from other sources (*Dynamic Routing Protocol Lists*). OSPF can redistribute IPv4 routes from connected networks, kernel routes, BGP, and FRR static routes.

Redistribute
Enables redistribution of routes from the given source.

Metric
Advertise the routes from this source as having the given metric.

Metric Type
The type of metric, either `1` or `2`. See *Metric Types* for details about each type operates.

Route Map
Apply the given route map to the redistributed route advertisements.

Distribute List
Applies the given *access list* to routes redistributed from a given route source.

Default Route Redistribution

Redistribute
Enables origination of a Type 5 AS-External LSA containing default route information into all areas capable of external routing.

Always Redistribute
Always advertise a default route, even when a default route is not present in the local routing table.

Default Metric
Advertise the default route as having the given metric.

Default Metric Type
The type of metric, either `1` or `2`. See *Metric Types* for details about each type operates.

Route Map
Apply the given route map to the outbound default route advertisement.

Advanced

RFC 1583 Compatibility
Enables compatibility with the older OSPF standard from RFC 1583, which has been obsoleted by the newer RFC 2328. The specific change this option enables relates to external path preference calculation and routing loop prevention. See RFC 2328 section **G.2** for specific details.

Opaque LSA
Enables support for Opaque LSAs, as described in RFC 2370.

Reference Bandwidth
A base value, in Mbit/s, which is used when OSPF automatically calculates cost values. The default value is `100` which means that an interface with 100Mbit/s of bandwidth or greater will have a cost of `1`, with lower bandwidth values incurring higher cost values.

All routers in the same area should use the same value, otherwise automatic cost calculations would fail to accurately represent total path costs between routers.

Max Metric

Administratively Enable Max Metric
Sets the administrative distance of routes through this router to infinity, so that other routers will avoid using this router to reach other networks. Networks on this router are still reachable. See RFC 3137 for more information.

Startup Seconds
Conditionally sets the administrative distance of routes through this router to infinity for a period of time after startup.

This allows other routers in the area to avoid using routes through this router until a full convergence is achieved.

Shutdown Seconds
Conditionally sets the administrative distance of routes through this router to infinity for a period of time after shutdown.

This allows other routers in the area to avoid using routes through this router until a full convergence is achieved.

Write Multiplier
Number of interfaces processed per write operation, from `1-100`. Default value is `20`.

ABR Type
Controls the behavior of Area Border Router (ABR) functionality.

cisco|ibm
The default behavior of OSPF in FRR, discussed in RFC 3509. This behavior allows an ABR without a backbone connection to act as an internal router for all connected areas.

shortcut
Discussed in draft-ietf-ospf-shortcut-abr-02, this behavior allows ABRs to consider summary LSAs from all attached areas, rather than being forced to route through a suboptimal path only because it is shorter.

standard
The ABR behavior described in the original OSPF standard. When set, a router attached to multiple areas requires a connection to a backbone. If no backbone is available, traffic attempting to cross areas will be dropped.

OSPF Area Configuration

OSPF Areas are managed at **Services > FRR OSPF** on the **Areas** tab.

The **Areas** tab contains a list of current OSPF areas, if any, and controls to manage the entries (e.g. edit, delete). The  **Add** button creates a new area.

The remaining sections on this page cover the various options available when creating or editing an area entry.

Area Options

Area
A designation for the set of networks. Can be any number capable of being expressed in dotted quad notation (IPv4 address) or as a 32-bit unsigned integer.

In typical OSPF configurations `0.0.0.0` is the backbone area between all routers and each local network has its own area. For simpler deployments, the only area may be `0.0.0.0` on every router and interface. Using a single area disables some features such as route summarization.

Description
Some text describing this area.

Area Type
Defines how this area behaves. For a list of all types and how they operate, see *Area Types*.

Default Route Cost
Sets the cost applied to default route summary LSA messages sent to stub areas.

ABR Shortcut
For use with **ABR Type** set to *Shortcut* (*Advanced*), this advertises the area as capable of supporting ABR shortcut behavior (draft-ietf-ospf-shortcut-abr-02).

Authentication

This option enables authentication for this area. Communication from peers must contain the expected authentication information to be accepted, and outgoing packets will have authentication information added.

Authentication passwords and keys are configured by the *OSPF interface settings*.

Authentication Type
Sets the type of authentication to use in this area.

None
Do not use authentication in this area.

Message Digest (MD5 Hash)
Enables MD5 HMAC authentication for this area. This is stronger authentication than simple passwords.

Simple Password
Enables simple password authentication for this area.

Route Summarization

Configure summarization of routes inside the given prefixes. Instead of Type 1 (Router) and Type 2 (Network) LSAs, it creates Type 3 Summary LSAs instead.

The options here can be repeated for multiple prefixes. Click  **Add** for each additional prefix.

Summary Prefix
The prefix to summarize.

Do Not Advertise
Disable advertisement for this prefix.

Cost
Apply the specified cost to summarized routes for this prefix.

Substitute Prefix
Instead of advertising the first prefix, advertise this prefix instead.

ABR Summary Route Filtering

Export List
Uses the given ACL to limit Type 3 summary LSA messages for intra-area paths that would otherwise be advertised. This behavior only applies if this router is the ABR for the area in question.

Import List
Similar to `export-list`, but for routes announced by other routers into this area.

Filter List (Out|In)
Similar to **Export List** and **Import List** but uses prefix lists instead of ACLs, and can work in either direction.

OSPF Interface Configuration

OSPF interfaces are managed at **Services > FRR OSPF** on the **Interface** tab.

The **Interfaces** tab contains a list of current OSPF interfaces, if any, and controls to manage the entries (e.g. edit, delete). The  **Add** button creates a new interface.

OSPF must use one or more interfaces to announce itself to neighbors and to receive announcements from neighbors. At least one interface must be configured and active in order to locate neighbors and form an adjacency.

The remaining sections on this page cover the various options available when creating or editing an interface entry.

Interface Options

Interface
The interface to use with OSPF. Entries should be added for interfaces which connect to other routers (neighbors) as well as interfaces containing networks which should be advertised to OSPF neighbors.

Description
Text describing the purpose of this interface in OSPF.

Network Type
Manually configures a specific type of network used on a given interface, rather than letting OSPF determine the type automatically. This controls how OSPF behaves and how it crafts messages when using an interface.

Tip: Most environments will use either *Broadcast* mode (e.g. Ethernet) or *Point-to-Point* mode (e.g. VPNs).

Broadcast
Broadcast networks, such as typical Ethernet networks, allow multiple routers on a segment and OSPF can use broadcast and multicast to send messages to multiple targets at once. OSPF assumes that all routers on broadcast networks are directly connected and can communicate without passing through other routers.

Non-Broadcast
Non-broadcast networks support multiple routers but do not have broadcast or multicast capabilities. Due to this lack of support, neighbors must be manually configured using the **Neighbor** tab (*OSPF Neighbor Configuration*).

When using this mode, OSPF simulates a broadcast network using Non-Broadcast Multi-Access (NMBA) mode, but transmits messages to known neighbors directly.

Point-to-Multipoint
Similar to *Non-Broadcast* mode, but connections to manually configured neighbors are treated as a collection of point-to-point links rather than a shared network. Similar to a point-to-point network, OSPF disables DR election.

Point-to-Point
A point-to-point network links a single pair of routers. The interface is still capable of broadcast, and OSPF will dynamically discover neighbors. With this type of network, OSPF disables election of a DR.

Interface is Passive
Configures the specified interface as passive. This prevents the interface from actively participating in OSPF, while still allowing OSPF to operate on networks connected to that interface. This is commonly used for local interfaces without other routers attached. OSPF will announce networks attached to passive interfaces as stub links.

Ignore MTU
When present, OSPF will ignore the MTU advertised by neighbors and can still achieve a full adjacency when peers do not have matching MTU values.

Tip: If two neighbors are stuck in an `ExStart` state, that is typically from an MTU mismatch. If fixing the MTU mismatch is not viable, set this option on both sides.

OSPF Interface Handling

Metric
A manual cost value to apply to this interface, rather than allowing automatic cost calculation to take place.

In situations where multiple paths are possible to the same destination, this allows OSPF to prefer one path over another when all else is equal.

Area
This defines the interface as a member of the given area. If this is left blank, FRR will take the value set in *Default Area*.

Accept Filter
When set, automatically configures lists behind the scenes to prevent this interface subnet from being advertised to, or received from, OSPF.

This can avoid problems seen in Multi-WAN deployments where there are multiple paths to a remote neighbor and a router can end up learning a route to itself across a VPN link, which is problematic.

Authentication

Configures authentication for OSPF neighbors on this interface. All routers connected to this interface must have identical authentication configurations. This can also be enabled in the area settings.

Authentication Type
Sets the type of authentication to use in this area.

None
Do not use authentication in this area. This is the default behavior, but may be explicitly configured to override the authentication configured for this area.

Message Digest (MD5 Hash)
Enables MD5 HMAC authentication for this area. This is stronger authentication than simple passwords.

Simple Password
Enables simple password authentication for this area.

Password
Password to use with *Simple Password* or key to use with *Message Digest* authentication.

This value must match all neighbors reachable through this interface. Simple passwords may be up to 8 characters, Message Digest passwords (keys) may be up to 16 characters.

Advanced

Router Priority
A priority value, from `0-255`, assigned to this router. When determining which router will become the Designated Router (DR), the router with the highest priority is more likely to be elected as the DR.

The default value is `1`. The value `0` is special and will prevent this router from being chosen as DR.

Retransmit Interval
The interval, in seconds from `1-65535`, at which this router will retransmit Link State Request and Database Description messages. This is also known as the `RxmtInterval` timer in OSPF. Default value is `5`.

Hello Interval
The interval, in seconds from `1-65535`, at which this router will send hello messages. This is also known as the `HelloInterval` timer in OSPF. Default value is `10`. This timer should be set to the same value for all routers.

A lower value will result in faster convergence times, but will consume more resources.

Dead Interval
Time, in seconds from `1-65535`, without communication from a neighbor on this interface before considering it dead. This is also known as the `RouterDeadInterval` timer in OSPF. Default value is `40`. This timer should be set to the same value for all routers.

Minimal Hello
When active, the **Dead Interval** is forced to a value of `1` and OSPF will instead send this number of Hello messages each second. This allows for faster convergence, but will consume more resources.

Note: When set, this overrides the values of both **Dead Interval** and **Hello Interval**. Custom values configured in those fields will be ignored by OSPF.

BFD

When set, enables *Bidirectional Forwarding Detection* for OSPF on this interface.

OSPF Neighbor Configuration

OSPF neighbors are managed at **Services > FRR OSPF** on the **Neighbors** tab.

The **Neighbors** tab contains a list of current OSPF neighbors, if any, and controls to manage the entries (e.g. edit, delete). The  **Add** button creates a new neighbor.

In most cases OSPF neighbors do not need to be added manually. In certain environments with links which do not support multicast, manual neighbor definitions allow FRR to locate neighbors statically. This can be useful to work around limitations imposed by certain point-to-point links or VPN configurations.

The remaining sections on this page cover the various options available when creating or editing a neighbor entry.

Neighbor Options

OSPF Neighbor IPv4 Address
The IPv4 address of this OSPF neighbor.

Description
Text describing this neighbor.

Neighbor Priority
A priority value applied to neighbors in a down state.

Dead Neighbor Polling Interval
Time, in seconds, between sending OSPF Hello messages to neighbors in a down state.

OSPF Status

The status page for OSPF can be found at **Status > FRR**, **OSPF** tab. It can also be accessed by visiting the **Status** tab while configuring OSPF options.

See also:

For general FRR status information, see *FRR Status*.

OSPF General
General information about the OSPF process, active configuration, and operation.

OSPF Neighbors
A list of OSPF neighbors detected by FRR and their status.

Tip: If a neighbor is stuck in a state such as "ExStart", check that the interface MTUs match. Consider checking the interface option to **Ignore MTU** which will bypass this check.

OSPF Routes
A list of routes being advertised to OSPF and received from OSPF. The list is broken into three parts:

OSPF Network Routing Table
A list of internal networks and their status, how they are reached through neighbors and areas, etc.

OSPF Router Routing Table
A list of other routers through which OSPF networks are reached.

OSPF External Routing Table
A list of external routes from OSPF.

OSPF Database
The OSPF link state database with information about each known router and area.

OSPF Router Database
Detailed information about OSPF routers and how they are connected.

OSPF Interfaces
Detailed information about interfaces on the firewall and how they are used by OSPF.

OSPF CPU Usage
The amount of CPU time used by OSPF for various tasks and threads.

OSPF Memory
The amount of memory (RAM) used by OSPF for various tasks and threads.

30.10.4 Open Shortest Path First v3 (OSPF6)

Open Shortest Path First v3 (OSPF6) is defined by RFC 5340 and is similar to OSPF v2, but operates with IPv6 networks. Thus, it is a link-state routing protocol that automatically locates neighboring IPv6 routers within an autonomous system, typically with multicast, and exchanges IPv6 routing information for networks each neighbor.

OSPF6 is an interior routing protocol (IGP), and facilitates routing between private links or segments of local networks.

Terms used in this section are shared with OSPF, and are covered in *OSPF Terminology*.

OSPF6 Required Information

Before starting, take the time to gather all of the information required to form an OSPF6 adjacency to a neighbor. This list is similar to *that of OSPF*. At a minimum, FRR will need to know these items:

Local Router ID
: Typically the highest numbered local address on the firewall. This is also frequently set as the internal or LAN side IP address of a router. It does not matter what this ID is, so long as it is given in IPv4 address notation and does not conflict with any neighbors.

OSPF6 Area
: A designation for the set of networks to which this router belongs. Can be any number capable of being expressed in dotted quad notation (IPv4 address) or as a 32-bit unsigned integer.

OSPF6 Active Interfaces
: The interfaces on this router upon which the OSPF6 daemon will advertise itself and monitor for neighbors. These interfaces are connected to network segments with other routers. They may be connected to local networks or remote point-to-point links. These interfaces only require an IPv6 link local address.

OSPF6 Active Interface Cost Values
: OSPF6 calculates the most efficient way to route between networks based on the total cost of a path from source to destination. Less desirable links (e.g. wireless) can be given a higher cost so that paths over faster networks will be used by traffic unless the preferred path is unavailable. For single connections to other networks, this value is not necessary and may be omitted or set to a simple default such as `5` or `10`.

OSPF6 Passive Interfaces
: These interfaces contain networks which FRR will advertise as reachable through this router, but do not contain other routers.

The example in this section uses the following values:

Table 3: Example OSPF Configuration

Item	Value
Local Router ID	10.2.0.1
OSPF6 Area	0.0.0.0
Active Interfaces (Cost)	OPT1 (10)
Passive Interfaces	LAN

OSPF6 Example Configuration

This example configuration implements an OSPF6 setup using the required information from *Example OSPF Configuration*.

Assumptions

This example makes a few assumptions for brevity and to keep the example simple, including:

- The remote peer is already configured for OSPF6 with equivalent settings.
- IPv6 transit to the peer across a directly attached shared network is already configured, for example over a VPN, shared network segment, or peer-to-peer link.
- The link to the peer is capable of handling multicast traffic.
- Firewall rules pass OSPF traffic, which is protocol `89`. It is not TCP or UDP. Firewall rules must allow multicast traffic destinations for OSPF, and it cannot be restricted to specific sources and destinations in this example.

Example Configuration

The OSPF6 configuration must be done in the following order initially. Later changes may be made in any order. This is because a valid OSPF6 configuration requires **Interface** tab entries which must exist before the main OSPF6 settings can be saved.

OSPF6 Interface Configuration

- Navigate to **Services > FRR OSPF6**, **Interfaces** tab
- Click  **Add** to create a new interface
- Set the following options:

  Interface
  LAN

  Interface is Passive
  Checked

  Area
  `0.0.0.0`

- Click **Save**
- Click  **Add** to create a new interface
- Set the following options:

  Interface
  OPT1

  Ignore MTU
  Checked

  Metric
  `10`

Area
`0.0.0.0`

- Click **Save**

OSPF6 Configuration

- Navigate to **Services > FRR OSPF6**, **OSPF6** tab
- Set the following options:

Enable
Checked

Router ID
`10.2.0.1`

Default Area
`0.0.0.0`

- Click **Save**

FRR Global Configuration

- Navigate to the **[Global Settings]** tab
- Set the following options:

Enable
Checked

Master Password
Create a random string to use

- Click **Save**
- Navigate to the **Status** tab
- Confirm that the OSPF6 neighbor is present and its routes are in the table

OSPF6 Configuration

There are a number of ways to fine-tune the behavior and create complex OSPF6 routing configurations. The available configuration parameters are covered throughout this section.

OSPF6 Tab Configuration

The options on this page configure the general behavior of OSPF6 in FRR, including various default values used when more specific options are not available.

Warning: When creating an initial OSPF6 configuration, configure the *interfaces to be used with OSPF6* first. The interface configuration must exist before these general OSPF6 settings can be saved.

General Options

Enable
Master enable switch for OSPF6 routing. When checked, FRR will start the OSPF6 routing daemon and attempt to use the OSPF6 settings in this section.

Log Adjacency Changes
When set, instructs the OSPF6 daemon to log changes in neighbor adjacencies. This is useful for tracking changes to neighbor relationships, especially during initial configuration.

Router ID
Typically the highest numbered local IPv4 address on the firewall. This is also frequently set as the internal or LAN side IPv4 address of a router. It does not matter what this ID is, so long as it is given in IPv4 address notation and does not conflict with any neighbors.

Note: Even though OSPF6 handles IPv6 routing, router IDs are specified using IPv4 addresses in dotted quad notation.

SPF Hold Time
SPF timers determine when the router will make SPF routing decisions. Lowest time allowed between SPF calculations. Specified in milliseconds from `0-600000`, with a default value of `1000`.

The maximum time is calculated as 10x this value.

SPF calculations are adaptive, and if a new event occurs which would otherwise trigger a calculation before the hold timer expires, then the hold is increased by the **SPF Hold Time** value, up to the maximum. This avoids excessive consecutive recalculations.

SPF Delay
Controls timers that determine when the router will make SPF routing decisions. Minimum time after an event occurs before allowing SPF calculation. Lower values will react faster to changes, but can be less stable. Specified in milliseconds from `0-600000`, with a default value of `200`.

Modules

Enable SNMP AgentX
Enable agentx support for accessing FRR OSPF6 data via SNMP with the net-snmp package.

Default Area

Default Area
Default OSPF area for this instance of OSPF6. Used when an area is required but not defined elsewhere. See *OSPF6 Area Configuration* for details.

Default Area Type
Sets the type for the **Default Area**. See *Area Types* and *OSPF6 Area Configuration* for details.

Route Distribution

The **Distribute Ranges** entries instruct OSPF to associate specific IPv6 prefixes with a given OSPF6 area and to advertise them to neighbors. Additional entries can be created by the  **Add** button.

Note: In most cases these entries are not necessary to add manually, as interface entries will add appropriate statements to distribute interface subnets as needed.

Subnet to Route
The IPv6 prefix to advertise.

Area ID
The area with which to associate the prefix.

Cost
The cost associated with the prefix.

Route Redistribution

This section controls which, if any, IPv6 routes are redistributed to OSPF6 neighbors from other sources (*Dynamic Routing Protocol Lists*). OSPF6 can redistribute IPv6 routes from connected networks, kernel routes, BGP, and FRR static routes.

Redistribute
Enables redistribution of routes from the given source.

Route Map
Apply the given route map to the redistributed route advertisements.

Route Filtering

Export List
Uses the given ACL to limit Type 3 summary LSA messages for intra-area paths that would otherwise be advertised.

Import List
Similar to `export-list`, but for routes announced by other routers into this area.

Filter List (Out|In)
Similar to **Export List** and **Import List** but uses prefix lists instead of ACLs, and can work in either direction.

Advanced

Reference Bandwidth
A base value, in Mbit/s, which is used when OSPF6 automatically calculates cost values. The default value is `100` which means that an interface with 100Mbit/s of bandwidth or greater will have a cost of 1, with lower bandwidth values incurring higher cost values.

All routers in the same area should use the same value, otherwise automatic cost calculations would fail to accurately represent total path costs between routers.

Distance
Sets an administrative distance for routes obtained via OSPF6. This can be configured globally as well as for specific types of OSPF6 routes.

External Distance
Sets the administrative distance for external OSPF6 routes.

Inter-area Distance
Sets the administrative distance for OSPF6 routes between areas.

Intra-area Distance
Sets the administrative distance for OSPF6 routes inside an area.

OSPF6 Interface Configuration

OSPF6 interfaces are managed at **Services > FRR OSPF6** on the **Interface** tab.

The **Interfaces** tab contains a list of current OSPF6 interfaces, if any, and controls to manage the entries (e.g. edit, delete). The  **Add** button creates a new interface.

OSPF6 must use one or more interfaces to announce itself to neighbors and to receive announcements from neighbors. At least one interface must be configured and active in order to locate neighbors and form an adjacency.

The remaining sections on this page cover the various options available when creating or editing an interface entry.

Interface Options

Interface
The interface to use with OSPF6. Entries should be added for interfaces which connect to other routers (neighbors) as well as interfaces containing networks which should be advertised to OSPF6 neighbors.

Description
Text describing the purpose of this interface in OSPF6.

Network Type
Manually configures a specific type of network used on a given interface, rather than letting OSPF6 determine the type automatically. This controls how OSPF6 behaves and how it crafts messages when using an interface.

Broadcast
Broadcast networks, such as typical Ethernet networks, allow multiple routers on a segment and OSPF6 can use broadcast and multicast to send messages to multiple targets at once. OSPF6 assumes that all routers on broadcast networks are directly connected and can communicate without passing through other routers.

Point-to-Point
A point-to-point network links a single pair of routers. The interface is still capable of broadcast, and OSPF6 will dynamically discover neighbors. With this type of network, OSPF6 disables election of a DR.

Interface is Passive
Configures the specified interface as passive. This prevents the interface from actively participating in OSPF6, while still allowing OSPF6 to operate on networks connected to that interface. This is commonly used for local interfaces without other routers attached. OSPF6 will announce networks attached to passive interfaces as stub links.

Ignore MTU
When present, OSPF6 will ignore the MTU advertised by neighbors and can still achieve a full adjacency when peers do not have matching MTU values.

Tip: If two neighbors are stuck in an `ExStart` state, that is typically from an MTU mismatch. If fixing the MTU mismatch is not viable, set this option on both sides.

OSPF6 Interface Handling

Area
This defines the interface as a member of the given area. If this is left blank, FRR will take the value set in *Default Area*.

Instance ID
An alternate OSPF6 instance identifier for this interface. Typically omitted or set to `0`.

Metric
A manual cost value to apply to this interface, rather than allowing automatic cost calculation to take place.

In situations where multiple paths are possible to the same destination, this allows OSPF6 to prefer one path over another when all else is equal.

Advanced

Router Priority
A priority value, from `0-255`, assigned to this router. When determining which router will become the Designated Router (DR), the router with the highest priority is more likely to be elected as the DR.

The default value is `1`. The value `0` is special and will prevent this router from being chosen as DR.

Hello Interval
The interval, in seconds from `1-65535`, at which this router will send hello messages. This is also known as the `HelloInterval` timer in OSPF6. Default value is `10`. This timer should be set to the same value for all routers.

A lower value will result in faster convergence times, but will consume more resources.

Dead Interval
Time, in seconds from `1-65535`, without communication from a neighbor on this interface before considering it dead. This is also known as the `RouterDeadInterval` timer in OSPF6. Default value is `40`. This timer should be set to the same value for all routers.

Retransmit Interval
The interval, in seconds from `1-65535`, at which this router will retransmit Link State Request and Database Description messages. This is also known as the `RxmtInterval` timer in OSPF6. Default value is `5`.

BFD

When set, enables *Bidirectional Forwarding Detection* for OSPF6 on this interface.

OSPF6 Area Configuration

OSPF6 Areas are managed at **Services > FRR OSPF6** on the **Areas** tab.

The **Areas** tab contains a list of current OSPF6 areas, if any, and controls to manage the entries (e.g. edit, delete). The  **Add** button creates a new area.

The remaining sections on this page cover the various options available when creating or editing an area entry.

Area Options

Area
A designation for the set of networks to which this router belongs. Can be any number capable of being expressed in dotted quad notation (IPv4 address) or as a 32-bit unsigned integer.

Description
Some text describing this area.

Area Type
Defines how this area behaves. For a list of all types and how they operate, see *Area Types*.

Note: The list of area types supported by OSPF6 is shorter than OSPF. Consult the GUI drop-down for a current list of supported area types.

Range Overrides

The **Ranges** list overrides the more specific ranges automatically determined from interfaces or by manual entry on the main configuration page. For example, this can be used to summarize routes or to prevent certain prefixes from being advertised.

When summarizing routes, instead of Type 1 (Router) and Type 2 (Network) LSAs, OSPF6 creates Type 3 Summary LSAs instead.

The options here can be repeated for multiple prefixes. Click  **Add** for each additional prefix.

Prefix
The prefix to override.

Do Not Advertise
Disable advertisement for this prefix.

Cost
Apply the specified cost to summarized routes for this prefix.

> **Warning:** An entry can either set **Do Not Advertise** or it can set **Cost**, but it **cannot** set both at the same time.

ABR Summary Route Filtering

Export List
Uses the given ACL to limit Type 3 summary LSA messages for intra-area paths that would otherwise be advertised. This behavior only applies if this router is the ABR for the area in question.

Import List
Similar to `export-list`, but for routes announced by other routers into this area.

Filter List (Out|In)
Similar to **Export List** and **Import List** but uses prefix lists instead of ACLs, and can work in either direction.

OSPF6 Status

The status for OSPF6 contains the same areas as the status for OSPF, but for IPv6 instead. See *OSPF Status* for more information.

See also:

For general FRR status information, see *FRR Status*.

30.10.5 Bidirectional Forwarding Detection

Bidirectional Forwarding Detection (BFD) is used to detect faults between two routers across a link, even if the physical link does not support failure detection. Even in cases where physical link issues occur and are detected, BFD can coordinate reaction to these failures rather than each component relying on its own failure detection methods.

FRR uses UDP as a transport for BFD between directly connected routers (single hop/next hop) as described in RFC 5880 and RFC 5881.

Each BFD session monitors one link. Multiple BFD sessions are necessary to detect faults on multiple links. BFD sessions must be manually configured between endpoints as there is no method for automated discovery.

When using BFD, both endpoints transmit "Hello" packets back and forth between each other. If these packets are not received within the expected time frame the link is considered down. Links may also be administratively configured as down and will not recover until manually changed.

FRR currently supports BFD integration with BGP, OSPF, and OSPF6.

BFD is configured at **Services > FRR BFD**.

The **BFD** tab contains only the master **Enable** switch for BFD.

> **Note:** The BFD implementation in FRR does not currently support authentication.

BFD Peers

A BFD **Peer** entry defines a relationship between this router and a peer so they can exchange BFD information and detect link faults.

Tip: For configurations with multiple peers which have similar settings, create a *BFD profile* with the common settings before creating peer entries.

BFD **Peers** are managed at **Services > FRR BFD** on the **Peers** tab.

The **Peers** tab contains a list of current BFD peers, if any, and controls to manage the entries (e.g. edit, delete). The

Add button creates a new peer.

The remaining sections on this page cover the various options available when creating or editing a peer entry.

Peer Configuration

Peer Address
The remote BFD peer address. The local and remote peer IP addresses must use the same address family (either IPv4 or IPv6)

Description
A text description of this BFD peer.

Profile
A *BFD Profile* from which settings will be used, unless overridden on this entry.

Options

Multihop
Expect packets with a TTL value less than `254` indicating there is more than one hop between peer addresses. Also listens on the multihop port, `4784`.

In most cases this option is not necessary, but certain configurations may require it, such as running BGP on loopback interfaces instead of an interface directly connected to a peer.

> **Warning:** When using multi-hop mode echo-mode will not work, see RFC 5883 section 3.

Shutdown
Enables or disables the peer administratively.

When the peer is disabled in this way an "administrative down" message is sent to the remote peer.

Source Address/Interface

Interface
The interface on which to enable BFD.

Local Source Address
The local address used as a source for BFD packets, if it differs from the primary IP address on **Interface**.

Advanced Options

Detect Multiplier
A non-zero value that is, roughly speaking, due to jitter, the number of packets that have to be missed in a row to declare the session to be down. Must be between `2` and `255`.

The remote transmission interval will be multiplied by this value to determine the connection loss detection timer. The default value is `3`.

Receive Interval
The minimum interval, in milliseconds, at which this router can receive control packets from a peer. The default value is `300`.

Transmit Interval
The minimum transmission interval, in milliseconds, for the router to send BFD control packets to peers. The default value is `300`.

Echo Interval
The minimum interval, in milliseconds, at which this router can receive echos from a peer. The default value is `50`.

Echo Mode
Enables or disables echo transmission mode. By default, this mode is disabled.

> **Warning:** Echo mode is not supported on multi-hop setups, see RFC 5883 section 3.

Tip: FRR documentation recommends that the transmission interval of control packets to be increased after enabling echo mode to reduce bandwidth usage.

For example, increase **Transmit Interval** from `300` to `2000`.

BFD Profiles

BFD profiles hold common sets of BFD settings which can be shared my multiple BFD peers. This can speed up the configuration process when there are numerous similar peers.

BFD **Profiles** are managed at **Services > FRR BFD** on the **Profiles** tab.

The **Profiles** tab contains a list of current BFD profiles, if any, and controls to manage the entries (e.g. edit, delete).

The  **Add** button creates a new profile.

The remaining sections on this page cover the various options available when creating or editing a profile entry.

Note: Most of the options in BFD profiles are the same as those for *BFD Peers*. This document only covers the options which are set on profiles only, not those shared with peers.

Profile Configuration

Name
The name of this profile. This name appears in the drop-down list for **Profile** on the *BFD Peers* configuration.

Passive
Marks sessions using this profile as passive.

A passive session will not attempt to start the connection and will wait for control packets from peer before it begins replying.

Profile Options

Minimum TTL
For multihop sessions only, configure a specific minimum expected TTL value for incoming BFD control packets.

This feature tightens the packet validation requirements to avoid receiving BFD control packets from other sessions.

The default value is `254` which means there is only one hop between this router and the peer.

Using BFD

For BFD to function fully, the BFD session status must be consumed by other interested parties. Currently this can be BGP, OSPF, or OSPF6.

BGP
BFD can be enabled for specific BGP neighbors using the *BFD options for BGP neighbors*.

OSPF/OSPF6
BFD can be enabled for OSPF and OSPF6 by using the appropriate *OSPF interface BFD option* or *OSPF6 interface BFD option*.

30.10.6 Raw FRR Configurations

Rather than using the GUI, administrators can opt to manually manage the FRR configuration. This allows for more complex configurations than can be supported in the GUI, but is also more prone to error and less capable of acting dynamically based on certain factors such as changing interface addresses.

Manual TCP MD5 Peers

When using TCP MD5 protection on BGP, this option defines MD5 passwords used to communicate with specific remote peers. This must be defined separately as it requires special handling in the operating system outside of FRR.

Raw Configuration Management

The **Update Running** button reads the current FRR configuration into the **Running frr.conf** field on this page.

Raw Configuration Files

Saved frr.conf
: This is the FRR configuration which will be loaded by FRR when starting up.

Running frr.conf
: This is the configuration data currently active in FRR. Editing the running configuration will result in changes to the active FRR configuration, but is not stored long term.

  To save the configuration for later use (e.g. when booting up or restarting FRR), click the **Copy frr.conf Running to Saved** button.

  To refresh this based on the current information from the running instance of FRR, click **Update Running** in the **Raw Configuration Management** section.

30.10.7 Dynamic Routing Protocol Lists

Throughout the FRR package, certain options specify a supported routing protocol or source of routes. Currently, the following values can be found in these locations, but not every option appears in each area:

connected
: Routes for directly connected networks on up and active interfaces.

kernel
: Routes from the kernel, including static routes defined outside of FRR and other non-dynamic routes.

FRR Static
: Static routes defined in the FRR configuration

bgp
: Routes obtained dynamically from BGP neighbors

ospf
: IPv4 routes obtained dynamically from OSPF neighbors

ospf6
: IPv6 routes obtained dynamically from OSPF6 neighbors

30.10.8 Multi-Path Routing

Current versions of pfSense® software include support for multi-path routing and this behavior is described in *Multi-Path Routing*.

Currently the only way for multi-path routing to work is via FRR. If FRR has a route to the same destination across multiple paths, the traffic can be balanced across all of the available paths. In most cases the weight of the balancing is even, resulting in Equal-cost multi-path routing (ECMP).

See also:

See *Multi-Path Routing Behavior* for details on how the OS makes balancing decisions for traffic across multiple paths.

30.11 HAProxy package

HAProxy is a free, very fast and reliable solution offering high availability, load balancing, and proxying for TCP, HTTP and HTTPS-based applications. It is particularly suited for web sites struggling under very high loads while needing persistence or Layer7 processing.

Supporting tens of thousands of connections is clearly realistic with todays hardware. Its mode of operation makes integrating it into existing architectures very easy and riskless, while still offering the possibility not to expose fragile web servers to the Net.

Refer to the following articles for more information on the listed topics:

See also:

- *Troubleshooting the HAProxy Package*

30.11.1 Package Variants

Two versions of the haproxy packages are available on pfSense® software:

HAProxy
: Tracks a stable version of FreeBSD port.

HAProxy-devel
: Uses haproxy-devel from FreeBSD ports and loosely tracks a HAProxy development branch.

  New features are added to the HAProxy-devel package first then later copied over the HAProxy package.

For info about HAProxy versions, see: https://github.com/PiBa-NL/pfsense-haproxy-package-doc/wiki

30.11.2 Recent Changes

See github log for recent changes:

- https://github.com/pfsense/FreeBSD-ports/commits/devel/net/pfSense-pkg-haproxy
- https://github.com/pfsense/FreeBSD-ports/commits/devel/net/pfSense-pkg-haproxy-devel

30.11.3 Known issues

HAProxy has a list of known bugs by branch and by version.

See also:

The pfSense software issue tracker contains a list of known issues with this package.

30.11.4 Differences between this package and HAProxy used directly

HAProxy defines five main sections in its configuration.

Global
: Defines options that process-wide and often OS-specific.

Defaults
: Sets default parameters for all other sections following its declaration.

Frontend
: Describes a set of listening sockets accepting client connections.

Backend
: Describes a set of servers to which the proxy will connect to forward incoming connections.

Listen
: Defines a complete proxy with its frontend and backend parts combined in one section. It is generally useful for TCP-only traffic.

In the pfSense software package, tabs exist to define "frontends" and "servers" but the resulting configuration is actually made up completely of listen sections. This is okay for the most part, but it does prevent advanced usages that need to refer to several backends and the like.

In HAProxy, a single server directive can be made with a blank port and it will listen on all the ports of the frontend that it is assigned to. The package GUI implies that this will be the case by leaving the port blank.

What actually gets generated instead is a single server directive for each port that the frontend is listening on. This is an important difference when the ports that are being listened on are not interchangeable. Example:

Define a front end for SMTP connections listening on ports 25 and 465. The server is listening on both of those ports, but 25 does not accept SSL/TLS and 465 does. When someone connects to the proxy on port 25, they should get connected to the server on port 25, and when they connect on 465, they get connected to the server on port 465.

In a standard HAProxy configuration where the frontend is set to listen on both ports and a single server directive is made with no port, it will operate the expected way.

In pfSense software, two server directives will be generated; one for each port. HAProxy will not send connections the expected way. It will loadbalance between them, regardless of whether the frontend and server ports match.

Therefore in pfSense software a separate frontend must be created for this, as they are essentially different services. Listen on port 25 and 2525, and it doesn't matter whether someone connected on one port gets directed to the other, then they can be combined.

Splitting the servers up by port also means that a separate entry will exist for each one in the stats page, but the port will not be shown. In an HAProxy configuration where a single server directive has no ports and effectively handles multiple (due to inheriting from the frontend) it will only show up in the stats once.

30.12 iperf package

iperf is a tool used for network throughput testing.

30.12.1 Usage

iperf running on pfSense® software is NOT a suitable way of testing firewall throughput, as there is a significant difference between performance of traffic *initiated or terminated on the firewall* and traffic *traversing the firewall*. There are many suitable uses for iperf running on pfSense software, but testing the throughput capabilities of the firewall is not one of them.

Uses for iperf on pfSense software

- Measuring throughput from the internal network to the inside of the firewall
  - Useful in scenarios where portions of the internal network are behind links slower than the firewall network interface. Examples include testing the throughput of a wireless network or private WAN network connected to a router inside the network.
- Testing end to end throughput between two firewalls on the Internet
- Anything else where performance measurement excluding throughput capabilities of the firewall are desirable.

30.12.2 Additional Resources

- iperf Man Page
- iperf - The Easy Tutorial

30.12.3 Known issues

See also:

The pfSense software issue tracker contains a list of known issues with this package.

30.12.4 Package Support

This package is currently supported by Netgate TAC to those with an active support subscription.

30.13 IPsec Export Package

The IPsec Export package generates client configurations for mobile IPsec, making it easier to configure remote access clients. This package is available on pfSense® Plus software.

The IPsec Export package contains an IPsec Profile export page for Apple devices and an IPsec Export page for Windows. Both pages work in a similar manner, and give administrators a few extra options to control client behavior.

The package works with most types of mobile IPsec configurations, with some exceptions depending upon settings.

This utility checks configured Mobile Phase 1 and Phase 2 entries and attempts to locate a set of parameters which are compatible with clients. It uses the first match it finds, so order choices in the Phase 1 and Phase 2 list appropriately or manually edit the resulting profile or script as needed.

Note: Apple and Windows do not support certain settings. In these cases, the package will print a notice that it is not possible to export a configuration.

See the Apple Configuration Profile Reference Documentation for details about the contents of profiles and settings they support.

For a full list of parameters compatible with Windows clients, see the Microsoft Documentation for `Set-VpnConnectionIPsecConfiguration`.

30.13.1 Export Settings

When exporting an IPsec configuration, the following options are available to fine-tune the values put into the generated configuration.

VPN Name
The name of the VPN as seen by the client in their network list. This name is also used when creating the filename of the files exported by the package. It is pre-filled with some basic information, such as the firewall hostname, but it can be customized.

Server Address
Select the server address to be used by the client. This list is generated from the SAN entries on the server certificate.

The hostname used by the client to connect to the server must exist in DNS and it must be present in the server certificate SAN list for the client to properly validate the certificate.

Set to *Custom Hostname* to fill in a hostname other than one shown in the list.

Custom Hostname
A text field for a custom fully qualified domain name to which the client can connect. As with the **Server Address**, this must exist in DNS and be in the server certificate SAN list.

VPN Client (Apple)
The user for which the package will generate a configuration. Depending on the Mobile IPsec Phase 1 settings, this could either be a user or a TLS certificate.

When using certificates, the list contains certificates which were signed by the CA selected on the mobile IPsec Phase 1 **IPsec Peer Certificate Authority**.

Note: This differs from Windows because Windows can prompt for a username, but Apple requires it to be present in the profile.

TLS User Certificate (Windows)
The TLS user certificate to include in the exported configuration, if needed. This field is only visible when the Mobile IPsec Phase 1 settings require a client certificate (e.g. EAP-TLS).

30.13.2 Export a Client Configuration

The process to export a client for an existing *Mobile IPsec* configuration varies slightly for Apple and Windows.

Apple

- Navigate to **VPN > IPsec Export: Apple**
- Configure the settings as described in *Export Settings*
- Click **View** to display the generated configuration profile
- Review the profile contents and confirm it is acceptable
- Click **Download** to download the configuration profile

Apple Client Configuration

Visit the Apple Configurator Site for details about creating and using profiles. The process varies between iOS and macOS.

Windows

- Navigate to **VPN > IPsec Export: Windows**
- Configure the settings as described in *Export Settings*
- Click **View** to display the generated PowerShell script
- Review the script contents and confirm it is acceptable
- Click **Download** to download a ZIP archive containing the PowerShell script and the required certificates.

If the **Network List** option is active on the **Mobile Clients** tab in IPsec settings, the script will include parameters to setup Split Tunneling on the client as well as commands to configure routes on the VPN for networks configured in the mobile Phase 2 entries.

Windows Client Configuration

On the client system, unzip the configuration archive and run the script. The commands in the PowerShell script will import certificates and setup the VPN on the client workstation.

Running PowerShell scripts on Windows is disabled by default. If scripting is disabled, the commands may be copied and pasted into a PowerShell prompt.

See also:

Local policies may override that behavior. See the PowerShell Execution Policies Documentation for details.

> **Warning:** Some commands may require Administrator access, such as importing the CA certificate. Run these commands at an Administrator-level PowerShell prompt or use an alternate method.

30.14 Using LLDP on pfSense software

The lldpd daemon allows pfSense software to utilize LLDP.

30.14.1 Install

- Navigate to **System > Packages**, **Available Packages** tab
- Search for `lldp` or find it in the list
- Click **Install** and **Confirm**

The package adds a menu entry under **Services > LLDP**.

30.14.2 Setup

The settings are under **Services > LLDP**, **LLDP Settings** tab.

At a minimum, check **Enable**, pick **Interfaces**, and then set other options as desired.

30.14.3 Seeing neighbors

Navigate to **Services > LLDP**, **LLDP Status** tab. The neighbors will be printed in the lower box.

30.15 Netgate Firmware Upgrade Package

The Netgate Firmware Upgrade package provides a mechanism to update firmware on certain Netgate hardware models.

The mechanism used by the package varies by hardware and may be Coreboot, Blinkboot, or other types of firmware.

When installed, the package is located at **System > Netgate Firmware Upgrade**.

30.15.1 Checking for Upgrade

To see if a Netgate device has a firmware update available:

- Navigate to **System > Netgate Firmware Upgrade**
- Compare the **Current Firmware Version** and **Latest Firmware Version**

If the latest version is newer than the current version, the package will offer the option to upgrade.

30.15.2 Upgrading Firmware

When a firmware upgrade is available, upgrade as follows:

- Navigate to **System > Netgate Firmware Upgrade**
- Click **Upgrade and Reboot**
- Click **OK** to confirm the upgrade
- Read the output on the screen for any device-specific or version-specific instructions.

- Wait for the device to complete the upgrade and reboot

30.15.3 Device-Specific Notes

The following sections contain information relevant only to specific models of Netgate hardware.

Netgate 6100

Upgrades to the firmware (Blinkboot) on the Netgate 6100 which also upgrade the microcontroller code require a power cycle after firmware upgrade. This is due to the microcontroller always being on while the device has power. Thus, new microcontroller code will activate until after the device goes through a cold boot (power cycle, not reboot):

- Connect to the device console
- Run the firmware upgrade
- Wait for the firmware upgrade and automatic reboot to complete
- Halt the device gracefully using either the GUI or console menu (*Halting and Powering Off the Firewall*)
- Monitor the console and wait until the device has halted

  Alternately, wait until a few moments after all of the lights on the device (front and back) go out.
- Remove power from the device (e.g. unplug or remove power from PDU port)
- Wait a few seconds
- Reapply power to the device (e.g. plug in or apply power to PDU port)
- Monitor the console during the boot sequence for any errors
- Wait for the device to complete its boot sequence

Note: While it is possible to manually remove power after the initial firmware upgrade completes in one pass, it can be problematic to time it properly. Thus, it is safer to follow the procedure as stated to ensure success.

Netgate 7100

Updating the firmware (Coreboot) on the Netgate 7100 causes the device to lose customizations to its default boot order.

In the default boot order if the device has multiple disks (e.g. On-board eMMC plus an add-on SATA device), the device will prefer to boot from the add-on disk rather than the on-board eMMC.

For most users this behavior is correct and expected, but if someone with this configuration has manually opted to boot from eMMC instead of an add-on disk, this boot order preference change must be reconfigured after updating the firmware.

30.16 Nmap package

nmap is a powerful network scanner that provides port scanning, OS and service identification, and more.

30.16.1 Usage

After installing the package, `nmap` will be available at **Diagnostics > nmap** as well as in the shell (SSH or Console).

The nmap package also installs an OUI database that is used by the pfSense® software GUI to display manufacturer names on pages that list MAC addresses, such as the *ARP Table*, and *DHCP Leases*.

30.16.2 Package Support

This package is currently supported by Netgate TAC to those with an active support subscription.

30.17 Nut package

The NUT package provides a way to monitor an Uninterruptable Power Supply (UPS) using Network UPS Tools (NUT) on pfSense® software.

After installation, configure the package at **Services > UPS**.

See also:

Visit the NUT Package forum thread for assistance with this package.

30.17.1 Troubleshooting

If NUT will not start after configuration, it may be due to incorrect settings. The package GUI is unable to validate combinations of settings to ensure they are viable. Check the System log from the GUI from **Status > System Logs** for log entries starting with `nut:`. The culprit is likely explained there, such as selecting a cable for a driver type that does not need (nor permit) the cable selection.

If the system log does not offer adequate information, for example if it prints a generic error such as:

```
nut: Service failed to start: check configuration
```

Log in via SSH and choose option `8` and run the following command:

```
/usr/local/etc/rc.d/nut.sh start
```

Configuration errors will be displayed in the output if any are found.

If the daemon still will not start, users have also reported that rebooting the device after connecting the UPS and configuring the service may help resolve the problem.

See also:

The pfSense-packages Redmine project contains a list of known issues with this package.

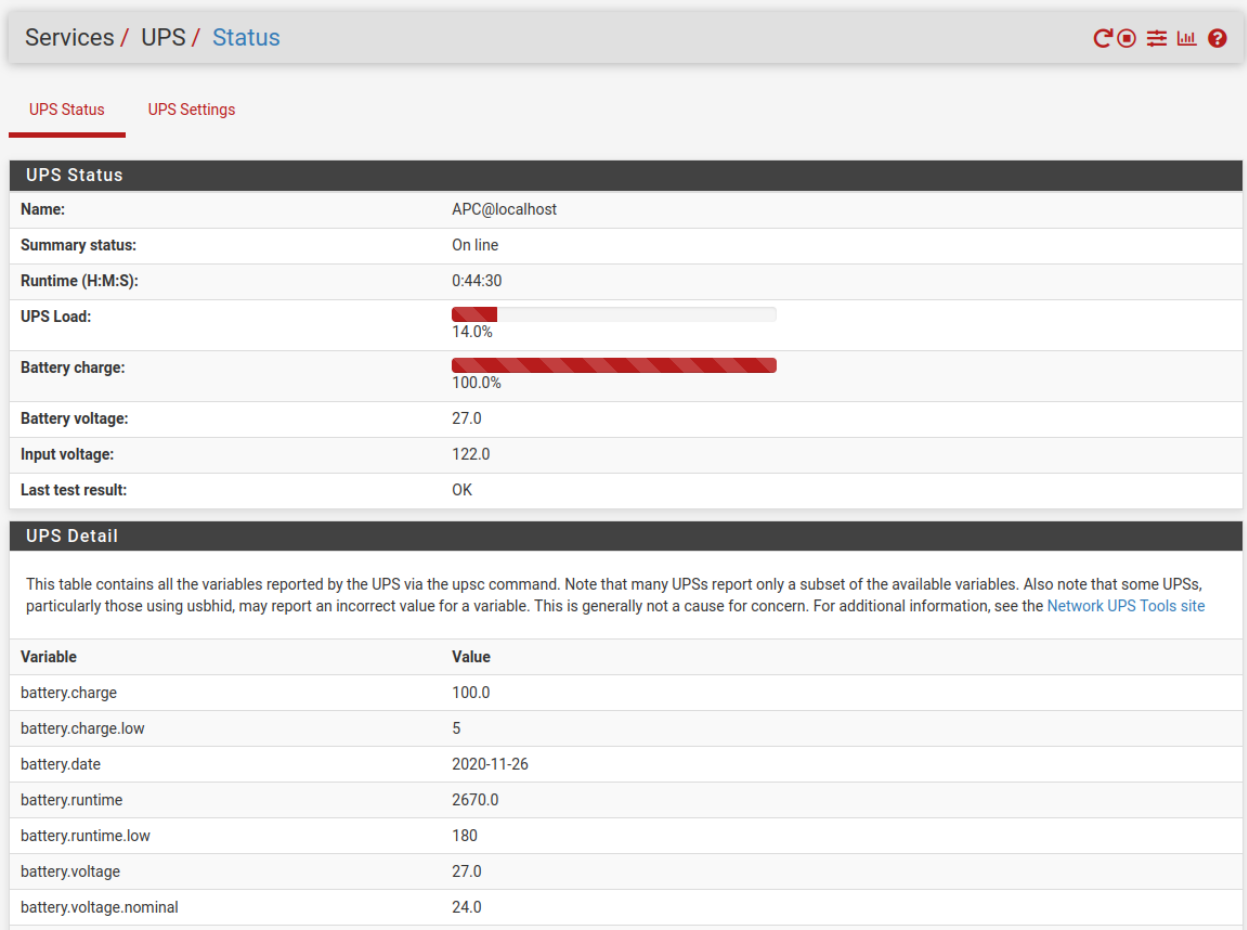

Fig. 4: NUT status screen

30.18 Open VM Tools package

This package installs VMware Tools for pfSense® software, using the Open VM Tools available from VMware. It is built using the open-vm-tools-nox11 FreeBSD port.

30.18.1 Usage

There is no GUI, the services are automatically started at boot time.

30.18.2 Verifying functionality

There are two portions of this package, the **vmware-guestd** process and the kernel modules.

Verifying vmtoolsd

Navigate to **Diagnostics > Command**, and in **Execute shell command**, enter the following:

```
ps uxawww | grep vmtoolsd
```

Output similar to the following will be shown:

```
$ ps uxawww | grep vmtoolsd
1026  ??  Ss     0:20.84 /usr/local/bin/vmtoolsd -c /usr/local/share/vmware-tools/tools.
↪conf -p /usr/local/lib/open-vm-tools/plugins/vmsvc
19157  ??  SN     0:00.00 sh -c ps ax|grep vmware
19159  ??  RN     0:00.00 grep vmware (sh)
```

As long as `vmtoolsd` is shown in the output, it is working.

30.18.3 Known issues

See also:

The pfSense software issue tracker contains a list of known issues with this package.

30.18.4 Package Support

This package is currently supported by Netgate TAC to those with an active support subscription.

30.19 OpenVPN Client Export Package

The easiest way to configure an OpenVPN client on most platforms is to use the OpenVPN Client Export Package on pfSense® software.

30.19.1 Installing the Export Package

Install the OpenVPN Client Export Utility package as follows:

- Navigate to **System > Packages**, **Available Packages** tab
- Locate the **OpenVPN Client Export** package in the list
- Click  **Install** next to that package listing to install
- Click  **Confirm** to confirm the installation

30.19.2 Using the Export Package

Once installed, the package is located at **VPN > OpenVPN**, on the **Client Export** tab. That page presents several options which control the behavior of exported clients. The firewall can optionally save selections on this page as new defaults for future use.

Settings

The options for the package include:

OpenVPN Server

Remote Access Server
The OpenVPN server instance for which the package will export a client.

The list includes only Remote Access mode OpenVPN servers. If there is only one OpenVPN remote access server there will only be one choice in the list. The list will be empty if the firewall has no OpenVPN servers set to a Remote Access mode.

Client Connection Behavior

Host Name Resolution
Controls the format of `remote` directive entries the package uses in client configuration files.

Interface IP Address
Uses the OpenVPN server interface IP address directly.

This is typically the best choice for installations with a static IP address on WAN.

Automagic Multi-WAN IPs
Searches all port forwards and automatically creates `remote` directives for all port forwards that target the OpenVPN server interface address and port. It uses the destination IP address on the port forward in the `remote` directives for the client configuration so the clients will use the correct external address(es).

This option is useful when redirecting connections using port forwards for deployments that utilize, multi-WAN, multiple ports on the same WAN, or servers which bind to *Localhost*.

Automagic Multi-WAN DDNS Hostnames
Similar to the previous option, but instead of using IP addresses it uses the first Dynamic DNS entry it finds which matches the chosen destination.

This is useful if one or more of the WANs involved in OpenVPN has a dynamic IP address.

Installation Hostname
Uses hostname assigned to the firewall at **System > General Setup** for the `remote` directive in the client configuration.

Note: The hostname must exist in public DNS so clients can resolve it by name.

Dynamic DNS Hostname Entries
The GUI includes entries in the selection list for each Dynamic DNS hostname in the firewall configuration.

These are typically the best choice for a server on a single WAN with a dynamic IP address.

Other
Displays a **Host Name** field for a custom hostname or IP address.

This is useful when the firewall is behind one or more layers of NAT, which may make the external address difficult or impossible for the package to discover. It is also useful for situations where the firewall does not manage the DNS entry (static or dynamic) for a hostname.

Verify Server CN
Controls how the client verifies the identity of the server certificate.

The package places the CN of the server certificate in the client configuration, so that if another valid certificate pretends to be the server with a different CN, it will not match and the client will refuse to connect.

Automatic - Use verify-x509-name where possible
Uses the `verify-x509-name` directive in OpenVPN to set a specific string the client will expect to match the common name on the server certificate.

Do not verify the server CN
Disables client verification of the server certificate common name. This is not a secure, as the client will accept any server certificate signed by the CA.

Block Outside DNS
Makes Windows 10 clients block access to DNS server except across OpenVPN while connected, forcing clients to use only VPN DNS servers.

This is only relevant on Windows 10 clients using OpenVPN version 2.3.9 and later as they are the only clients prone to leak DNS requests in this way. The option has no effect on other platforms and they will ignore the directive.

Legacy Client
Controls whether the package uses OpenVPN 2.5.x and later directives in the configuration, or directives for older legacy clients.

When set, the package forms configurations using older options accepted by outdated clients such as OpenVPN 2.4.x and avoids newer directives only understood by current versions of OpenVPN.

Silent Installer
When set, the package adds flags to the Windows installer which allows for silent and unattended client deployment.

Note: The installer generated by the package is not signed. As such, deploying the installer executable may require special software.

Use Random Local Port
Controls whether or not the client binds to a specific local port.

When checked, which is the best practice, the client will use a random source port. When unchecked, two OpenVPN connections cannot be run simultaneously on the client device as they would attempt to use the same port.

Note: Some older clients do not support this option.

Certificate Export Options

PKCS#11 Certificate Storage
Configures the client to use PKCS#11 storage device (e.g. cryptographic token, HSM, smart card) instead of local files.

PKCS#11 Providers
The client-side path to PKCS#11 provider(s) files (e.g. DLL, module). Separate multiple entries with a space.

PKCS#11 ID
The object ID on the PKCS#11 device.

Use Microsoft Certificate Storage
Creates the installer in such a way that it places the CA and user certificate in Microsoft certificate storage rather than using inline entries or files directly.

Use a password to protect the PKCS#12 file contents or key in Viscosity bundle
Controls whether or not the package protects the certificates and keys supplied to the client with a password.

When checked, the GUI displays fields to enter and confirm a password.

Note: If the OpenVPN server requires user authentication this will cause users to see two different password prompts when loading the client: One to decrypt the keys and certificates and another for OpenVPN user authentication upon connecting.

Proxy Options

Use Proxy
If the client is located behind a proxy, check this options. The GUI displays several fields to configure the proxy. Supply a Proxy **Type**, **IP Address**, **Port**, and **Proxy Authentication** with credentials (if the proxy server requires authentication).

Advanced

Additional configuration options
Any extra *custom OpenVPN directives* for the package to include in the client configuration.

This is roughly equivalent to the **Advanced options** box on the OpenVPN configuration screens, but from the perspective of the client.

Save as default

The package does not save the settings on this page by default, so they must be set each time the package is used. The **Save as default** button stores the current package settings as new default values for future use.

OpenVPN Clients List

OpenVPN Clients contains a list of potential clients that the package can export. The contents of the list depend on the server configuration and which users and/or certificates are present on the firewall.

The following list describes how the server configuration style affects the list in the package:

Remote Access (SSL/TLS)
The list contains entries for user certificates signed by the same CA as the OpenVPN server

Remote Access (SSL/TLS + User Auth – Local Users)
The list contains entries for local users which also have an associated certificate signed by the same CA as the OpenVPN server.

Tip: This is the type of server configured by the OpenVPN wizard.

Remote Access (SSL/TLS + User Auth – Remote Authentication)
The list contains user certificates signed by the same CA as the OpenVPN server. Because the users are remote, the package cannot determine the usernames, so the package assumes that the username is identical to the common name of the certificate.

Remote Access (User Auth – Local Users or Remote Authentication)
The list contains a single configuration entry for all users since there are no per-user certificates or settings. Each client uses the same configuration.

The **Search** box above the client list filters the list to only entries which match a given string. This feature is particularly useful on firewalls with many clients, allowing administrators to quickly locate a specific entry.

Note: If the list contains no entries, or if a specific entry is missing from the list, then either the user does not exist or the user does not have an appropriate certificate.

See *Local Database* for the correct procedure to create a user and certificate.

Client Install Package Types

Each client entry contains numerous options which export the configuration and associated files in different ways. Each choice accommodates a different potential type of client.

Inline Configurations

These choices export a single configuration file with the certificates and keys inline. This format is ideal for use on all platforms, especially Android and iOS clients, or for manually copying a configuration to a device which already has a client installed.

This option will work for any client type based on OpenVPN version 2.1 or newer.

Most Clients
Exports a configuration which is usable by any standard OpenVPN client on platforms such as Windows, macOS, or BSD/Linux.

Tip: This format works well with Tunnelblick on macOS. Download the inline configuration and drag it into the configurations folder for Tunnelblick.

Android
Exports a configuration for the Android OpenVPN client mentioned in *Installing the OpenVPN Client on Android*, which may support a different set of directives or omit certain features.

OpenVPN Connect (iOS/Android)
Exports a configuration for the OpenVPN Connect client on iOS or Android described in *Installing the OpenVPN Client on iOS*.

Bundled Configurations

Archive
Exports a ZIP archive containing the configuration file, the server TLS key (if it has one), and a PKCS#12 file which contains the CA certificate, client key, and client certificate. This option is usable with Linux clients, Tunnelblick, Windows, and many others when configuring the files manually.

File Only
Exports only the basic configuration file, no certificates or keys. This would mainly be used to update the configuration file for systems which used the ZIP archive or executable installer before, without downloading the other associated files. For example, this is useful if the user authentication did not change but some aspect of the server configuration or package preferences is different.

Windows Installers

The Windows installer options export a simple-to-use executable installer file which contains the OpenVPN client software plus the configuration data. The installer runs like the normal Windows OpenVPN client installer, but it also copies all of the settings and certificates the clients needs when it connects to the VPN.

See also:

See *Installing the OpenVPN Client on Windows* for notes on how to install and run the Windows client.

Currently, there are four options available:

Current Windows Installer - 64-bit/32-bit
Export an installation bundle for the latest available version of the Windows OpenVPN client, currently version 2.5.x. The installer is available in 64-bit and 32-bit varieties. This is the best version to use where possible, and it works on Windows 11, Windows 10, and more.

Legacy Windows Installer - 10/2016/2019
Export an installation bundle for the legacy version of the Windows OpenVPN client, currently version 2.4.x. This version is specific to Windows 10 and similar vintage versions of Windows.

Legacy Windows Installer - 7/8/8.1/2012r2
Export an installation bundle for the legacy version of the Windows OpenVPN client, currently version 2.4.x. This version is specific to Windows 7/8.x and similar vintage versions of Windows.

Note: Users must click next/finish **all the way through** the installation process. Do not click cancel or X out the installer at any step, as this can leave the client system with the client installed but without an imported configuration.

Viscosity Bundle

This exports the configuration similar to the archive method, but in a format used by the Viscosity OpenVPN client for macOS and Windows. Install the Viscosity client separately, then export this bundle and click it to import the configuration.

SIP Phone archives

The package can export configurations formatted for several popular VoIP phones which natively support OpenVPN. Notable examples are the Yealink T28 and T38G, and SNOM phones.

The process to install and configure OpenVPN on the phone varies by model, check the manufacturer documentation for more information.

The package only displays these options for OpenVPN servers set to SSL/TLS only *without* authentication.

Note: The phone must have a proper clock setup and/or NTP server otherwise the certificates will fail to validate and the VPN will not connect.

Warning: Typically these handsets only support the use of SHA1 as a certificate hash. Ensure the CA, server certificate, and client certificates all use *SHA1* or they may fail. They may also only support a limited set of encryption algorithms such as AES-128-CBC. Consult the phone documentation for details, and use the strongest possible combination of options.

30.20 OpenVPN Client Import Package

Note: This package is only available on Netgate pfSense® Plus software.

The OpenVPN client import package can take a unified OpenVPN client configuration file as exported by an OpenVPN server and automatically turn it into an OpenVPN client instance on pfSense Plus software. The unified OpenVPN configuration file format includes all of the certificates and keys required for the connection, allowing the client instance to be created with minimal effort.

In many cases the newly imported client instance starts and passes traffic on completion of the import, but in some cases adjustments must be made to the imported client configuration by editing the resulting OpenVPN client instance.

The package can be installed using the *Package Manager* on pfSense Plus software. Once the package is installed, it can be accessed at **VPN > OpenVPN** on the **Import** tab.

30.20.1 How it Works

The import process attempts to read the configuration file and map directives from the file to their equivalent settings in pfSense Plus software. Unknown directives are placed into the **Custom options** area in the resulting client instance.

If the configuration being imported contains certificates, the import package will create appropriate CA and certificate entries if they do not already exist.

Note: If the configuration requires certificates but they are not present in the imported configuration file, they can be manually imported in the certificate manager and then manually selected in the OpenVPN client instance after it has been imported.

Once the import process is complete, the new client is stored and, if it is enabled and has a complete configuration, the client is immediately started.

30.20.2 Imported OpenVPN Client Configuration

When importing a configuration there are several options specific to pfSense Plus software which cannot be automatically determined from the imported configuration. These must be filled in manually before the import process can be completed.

These options are equivalent to their counterparts in the *OpenVPN Configuration Options*. Consult that document for additional details on these settings.

Config File
: The OpenVPN configuration file (e.g. `<name>.ovpn`) to import.

  The OpenVPN client configuration file can be from another instance of pfSense software, a VPN provider, or other OpenVPN compatible server so long as it uses the standard OpenVPN configuration format.

Disabled
: When set, the client will be marked as disabled on import so it will not start automatically.

Server Mode
: Chooses between whether this client is connecting to an SSL/TLS server with certificates, or to a shared key server.

Name
A descriptive name for this client instance.

Interface
The firewall interface to be used by this client instance for outbound connections. In most cases this will be **WAN** but may also be another interface, or a virtual IP address.

Username
The username to use if the OpenVPN server requires a username and password. May be left blank if the server does not require user authentication.

Password
The password to use if the OpenVPN server requires a username and password. May be left blank if the server does not require user authentication.

30.20.3 Client Import Example

The process to import a client generally follows this format:

- Obtain an OpenVPN configuration file in inline format from the OpenVPN server (e.g. `username.ovpn`)

Note: If the server is also running pfSense software, use the *OpenVPN Client Export Package* and download the inline configuration using the **Most Clients** button.

- Navigate to **VPN > OpenVPN**, **Import** tab on the client firewall
- Click **Browse** in the **.ovpn config file** field and select the configuration file obtained from the server (e.g. `username.ovpn`)
- Fill in the other options as described in *Imported OpenVPN Client Configuration*
- Click **Import**

At that point the client instance will be created and started automatically. If the configuration was incomplete or needs other changes, then do so as follows:

- Navigate to **VPN > OpenVPN**, **Clients** tab
- Find the newly imported client in the list and click  on its row
- Make final adjustments needed
- Click **Save**

See also: *OpenVPN Configuration Options*

30.21 pfBlocker-NG Package

pfBlocker-NG introduces an enhanced alias table feature to pfSense® software.

This package enables users to:

- Assign many IP address URL lists from sites like I-blocklist to a single alias and then choose a rule action.
- Block countries and IP address ranges.
- Use native functions of pfSense software instead of file hacks and table manipulation.

Features include:

- Geographical/Country Blocking
- IP block lists
- Dashboard widget
- XMLRPC Sync
- Frequently updated lists
- Many options to control what to block and how to block
- Network lists can be used in custom rules

30.21.1 General Setup

Set the interfaces to be monitored by pfBlocker-NG (both inbound and outbound), where the inbound is the Internet connection.

To prevent devices or users from accessing sites in the selected countries/IP addresses, select local interfaces under **outbound**.

30.21.2 Setting up Lists

This is the IPBlocklist feature, enter IP addresses here to specifically block. It must be in the file format or CIDR. Create a list for each type of action to be taken by pfBlocker.

Options are:

Deny Both
Will deny access on Both directions.

Deny Inbound
Will deny access from selected lists to the local network.

Deny Outbound
Will deny access from local users to IP address lists selected to block.

Permit Inbound
Will allow access from selected lists to the local network.

Permit Outbound
Will allow access from local users to IP address lists selected to block.

Disabled
Will just keep selection and do nothing to selected Lists.

Alias Only
Will create an alias with selected Lists to help custom rule assignments.

The rest of the tabs (except sync) specify the other lists included with the package. They are separated by continent with the exception of the spammer list which contains countries from around the globe that are known to harbor spammers.

Sync tab configures pfBlocker to sync its configuration to other pfSense devices.

30.21.3 Available lists

Spamhaus
DROP and EDROP.

- http://www.spamhaus.org/drop/drop.txt
- http://www.spamhaus.org/drop/edrop.txt

DShield
Most Active Attacking IPs.

- http://feeds.dshield.org/top10-2.txt

iblocklist.com
A number of lists are available.

- http://www.iblocklist.com/lists.php

30.21.4 FAQ

I'm getting memory errors while applying pfblocker lists, how to fix this?
Increase table size to avoid memory errors in Advanced settings.

I can't see any pfblocker rules applied, whats wrong?
pfblocker requires at least one firewall entry (any interface) for it to be active. One way to verify is to check the front page widget.

pfBlocker always moves its rules to the top, how can I stop this?
Change rule action to Alias only and then apply custom rules using pfBlocker aliases with an arbitrary sequence.

How can I apply pfBlocker lists in floating rules?
Aliases are used for customized filter entries and float rules.

See also:

The pfSense software issue tracker contains a list of known issues with this package.

30.22 Siproxd package

Warning: For many modern SIP configurations this package is unnecessary. Please only install and use siproxd if it is absolutely required.

Siproxd is a proxy/masquerading daemon for SIP. It handles registrations of SIP clients on a private IP network and performs rewriting of the SIP message bodies to make SIP connections possible via a masquerading firewall. It allows SIP phones and soft phones (like kphone, linphone) to work behind an IP masquerading firewall or router.

The most useful thing siproxd does is allow multiple phones to use a static source port of 5060 when registering to the same remote PBX. **If the PBX is local, this package should not be installed or used**. Most remote PBX systems are OK with the phones having random source ports, but that was not the case many years ago. Unless the remote PBX is absolutely strict about the 5060 source port requirement for each phone, this package is not needed.

30.22.1 Install siproxid

In the pfSense® software GUI, navigate to **System > Packages**:

- Find the **siproxd** package.
- Click  to install, and confirm installation.
- Wait for it finish.

30.22.2 Configure siproxd

Under **Services > siproxd**:

- **Inbound interface** will generally be `LAN`.
- **Outbound interface** will generally by `WAN`.
- Fill in any other values (where appropriate).
- **RTP port range (lower)** should be an even number.
- Click **Save**.

30.22.3 Known issues

See also:

The pfSense software issue tracker contains a list of known issues with this package.

30.22.4 Package Support

This package is currently supported by Netgate TAC to those with an active support subscription.

30.23 IDS / IPS

pfSense® software can act in an Intrusion Detection System (IDS) / Intrusion Prevention System (IPS) role with add-on packages like Snort and Suricata.

Note: The Snort and Suricata packages share many design similarities, so in most cases the instructions for Snort carry over to Suricata with only minor adjustments.

30.23.1 Snort

Configuring the Snort Package

Snort is an intrusion detection and prevention system. It can be configured to simply log detected network events to both log and block them. Thanks to OpenAppID detectors and rules, Snort package enables application detection and filtering. The package is available to install in the pfSense® software GUI from **System > Package Manager**. Snort operates using detection signatures called rules. Snort rules can be custom created by the user, or any of several pre-packaged rule sets can be enabled and downloaded.

The Snort package currently offers support for these pre-packaged rules:

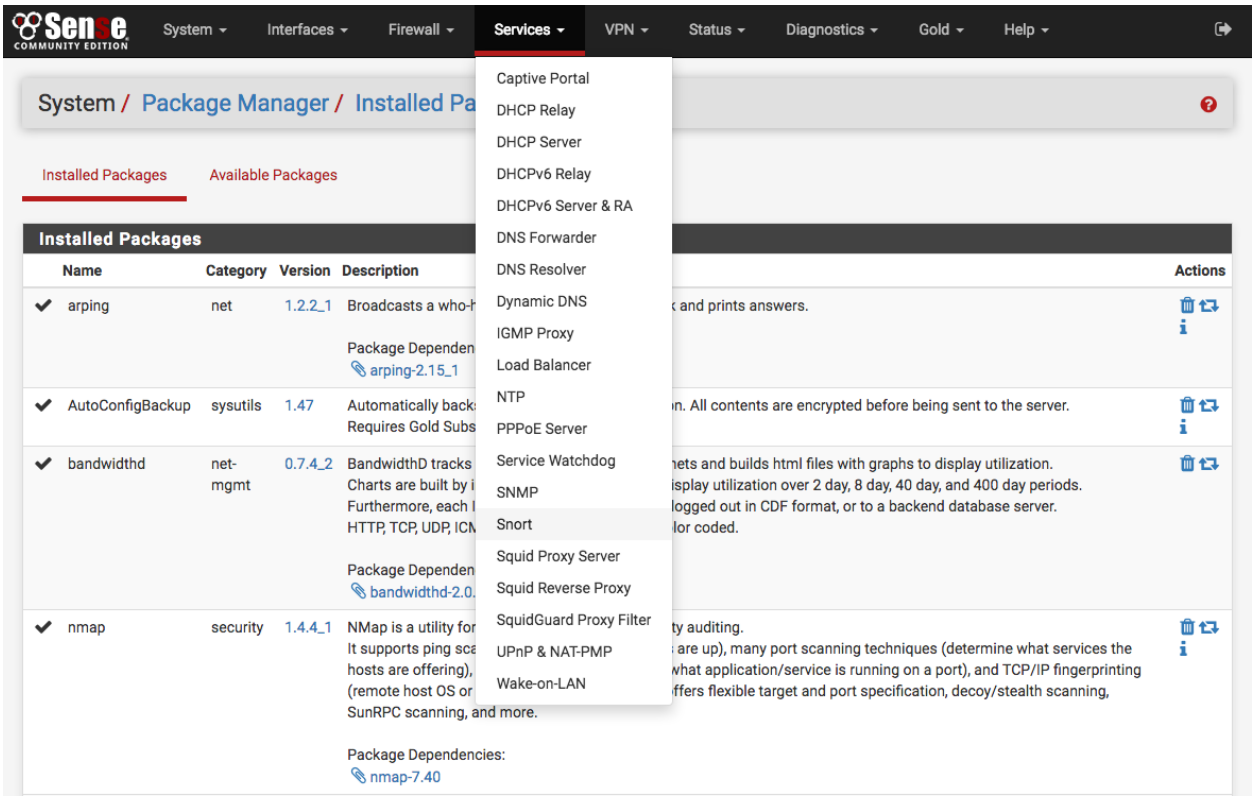
- Snort VRT (Vulnerability Research Team) rules
- Snort GPLv2 Community Rules
- Emerging Threats Open Rules
- Emerging Threats Pro Rules
- OpenAppID Open detectors and rules for application detection

The Snort GPLv2 Community Rules and the Emerging Threats Open Rules are both available for free with no registration required. The Snort VRT rules are offered in two forms. One is a registered-user version which is free, but requires registration at http://www.snort.org. The registered-user free version only provides access to rules that are 30-days old or more in age. A Snort VRT paid subscription can be purchased, and it offers twice-weekly (and sometimes more frequent) updates to the rules. The Emerging Threats Pro rules are offered to paid subscribers only and offer almost daily updates to address fast-changing threats.

The best practice is to obtainin a paid subscription from Snort or Emerging Threats in order to download the most current rules. This is highly recommended for commercial applications.

Launching Snort configuration GUI

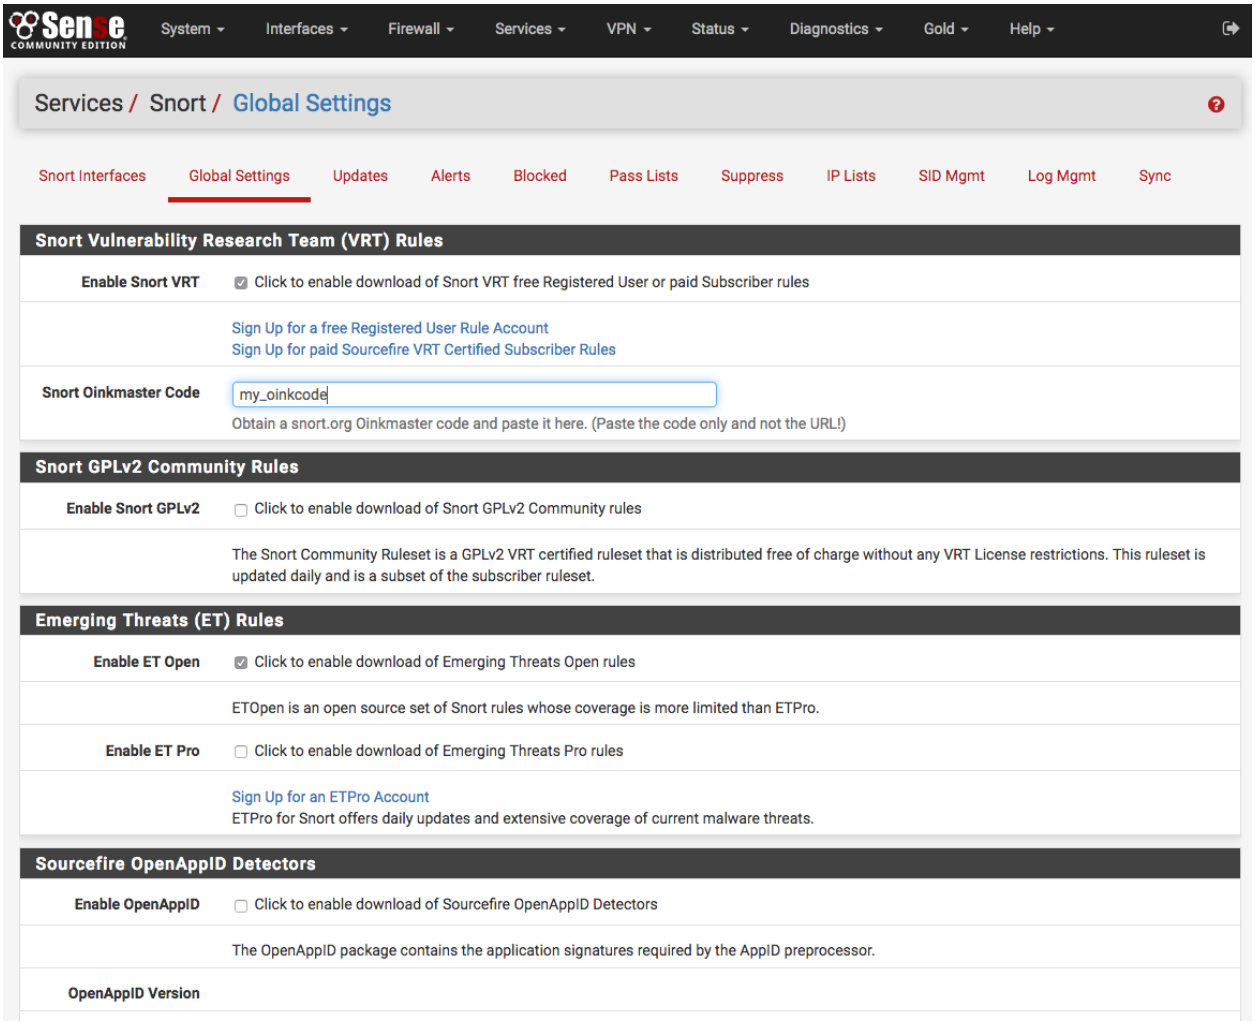
To launch the Snort configuration application, navigate to **Services > Snort** from the menu in the GUI.



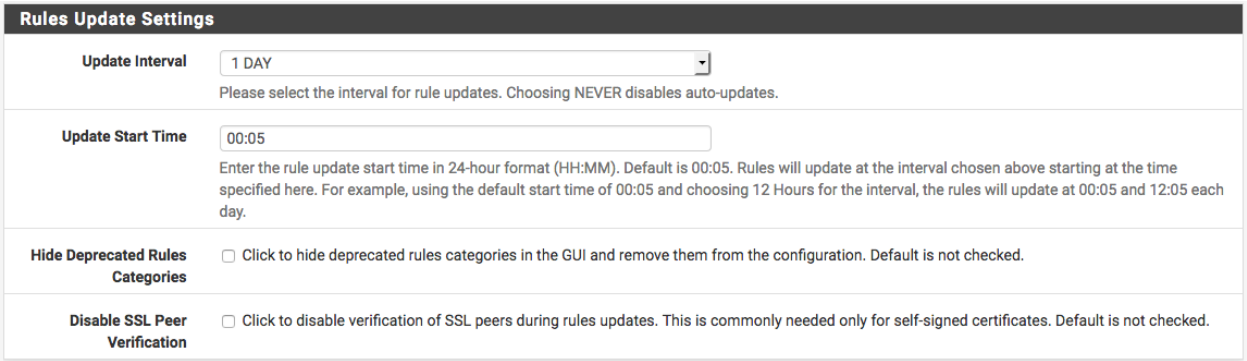
Setting up Snort package for the first time

Click the **Global Settings** tab and enable the rule set downloads to use. If either the Snort VRT or the Emerging Threats Pro rules are checked, a text box will be displayed to enter the unique subscriber code obtained with the subscription or registration.

More than one rule set may be enabled for download, but note the following caveats. If a paid subscription is available for the Snort VRT rules, then all of the Snort GPLv2 Community rules are automatically included within the file downloaded with the Snort VRT rules; therefore, do not enable the GPLv2 Community rules if a paid-subscriber account is used for the Snort VRT rules. All of the Emerging Threats Open rules are included within the paid subscription for the Emerging Threats Pro rules. If the Emerging Threats Pro rules are enabled, the Emerging Threats Open rules are automatically disabled.



Once the desired rule sets are enabled, next set the interval for Snort to check for updates to the enabled rule packages. Use the **Update Interval** drop-down selector to choose a rule update interval. In most cases every *12* hours is a good choice. The update start time may be customized if desired. Enter the time as hours and minutes in 24-hour time format. The default start time is *3* minutes past midnight local time. So with a *12*-hour update interval selected, Snort will check the Snort VRT or Emerging Threats web sites at 3 minutes past midnight and 3 minutes past noon each day for any posted rule package updates.

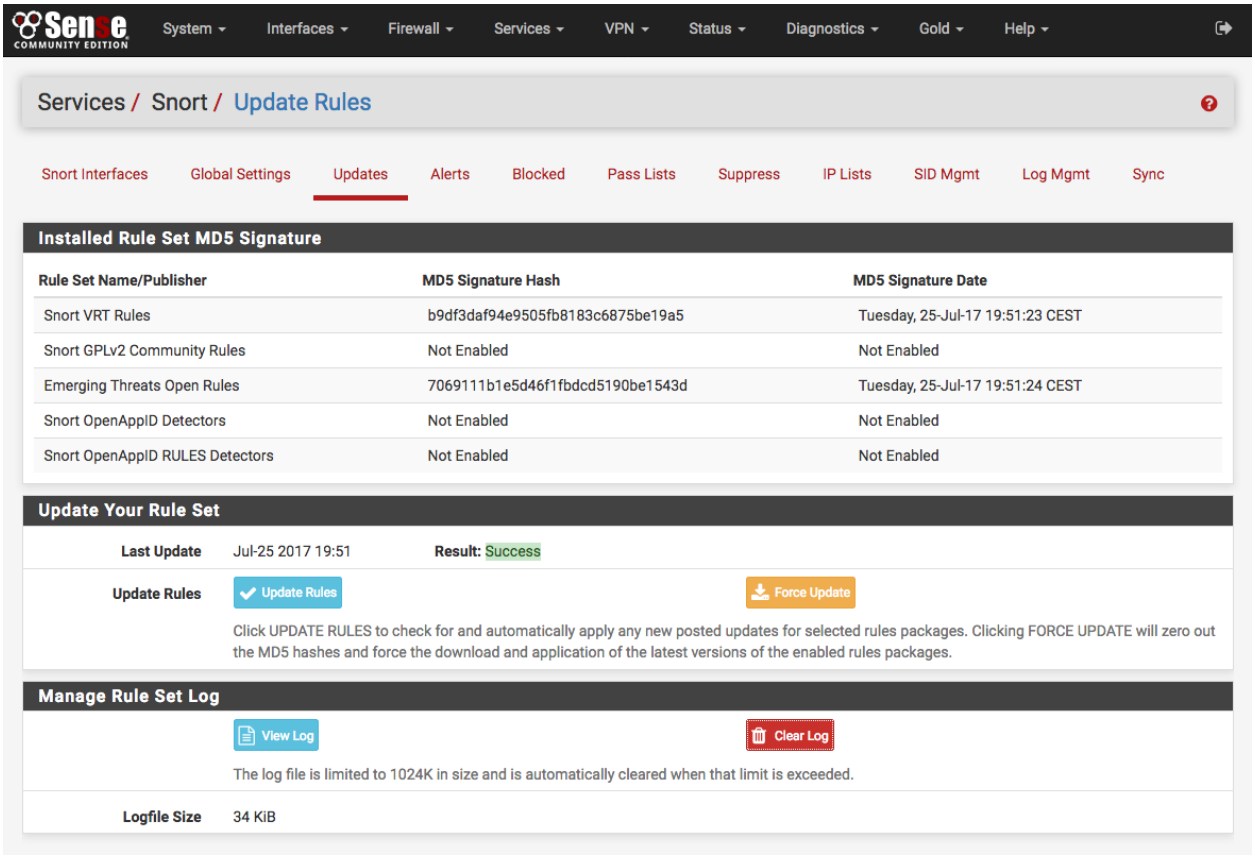


Update the rules

The **Updates** tab is used to check the status of downloaded rules packages and to download new updates. The table shows the available rule packages and their current status (not enabled, not downloaded, or a valid MD5 checksum and date).

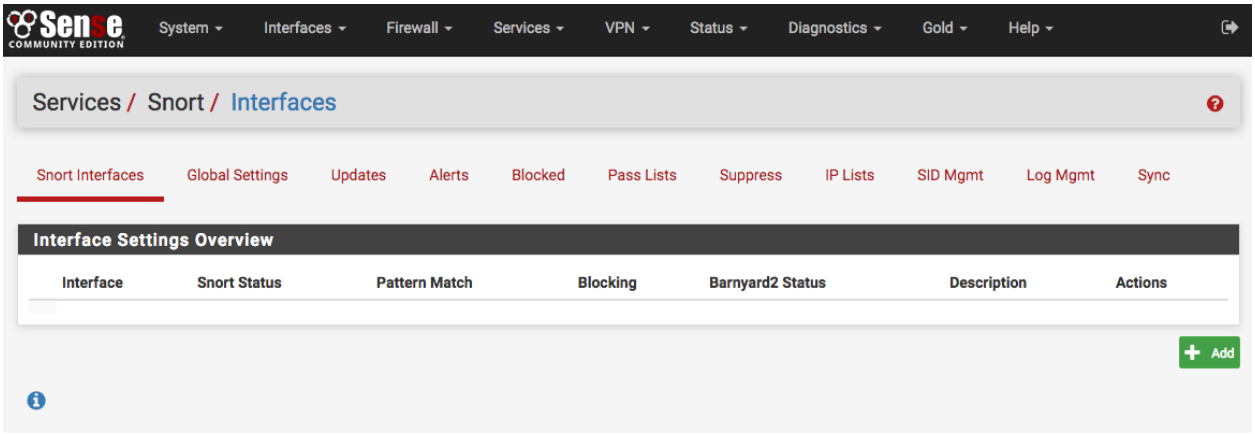
Click on the **Update Rules** button to download the latest rule package updates. If there is a newer set of packaged rules on the vendor web site, it will be downloaded and installed. The determination is made by comparing the MD5 of the local file with that of the remote file on the vendor web site. If there is a mismatch, a new file is downloaded. The **FORCE** button can be used to force download of the rule packages from the vendor web site no matter how the MD5 hash tests out.

In the screenshot below, the Snort VRT and Emerging Threats Open rule packages have been successfully downloaded. The calculated MD5 hash and the file download date and time are shown. Also note the last update time and result are shown in the center of the page.

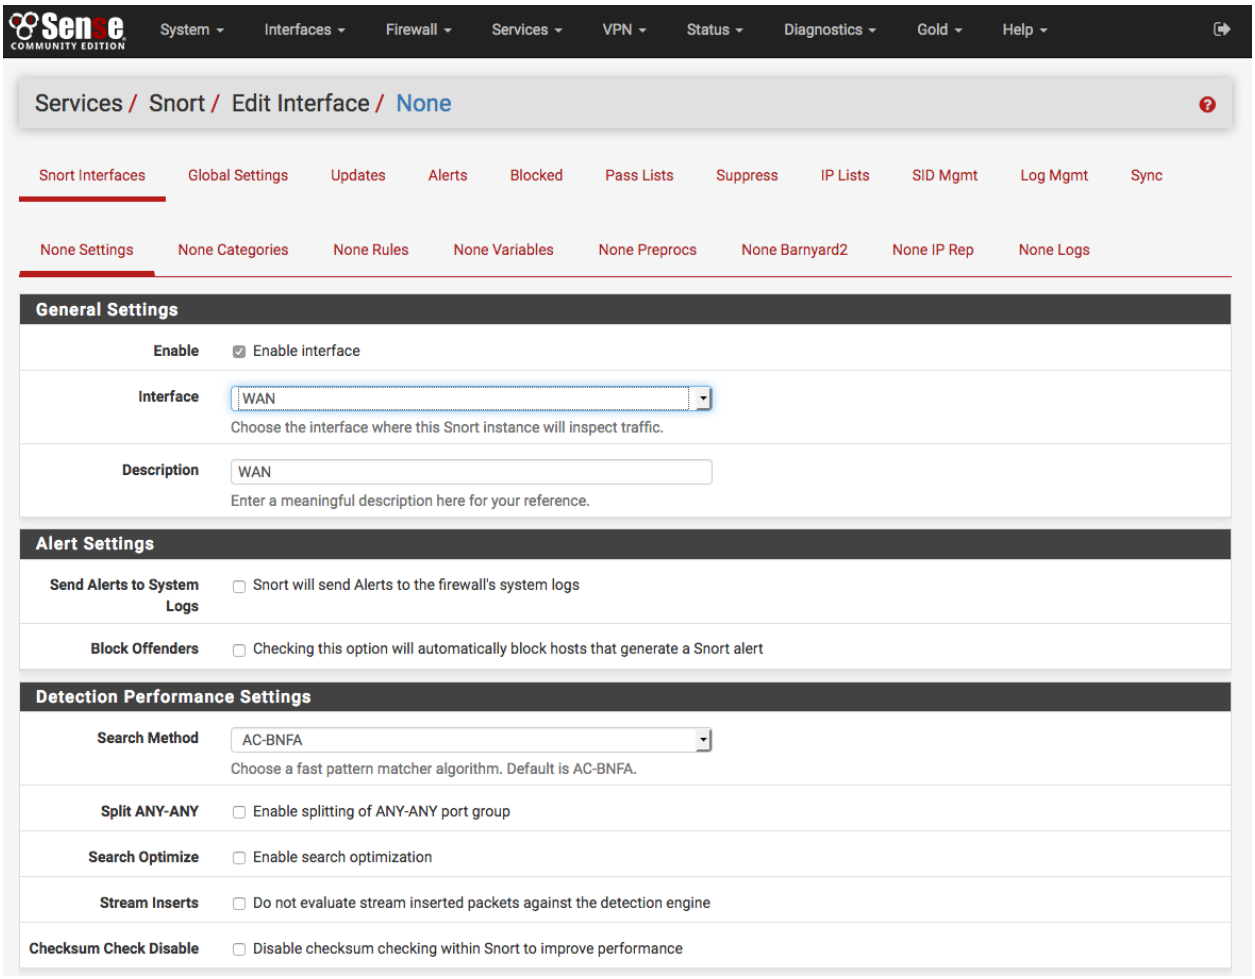


Add Snort to an interface

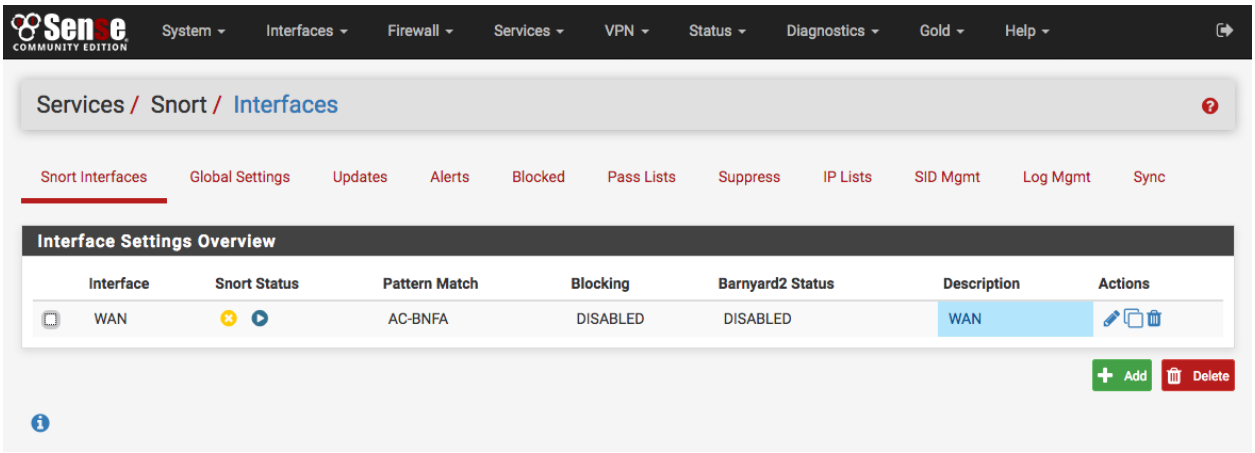
Click the **Snort Interfaces** tab and then the + icon to add a new Snort interface.



A new Interface Settings tab will open with the next available interface automatically selected. The interface selection may be changed using the **Interface** drop-down if desired. A descriptive name may also be provided for the interface. Other interface parameters may also be set on this page. Be sure to click the **SAVE** button down at the bottom of the page when finished.



After saving, the browser will be returned to the **Snort Interfaces** tab. Note the warning icons in the image below showing no rules have been selected for the new Snort interface. Those rules will be configured next. Click the  icon (shown highlighted with a red box in the image below) to edit the new Snort interface again.



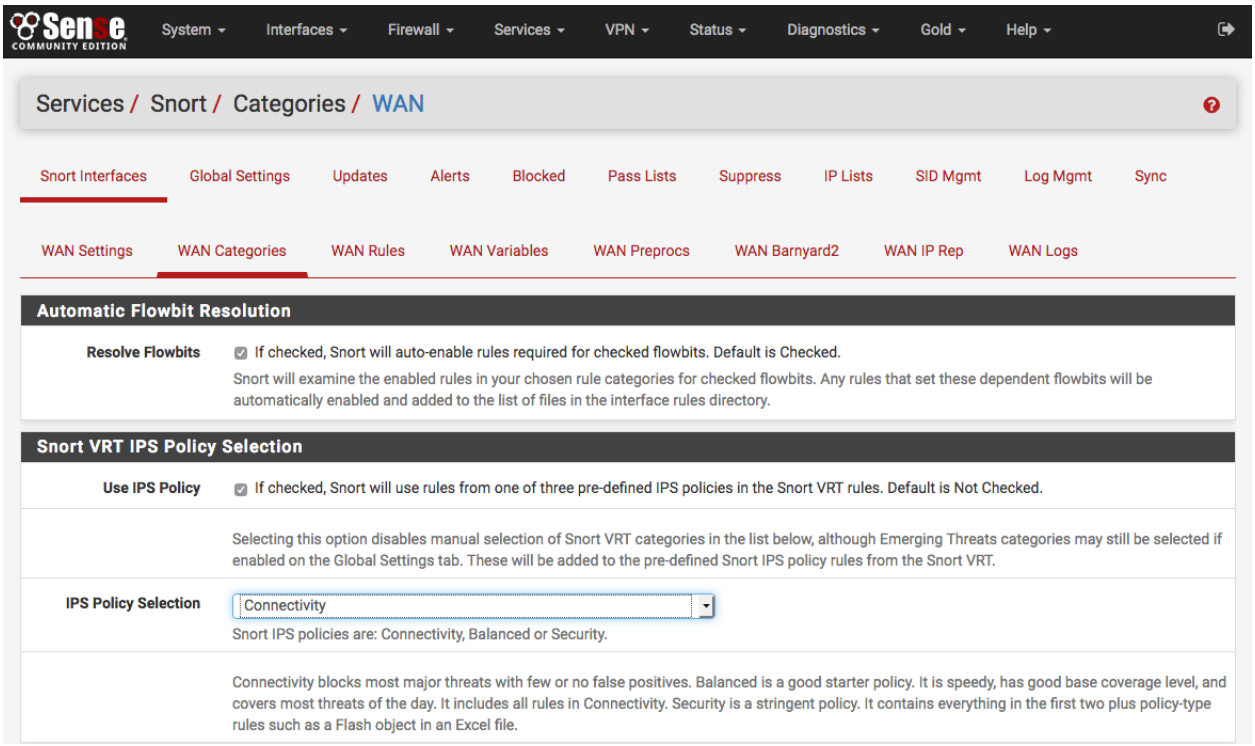
Select which types of rules will protect the network

Click the **Categories** tab for the new interface.

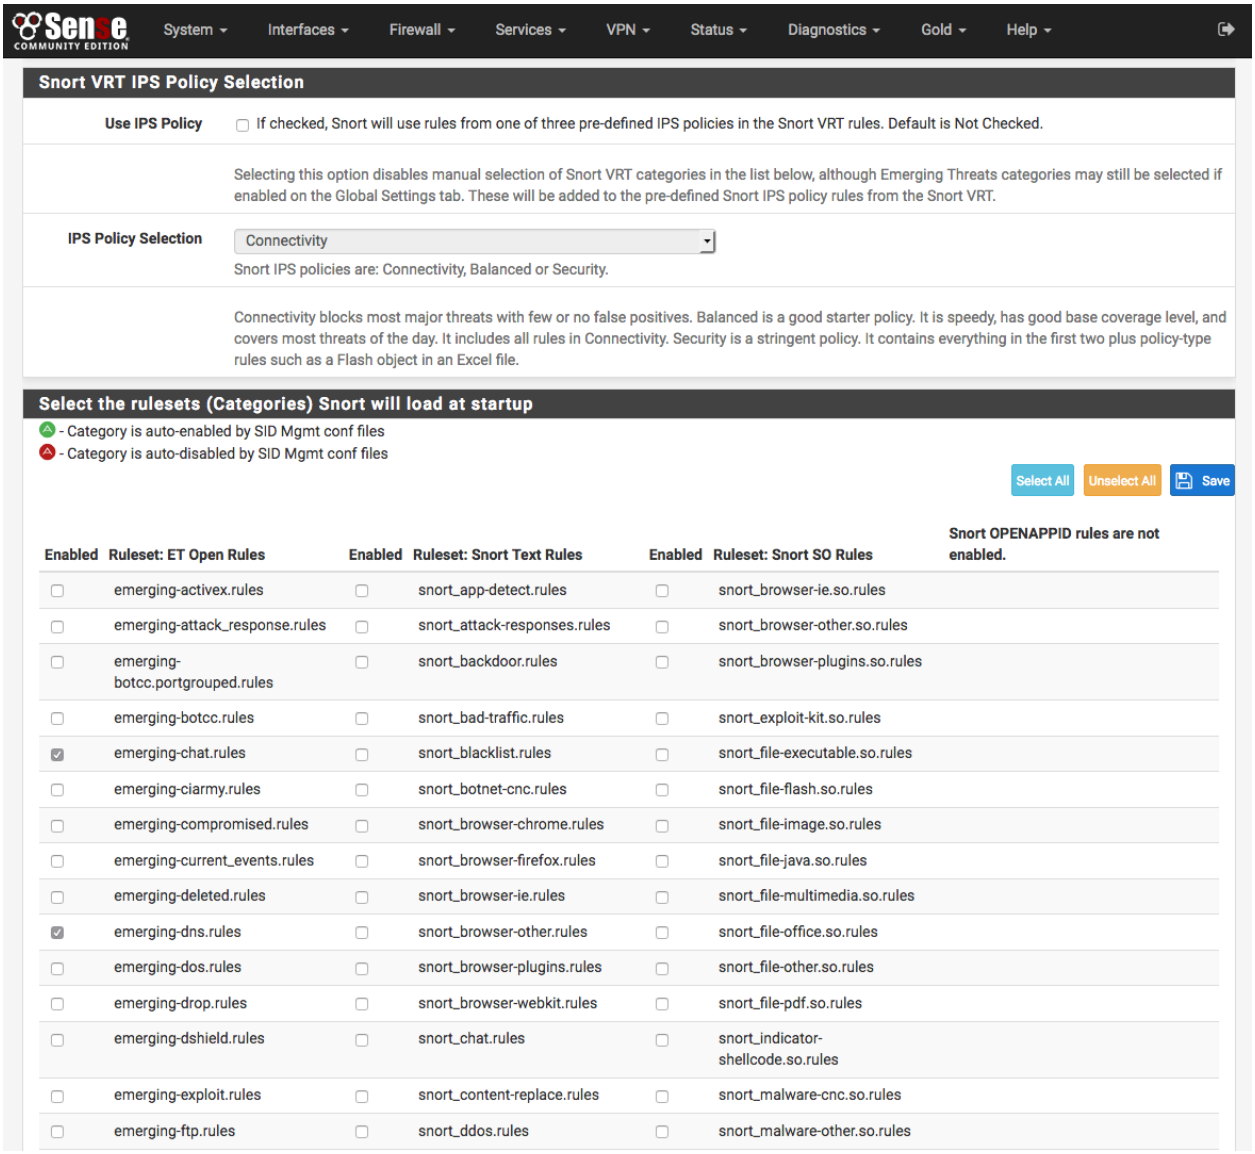
If a Snort VRT Oinkmaster code was obtained (either free registered user or the paid subscription), enabled the Snort VRT rules, and entered the Oinkmaster code on the Global Settings tab then the option of choosing from among three pre-configured IPS policies is available. These greatly simplify the process of choosing enforcing rules for Snort to use when inspecting traffic. The IPS policies are only available when the Snort VRT rules are enabled.

The three Snort VRT IPS Policies are: (1) Connectivity, (2) Balanced and (3) Security. These are listed in order of increasing security. However, resist the temptation to immediately jump to the most secure *Security* policy if Snort is unfamiliar. False positives can frequently occur with the more secure policies, and careful tuning by an experienced administrator may be required.

Tip: If Snort is unfamiliar, then using the less restrictive *Connectivity* policy in non-blocking mode (the default setting) is recommended as a starting point to identify and whitelist false positives. Once experience with Snort has been gained in this network environment, blocking mode may be enabled (via the **Block Offenders** option in the **Snort Interface Settings** tab) and a more restrictive IPS policy may be chosen.



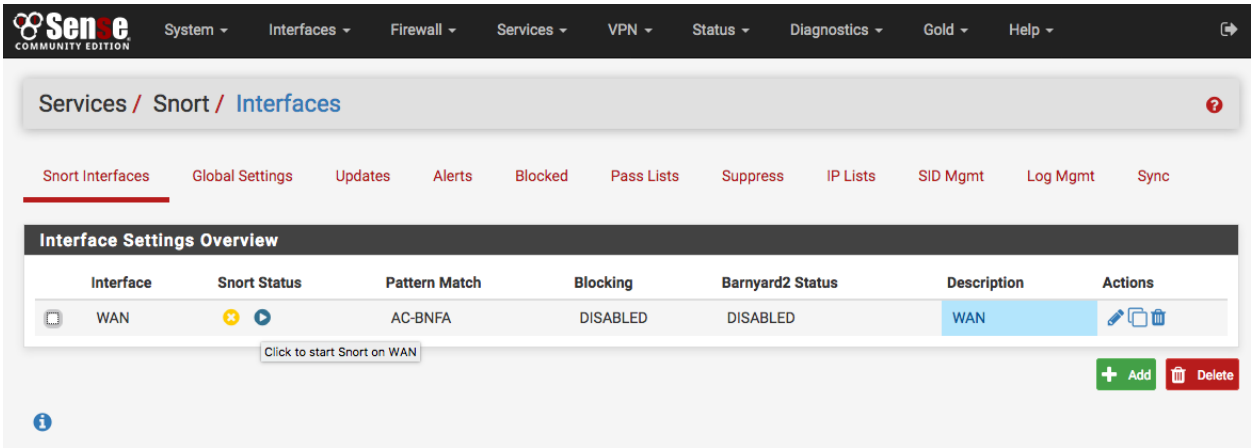
If the Snort VRT rules were not enabled, or if any of the other rule packages are to be used, then make the rule category selections by checking the checkboxes beside the rule categories to use.



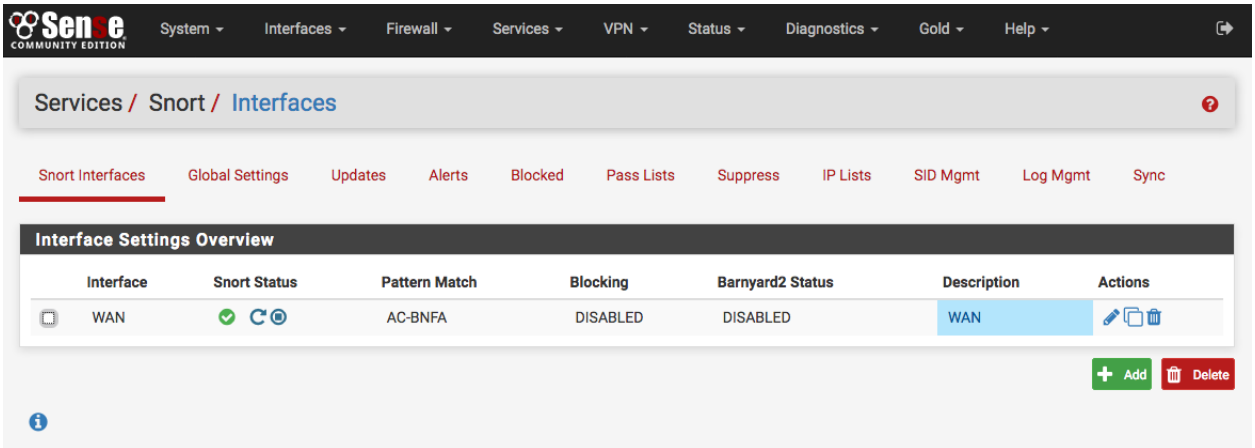
Be sure to click **SAVE** when finished to save the selection and build the rules file for Snort to use.

Starting Snort on an interface

Click the **Snort Interfaces** tab to display the configured Snort interfaces. Click the  icon (shown highlighted with a red box in the image below) to start Snort on an interface.



It will take several seconds for Snort to start. Once it has started, the icon will change to as shown below. To stop a running Snort instance on an interface, click the icon.



Select which types of signatures will protect the network

Click the **Rules** tab for the interface to configure individual rules in the enabled categories. Generally this page is only used to disable particular rules that may be generating too many false positives in a particular network environment. Be sure they are in fact truly false positives before taking the step of disabling a Snort rule!

Select a rules category from the **Category** drop-down to view all the assigned rules. Click the or icon at the far-left of a row to toggle the rule's state from enabled to disabled, or click or to toggle from disabled to enabled. The icon will change to indicate the state of the rule. At the top of the rule list is a legend showing the icons used to indicate the current state of a rule.

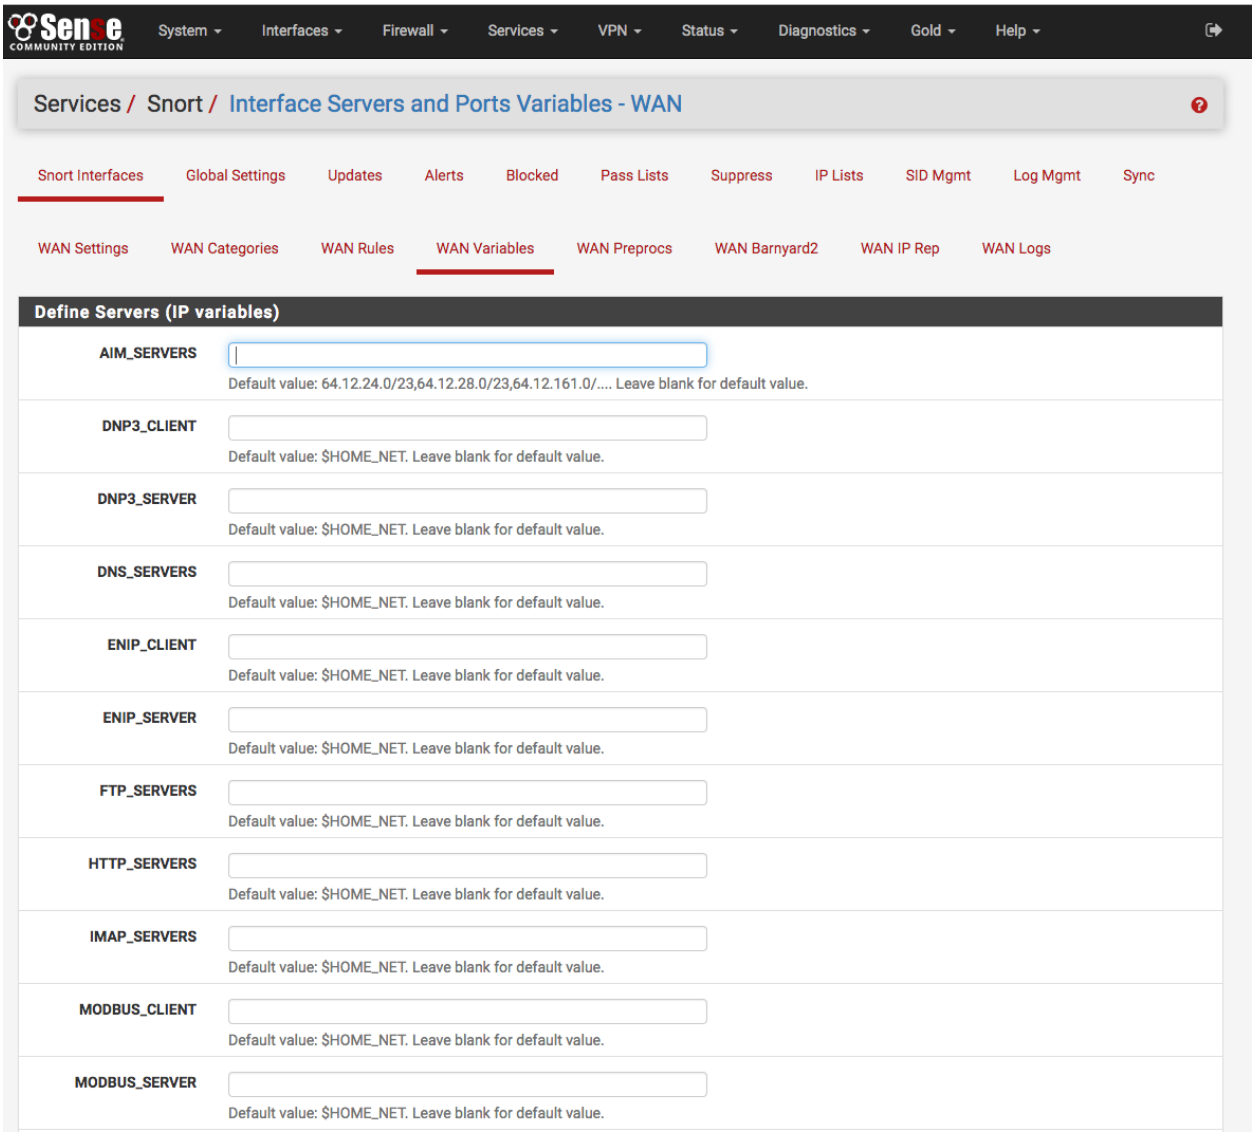
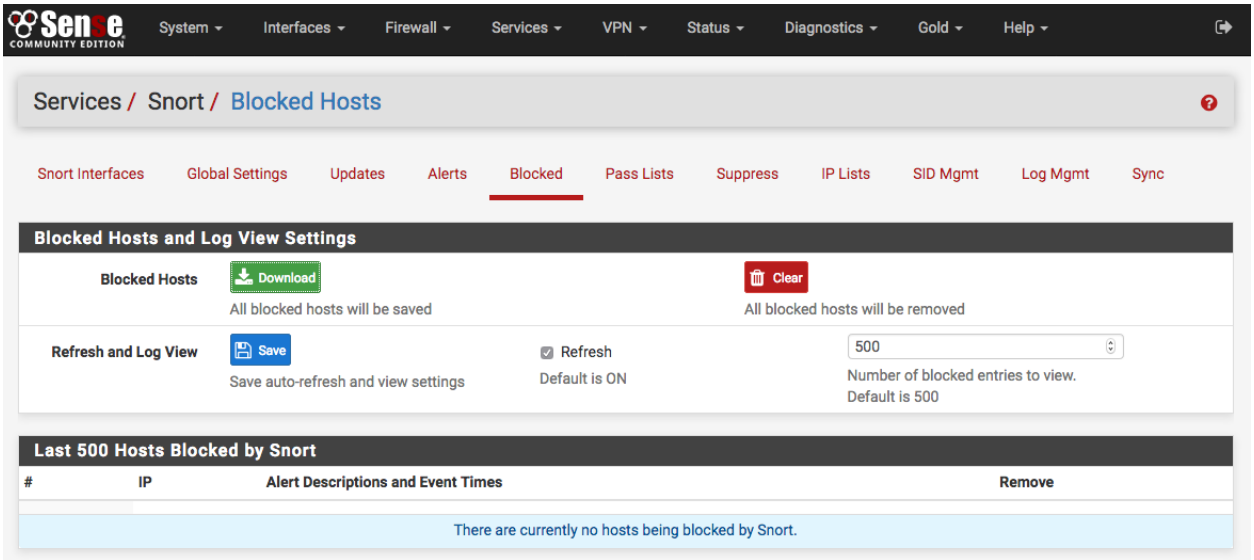
Define servers to protect and improve performance



Managing blocked hosts

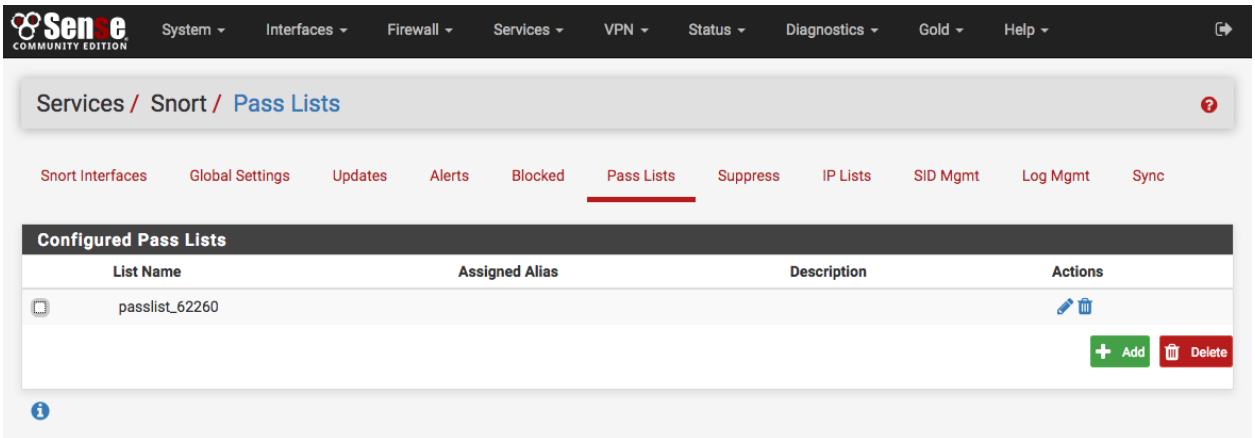
The **Blocked** tab shows what hosts are currently being blocked by Snort (when the block offenders option is selected on the **Interface Settings** tab). Blocked hosts can be automatically cleared by Snort at one of several pre-defined intervals. The blocking options for an interface are configured on the Snort **Interface Settings** tab for the interface.



Managing Pass lists

Pass Lists are lists of IP addresses that Snort should never block. These may be created and managed on the **Pass Lists** tab. When an IP address is listed on a Pass List, Snort will never insert a block on that address even when malicious traffic is detected.

To create a new Pass List, click . To edit an existing Pass List, click the . To delete a Pass List, click . Note that a Pass List may not be deleted if it is currently assigned to one or more Snort interfaces.

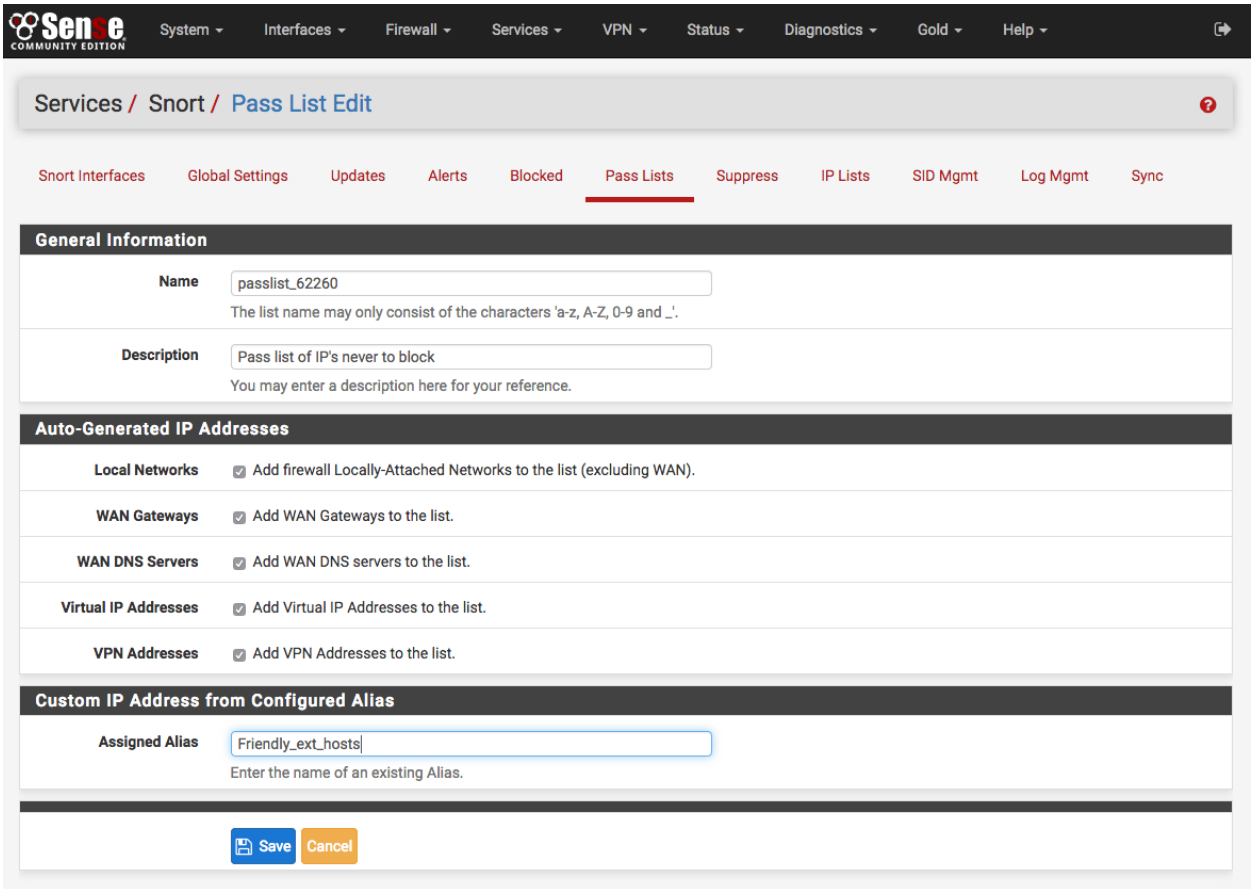


A default Pass List is automatically generated by Snort for every interface, and this default list is used when no other list is specified. Pass Lists are assigned to an interface on the **Interface Settings** tab.

Customized Pass List may be created and assigned to an interface. This might be done when trusted external hosts exist that are not located on networks directly connected to the firewall. To add external hosts in this manner, first create an Alias under **Firewall > Aliases** and then assign that alias to the **Assigned Aliases** field. In the example shown below, the alias "*Friendly_ext_hosts*" has been assigned. This alias would contain the IP addresses of the trusted external hosts.

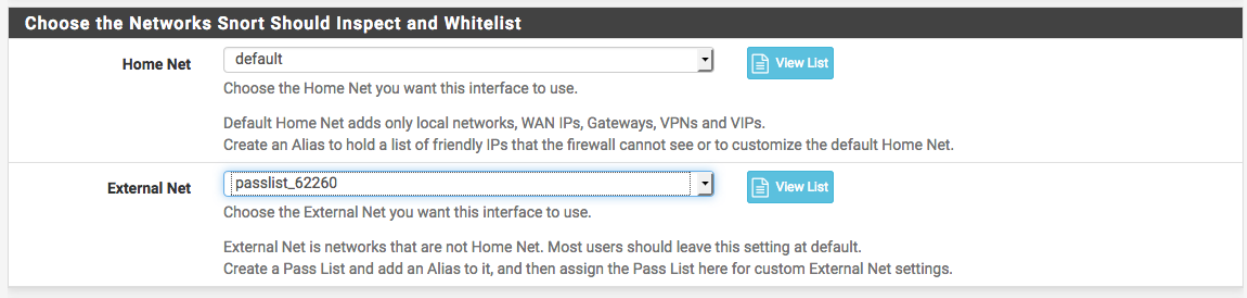
When creating a custom Pass List, leave all the auto-generated IP addresses checked in the **Add auto-generated IP addresses** section. Not selecting the checkboxes in this section can lead to blocking of critical addresses including the

firewall interfaces themselves. This could result in being locked out of the firewall over the network! Only uncheck boxes in this section when absolutely necessary.



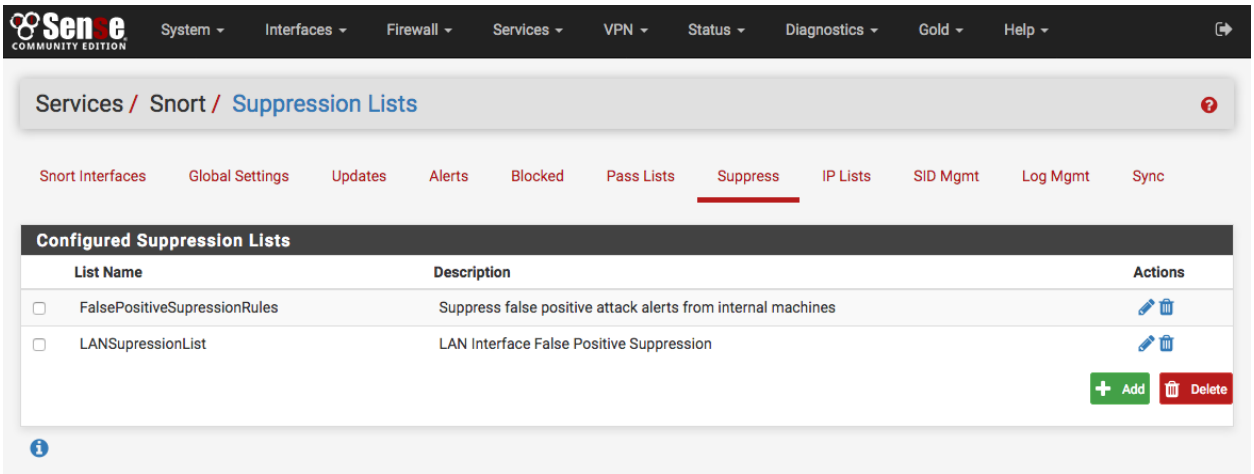
Click the **ALIASES** button to open a window showing previously defined aliases for selection. Remember to click **SAVE** to save changes.

Note: Remember that simply creating a Pass List is only the first step! It must be selected by going to the **Interface Settings** tab for the Snort interface and assigning the newly created Pass List as shown below. After assigning and saving the new Pass List, restart Snort on the affected interface to pick up the change.

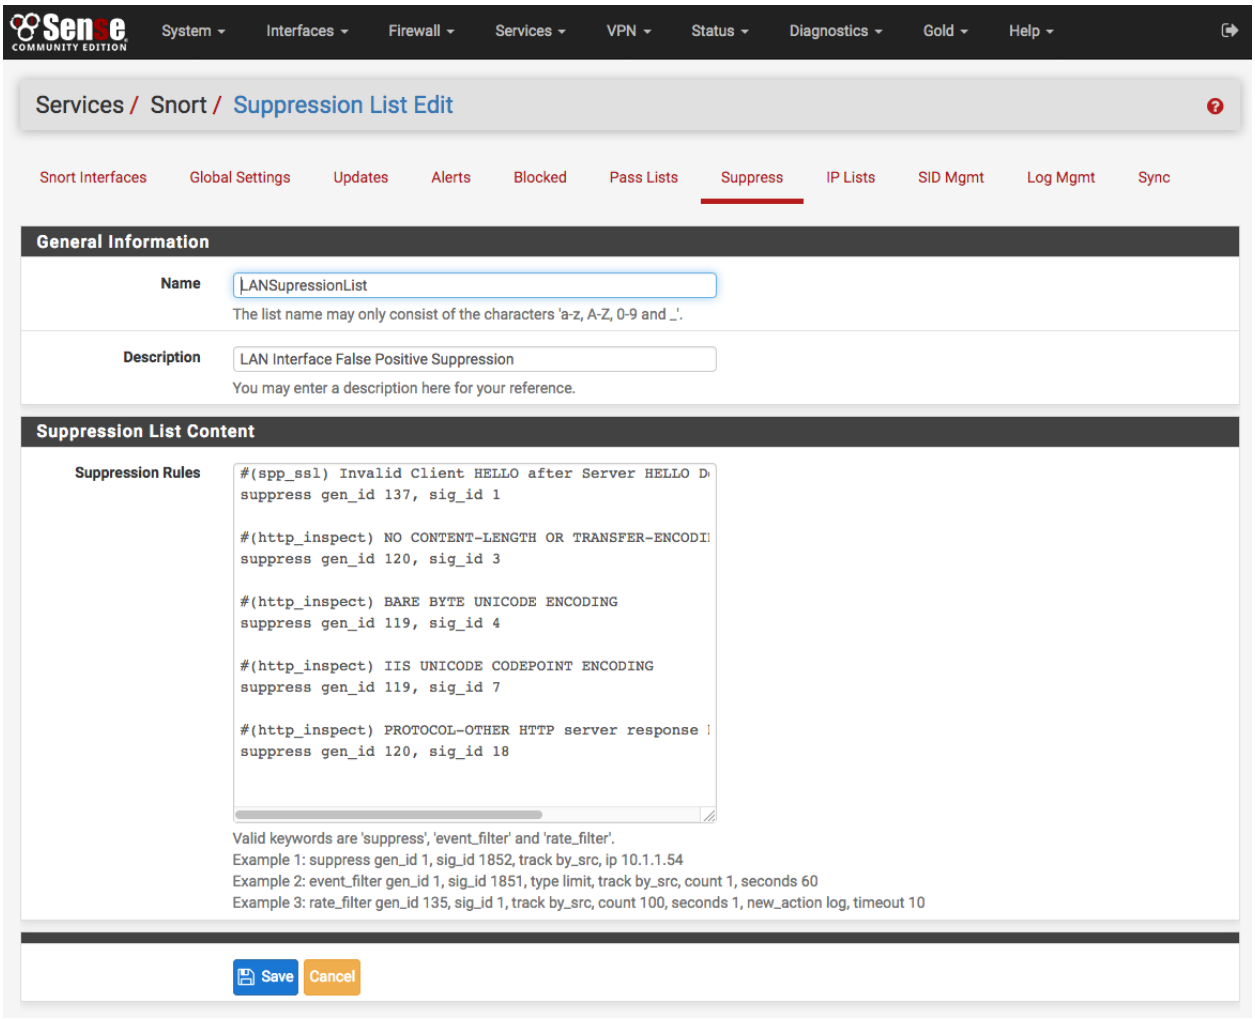


Alert Thresholding and Suppression

Suppression Lists allow control over the alerts generated by Snort rules. When an alert is suppressed, then Snort no longer logs an alert entry (or blocks the IP address if block offenders is enabled) when a particular rule fires. Snort still inspects all network traffic against the rule, but even when traffic matches the rule signature, no alert will be generated. This is different from disabling a rule. When a rule is disabled, Snort no longer tries to match it to any network traffic. Suppressing a rule might be done in lieu of disabling the rule when alerts should only be stopped based on either the source or destination IP. For example, to suppress the alert when traffic from a particular trusted IP address is the source. If any other IP is the source or destination of the traffic, the rule would still fire. To eliminate all alerts from the rule, then it is more efficient to simply disable the rule rather than to suppress it. Disabling the rule will remove it from Snort's list of match rules and therefore makes for less work Snort has to do.



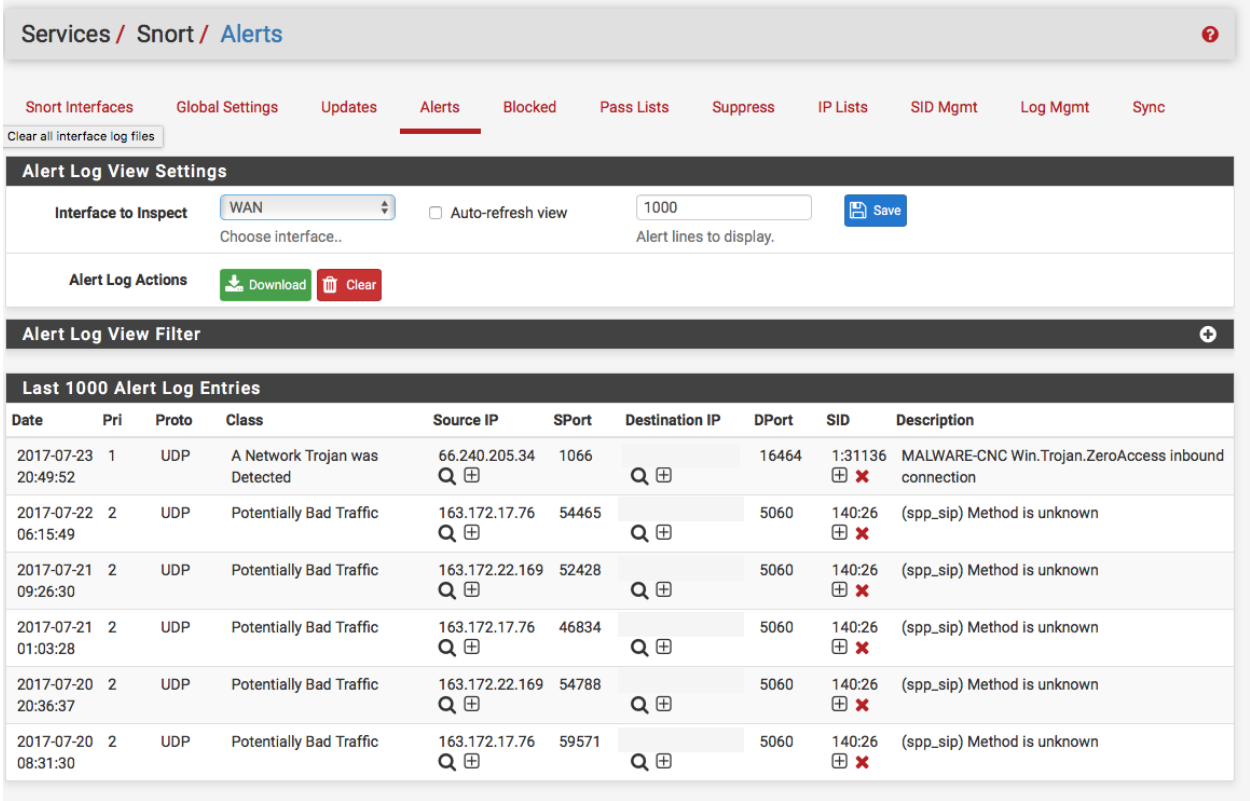
On the Suppress List Edit page, a new suppress list entry may be manually added or edited. It is usually easier and faster to add suppress list entries by clicking  shown with the alert entries on the **Alerts** tab. Remember to click the **SAVE** button to save changes when manually editing Suppress List entries.



Getting to know the alerts

The **Alerts** tab is where alerts generated by Snort are viewed. If Snort is running on more than one interface, choose the interface whose alerts should be viewed in the drop-down selector.

Use the **DOWNLOAD** button to download a gzip tar file containing all of the logged alerts to a local machine. The **CLEAR** button is used to erase the current alerts log. Destination IP's have been redacted from the screenshot.



Alert Details

Date	Pri	Proto	Class	Source IP	SPort	Destination IP	DPort	SID	Description
2017-07-23 20:49:52	1	UDP	A Network Trojan was Detected	66.240.205.34	1066		16464	1:31136	MALWARE-CNC Win.Trojan.ZeroAccess inbound connection
2017-07-22 06:15:49	2	UDP	Potentially Bad Traffic	163.172.17.76	54465		5060	140:26	(spp_sip) Method is unknown

The **Date** column shows the date and time the alert was generated. The remaining columns show data from the rule that generated the alert.

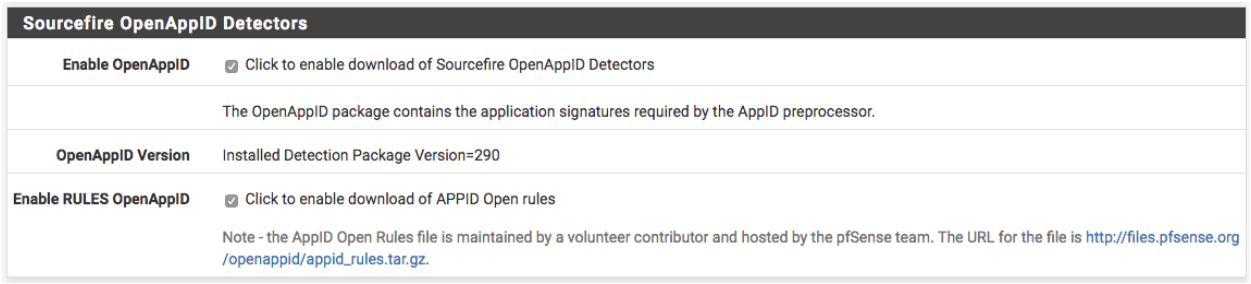
In the **Source**, **Destination** columns are  icons for performing reverse DNS lookups on the IP addresses as well as a  icon used to add an automatic *Suppress List* entry for the alert using the IP address and SID (signature ID). This will prevent future alerts from being generated by the rule for that specific IP address only. If either of the Source or Destination addresses are currently being blocked by Snort, then a  icon will also be shown. Clicking that icon will remove the block for the IP address.

The SID column contains two icons. The  icon will automatically add that SID to the *Suppress List* for the interface and suppress future alerts from the signature for all IP addresses. The  icon in the SID column will disable the rule and remove it from the enforcing rule set. When a rule is manually disabled, the icon in the SID column changes to  .

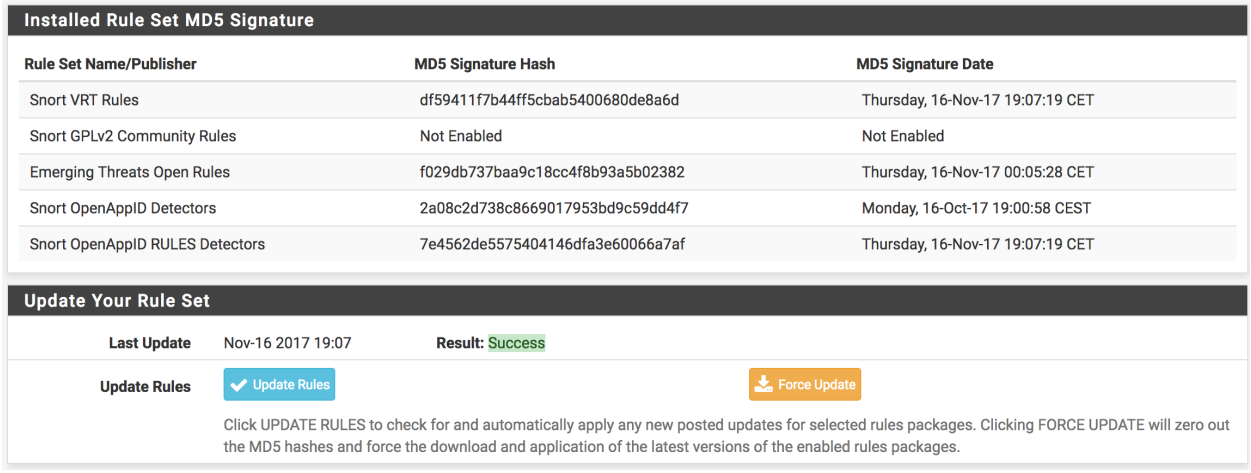
Application ID detection with OpenApp ID

OpenAppID is an application-layer network security plugin for the open source intrusion detection system Snort. Learn more about it here.

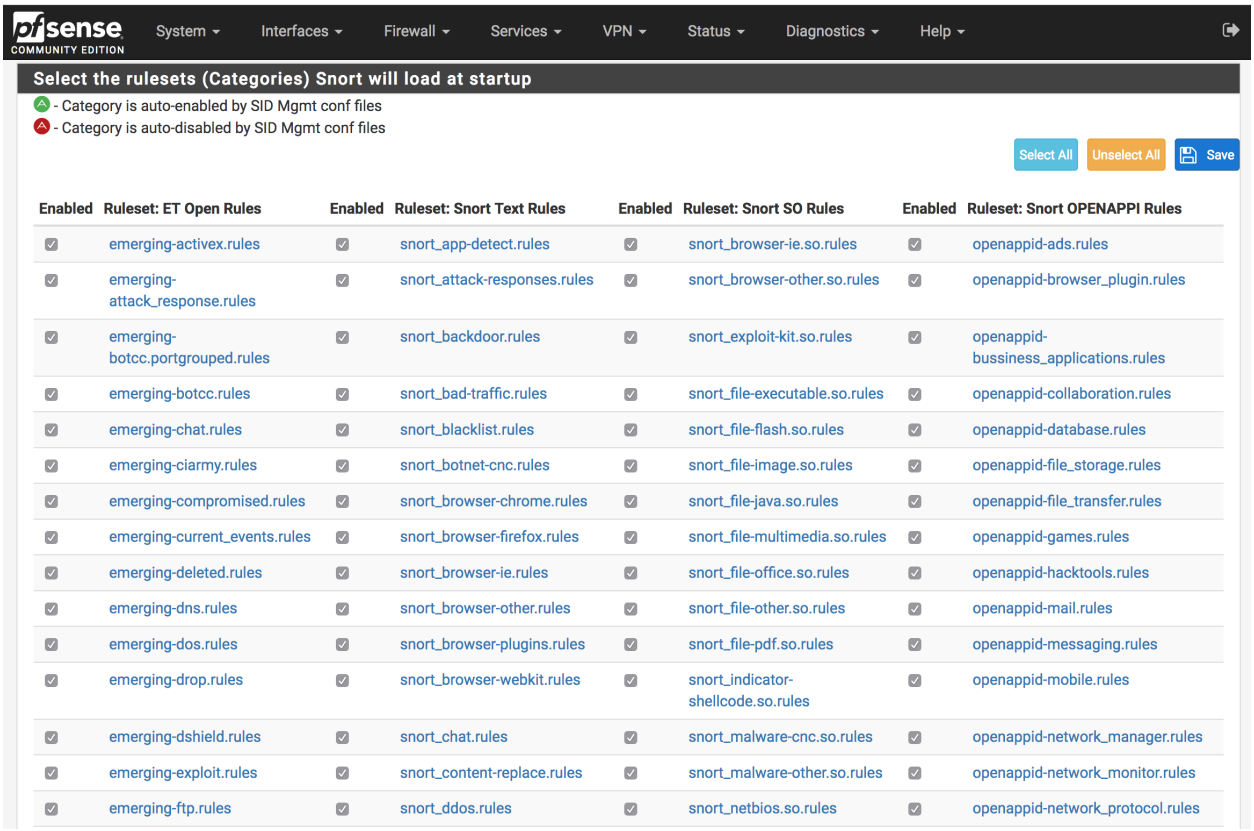
Enabling OpenAppID and its rules is done from Snort **Global Settings**. Select both checkboxes to enable detectors and rules download. Save the page.



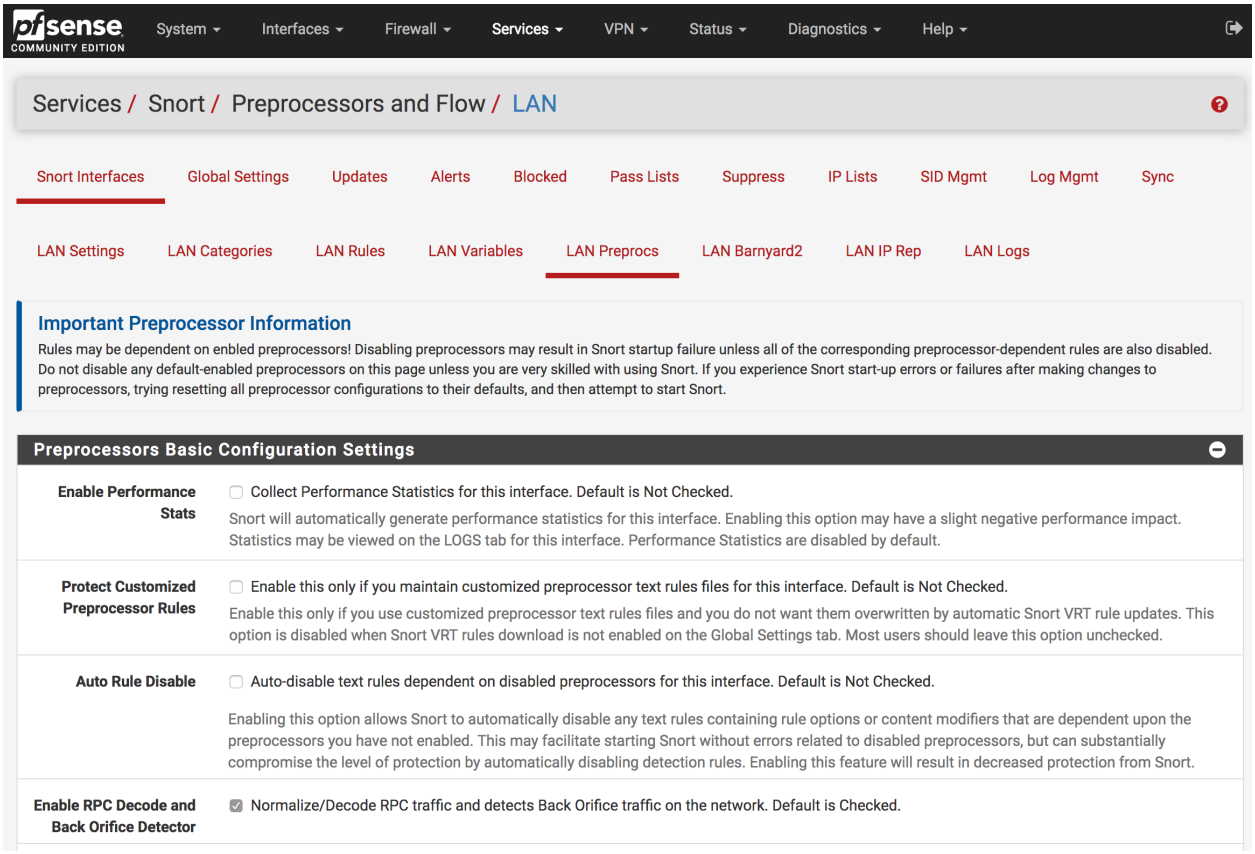
After enabling the detectors and rules go to Snort Updates tab and click on **Update Rules**. Wait for all the rules to update. Once done, the page will show OpenAppID detectors and rules have been updated.



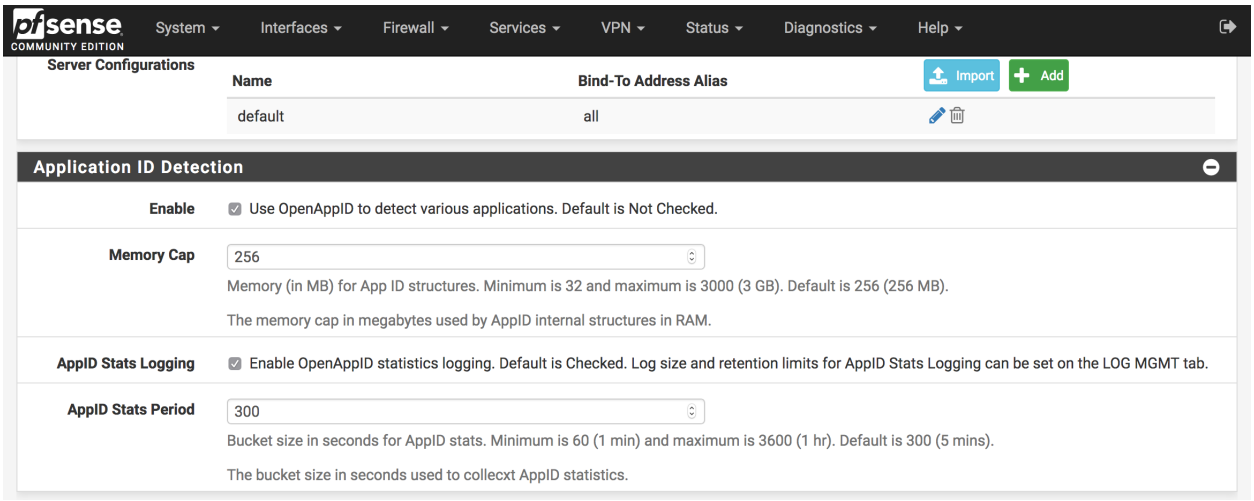
The following steps assume the firewall already has a Snort interface for LAN. Edit the LAN interface and navigate to LAN categories tab. When there, make sure the **Snort OPENAPPID Rules** from the right column are all selected and click **Save**.



Lastly, while still editing Snort interface, navigate to **LAN Preprocessor** tab.

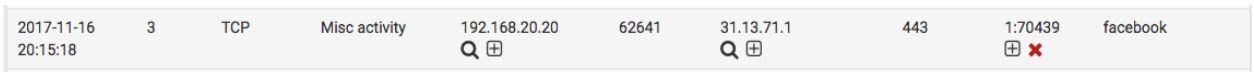


Scroll down to **Application ID Detection** section and select both **Enable** and **AppID Stats Logging** checkboxes. Save the page the OpenApp ID will be activated on the Snort interface.

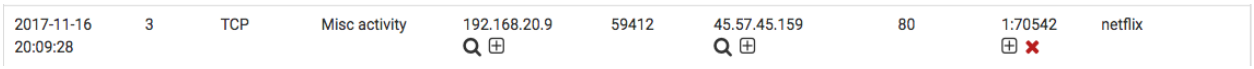


Viewing detected applications can be done from **Alerts** tab. The following screenshots are examples of identified services and applications:

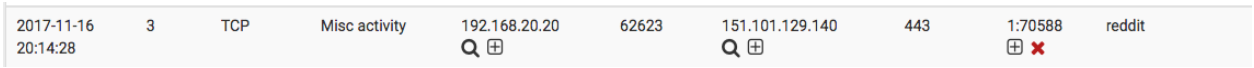
Facebook



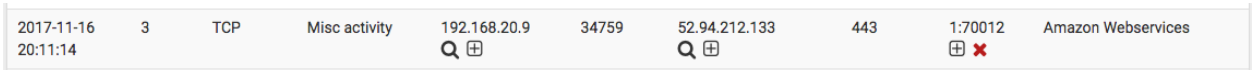
Netflix



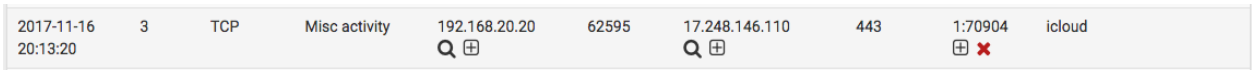
Reddit



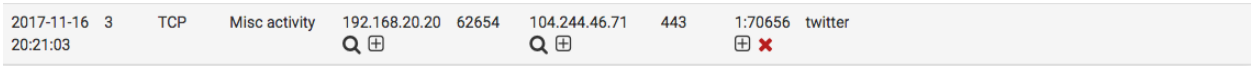
Amazon Web Services



iCloud



Twitter



Known issues

The pfSense software issue tracker contains a list of known issues with this package.

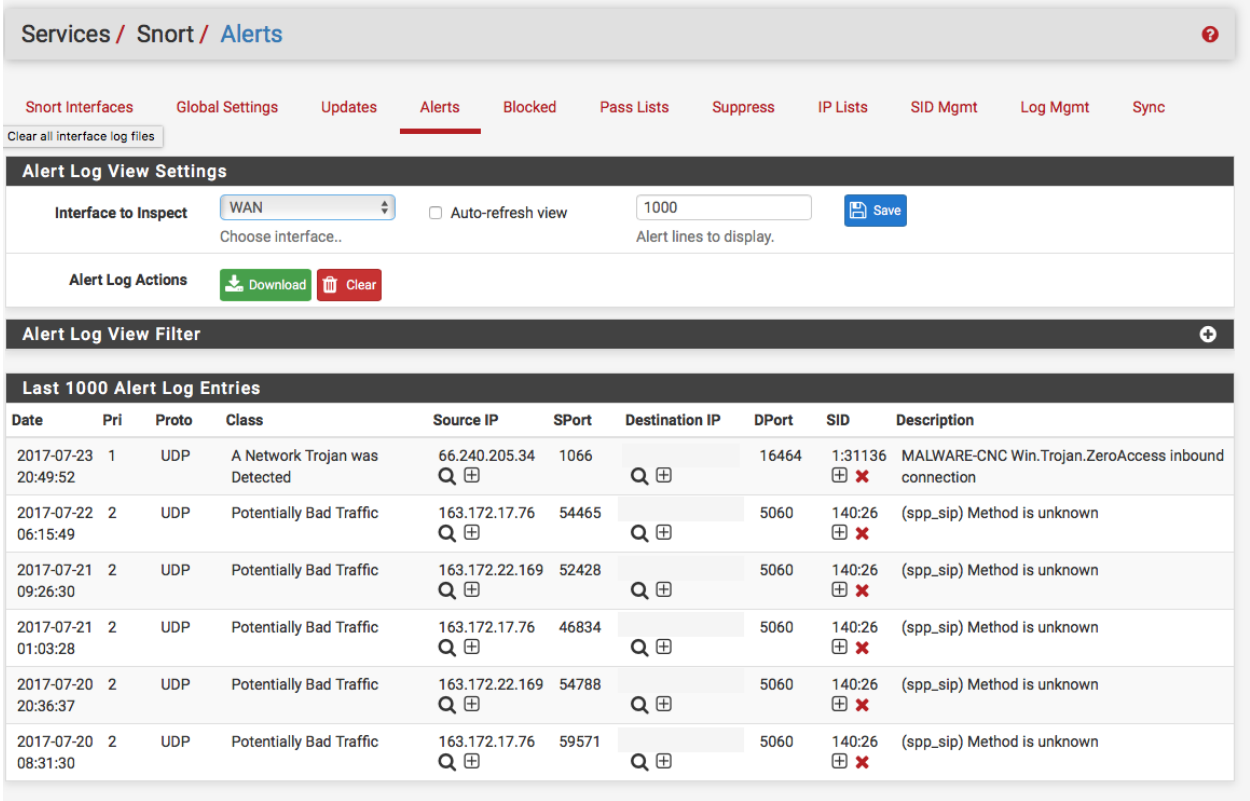
Package Support

Netgate TAC can only assist with the installation of this package. Netgate Professional Services can assist with custom configurations.

Snort Alerts

The **Alerts** tab is where alerts generated by Snort may be viewed. If Snort is running on more than one interface, choose the interface to view alerts for in the drop-down selector.

Use the **DOWNLOAD** button to download a gzip tar file containing all of the logged alerts to a local machine. The **CLEAR** button is used to erase the current alerts log.



Alert Details

Date	Pri	Proto	Class	Source IP	SPort	Destination IP	DPort	SID	Description
2017-07-23 20:49:52	1	UDP	A Network Trojan was Detected	66.240.205.34	1066		16464	1:31136	MALWARE-CNC Win.Trojan.ZeroAccess inbound connection
2017-07-22 06:15:49	2	UDP	Potentially Bad Traffic	163.172.17.76	54465		5060	140:26	(spp_sip) Method is unknown

The **Date** column shows the date and time the alert was generated. The remaining columns show data from the rule that generated the alert.

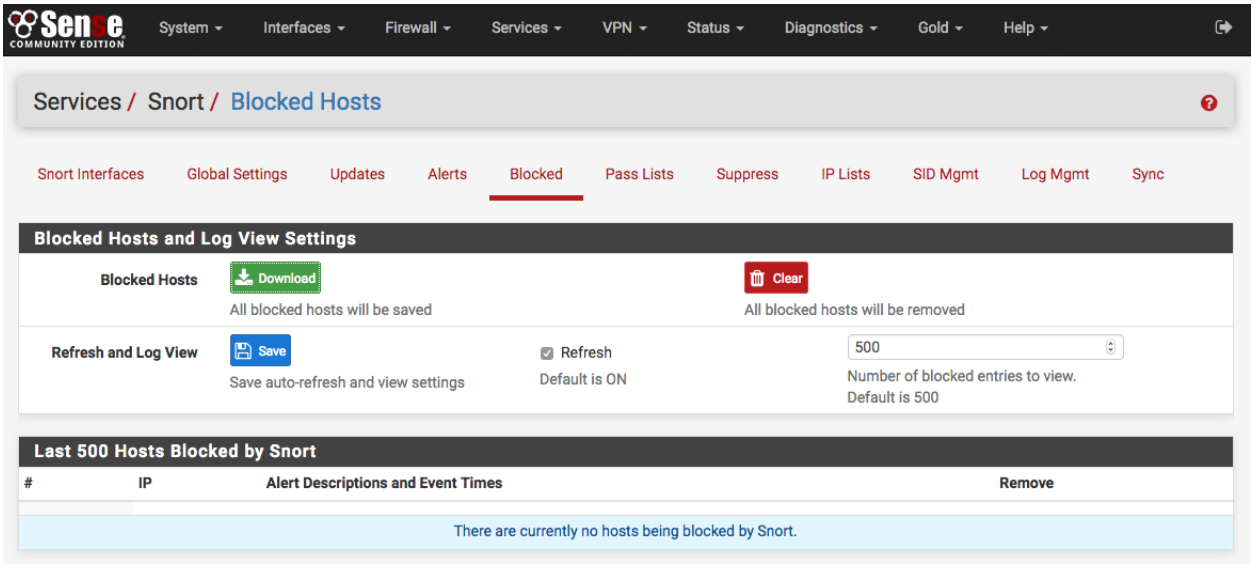
In the **Source**, **Destination** columns are  icons for performing reverse DNS lookups on the IP addresses as well as a  icon used to add an automatic *Suppress List* entry for the alert using the IP address and SID (signature ID). This will prevent future alerts from being generated by the rule for that specific IP address only. If either of the Source or Destination addresses are currently being blocked by Snort, then a  icon will also be shown. Clicking that icon will remove the block for the IP address.

The SID column contains two icons. The  icon will automatically add that SID to the *Suppress List* for the interface and suppress future alerts from the signature for all IP addresses. The  icon in the SID column will disable the rule and remove it from the enforcing rule set. When a rule is manually disabled, the icon in the SID column changes to  .

Snort Blocked Hosts

The **Blocked** tab shows what hosts are currently being blocked by Snort (when the **block offenders** option is selected on the **Interface Settings** tab). Blocked hosts can be automatically cleared by Snort at one of several pre-defined intervals. The blocking options for an interface are configured on the Snort **Interface Settings** tab for the interface. To manually remove a blocked host, click the  icon in the right-hand column.

The  icon performs a reverse DNS lookup on the blocked host IP address when clicked.



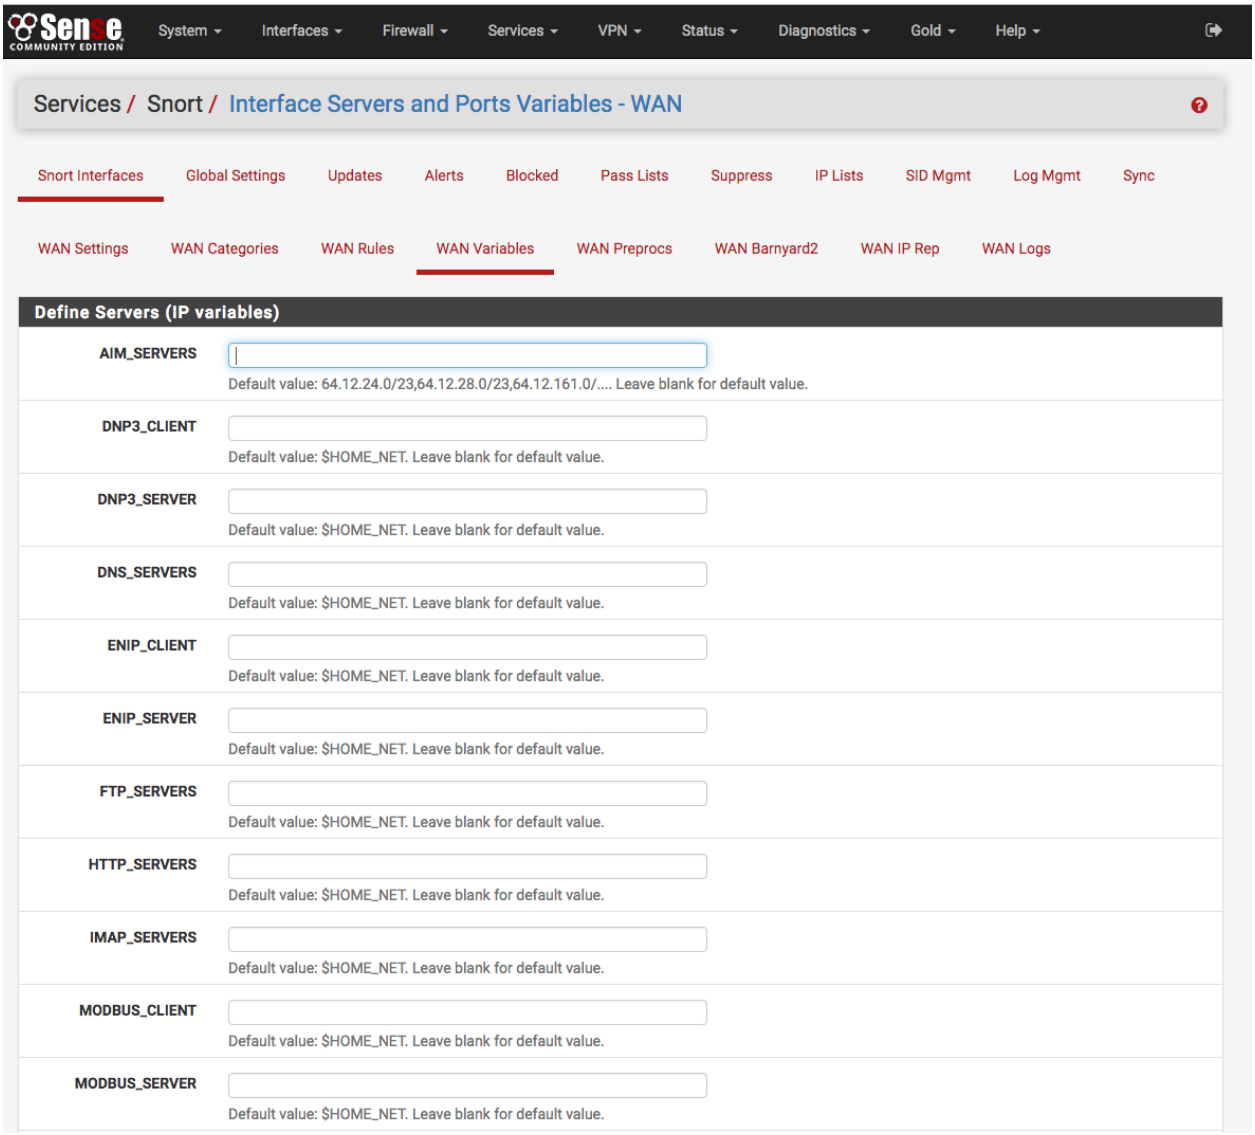
Snort Server Definitions

Define servers to protect and improve performance

The **Variables** tab is where the specific types of hosts on the network are configured. For example, the specific IP addresses or network ranges containing web servers to protect may be defined. This can make Snort more efficient because it won't waste time scanning for web server threats on IP addresses where web servers do not exist. Similarly, Snort performance can be optimized by instructing it which addresses contain other critical servers such as SMTP, POP, DNS, etc.

The exact ports or port ranges used for certain services on the network may also be specified.

Each value entered on this page can only be an existing Alias. Start typing the name of the Alias into a textbox and a drop-down selection of matching entries will appear for selection. Aliases are created under **Firewall > Aliases** from the menu.



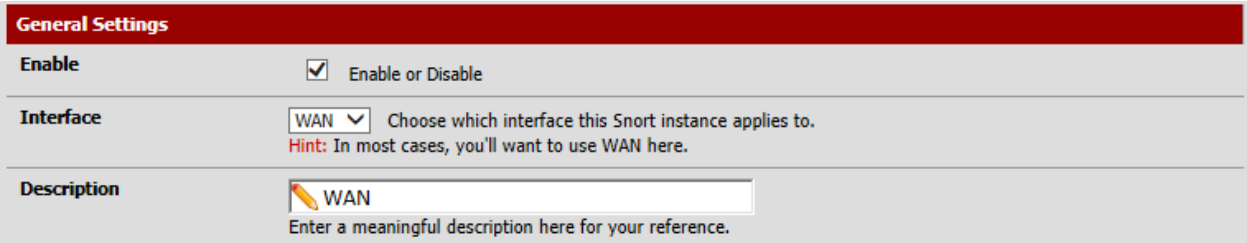
Snort interface Settings

General Settings

Enable
Used to enable or disable Snort on the selected interface. Snort is enabled on the interface when this box is checked.

Interface
Used to choose which physical firewall interface this Snort instance protects.

Description
Used to provide an optional friendly name for the interface.



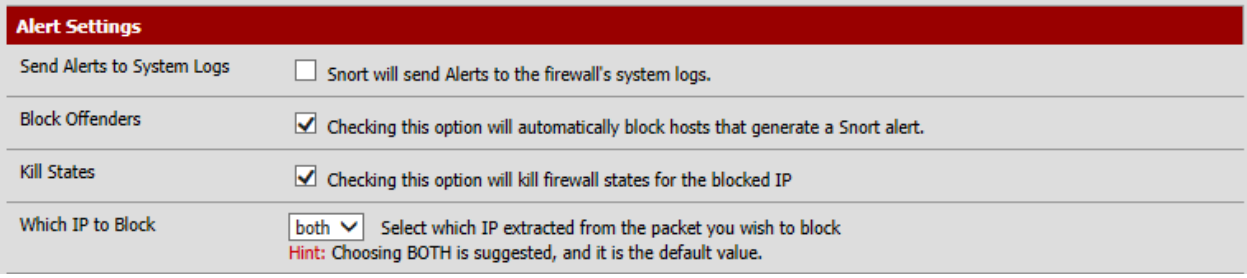
Alert Settings

Send Alerts to System Logs
When checked, all Snort alerts will be copied to the system log on the firewall.

Block Offenders
When checked, Snort will automatically insert a firewall block of the host generating an alert.

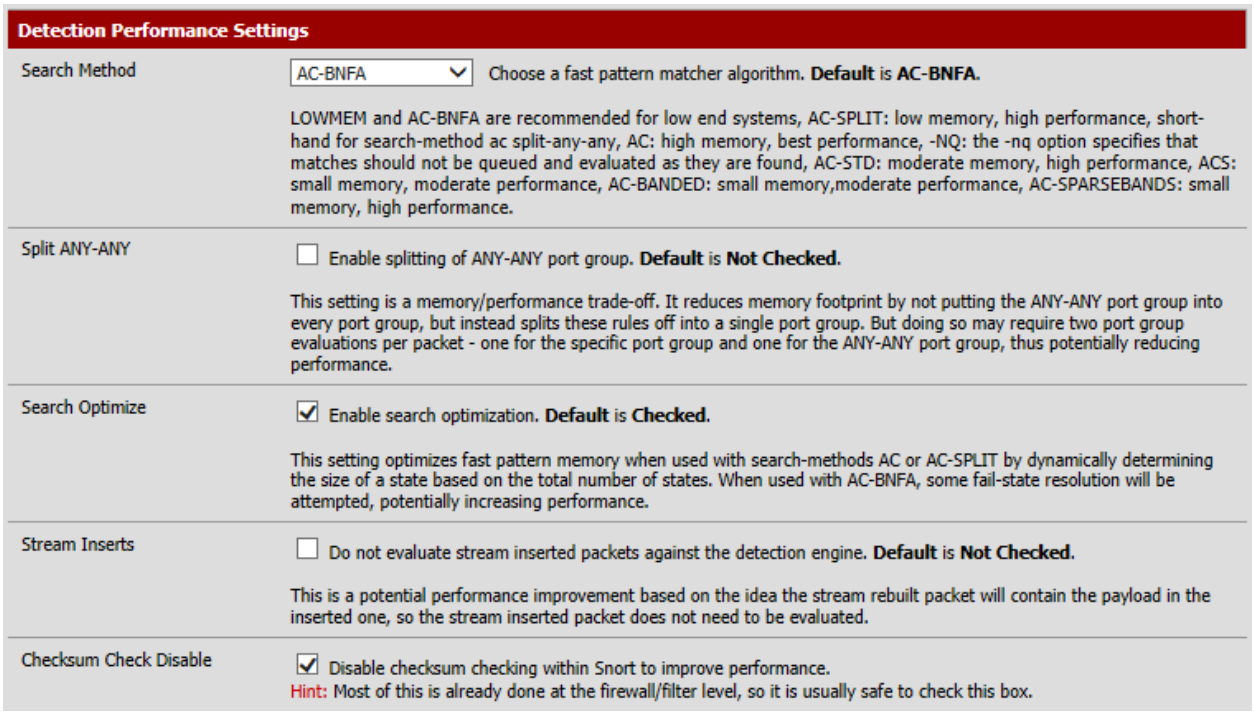
Kill States
When checked, Snort will kill all existing state table entries for the IP address it blocks. This should generally be enabled (box checked).

Which IP to Block
This determines which IP address extracted from the packet that generated an alert will be blocked. The choices are SOURCE, DESTINATION or BOTH. BOTH is the recommended default.



Detection Performance Settings

Search Method
Used to select the pattern matcher algorithm used by Snort in the signature detection engine.

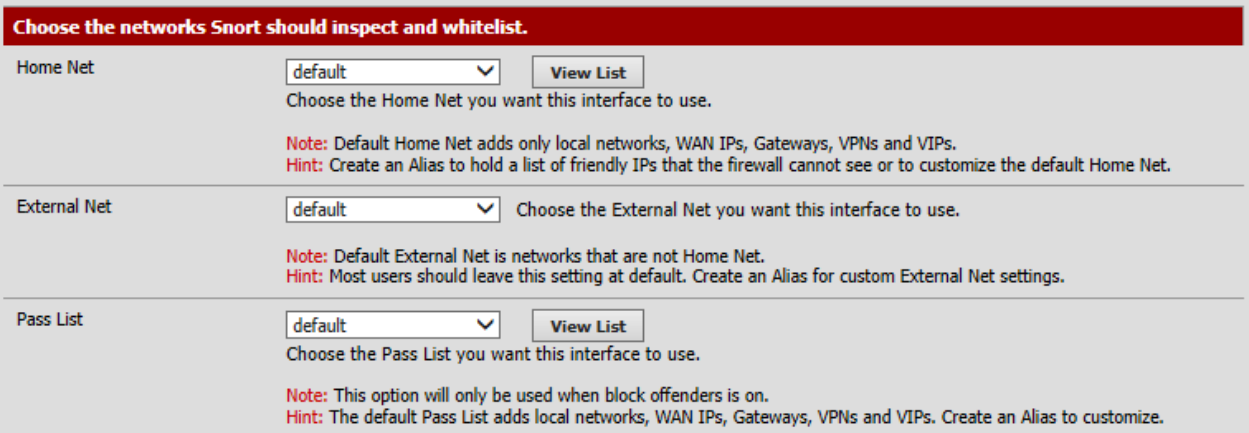


Choose the networks Snort should inspect and whitelist

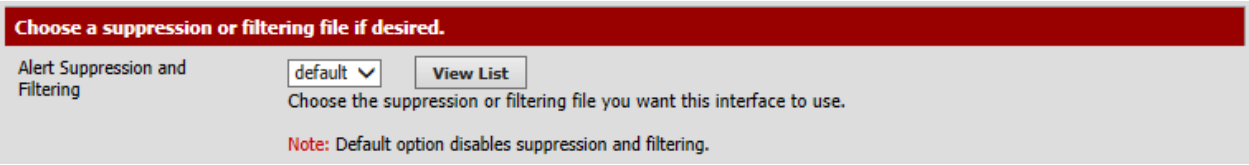
Home Net
: Selects the network Snort will use as the HOME_NET variable. Default is the recommended choice and contains the firewall WAN IP address and WAN gateway, all networks locally-attached to a firewall interface, the configured DNS servers, VPN addresses and Virtual IP addresses. Additional HOME_NET networks may be created on the IP LISTS tab, and then return to this tab to assign them to the Snort interface by selecting the appropriate list in the drop-down selector. View the contents of the selected list by clicking the **View List** button.

External Net
: Selects the network will use as the EXTERNAL_NET variable. Default is the recommended choice and contains all networks not included in HOME_NET. Create additional EXTERNAL_NET networks on the IP LISTS tab, and then return to this tab to assign them to the Snort interface by selecting the appropriate list in the drop-down selector.

Pass List
: Selects the networks and IP addresses that Snort will never block. These represent "trusted hosts". Even if a trusted host generates a Snort alert, it will not be blocked if the IP address is on a Pass List. The default Pass List contains the same addresses as HOME_NET. Create additional pass lists on the IP LISTS tab, and then return to this tab to assign them to the Snort interface by selecting the appropriate list in the drop-down selector. Snort must be restarted on the interface when making changes to the Pass List. View the contents of the selected list by clicking the **View List** button.



Choose a suppression or filtering file if desired

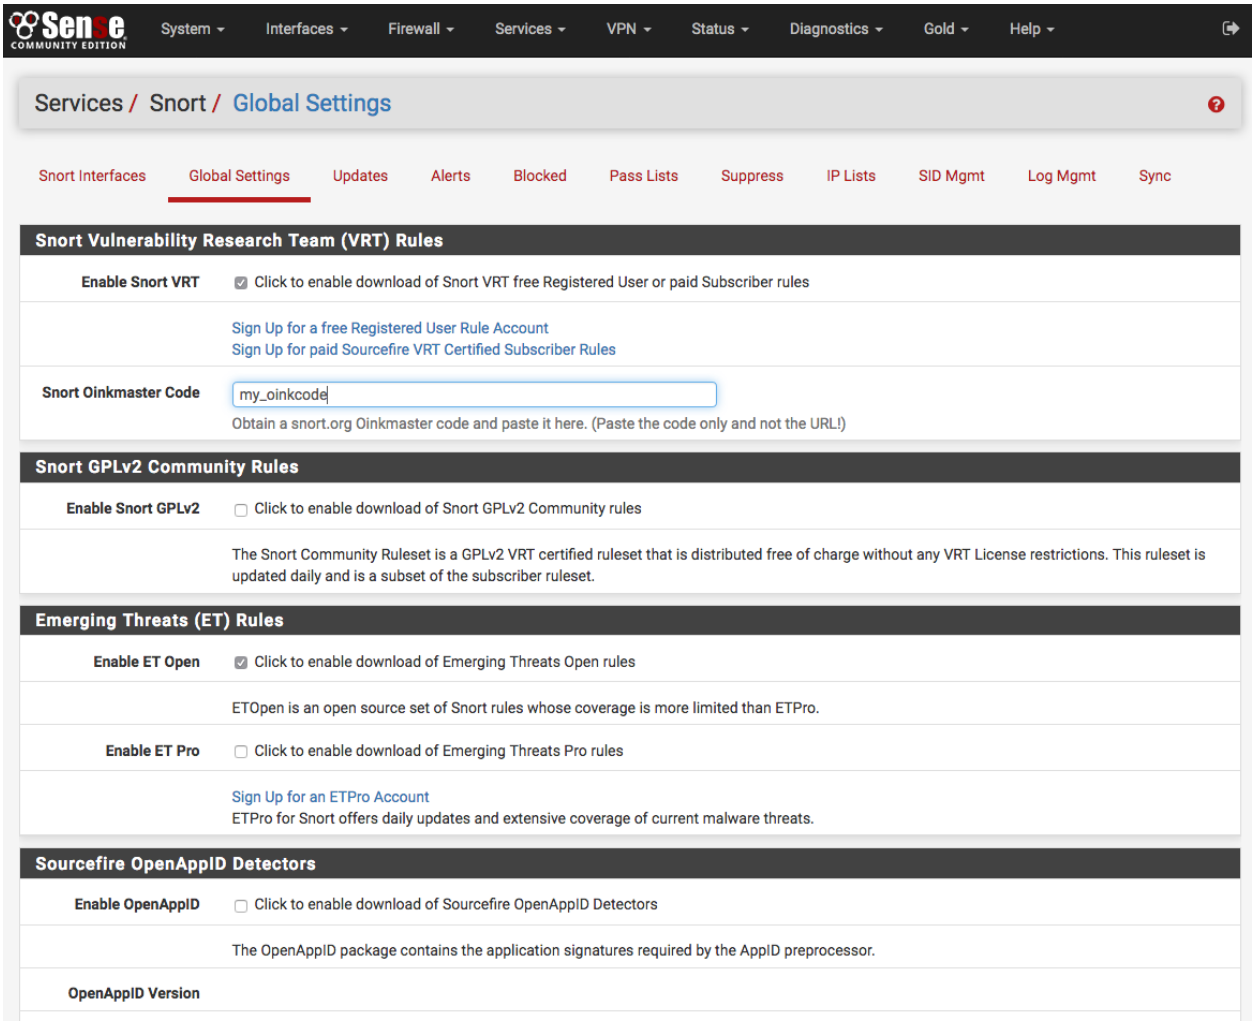


Snort interface Global Settings

This tab is used to enable rule set packages for download, configure the rules package update interval and start time, configure Snort logging directory size limits and determine whether Snort settings are saved when the package is removed from the system.

Please Choose The Type Of Rules To Download

More than one rule set may be enabled for download, but note the following caveats. If there is a paid subscription for the Snort VRT rules, then all of the Snort GPLv2 Community rules are automatically included within the file downloaded with the Snort VRT rules; therefore do not enable the GPLv2 Community rules if there is a paid-subscriber account for the Snort VRT rules. All of the Emerging Threats Open rules are included within the paid subscription for the Emerging Threats Pro rules. If the Emerging Threats Pro rules are enabled, the Emerging Threats Open rules are automatically disabled.



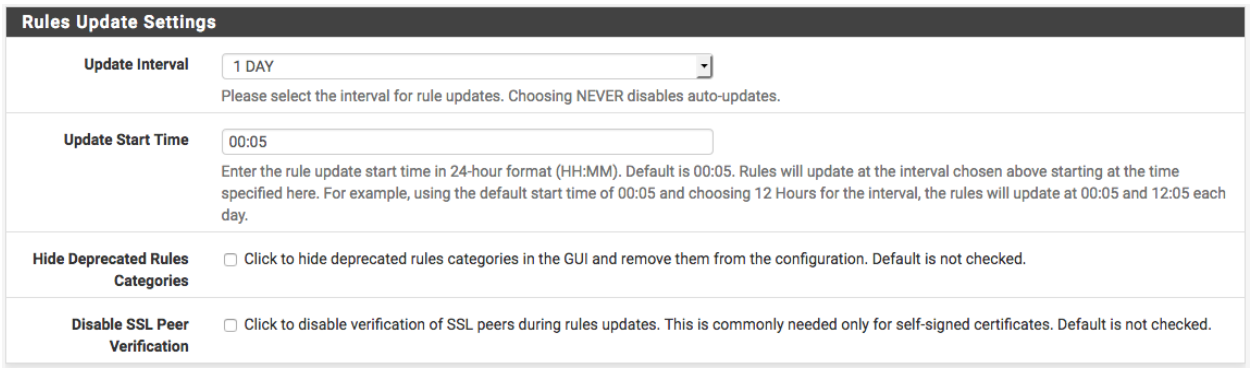
To use the Snort VRT rules package, check the **Install Snort VRT rules** checkbox and then enter the Oinkmaster code in the textbox that appears.

To use the ETPro rules package, check the box next to **ETPro** and then enter the ETPro subscription code in the textbox that appears.

Rules Update Settings

Use the **Update Interval:** drop-down selector to choose the periodicity for checking for updates to the enabled rules packages. When any value other than NEVER is selected, the **Update Start Time** textbox is available for entering a start time in 24-hour format using hours and minutes only.

In most cases every 12 hours is a good choice. The update start time can be customized if desired. Enter the time as hours and minutes in 24-hour time format. The default start time is 3 minutes past midnight local time. So with a 12-hour update interval selected, Snort will check the Snort VRT or Emerging Threats web sites at 3 minutes past midnight and 3 minutes past noon each day for any posted rule package updates.



General Settings

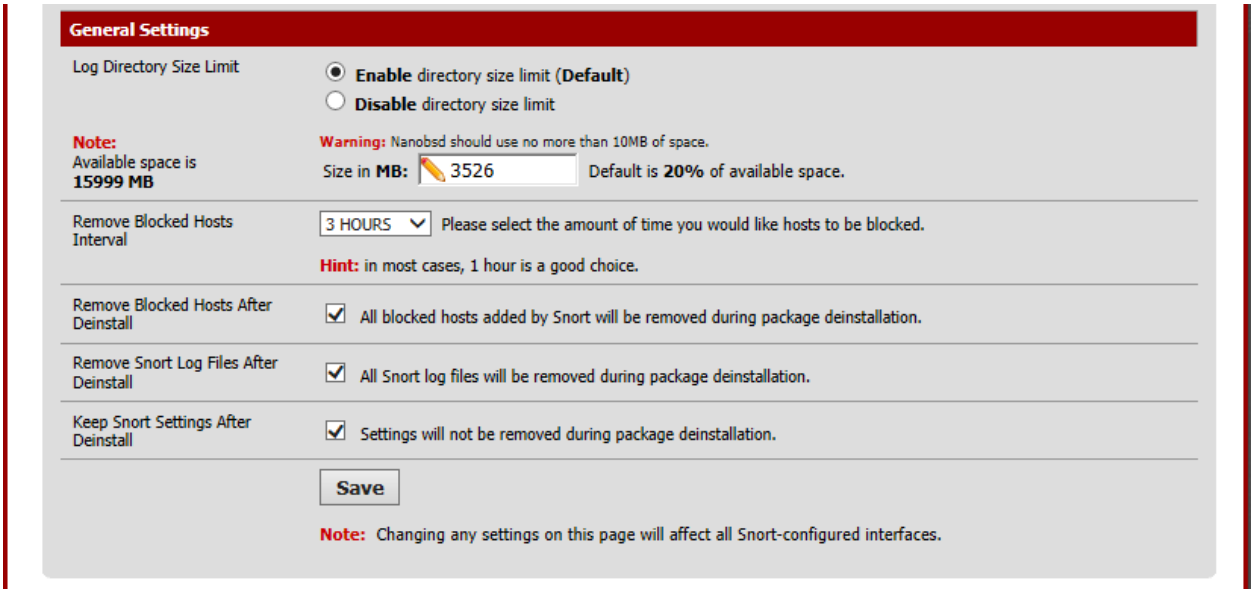
Log Directory Size Limit
When enabled, sets an absolute hard upper limit on the total size of the Snort logging sub-directory in `/var/log/snort`. This can prevent Snort from filling up the `/var` volume on the firewall. When the Snort logging directory size (the total size of all files within the Snort log directory tree) exceed the value set, all files are automatically pruned (deleted) and the Snort process is signaled to soft-restart and resynchronize logging. The default size limit is 20% of the available space on the volume. This may be overridden by setting a value in megabytes (MB) in the textbox provided.

Remove Blocked Hosts Interval
Controls how long Snort-blocked IP addresses must be inactive before being cleared. Once per interval specified, Snort executes a cron job that tests all the IP addresses it has inserted into the firewall's block table for activity. IP addresses that have had no further network activity within the time specified are removed from the block table.

Remove Blocked Hosts After Deinstall
Determines whether or not Snort-blocked IP addresses are automatically removed when the Snort package is uninstalled.

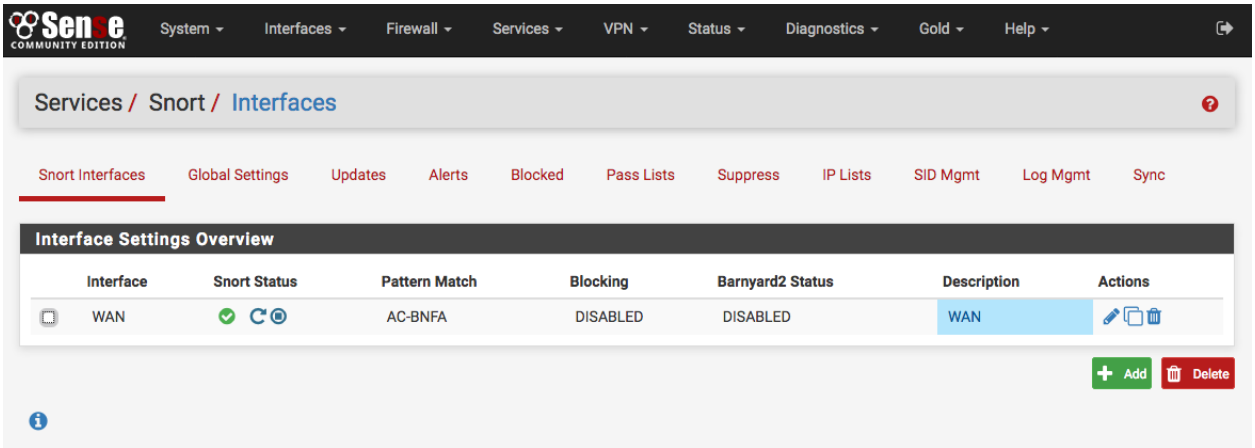
Remove Snort Log Files After Deinstall
Determines whether or not log files generated by Snort are retained or removed when the Snort package is removed.

Keep Snort Settings After Deinstall
Controls whether the Snort configuration is retained when the Snort package is removed.

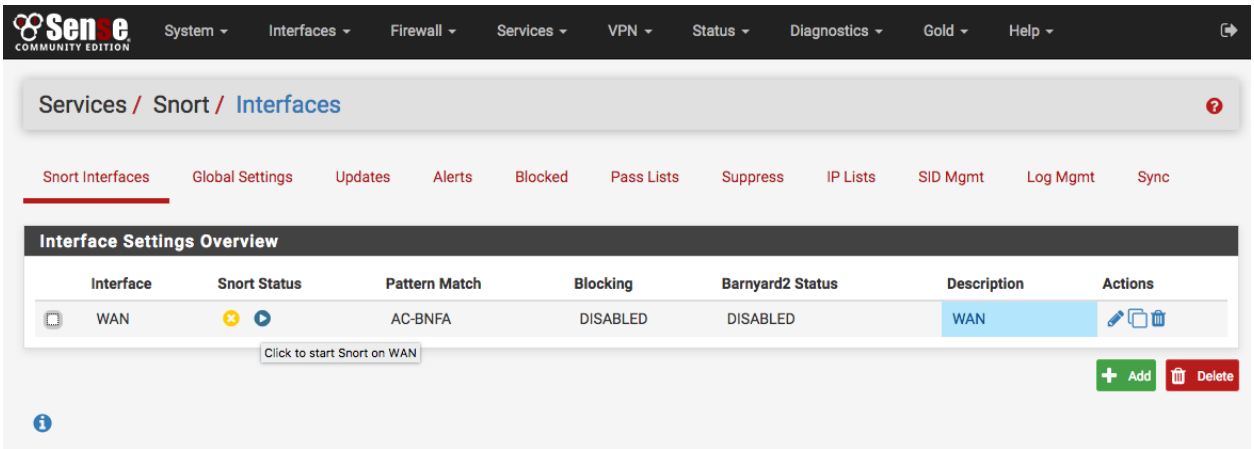


Snort Interfaces

The **Snort Interfaces** tab is where one can add, edit or delete a Snort instance from a physical network interface. A snort instance can also manually started and stopped. If *Barnyard2* is configured on an interface, it can also be started or stopped.



The green icon indicates a running Snort process for the interface. To stop a running process, click the  icon and wait for it to change to  as shown below.



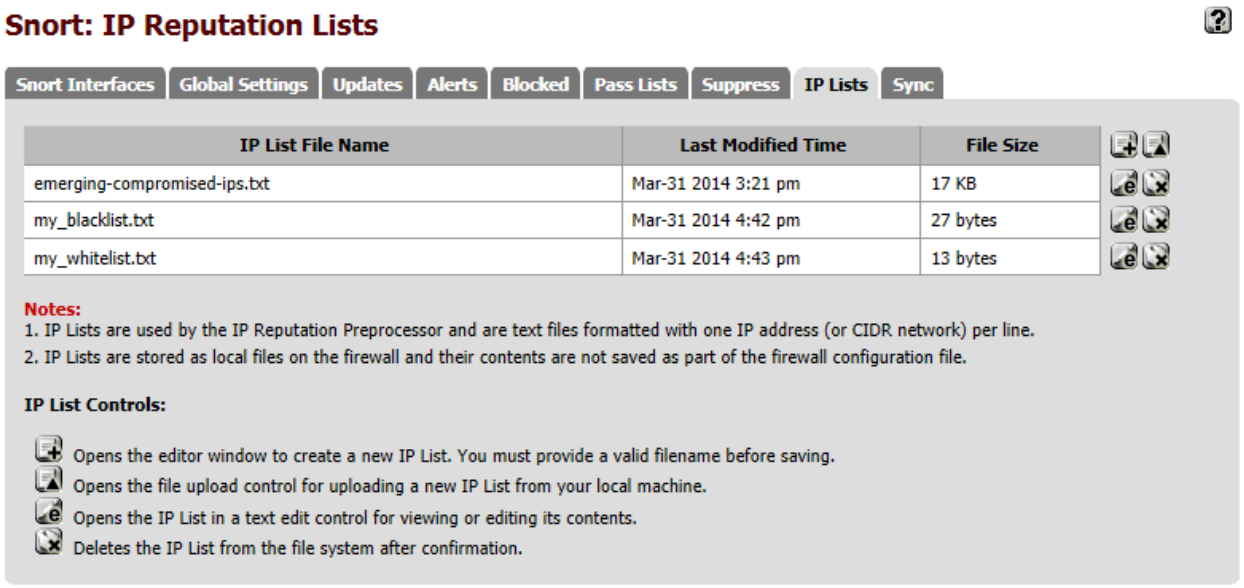
To add a new Snort configuration for an interface, click **Add**.

To edit an existing Snort configuration, click edit icon.

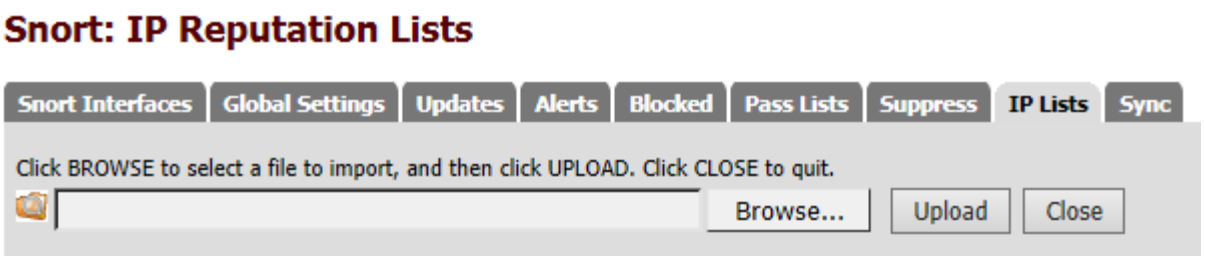
To delete an existing Snort configuration, click the checkbox on the left of the interface to select it, then click **Delete**. A prompt for confirmation will appear before deleting the chosen interface. Multiple interfaces may be selected and deleted at once.

Managing Snort IP Address Lists

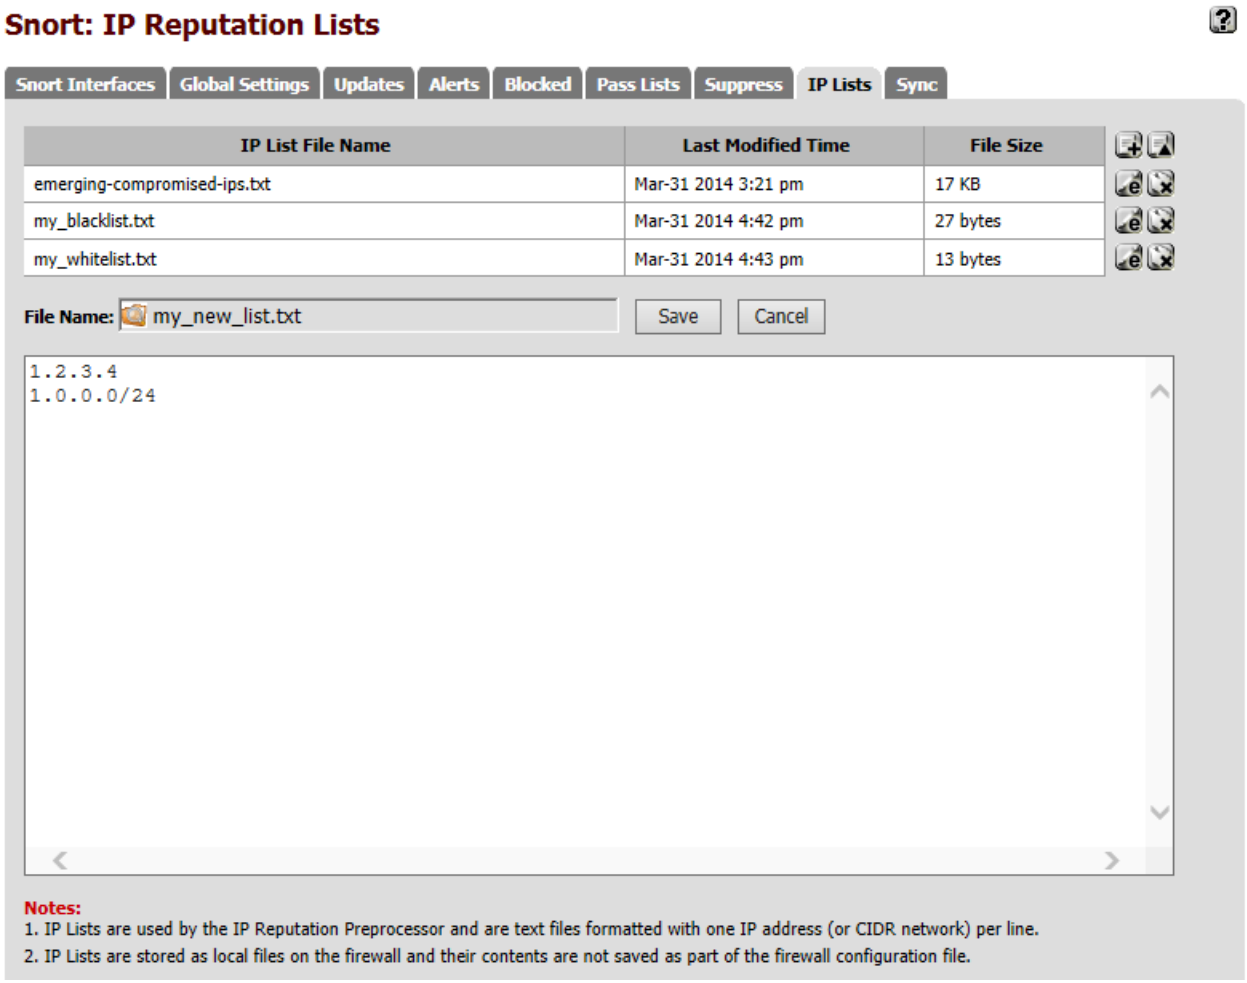
Use this tab to manage the IP lists files for the IP Reputation preprocessor. IP lists are text-format files containing one IP address or network (expressed in CIDR notation) per line.



To upload an IP list file to the firewall, click the  icon to open the file upload dialog as shown below. Browse to the file on the local machine using the **BROWSE** button, then click the **UPLOAD** button to upload the file to the firewall for use by the IP Reputation preprocessor in Snort.



To create a new IP list, click the  icon. To edit an existing IP list, click the  icon beside the list to edit. Click SAVE when finished to save changes to the list, or CANCEL to abandon any changes.



Snort IP Address Reputation Preprocessor

This tab allows configuration of the parameters specific to the IP Reputation preprocessor on the interface. It also allows the assignment of blacklist and whitelist files of IP addresses to the interface.

The available fields are:

Enable
When checked, the IP Reputation preprocessor is active on this Snort instance.

Memory Cap
Sets the amount of system memory in megabytes (MB) to reserve for storage of the IP lists associated with this preprocessor. The default is 500 MB and should be sufficient for most installations.

Scan Local
When checked, Snort will include RFC 1918 IP addresses ranges when comparing IP addresses to the blacklists and whitelists. If an RFC 1918 IP addresses is in the whitelist files, or some are blacklist files, then this option should be enabled. The default is disabled.

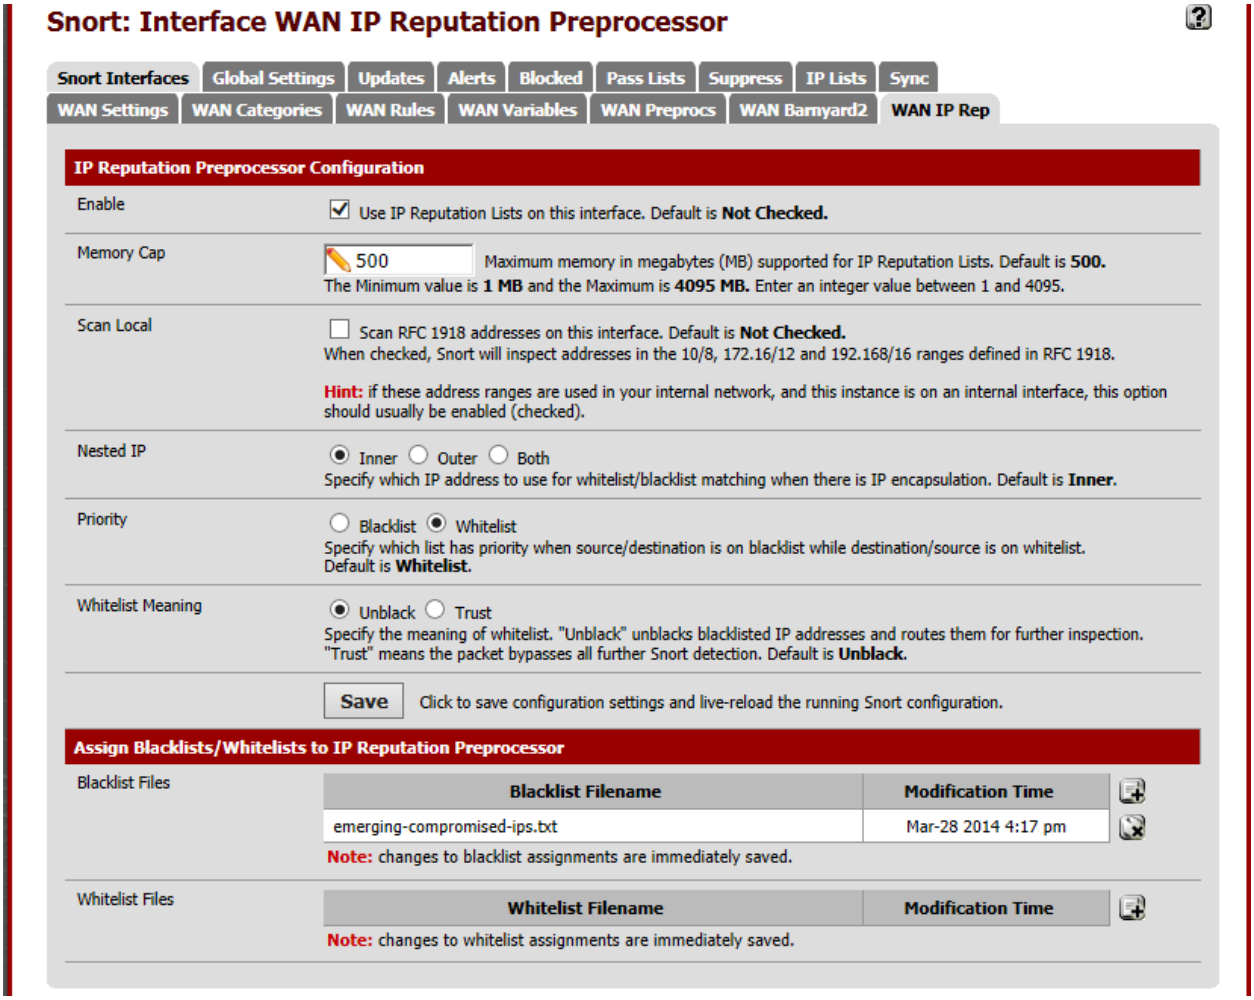
Nested IP
This tells Snort which IP address to compare to the IP lists in the whitelist and blacklist files when there is IP encapsulation. The default is **Inner**.

Priority
Instructs Snort which IP list has priority when the source and destination IP addresses of a packet are each on separate IP lists. For example, if the source IP address is on a blacklist while the destination IP address is on a whitelist, this option tells Snort whether to block the traffic if blacklist has priority, or pass the traffic if whitelist has priority.

Whitelist Meaning
This tells Snort what action to take with whitelisted IP addresses. The two options are **Un-black** and **Trust**.

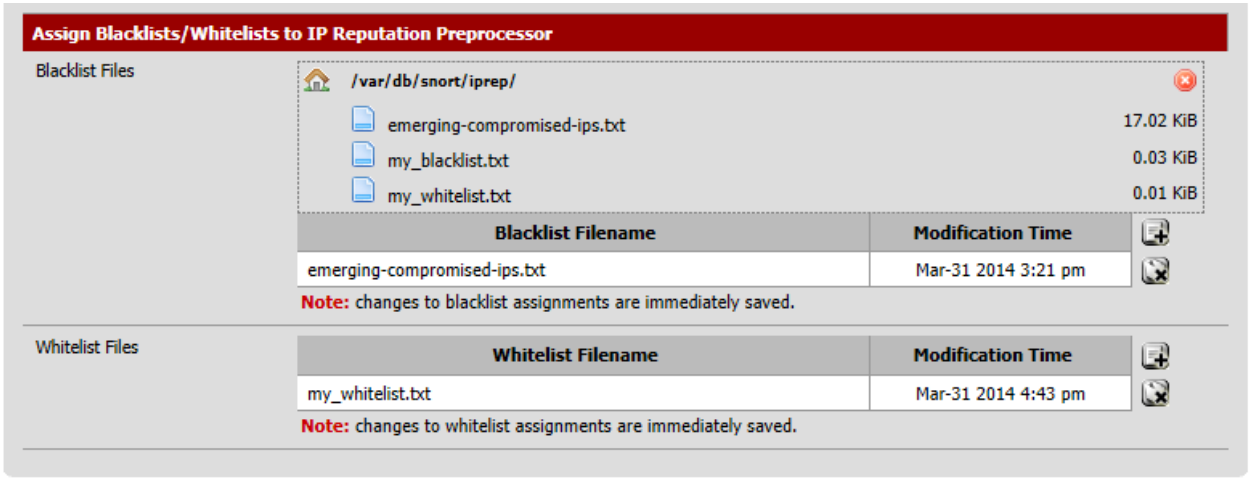
Un-black
A blacklisted IP which is listed in the whitelist is not immediately blocked. Instead it is routed through the Snort detection engine for normal inspection. If it generates no alerts, the traffic is allowed. If the inspection results in a Snort alert for the traffic, it will be blocked.

Trust
Any IP address on the whitelist (including any that may also be on a blacklist) is immediately allowed to pass with no further inspection. Caution should be exercised when using the Trust mode of operation to insure the IP addresses on the whitelist are in fact trustworthy.



The  and  icons at the bottom of the page are used to assign or remove blacklist and whitelist files to or from the interface.

Click the  icon to open a file selection dialog. Choose an IP list file from the list by clicking on the name.



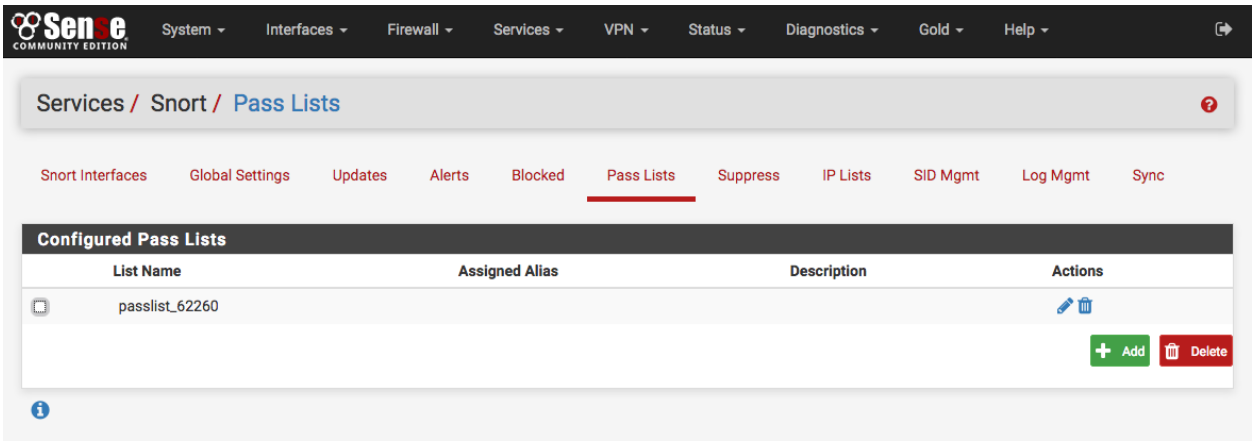
Snort IP Address Reputation

Coming soon…

Snort Pass Lists

Pass Lists are lists of IP addresses that Snort should never block. Pass lists can be created and managed on the **Pass Lists** tab. When an IP address is listed on a Pass List, Snort will never insert a block on that address even when malicious traffic is detected.

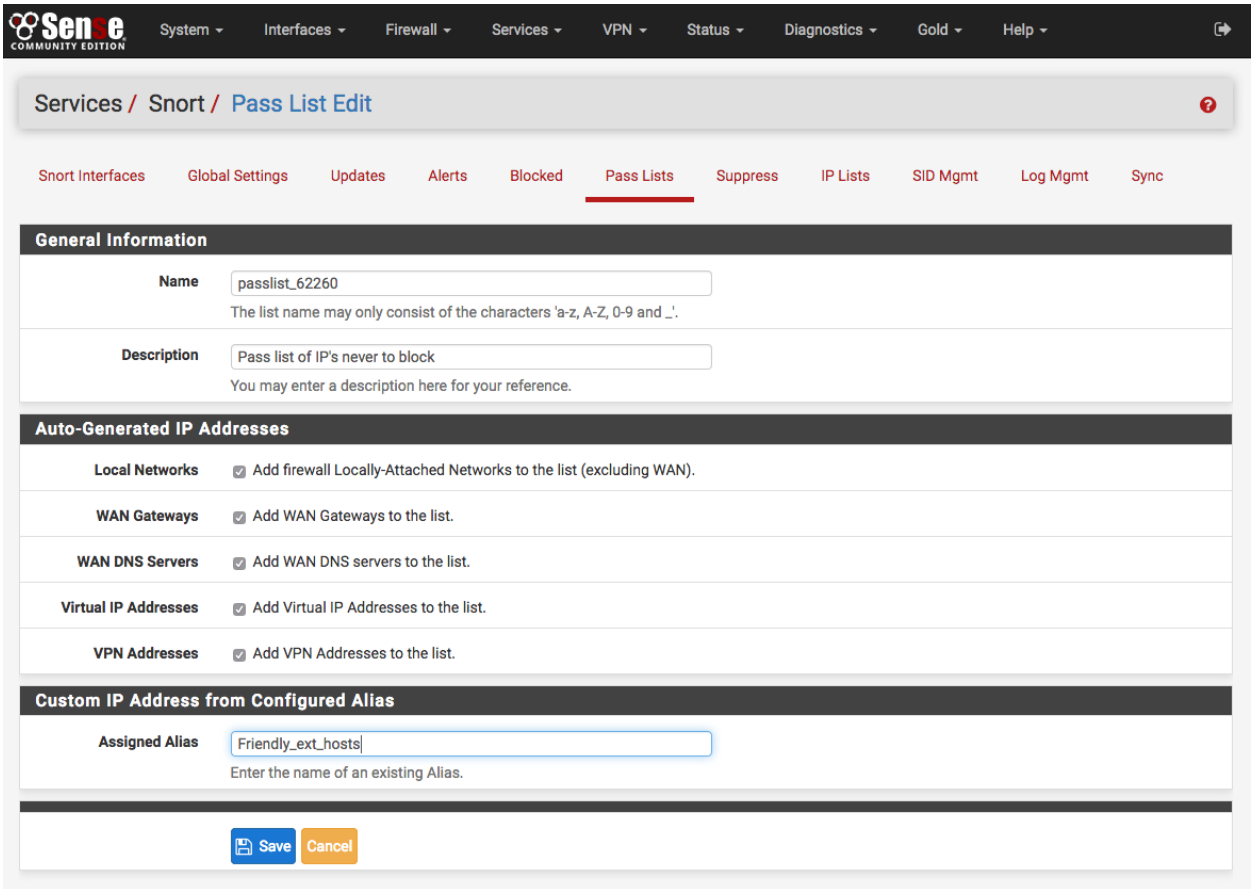
To create a new Pass List, click the  icon. To edit an existing Pass List, click the  icon. To delete a Pass List, click the  icon. Note that a Pass List cannot be deleted if it is currently assigned to one or more Snort interfaces.



A default Pass List is automatically generated by Snort for every interface, and this default list is used when no other list is specified. Assign Pass Lists to an interface on the **Interface Settings** tab.

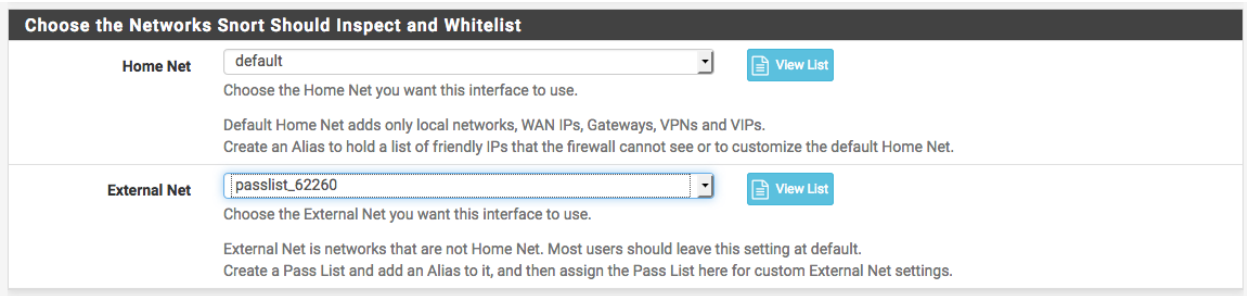
Customized Pass Lists can be created and then assigned to an interface. This might be needed when trusted external hosts are needed that are not located on networks directly connected to the firewall. To add external hosts in this manner, first create an Alias under **Firewall > Aliases** and then assign that alias to the **Assigned Aliases:** field. In the example shown below, the alias "*Friendly_ext_hosts*" has been assigned. This alias would contain the IP addresses of the trusted external hosts.

When creating a custom Pass List, leave all the auto-generated IP addresses checked in the **Add auto-generated IP addresses** section. Not selecting the checkboxes in this section can lead to blocking of critical addresses including the firewall interfaces themselves. This could result in being locked out of the firewall over the network! Only uncheck boxes in this section when a valid need is present.



Click the **ALIASES** button to open a window showing previously defined aliases for selection. Remember to click **SAVE** to save changes.

Note: Remember that simply creating a Pass List is only the first step! Go to the **Interface Settings** tab for the Snort interface and assign the newly created Pass List as shown below. After assigning and saving the new Pass List, restart Snort on the affected interface to pick up the change.

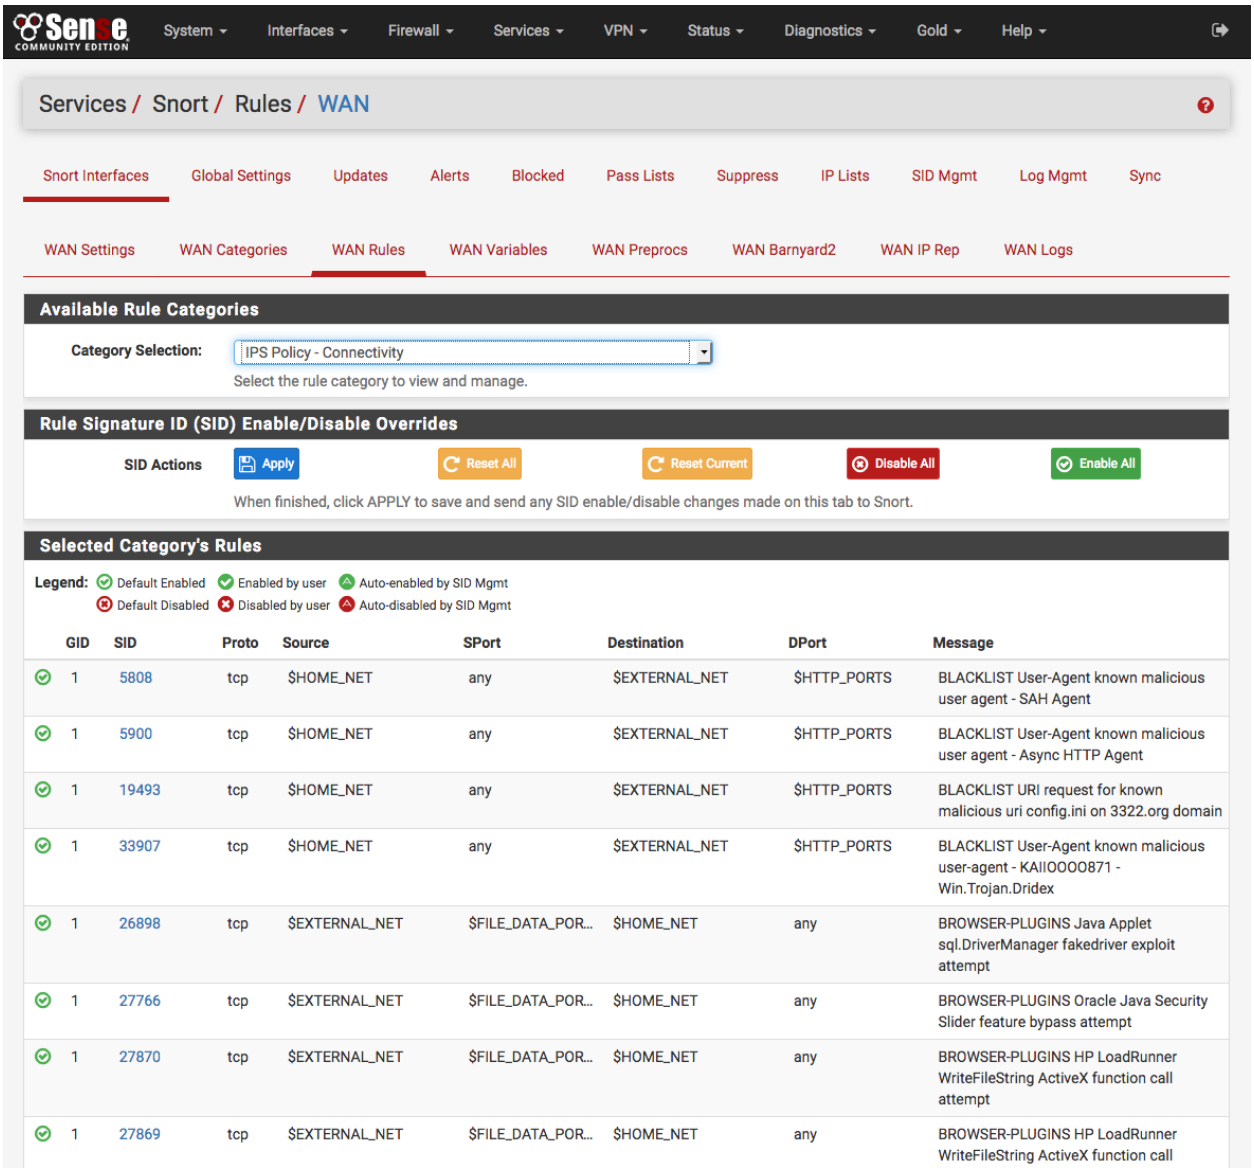


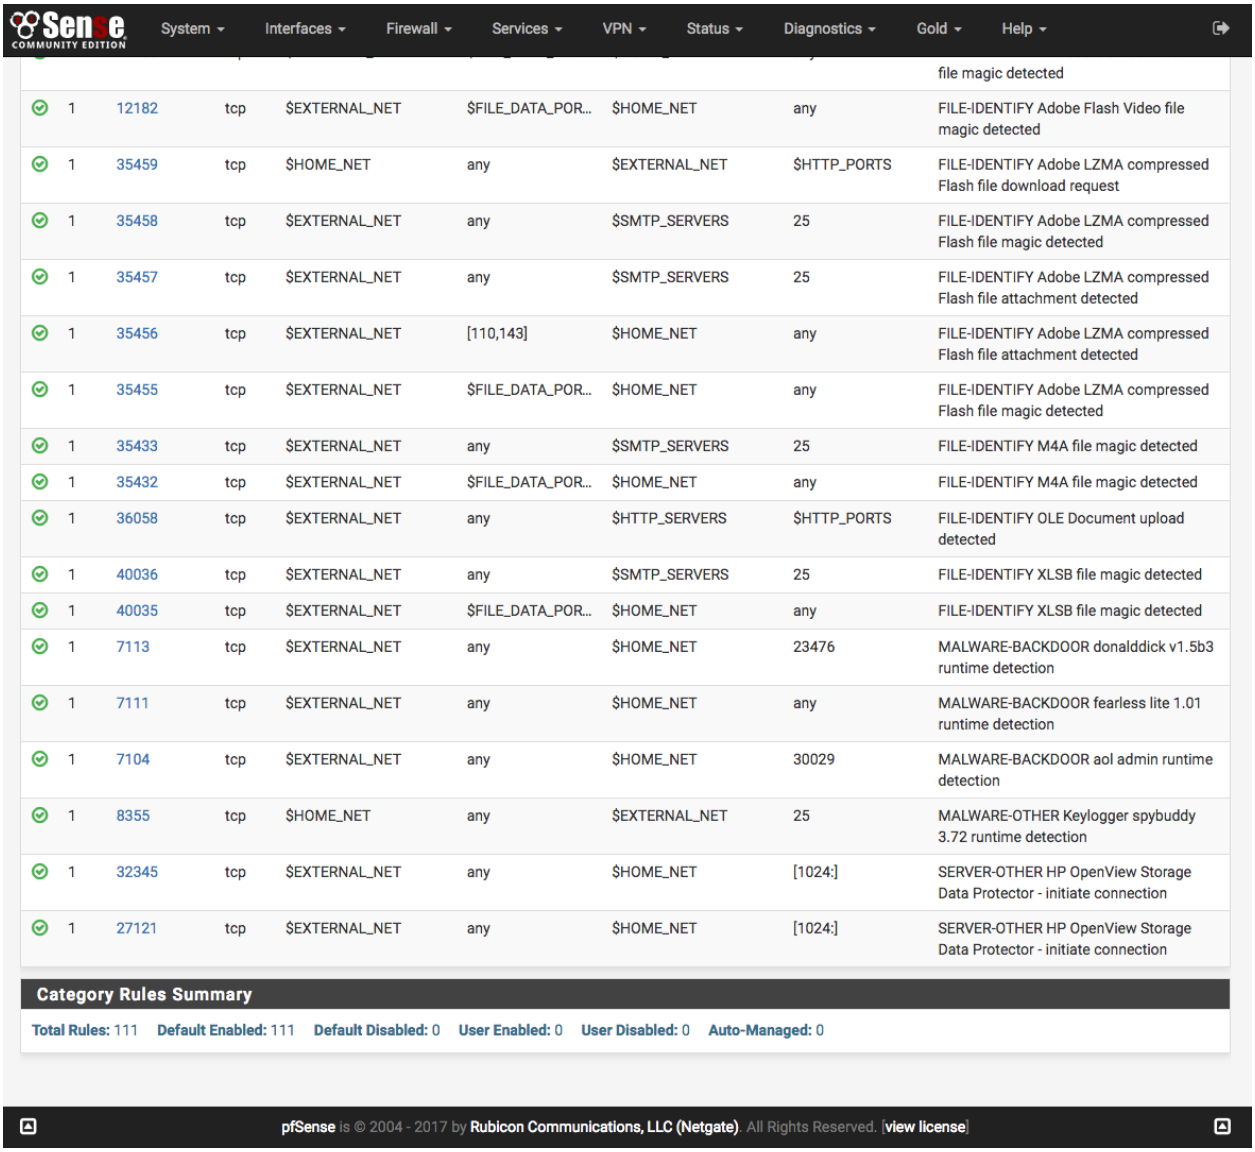
Snort Rules

Rules

Use the **Rules** tab for the interface to configure individual rules in the enabled categories. Generally this page is only used to disable particular rules that may be generating too many false positives in a network environment. Be sure they are in fact truly false positives before taking the step of disabling a Snort rule!

Select a rules category from the **Category:** drop-down to view all the assigned rules. Click the  or  icon at the far-left of a row to toggle the rule's state from enabled to disabled, or click  or  to toggle from disabled to enabled. The icon will change to indicate the state of the rule. At the top of the rule list is a legend showing the icons used to indicate the current state of a rule.



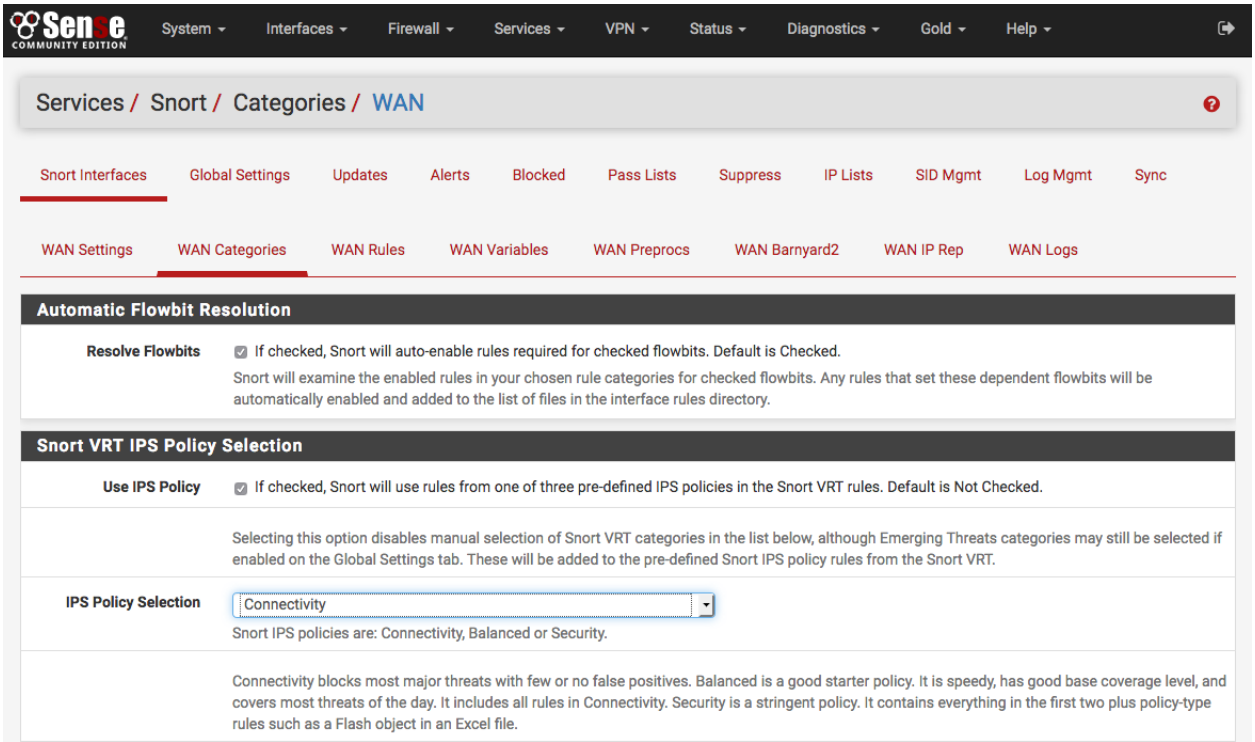


Snort Rulesets

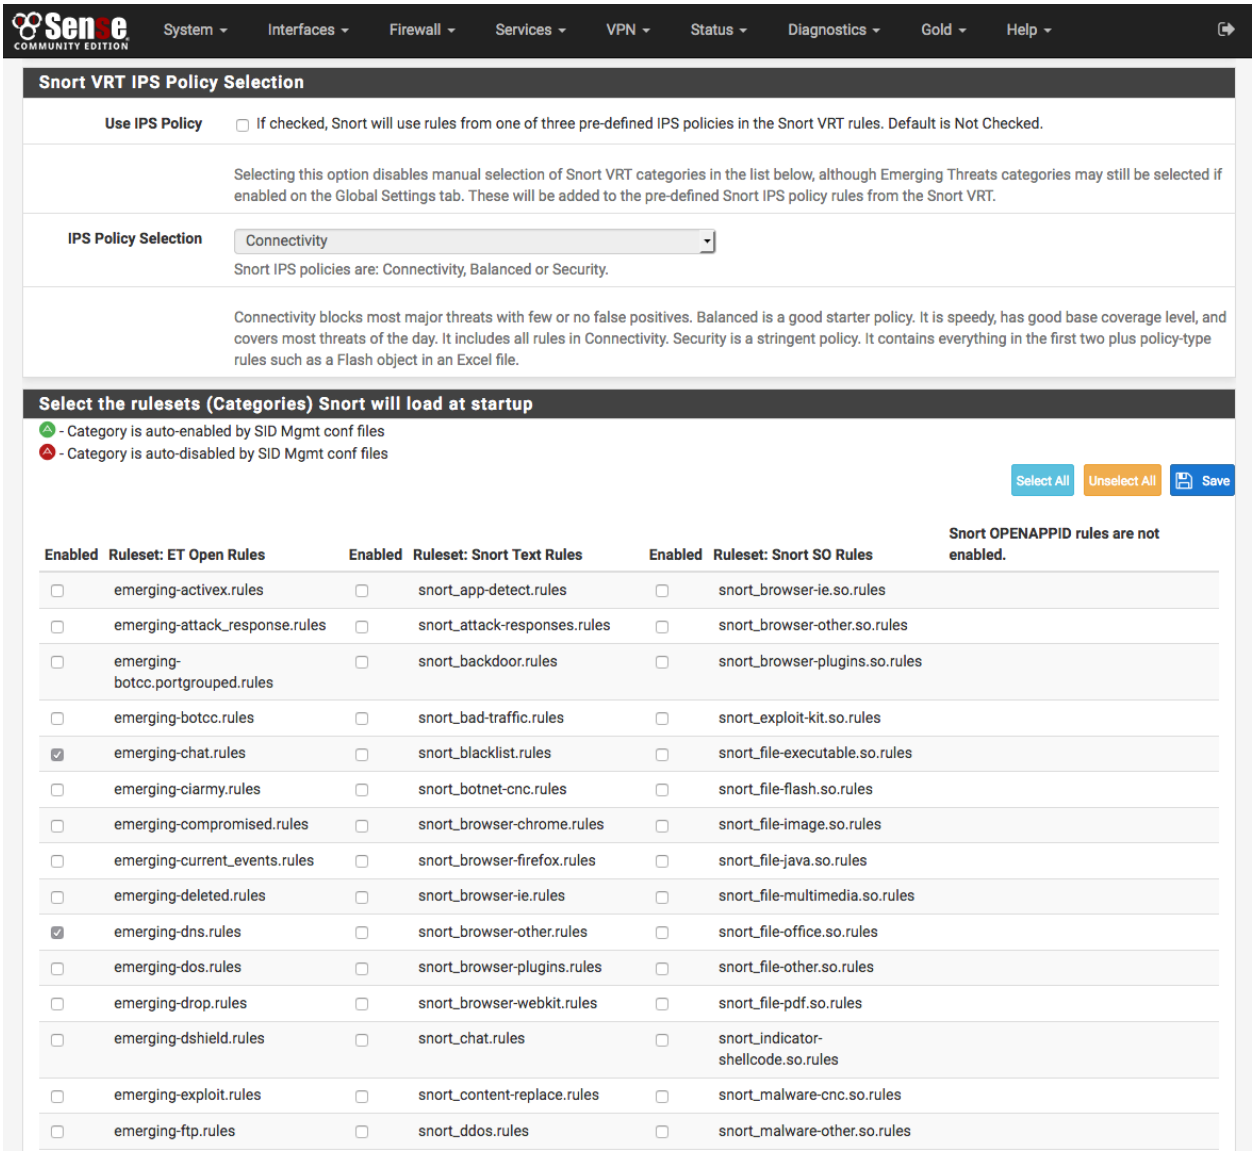
Categories

If a Snort VRT Oinkmaster code has been obtained (either free registered user or the paid subscription), and the Snort VRT rules have been enabled, and the Oinkmaster code has been entered on the Global Settings tab then the option of choosing from among three pre-configured IPS policies is available. These greatly simplify the process of choosing enforcing rules for Snort to use when inspecting traffic. The IPS policies are only available when the Snort VRT rules are enabled.

The three Snort VRT IPS Policies are: (1) Connectivity, (2) Balanced and (3) Security. These are listed in order of increasing security. However, resist the temptation to immediately jump to the most secure “Security” policy if new to using Snort. False positives can frequently occur with the more secure policies, and careful tuning by an experienced administrator may be required. So if new to Snort, then using the less restrictive “Connectivity” policy in non-blocking mode is recommended as a starting point. Once experience with Snort has been gained in the network environment, blocking mode can be enabled and then move up to more restrictive IPS policies.



If the Snort VRT rules are not enabled, or to use any of the other rule packages, then make the rule category selections by checking the checkboxes beside the rule categories to use.

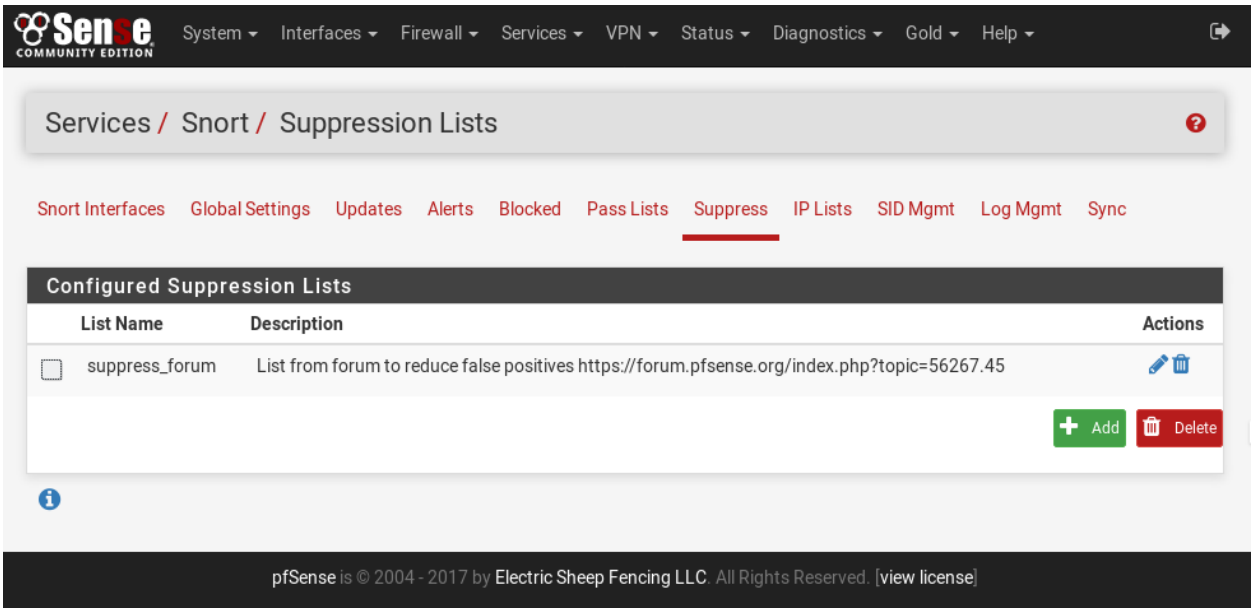


Be sure to click **SAVE** when finished to save the selection and build the rules file for Snort to use.

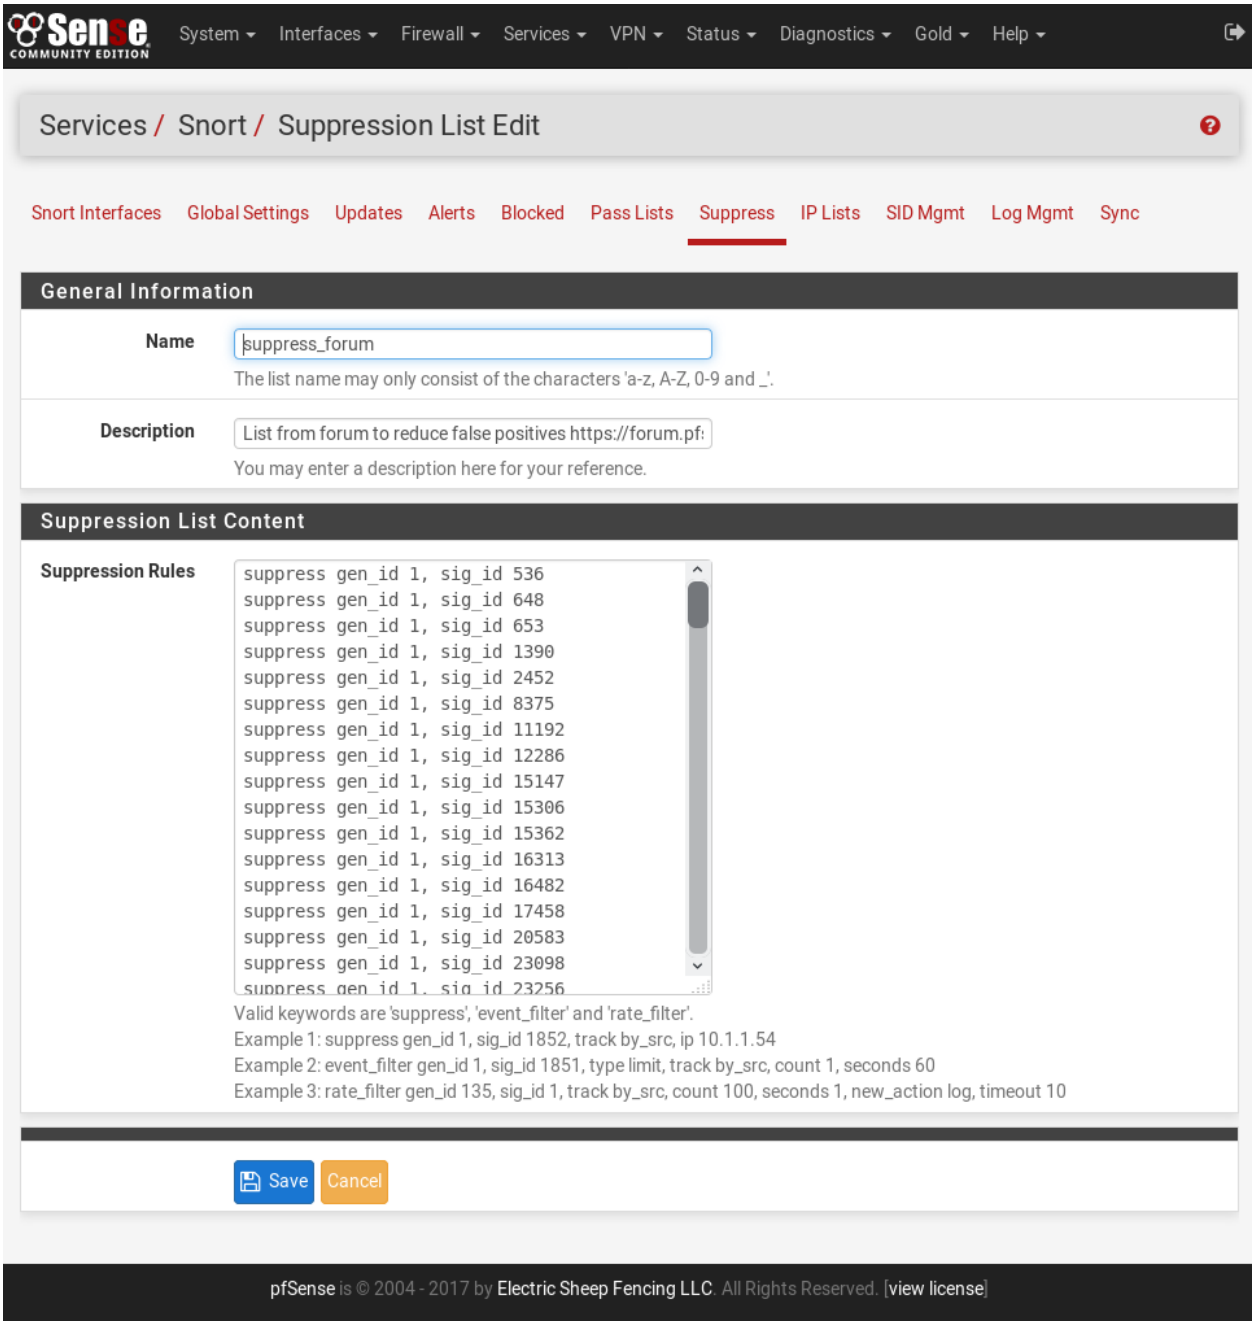
Snort Suppression Lists

Alert Thresholding and Suppression

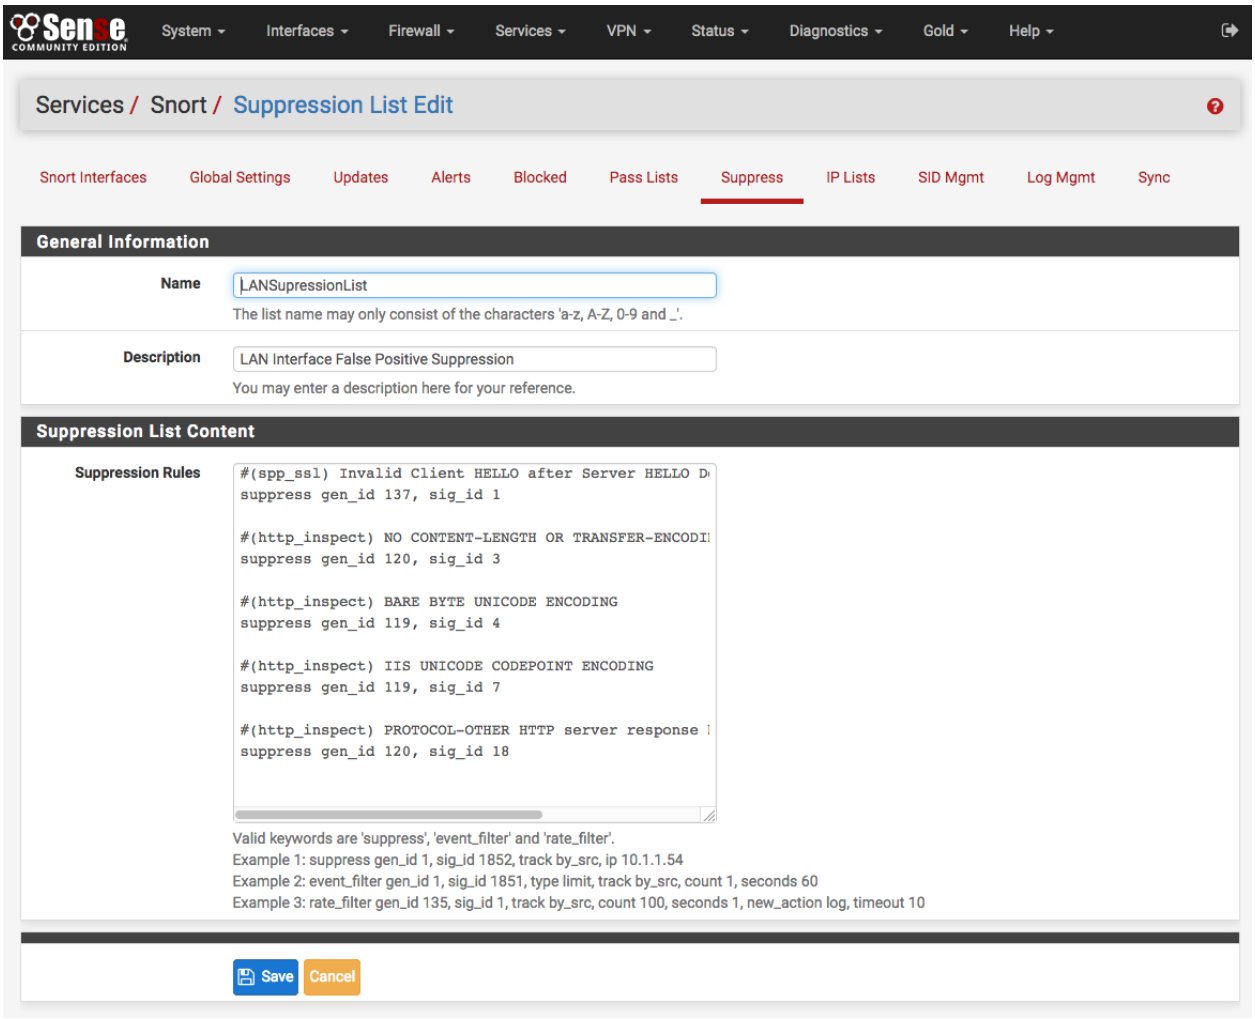
Suppression Lists allow control over the alerts generated by Snort rules. When an alert is suppressed, then Snort no longer logs an alert entry (or blocks the IP address if block offenders is enabled) when a particular rule fires. Snort still inspects all network traffic against the rule, but even when traffic matches the rule signature, no alert will be generated. This is different from disabling a rule. When a rule is disabled, Snort no longer tries to match it to any network traffic. Suppressing a rule might be done in lieu of disabling the rule to stop alerts based on either the source or destination IP. For example, to suppress the alert when traffic from a particular trusted IP address is the source. If any other IP is the source or destination of the traffic, the rule may still be desired. To eliminate all alerts from the rule, then it is more efficient to simply disable the rule rather than to suppress it. Disabling the rule will remove it from the list of match rules in Snort and therefore makes for less work Snort has to do.



On the Suppress List Edit page, suppress lists may be manually added or edited. It is usually easier and faster to add suppress list entries by clicking the + icons shown with the alert entries on the **Alerts** tab. Remember to click the **SAVE** button to save changes when manually editing Suppress List entries.



Lists with comments are easier to manipulate and fine tune. Neither screen shot shows IP address suffix in a suppress entry.



Updating Snort

Update the rules

The **Updates** tab is used to check the status of downloaded rules packages and to download new updates. The table shows the available rule packages and their current status (not enabled, not downloaded, or a valid MD5 checksum and date).

Click on the **Update Rules** button to download the latest rule package updates. If there is a newer set of packaged rules on the vendor web site, it will be downloaded and installed. The determination is made by comparing the MD5 of the local file with that of the remote file on the vendor web site. If there is a mismatch, a new file is downloaded. The **FORCE** button can be used to force download of the rule packages from the vendor web site no matter how the MD5 hash tests out.

In the screenshot below, the Snort VRT and Emerging Threats Open rule packages have been successfully downloaded. The calculated MD5 hash and the file download date and time are shown. Also note the last update time and result are shown in the center of the page.

Troubleshooting Snort Rule Updates

Tip: For more information or to get help, check out the IDS/IPS category on the Netgate forum.

30.24 Stunnel package

The stunnel program is designed to work as an SSL encryption wrapper between remote client and local (inetd-startable) or remote servers. It can be used to add SSL functionality to commonly used inetd daemons like POP2, POP3, and IMAP servers without any changes in the program's code.

It will negotiate an SSL connection using the **OpenSSL** or **SSLeay** libraries. It calls the underlying crypto libraries, allowing stunnel to support whatever cryptographic algorithms were compiled into the crypto package.

Note: The pfSense® software package implements only a subset of the configuration options available in stunnel. For more advanced configurations, please consider configuring stunnel manually on the firewall, run it in a dedicated jail, or on a different system.

The package has two configuration screens (tabs):

- Tunnel definitions
- Certificates

30.24.1 Tunnels

For each tunnel, the following options are available:

- Listening socket IP address and port.
- Certificate to use for the listening socket.
- Target IP address and port.
- IP address to bind to when connecting to the target.

If no certificate is specified for a tunnel, the default certificate will be used. This is a self-signed certificate which is generated upon package (re)installation, and is not suited for production use.

30.24.2 Certificates

Certificates are managed in the simplest possible way, by requiring the user to provide RSA key and certificates/chains in PEM format. The **Certificates** tab will list the configured certificates along with status information, indicating whether the certificate is valid, will expire soon, or is already expired. A sanity check is also performed to make sure the key and certificate matches.

Note that for private certificates and certain commercial ones (Extended Validation), a complete certificate chain may be required. This is to ensure that the client is able to verify the certificate validity. A chain should be built in the following way:

1. Root certificate of the certificate issuer/CA
2. Any intermediate certificates between the root and the server certificate
3. Server certificate

See also:

Refer to the stunnel documentation for more information on how to format a certificate chain.

See also:

The pfSense software issue tracker contains a list of known issues with this package.

30.25 Sudo Package

The sudo package configures basic rules for allowing unprivileged users (i.e. anyone but `root/admin`) to run commands as `root` or another user/group in the shell.

Once the `sudo` package is installed, it is located at **System > sudo** in the GUI.

30.25.1 Sudo Settings

The package allows multiple entries for privileges. To add a new entry, click  **Add**, and fill in the settings:

User/Group
: The user or group name to which this privilege is being granted.

  The list includes users and groups defined in the GUI as well as those from the operating system (e.g. daemon users and groups added by packages).

Run As
The user or group name under which the command will be run.

In most cases this is `root`, so that users may run commands as `root` without knowing the `root/admin` credentials.

No Password
Controls whether or not the user is not prompted for their own password when executing commands using `sudo`.

This is unset by default, so users are prompted for their password when running `sudo`. `sudo` caches credentials in a login session for at least five minutes after each execution of `sudo` so that the user is not prompted on each attempt. Users can execute `sudo` without reauthenticating inside that time frame, but if they stop for five minutes they will be prompted again on the next run.

When set, the user is not prompted for their password when running `sudo`. This is less secure, but more convenient. If `sudo` is invoked non-interactively, such as from a cron script, this is required as there is no way for a user to enter their credentials.

Command List
A list of commands the **User/Group** can run.

See also:

More information on the full command options may be found in the sudoers manual.

By default the command is `ALL` meaning the user can run any commands. Leaving the commands field blank assumes `ALL`.

A comma-separated list of one or more commands can be supplied to limit the user to individual binaries. Full paths to commands are required by `sudo` to ensure the user is properly restricted to specific binaries or scripts.

If parameters are specified after a command, they will be required. To disallow running a command with parameters, add `""` after the command.

Custom Configuration
This option controls whether or not `sudo` will read additional configuration files from `/usr/local/etc/sudoers.d`.

> **Warning:** Including custom configuration files allows options to be set which are not supported by the GUI, but these files can be a potential security risk and they are not included in backups.

The setting can be one of:

Do Not Include
`sudo` will **not** include additional configuration files.

Include at Start
`sudo` will include additional configuration files **before** the GUI settings.

Include at End
`sudo` will include additional configuration files **after** the GUI settings.

30.25.2 Sudo Examples

Example 1

Allow `bob` to run `ping` commands only as `root` without a password:

User/Group
User: `bob`

Run As
User: `root`

No Password
checked

Commands
`/sbin/ping`

Example 2

Allow anyone in the admins group to run all commands as any user, but prompted for a password:

User/Group
Group: `admins`

Run As
User: *ALL Users*

No Password
Unchecked

Commands
`ALL`

Command Examples

These examples demonstrate how to specify commands in various ways.

- Run `ping` with any parameters:

```
/sbin/ping
```

- Run `ping` only to `192.168.1.2`:

```
/sbin/ping 192.168.1.2
```

- Run command `blah` without any parameters:

```
/usr/local/bin/blah ""
```

- Run `ping` and `traceroute` and their IPv6 variants with any parameters:

```
/sbin/ping, /sbin/ping6, /usr/sbin/traceroute, /usr/sbin/traceroute6
```

30.25.3 Package Support

This package is currently supported by Netgate TAC to those with an active support subscription.

30.26 Status Traffic Totals

This package displays different ways to view the traffic usage generated by the network traffic monitoring tool vnStat.

See also:

Similar tools are available for firewall bandwith monitoring: *How can I monitor bandwidth usage*

30.26.1 Notes

Every NIC is added on install. So if a NIC is added (or removed) on the firewall, remove the package and install again. If the firewall has data for a NIC vnStat will report the data even if the NIC has been removed.

A reinstall of the package will not change this as the firewall has data pertaining to the non existent data and thus other packages such as vnstat2 will report the data it has or has found.

30.26.2 Known Issues

See also:

The pfSense software issue tracker contains a list of known issues with this package.

30.26.3 Package Support

This package is currently supported by Netgate TAC to those with an active support subscription.

30.27 UDP Broadcast Relay

The UDP Broadcast Relay package listens for UDP broadcast packets and retransmits them on additional interfaces. This enables UDP broadcast discovery protocols to cross separate networks.

Important: Firewall rules are not automatically created for configured instances. If hosts on separate networks need to respond to the relayed broadcast packets, firewall rules may be needed to allow traffic back to the original sender.

30.27.1 General Settings

Enable
: Enable the UDP Broadcast Relay service. If checked, enabled instances will be active.

Track CARP Status
: Tracks the CARP status of the selected CARP VIP. The service will only run when the selected VIP is in the MASTER state.

Configured Instances

ID
The instance ID.

Port
UDP port being relayed.

Interfaces
Interfaces to relay packets on.

Description
The user-specified description.

Actions
Administrative actions available for the instance.

Edit
Edit the instance settings.

Add
Configure a new instance.

Delete
Delete the selected instance(s).

30.27.2 Instance Settings

Enable
Enable this instance. If unchecked, the instance will not be active.

Description
A description for administrative reference (not parsed).

Network Interfaces
Interfaces to receive and transmit packets on; must select at least **two**. When a packet is received, it's sent to all specified interfaces except for the one it originated on. Unassigned and special interfaces (including `lo0` and `enc0`) are omitted.

Note: Only interfaces with a broadcast flag and an IPv4 address are supported. Point-to-point interfaces such as those used in WireGuard are not supported.

Spoof Source
Spoof the source IP address and/or port when relaying packets.

Keep Original (default)
The source IP address and UDP port of the broadcast packet will remain unchanged.

Use Interface Address and Destination Port
Sets the source IP address to that of the outgoing interface and the source UDP port to the same as the destination port.

Use Interface Address only
Sets the source IP address to that of the outgoing interface and keeps the original source UDP port.

Instance ID
A unique number between instances (1-63). This is used to set the DSCP of outgoing packets to determine if a packet is an echo and should be discarded.

Destination Port
Destination UDP port to listen on (1-65535).

> **Note:** Instances need to bind to the specified port on any/all interfaces. If another service such as UPnP (port `1900`) or Avahi (port `5353`) is running, the instance will fail to start.

Multicast Address
Multicast group to listen for and relay packets on (optional).

30.27.3 Examples

A list of example use cases are given below.

UDP Port	Spoof Source	Multicast Address	Description
5353	Address/Port	224.0.0.251	mDNS: used for e.g. Chromecast and Bonjour
1900	Original	239.255.255.25	SSDP: used for e.g. DLNA, Sonos, and UPnP
1900	Original	239.255.255.25	Windows Network Neighborhood Discovery: uses SSDP,
138	Original	-	NetBIOS-NS, and NetBIOS-SS
137	Original	-	
21027	Original		Syncthing Discovery
19132	Original		Minecraft

CHAPTER

THIRTYONE

VIRTUALIZATION

pfSense® software supports a variety of Type-1 (bare metal/native) and Type-2 (hosted) virtualization environments, such as VMware (vSphere, Fusion or Workstation), Proxmox VE, VirtualBox, Xen, KVM, Hyper-V and so on.

Warning: The best practice is to use Type-1 hypervisors for production. Type-2 hypervisors such as VirtualBox or VMware Workstation work fine for testing, but avoid using them for production roles where possible.

Set up and install is straightforward and similar to set up on a physical machine using the ISO image.

31.1 VirtIO Driver Support

The FreeBSD kernel used by pfSense® software includes VirtIO drivers built into the kernel. No special action is necessary to enable the drivers.

31.1.1 Disable Hardware Checksum Offloading

With the current state of VirtIO network drivers in FreeBSD, it is necessary to disable hardware checksum offload to reach systems (at least other VM guests, possibly others) protected by pfSense software **directly from the VM host**. The firewall attempts to do this automatically when it detects `vtnet` interfaces, but the setting may also be changed manually under **System > Advanced** on the **Networking** tab.

Note: After changing the setting manually *reboot the firewall, even though there is no prompt instructing to do so*.

The issue is most likely caused by FreeBSD Bug 165059.

Hardware checksums and other NIC offloading features like TSO may also need to be disabled on the hypervisor system in addition to the pfSense VM.

31.2 Guides

CHAPTER

THIRTYTWO

WIRELESS

32.1 Should pfSense software act as an access point?

Historically, the access point functionality in FreeBSD has suffered from serious compatibility or performance problems with some wireless clients. Over time this has improved significantly. pfSense® software access points are used in various locations with no trouble. It is used with various clients such as MacBook Pro, Apple AirTunes, Mac mini, iPod Touch, Android devices, Palm, various Windows laptops, Xbox 360, and FreeBSD clients and it works very reliably.

There is the possibility of finding incompatible devices with any access point. FreeBSD is no exception and it can be more common with FreeBSD than other access points. Using pfSense software as an access point can work quite well with the right card and configuration.

In general, the best practice is *Using an External Wireless Access Point*, especially if clients require 802.11ac or newer standards. Placing that burden on an external device and allowing pfSense software to focus on the firewall/routing/NAT/etc is simpler in the long run. An access point may still be connected to a dedicated interface or VLAN for isolation purposes.

32.1.1 Incompatible wireless clients

There are no known incompatible devices at this time.

32.2 Recommended Wireless Hardware

A variety of wireless cards are supported in FreeBSD 15.0-CURRENT@bf06074106cf, and pfSense® software includes support for every card supported by FreeBSD. Some have better support than others. Most development of wireless features on pfSense software uses Atheros hardware, so they are the most likely to work. Users have reported success with other cards as well, with Ralink being another popular choice.

FreeBSD and pfSense software may support other cards, but those cards may not support all available features. In particular, some cards manufactured by Intel can be used in infrastructure mode as clients but cannot run in access point mode due to limitations of the hardware itself.

32.2.1 Wireless cards from big name vendors

Linksys, D-Link, Netgear and other major manufacturers commonly change the chipset used in their wireless cards without changing the model number. There is no way to ensure a specific model card from these vendors will be compatible because there is no reliable way of knowing which "minor" card revision and chip a package contains. While one revision of a particular model may be compatible and work well, another card of the same model may be incompatible. For this reason, the best practice is to avoid cards from major manufacturers. If a card is already on hand, it is worth trying to see if it is compatible. Be wary when purchasing because even if the "same" model worked for someone else, a new purchase may result in a completely different piece of hardware that is incompatible.

32.2.2 Status of 802.11n Support

pfSense software version 2.8.0-RELEASE is based on FreeBSD 15.0-CURRENT@bf06074106cf which has support for 802.11n on certain hardware such as those based on the Atheros AR9280 and AR9220 chipsets. Netgate has tested cards using those chipsets and they work well. Some other non-Atheros cards are documented by FreeBSD to work on 802.11n, specifically, `mwl(4)` and `iwn(4)`. These may work using the 802.11n standard but experiences with 802.11n speeds may vary.

The FreeBSD Wiki Article for 802.11n Support contains the most up-to-date information about supported chipsets and drivers that work with 802.11n.

32.2.3 Status of 802.11ac Support

Currently, there is no support for 802.11ac in FreeBSD nor in pfSense software. Development on FreeBSD can be tracked by checking the FreeBSD Wiki Article for 802.11ac Support.

32.2.4 Radio Frequencies and Dual Band Support

Some cards have support for 2.4GHz and 5GHz bands, such as the Atheros AR9280, but only one band may be used at a time. Currently there are no cards supported and working in FreeBSD that will operate in both bands concurrently. Using two separate cards in one unit is not desirable as their radios may interfere. In cases which require dual or multiple band support, the best practice is to use an external AP.

32.2.5 Wireless drivers included in pfSense software

This section lists the wireless drivers included in pfSense software and the chipsets those drivers support. This information was derived from the FreeBSD man pages for the drivers in question. Drivers in FreeBSD are referred to by their driver name, followed by `(4)`, such as `ath(4)`. The `(4)` refers to the kernel interfaces section of the man page collection, in this case specifying a network driver. The drivers are listed in order of frequency of use based on reports from users.

Cards Supporting Access Point (hostap) Mode

The cards in this section support acting as an access point to accept connections from other wireless clients. This is referred to as *hostap* mode.

ath(4)

The `ath(4)` driver supports cards based on the Atheros AR5210, AR5211, AR5212, AR5416, and AR92xx APIs which are used by many other Atheros chips of varying model numbers. Most Atheros cards support four virtual access points (VAPs) or stations or a combination to create a wireless repeater.

Though not explicitly listed in the man page, the FreeBSD Wiki Article for 802.11n Support also states that the driver has support for AR9130, AR9160, AR9280, AR9285, AR9287, and potentially other related chipsets.

ral(4) / ural(4) / run(4) / rum(4)

There are several related Ralink Technology IEEE 802.11 wireless network drivers, each for a different set and type of card.

ral(4)
: Supports cards based on the Ralink Technology RT2500, RT2501 and RT2600, RT2700, RT2800, RT2900, RT3090, and RT3900E chipsets.

ural(4)
: Supports RT2500USB.

run(4)
: Supports RT2700U, RT2800U, RT3000U, RT3900E, and similar.

rum(4)
: Supports RT2501USB and RT2601USB and similar.

Of these, only certain chips supported by `run(4)` support VAPs.

The RT3090 `ral(4)` chip is the only model listed as capable of 802.11n on FreeBSD. The RT2700 and RT2800 `ral(4)` and the RT3900E `run(4)` hardware are capable of 802.11n but the drivers on FreeBSD do not currently support their 802.11n features.

mwl(4)

The Marvell IEEE 802.11 wireless network driver, `mwl(4)`, supports cards based on the 88W8363 chipset and fully supports 802.11n. This card supports multiple VAPs and stations, up to eight of each.

Cards Only Supporting Client (station) Mode

The cards in this section are not capable of acting as access points, but may be used as clients in station mode, for example as a wireless WAN.

uath(4)

Atheros USB 2.0 wireless devices using AR5005UG and AR5005UX chipsets are supported by the `uath(4)` driver.

ipw(4) / iwi(4) / iwn(4) / wpi(4)

Intel wireless network drivers cover various models with different drivers.

ipw(4)
: Supports Intel PRO/Wireless 2100 MiniPCI adapters.

iwi(4)
: Supports Intel PRO/Wireless 2200BG/2915ABG MiniPCI and 2225BG PCI adapters.

iwn(4)
: Supports Intel Wireless WiFi Link 4965, 1000, 5000 and 6000 series PCI Express adapters.

wpi(4)
: Supports Intel 3945ABG adapters.

Cards supported by the `iwn(4)` driver are documented by FreeBSD as supporting 802.11n in client mode.

Several Intel adapters have a license restriction with a warning that appears in the boot log. The `ipw(4)`, `iwi(4)`, and `wpi(4)` drivers have license files that must be read and agreed to. These license are located on the firewall in `/usr/share/doc/legal/intel_ipw/LICENSE`, `/usr/share/doc/legal/intel_iwi/LICENSE`, and `usr/share/doc/legal/intel_wpi/LICENSE` respectively. To agree to the license, and *Loader Tunables* indicate the license acknowledgment, such as:

```
legal.intel_ipw.license_ack=1
```

Given the limited use of these adapters as clients only, development of a GUI-based solution to acknowledge these licenses is unlikely.

bwi(4) / bwn(4)

The Broadcom BCM43xx IEEE 802.11b/g wireless driver is split in two depending on the specific models in use.

bwi(4)
: Supports BCM4301, BCM4303, BCM4306, BCM4309, BCM4311, BCM4318, BCM4319 using an older v3 version of the Broadom firmware.

bwn(4)
: Supports BCM4309, BCM4311, BCM4312, BCM4318, BCM4319 using a newer v4 version of the Broadcom firmware.

Support offered by the drivers does overlap for some cards. The `bwn(4)` driver is preferred for the cards it supports while the `bwi(4)` driver must be used on the older cards not covered by `bwn(4)`.

malo(4)

Marvell Libertas IEEE 802.11b/g wireless driver, `malo(4)`, supports cards using the 88W8335 chipset.

upgt(4)

The Conexant/Intersil PrismGT SoftMAC USB IEEE 802.11b/g wireless driver, `upgt(4)`, supports cards using the GW3887 chipset.

urtw(4) / urtwn(4) / rsu(4)

The trio of related Realtek wireless drivers cover several different models:

urtw(4)
: Supports RTL8187B/L USB IEEE 802.11b/g models with a RTL8225 radio

urtwn(4)
: Supports RTL8188CU/RTL8188EU/RTL8192CU 802.11b/g/n

rsu(4)
: Supports RTL8188SU/RTL8192SU 802.11b/g/n

As in other similar cases, though the chips supported by `urtwn(4)` and `rsu(4)` are capable of 802.11n, FreeBSD does not support their 802.11n features.

zyd(4)

The ZyDAS ZD1211/ZD1211B USB IEEE 802.11b/g wireless network device driver, `zyd(4)`, supports adapters using the ZD1211 and ZD1211B USB chips.

32.3 Working with Virtual Access Point Wireless Interfaces

pfSense® software supports virtual wireless interfaces using Multi-BSS. These are known as Virtual Access Point or VAP interfaces, even if they are being used for client mode. VAPs allow multiple access points or clients to be run on the same wireless card, or to use a combination of access point and client mode. The most common use case is for multiple access points with different SSIDs each with unique security requirements. For example, one with no encryption but with captive portal and strict access rules and a separate network with encryption, authentication, and less strict access rules.

Even if a card does not support multiple VAP instances, the first entry must be created manually before it can be assigned.

Support for VAPs varies by card and driver, consult the information on driver support in *Recommended Wireless Hardware* to learn more. Odds are, however, if an Atheros wireless card is in use, it will work. While there is no theoretical limit to the number of VAPs a card may use, driver and hardware support varies, so the practical limit is four VAPs on *ath(4)* and eight on *mwl(4)*.

All VAPs on a given card share some common settings, such as the channel, regulatory settings, antenna settings, and wireless standard. Other settings such as the mode, SSID, encryption settings and so on may vary between VAPs.

32.3.1 Creating and Managing Wireless Instances

To create a new wireless instance:

- Navigate to **Interfaces > Assignments** on the **Wireless** tab.
- Click  **Add** to create a new entry
- Select the **Parent Interface**, for example *ath0*
- Pick the **Mode** from one of *Access Point*, *Infrastructure* (BSS, client mode), or *Ad-hoc* (IBSS)
- Enter a **Description**
- Click **Save**

An example is shown in Figure *Adding a Wireless Instance*.

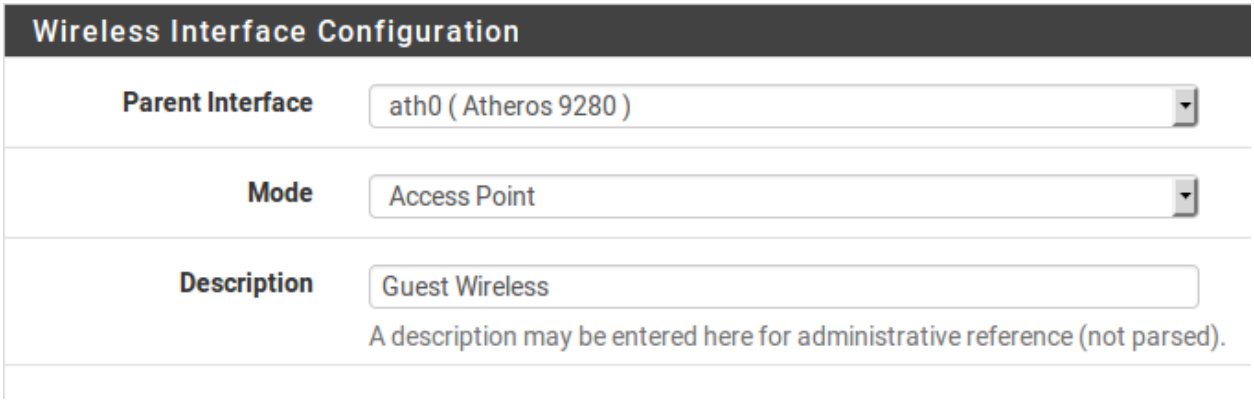

Fig. 1: Adding a Wireless Instance

Once the entry has been saved it is then available for assignment under **Interfaces > Assignments**. From there, assign and then edit the settings like any other wireless interface.

Note: The assigned interface must be configured to use the same mode specified when the VAP was created.

32.4 pfSense Software as an Access Point

With a wireless card that supports hostap mode (See *Cards Supporting Access Point (hostap) Mode*), pfSense® software can be configured as a wireless access point.

32.4.1 Should an external AP or pfSense software be used for an access point?

The access point functionality in FreeBSD, and thus pfSense, has improved dramatically over the years and is considered stable currently for most uses. That said, many use cases behave better with an external access point, especially deployments that have requirements such as 802.11ac, concurrent operation in 2.4GHz and 5GHz, wireless mesh networks, or rare cases with clients that will not associate with an access point run using pfSense software.

Access points on pfSense software have been used with success in small-to-medium deployments, with gear such as a MacBook Pro, Apple AirTunes, iPod Touch, iPad, Android phones and tablets, various Windows laptops, Xbox, and FreeBSD clients and it works very reliably across all these devices. There is the possibility of finding incompatible devices with any access point, and FreeBSD is no exception.

The main deciding factor these days is 802.11n or 802.11ac support; Support for 802.11n hardware in pfSense software is somewhat limited and 802.11ac support does not exist. This is a deal breaker for some, and as such using an external access point would be best for networks requiring 802.11ac and in some cases 802.11n if suitable hardware cannot be obtained.

The next most common factor is location of the antennas or the wireless access point in general. Often, the firewall running pfSense software is located in an area of the building that is not optimal for wireless, such as a server room in a rack. For ideal coverage, the best practice is to locate the AP in an area that is less susceptible to wireless interference and that would have better signal strength to the area where wireless clients reside. If the firewall running pfSense software is located alone on a shelf in a common area or other similar area conducive to good wireless signal, this may not be a concern.

32.4.2 Configuring pfSense software as an access point

The process of configuring pfSense software to act as a wireless access point (AP) is relatively easy. Many of the options will be familiar to anyone who has configured other wireless routers before, and some options may be new unless commercial-grade wireless equipment has been used. There are dozens of ways to configure access points, and they all depend upon the environment in which it will be deployed. In this example pfSense software is configured as a basic AP that uses WPA2 encryption with AES. In this example, ExampleCo needs wireless access for laptops in the conference room.

Preparing the Wireless Interface

Before starting, ensure that the wireless card is installed in the firewall and the pigtails and antennas are firmly attached.

Create the wireless instance as described in *Creating and Managing Wireless Instances* if it does not already exist. When working as an access point, it must use *Access Point* mode. The wireless card must be assigned as an OPT interface and enabled before the remaining configuration can be completed.

Interface Description
: When in use as an access point, naming the interface *WLAN* (Wireless LAN) or *Wireless*, or naming it after the SSID makes it easier to identify. If pfSense software will be driving multiple access points, there should be some way to distinguish them, such as "WLANadmin" and "WLANsales". In this example, it is named `ConfRoom`.

Interface Type
: Since this example will be an AP on a dedicated IP subnet, the IPv4 Configuration Type must be set to *Static IPv4*

IP Address
: An IPv4 Address and subnet mask must be specified. This is a separate subnet from the other interfaces. For this example it can be `192.168.201.0/24`, a subnet that is otherwise unused in the ExampleCo network. Using that subnet, the IPv4 Address for this interface will be `192.168.201.1`.

Common Wireless Settings

These settings are shared for all VAPs on a given physical wireless card. Changing these settings on one interface will change them on all other virtual interfaces using the same physical adapter.

Persist common settings
By checking **Persist common settings**, the configuration values in this section will be preserved even if all the interfaces and VAPs are deleted or reassigned, when they would otherwise be lost.

Wireless Standard
Depending upon hardware support, there are several choices available for the wireless **Standard** setting, including *802.11b*, *802.11g*, *802.11g turbo*, *802.11a*, *802.11a turbo*, *802.11ng*, *802.11na*, and possibly others. For this example, choose *802.11ng* for an 802.11n access point operating in the 2.4GHz band.

802.11g OFDM Protection Mode
The **802.11g OFDM Protection Mode** setting is only useful in mixed standard environments where 802.11g and 802.11b have to interact. Its primary use is for avoiding collisions. Given the age of 802.11b and scarcity of working devices that use it, the setting is best left at *Protection mode off*. There is a performance penalty for using it, since it has some overhead on each frame and also requires extra steps when transmitting frames.

Wireless Channel Selection
When selecting a **Channel**, knowledge of nearby radio transmitters in similar frequency bands is required to avoid interference. In addition to wireless access points, there are also cordless phones, Bluetooth, baby monitors, video transmitters, microwaves, and many other devices that utilize the same 2.4 GHz spectrum that can cause interference.

Often any channel will work so long as the AP clients are near the antenna. With 802.11g and before, the safest channels to use were *1* , *6* , and *11* since their frequency bands did not overlap each other. This is no longer true with 802.11n and later or even some 802.11g setups which use wider ranges of frequencies to attain higher speeds. For this network, since there are no others around, channel *1* is a fine choice.

Note: Always pick a specific channel. Do not select *Auto* for the channel of an Access Point. The input validation on current versions of pfSense software prevents this from being selected.

When using other standards, or using wireless in countries other than the US, there may be many more channels available than described here. Cards that support 802.11a or 802.11n may also support channels in the 5 GHz spectrum.

The full list of channels supported by the card is shown in the **Channel** drop- down and must agree with the chosen *Standard*. For example, do not choose *802.11ng* for the **Standard** and then pick a **Channel** used only for *802.11na*. The channel list also includes some information about the standard, frequency of the channel, and the maximum transmit power both of the card and in the regulatory domain for that particular channel. Be careful to watch the power when selecting a channel, because some channels, especially in the 5GHz band, vary widely in their allowed power levels.

See also:

Survey tools such as NetSurveyor, InSSIDer, Wi-Spy, and countless other apps for various operating systems, phones, tablets, and so on may help to choose a less busy channel or area of the spectrum. Mileage may vary.

Distance setting
Measured in meters, and only supported by Atheros cards, The **Distance Setting** field tunes

ACK/CTS timers to fit the distance between AP and Client. In most cases it is not necessary to configure this value, but it may help in certain tricky wireless setups such as long-range clients.

Regulatory settings

The **Regulatory settings** section controls how the card is allowed to transmit legally in a specified region. Different countries typically have different regulatory settings, and some countries have none. If unsure, check with the local government to see which laws apply in a given area. The default values are usually OK, as the cards may be set to a specific region already. In some cases **Regulatory settings** must be set manually if the card has a default not understood by the driver. Similar to the previous section, these values are applied to the card itself and cannot vary between VAPs on the card.

While it may be tempting to set the card to *Debug* in order to use settings not otherwise allowed, this action could result in legal trouble should it be noticed. The likelihood of this happening varies greatly by country/area so use that with caution.

Regulatory domain
The **Regulatory Domain** is the governmental body that controls wireless communications in a region. For example, the US and Canada follow FCC regulations while in the UK it's ETSI. If unsure of the regulatory domain in a region, see the **Country** setting.

Country
Sometimes specific countries inside a regulatory domain have different restrictions. The **Country** option contains a drop-down list of many countries throughout the world and their associated country codes and regulatory domains.

Location
Certain restrictions exist for *Indoor* and *Outdoor* transmissions as well. Setting the **Location** of the transmitter will further adjust the allowed transmission power and/or channels.

Network-specific wireless configuration

These settings are unique per interface, even on virtual wireless interfaces. Changing these settings does not affect any other interfaces.

Wireless Mode
Set the **Mode** field to *Access Point* , and pfSense software will use `hostapd` to act as an AP.

Service Set Identifier (SSID)
The **SSID** is the "name" of the AP as seen by clients. Set the SSID to something readily identifiable yet unique. Keeping with the example, `ConfRoom` is a good name to use.

Minimum wireless standard
The **Minimum wireless standard** drop-down controls whether or not older clients are able to associate with this access point. Allowing older clients may be necessary in some environments if devices are still around that require it. Some devices are only compatible with 802.11g and require a mixed network g/n in order to work. The flip side of this is that slower speeds may be seen as a result of allowing such devices on the network as the access point will be forced to cater to the lowest common denominator when an 802.11g device is transmitting at the same time as an 802.11n device. In our example conference room, users will only be using recently purchased company-owned laptops that are all capable of 802.11n, so *802.11n* is the best choice.

Intra-BSS Communication
If **Allow intra-BSS communication** is checked, wireless clients will be able to see each other directly. If clients will only need access to the Internet, it is typically safer to uncheck this option. In this scenario, users in the conference room may need to share files back and forth directly between laptops, so this will stay checked.

Enable WME
Wireless Multimedia Extensions, or **WME**, is a part of the wireless standard that provides some Quality of Service for wireless traffic to ensure proper delivery of multimedia content. It is required for 802.11n to operate, but is optional for older standards. This feature is not supported by all cards/drivers.

Hide SSID
Normally the AP will broadcast its SSID so that clients can locate and associate with it easily. This is considered by some to be a security risk, announcing to all who are listening that a wireless network is available, but in most cases the convenience outweighs the (negligible) security risk. The benefits of disabling SSID broadcasting are overblown by some, as it does not actually hide the network from anyone capable of using many freely available wireless security tools that easily find such wireless networks. For the conference room AP, this example leaves the option unchecked to make it easier for meeting attendees to find and use the service.

Wireless Encryption (WPA)

Two types of encryption are supported for 802.11 networks: WPA, and WPA2. WPA2 with AES is the most secure. Even when not worrying about encrypting the over-the-air traffic (which should be done), it provides an additional means of access control. All modern wireless cards and drivers support WPA2.

Warning: Wireless Encryption Weaknesses

WEP has serious known security problems for years, and support for WEP has been removed from pfSense software. It is possible to crack WEP in a matter of minutes at most, and it should never be relied upon for security. If WEP is required, an external AP must be used.

TKIP (Temporal Key Integrity Protocol), part of AES, became a replacement for WEP after it was broken. It uses the same underlying mechanism as WEP, and hence is vulnerable to some similar attacks. These attacks have become more practical and TKIP is no longer considered secure. TKIP should never be used unless devices are present that are incompatible with WPA or WPA2 using AES. WPA and WPA2 in combination with AES are not subject to these flaws in TKIP.

In this example, the ConfRoom wireless must be secured with WPA2.

Enable
This checkbox enables *WPA* or WPA2 encryption, so it should be **checked**

WPA Pre-Shared Key
Enter the desired wireless key, in this example `excoconf213`.

WPA Mode
WPA or WPA2, in this example, *WPA2*

WPA Key Management Mode
Can be *Pre-Shared Key* (PSK) or *Extensible Authentication Protocol* (EAP). In this example, PSK is sufficient.

WPA Pairwise
This should almost always be set to *AES*, due to the weaknesses in *TKIP* mentioned previously.

Group Key Rotation
This option allows setting how often the broadcast/multicast encryption keys (Group Transient Key, GTK) are rotated, in seconds. It can be any value from `1` to `9999` but it should be shorter than the **Group Master Key Regeneration** value. The default value of `60` seconds (one minute) is adequate. Lower values may be more secure but may bog things down with frequent rekeying.

Group Master Key Regeneration
This parameter controls how often, in seconds, the master key (Group Master Key, GMK) used internally to generate GTKs is regenerated. It can be any value from `1` to `9999` but it should be longer than the **Group Key Rotation** value. The default value of `3600` seconds (one hour) is adequate.

Strict Key Regeneration
This option causes the firewall to change the GTK whenever a client leaves the access point, much like changing the passwords when an employee leaves. There may be a slight performance penalty in cases where there is a high turnover of clients. In cases where security is not a primary concern, this can be left disabled.

IEEE 802.1X Authentication (WPA Enterprise)

Another type of supported wireless security is known as IEEE 802.1X Authentication, or more commonly referred to as *WPA Enterprise* or *WPA2 Enterprise*. This mode allows using a more traditional username and password entry in order to gain access to the wireless network. The downside is that this authentication must be done via RADIUS servers. If an existing RADIUS server is already present or easily deployed, it may be a viable source of wireless access control. In this example, 802.1X is not used but the options are explained.

See also:

The FreeRADIUS package (*FreeRADIUS package*) can fulfill this purpose.

Note: Some older operating systems may not properly handle 802.1X or may have long delays after failed authentication attempts, but there are typically workarounds for those issues via OS updates or patches.

Clients must also be configured to properly access the service. Some may pick up the proper settings automatically, others may need set for a specific mode (e.g. *PEAP*) or may need certificates loaded. The specific values depend on the RADIUS server settings.

To get started with 802.1X authentication, first set **WPA Key Management** to *Extensible Authentication Protocol*.

Enable 802.1X Authentication
When checked, 802.1X authentication support is enabled and required of clients.

Primary 802.1X Server
The preferred server for 802.1X authentication.

IP Address
The IP address of the preferred RADIUS server to use for 802.1X client authentication.

Port
The port upon which to contact the RADIUS server for authentication requests, typically `1812`.

Shared Secret
The password to use when communicating with the RADIUS server from this firewall. This must match the shared secret defined for this firewall on the RADIUS server.

Secondary 802.1X Server
The same parameters as above, but for a secondary RADIUS server in case the first one is unreachable.

Authentication Roaming Preauth
This option sets up pre-authentication to speed up roaming between access points. This will perform part of the authentication process before the client fully associates to ease the transition.

Finishing AP Settings

The previous settings are enough to get a wireless access point running with 802.11n with WPA2 + AES encryption. When the settings are complete, click **Save**, then **Apply Changes**.

Configuring DHCP

Now that an entirely separate network has been created, DHCP must be enabled to automatically provide associating wireless clients an IP address. Browse to **Services > DHCP Server**, click on the tab for the wireless interface (**ConfRoom** for this example). Check the box to **Enable**, set whatever size range will be needed, and any additional options desired, then click **Save** and **Apply Changes**. For more details on configuring the DHCP service, see *DHCP*.

Adding Firewall Rules

Since this wireless interface is an OPT interface, it will have no default firewall rules. At the very least a rule must be added to allow traffic from this subnet to any destination. Since the conference room users will need internet access and access to other network resources, a default allow rule will be fine in this case. To create the rule:

- Navigate to **Firewall > Rules**
- Click on the tab for the wireless interface (**ConfRoom** for this example).
- Click  **Add** and configure a rule as follows:

  Interface
  ConfRoom

  Protocol
  Any

  Source
  ConfRoom Net

  Destination
  Any

- Click **Save**
- Click **Apply Changes**

See also:

For more information about creating firewall rules, see *Firewall*.

Associating Clients

The newly configured pfSense software AP should appear in the list of available access points from a wireless device, assuming broadcasting of the SSID was not disabled. A client should now be able to associate with it as it would with any other access point. The exact procedure will vary between operating systems, devices, and drivers, but most manufacturers have streamlined the process to make it simple for everyone.

Viewing Wireless Client Status

When a wireless interface is configured for access point mode, the associated clients will be listed on **Status > Wireless**.

Interesting sysctls from shell that cannot be controlled from GUI

dev.ath.0.tpc
`0` = disable 1 = enable

Switch on or off Transmission Power Control. Can be tricky in point to multipoint applications.

dev.ath.0.tpscale
`0,1,2,3,4`

Size of the increment that TPC will use to up/down the power, normally 1 is the best choice. A higher scale value will most likely make the link drop if the signal is close to what it needs to be and the TPC is throttled down.

dev.ath.0.tpack
`0 -> 99`

Controls the ACK power separately. Normally it is the same as `tpcts`

dev.ath.0.tpcts
`0 -> 99`

Controls the CTS power separately. Normally it is the same as `tpack`

Tuning ACK timers manually:

```
Real life values:

range                ack-timeout

5GHz 5GHz-turbo      2.4GHz-G
0km  default default         default
5km  52      30              62
10km 85      48              96
15km 121     67              133
20km 160     89              174
25km 203     111             219
30km 249     137             268
35km 298     168             320
40km 350     190             375
45km 405     -               -
```

32.5 Wireless WAN

A wireless card in a firewall running pfSense® software can be used as the primary WAN interface or an additional WAN in a multi-WAN deployment.

32.5.1 Interface assignment

If the wireless interface has not yet been assigned, there are two possible choices: Add it as an additional OPT interface or reassign it as WAN.

Before starting, create the wireless instance as described in *Creating and Managing Wireless Instances* if it does not already exist. When working as a WAN, it must use *Infrastructure* mode (BSS).

To add the interface as a new OPT interface:

- Browse to **Interfaces > Assignments**
- Select the wireless interface from the **Available network ports** drop-down below the other interfaces
- Click **Add** to add the interface as an OPT interface

To reassign the wireless interface as WAN:

- Browse to **Interfaces > Assignments**
- Select the wireless interface as **WAN**
- Click Save

Figure *Wireless WAN Interface Assignment* shows an Atheros card assigned as WAN.

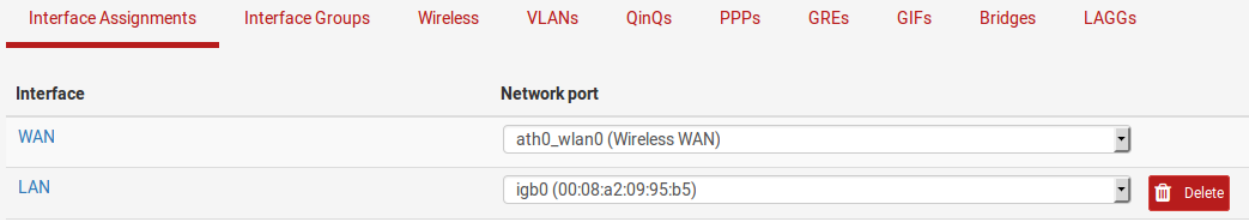

Fig. 2: Wireless WAN Interface Assignment

32.5.2 Configuring the wireless network

Most wireless WANs need only a handful of options set, but specifics vary depending on the Access Point (AP) to which this client interface will connect.

- Browse to the **Interfaces** menu for the wireless WAN interface, for example **Interfaces > WAN**
- Select the type of configuration (*DHCP*, *Static IP*, etc.)
- Scroll down to **Common Wireless Configuration**
- Set the **Standard** to match the AP, for example *802.11g*
- Select the appropriate **Channel** to match the AP
- Scroll down to **Network-specific Wireless Configuration**
- Set the **Mode** to *Infrastructure (BSS)* mode
- Enter the **SSID** for the AP
- Configure encryption such as WPA2 (Wi-Fi Protected Access) if in use by the AP
- Review the remaining settings if necessary and select any other appropriate options to match the AP
- Click **Save**

- Click **Apply Changes**

32.5.3 Checking wireless status

Browse to **Status > Interfaces** to see the status of the wireless interface. If the interface has successfully associated with the AP it will be indicated on the status page. A **status** of **associated** means the interface has connected to the AP successfully, as shown in Figure *Associated Wireless WAN Interface*

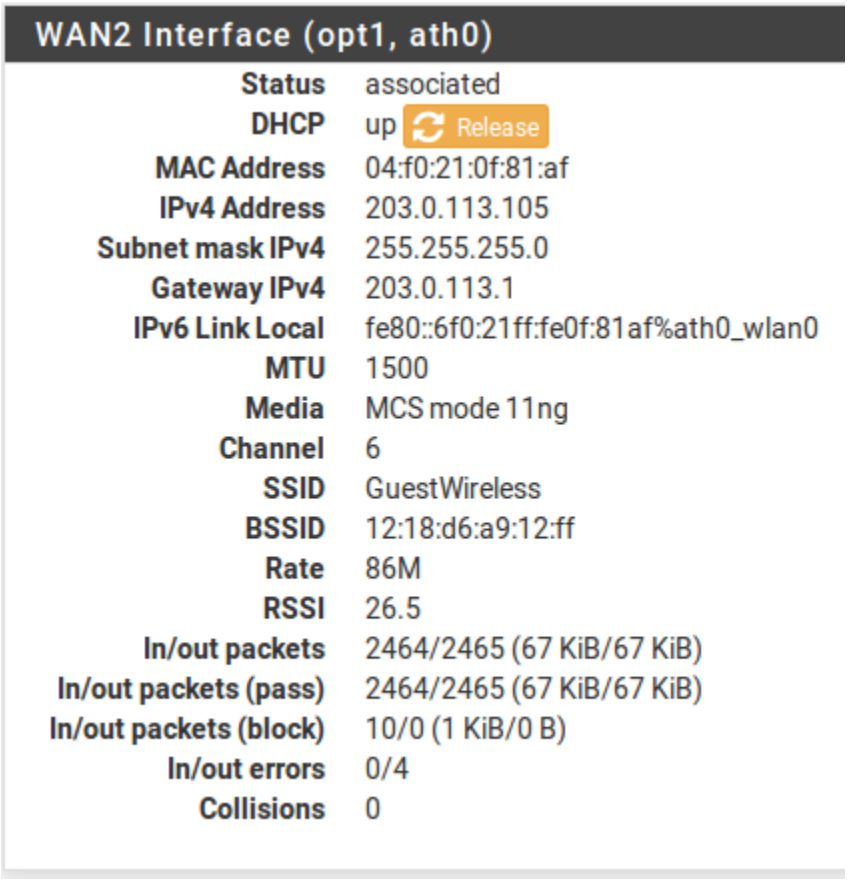

Fig. 3: Associated Wireless WAN Interface

If the interface **status** shows **No carrier**, it was unable to associate. Figure *No carrier on wireless WAN* shows an example of this, where the antenna was disconnected so it could not connect to a wireless network that was some distance away.

32.5.4 Showing available wireless networks and signal strength

The wireless access points visible by the firewall may be viewed by navigating to **Status > Wireless** as shown in Figure *Wireless Status*.

A wireless interface must be configured before this menu item will appear.

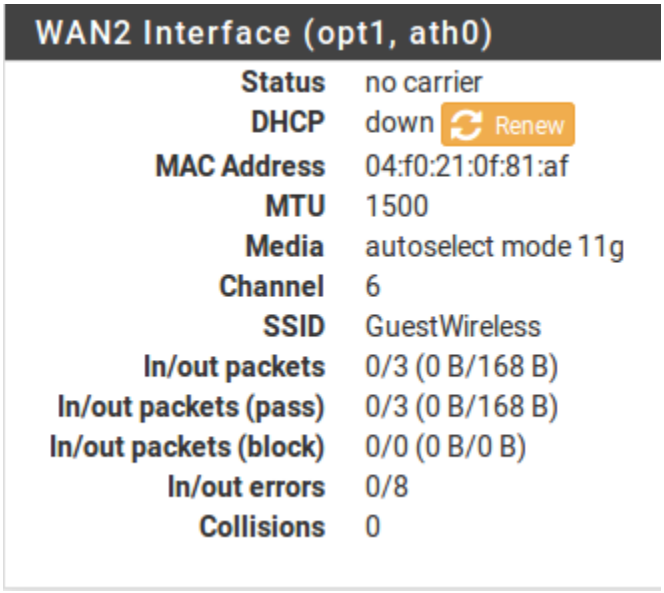

Fig. 4: No carrier on wireless WAN

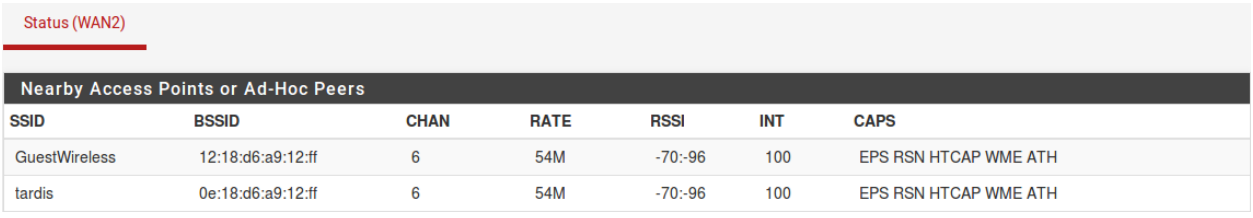

Fig. 5: Wireless Status

32.6 Bridging and wireless

Bridging two interfaces together places them on the same broadcast domain as if they were connected to the same switch. Typically this is done so that two interfaces will act as though they are on the same flat network using the same IP subnet, in this case a wireless interface and wired interface. When two interfaces are bridged, broadcast and multicast traffic is forwarded to all bridge members.

Certain applications and devices rely on broadcast traffic to function. For example, Apple's AirTunes will not function across two broadcast domains. So if AirTunes is present on the wireless network and it must be accessed from a system on the wired network, the wired and wireless networks must be bridged. Other examples include media services provided by devices such as Chromecast, TiVo, Xbox, and Playstation. These rely on multicast or broadcast traffic that can only function if the wired and wireless networks are bridged.

32.6.1 Wireless Access Points and Bridging

Only wireless interfaces in access point (hostap) mode will function in a bridged configuration. A wireless interface configured for hostap can be bridged to another interface which combines them on the same broadcast domain. This may be desirable for certain devices or applications that must reside on the same broadcast domain to function properly, as mentioned previously.

32.6.2 BSS and IBSS wireless and Bridging

Due to the way wireless works in BSS mode (Basic Service Set, client mode) and IBSS mode (Independent Basic Service Set, Ad-Hoc mode), and the way bridging works, a wireless interface cannot be bridged in BSS or IBSS mode. Every device connected to a wireless card in BSS or IBSS mode must present the same MAC address. With bridging, the MAC address passed is the actual MAC of the connected device. This is normally a desirable facet of how bridging works. With wireless, the only way this can function is if all the devices behind that wireless card present the same MAC address on the wireless network. This is explained in depth by noted wireless expert Jim Thompson in a mailing list post.

As one example, when VMware Player, Workstation, or Server is configured to bridge to a wireless interface, it automatically translates the MAC address to that of the wireless card. Because there is no way to translate a MAC address in FreeBSD, and because of the way bridging in FreeBSD works, it is difficult to provide any workarounds similar to what VMware offers. At some point pfSense® software may support this, but it is not currently on the roadmap.

32.6.3 Choosing Routing or Bridging

The choice between bridging (using the same IP subnet as the existing LAN) or routing (using a dedicated IP subnet for wireless) for wireless clients will depend on what services wireless clients require. In many home network environments there are applications or devices that require wired and wireless networks to be bridged. In most corporate networks, there are few if any applications that require bridging. Which to choose depends on the requirements of network applications in use, as well as personal preference.

There are some compromises to this, one example being the Avahi package. It can listen on two different broadcast domains and rebroadcast messages from one to the other in order to allow multicast DNS to work (aka Rendezvous or Bonjour) for network discovery and services. If the required services all use protocols that can be handled by Avahi, then using a routed method may be possible.

For services running on the firewall, bridging can also be problematic. Features such as limiters, Captive Portal, and transparent proxies require special configuration and handling to work on bridged networks. Specifically, the bridge itself must be assigned and the only interface on the bridge with an IP address must be the assigned bridge. Also, in order for these functions to work, the IP address on the bridge must be the address used by clients as their gateway.

32.7 Additional protection for a wireless network

In addition to strong encryption from WPA2 with AES, some users like to employ an additional layer of encryption and authentication before allowing access to network resources. The two most commonly deployed solutions are *Captive Portal* and *Virtual Private Networks*. These methods can be employed whether an external access point is used on an OPT interface or an internal wireless card as the access point.

Note: In theory, The PPPoE server could also be used in this role but support would be impossible on some clients and non-trivial on most others, so it is not typically a viable option when combined with wireless.

32.7.1 Additional wireless protection with Captive Portal

By enabling Captive Portal on the interface where the wireless resides, authentication can be required before users may access network resources beyond the firewall. In corporate networks, this is commonly deployed with RADIUS authentication to Microsoft Active Directory so users can use their Active Directory credentials to authenticate while on the wireless network. Captive Portal configuration is covered in *Captive Portal*.

Note: If the sole requirement is per-user RADIUS authentication, a better solution for RADIUS is 802.1X rather than using Captive Portal, unless there are clients present which do not support 802.1X.

Captive Portal is more likely to be used on open or limited access wireless networks, such as those in a hotel, restaurant, or similar setting where there is either no encryption enabled or a common knowledge/shared key.

32.7.2 Additional protection with VPN

Adding Captive Portal provides another layer of authentication, but does not offer any additional protection from eavesdropping of wireless traffic. Requiring a VPN connection before allowing access to the internal network and Internet adds another layer of authentication as well as an additional layer of encryption for wireless traffic. The configuration for the chosen type of VPN will be no different from a remote access configuration, but the firewall rules must be configured on the pfSense® interface to only allow VPN traffic from wireless clients.

Configuring firewall rules for IPsec

Figure *Rules to allow only IPsec from wireless* shows the minimal rules required to allow only access to IPsec on the WLAN interface IP address. Pings to the WLAN interface IP address are also allowed to assist in troubleshooting.

Configuring firewall rules for OpenVPN

Figure *Rules to allow only OpenVPN from wireless* shows the minimal rules required to allow access only to OpenVPN on the WLAN interface IP address. Pings to the WLAN interface IP address are also allowed to assist in troubleshooting. This assumes the default UDP port 1194 is in use. If another protocol or port was chosen, adjust the rule accordingly.

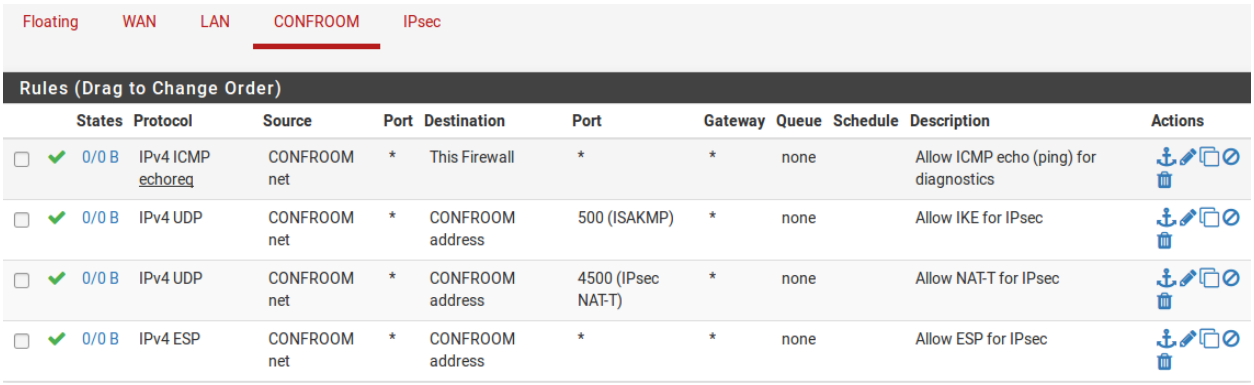

Fig. 6: Rules to allow only IPsec from wireless

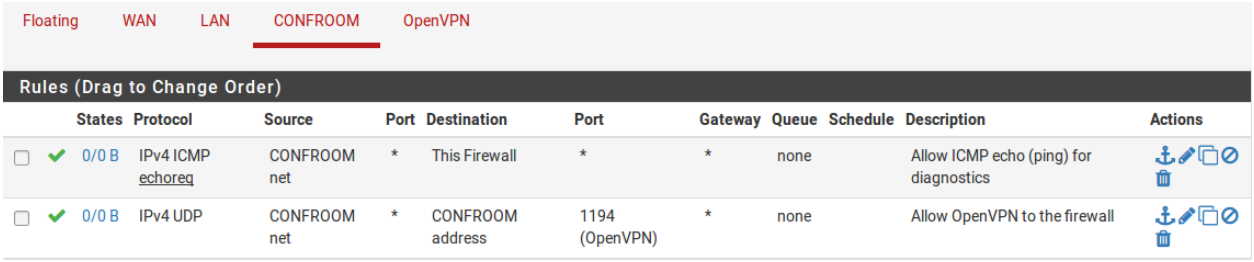

Fig. 7: Rules to allow only OpenVPN from wireless

32.8 Configuring a Secure Wireless Hotspot

A company or organization may wish to provide Internet access for customers or guests using an existing Internet connection. This can be a boon to the customers and business, but can also expose the existing private network to attack if not done properly. This section covers the common means of providing Internet access to guests and customers, while protecting the internal network.

32.8.1 Multiple firewall approach

For the best protection between a private network and a public network, obtain at least two public IP addresses from the ISP and use a second firewall for the public network. To accommodate this, place a switch between the Internet connection and the WAN interface of both firewalls.

This has the added benefit of putting the public network on a different public IP address from the private network, so if a report of abuse is received, it is easy to tell the origin. The firewall protecting the private network will see the public network no differently than any Internet host and vice versa.

32.8.2 Single firewall approach

In environments where the multiple firewall approach is cost prohibitive or otherwise undesirable, the internal network can still be protected by connecting the public network to an OPT interface on a firewall running pfSense® software. Assign a dedicated private IP subnet to this OPT interface, and configure its firewall rules to allow access to the Internet but not the internal network.

In *Rules to allow only Internet access from wireless* the firewall rules allow clients to reach the firewall for DNS requests and ICMP echo request (ping), but prevent all access to other private networks. The RFC1918 alias referenced in the figure includes the RFC1918 private network list, `192.168.0.0/16`, `172.16.0.0/12`, and `10.0.0.0/8`.

Floating | WAN | LAN | EXTERNALAP | IPsec | OpenVPN

Rules (Drag to Change Order)

	States	Protocol	Source	Port	Destination	Port	Gateway	Queue	Schedule	Description	Actions
☐ ✔	0/0 B	IPv4 ICMP echoreq	EXTERNALAP net	*	EXTERNALAP address	*	*	none		Allow ping to the firewall	
☐ ✔	0/0 B	IPv4 TCP/UDP	EXTERNALAP net	*	*	53 (DNS)	*	none		Allow DNS -- will be trapped by NAT rule	
☐ ✋	0/0 B	IPv4 *	*	*	RFC1918	*	*	none		Deny access to any other private networks	
☐ ✔	0/0 B	IPv4 *	EXTERNALAP net	*	*	*	*	none		Allow Internet access	

Fig. 8: Rules to allow only Internet access from wireless

32.8.3 Access control and egress filtering considerations

Other than not allowing traffic from the publicly accessible network to the private network, there are additional things to consider in the configuration of a hotspot.

Restrict network access

While many hotspots use open wireless networks with no other authentication, consider additional protections to prevent network abuse. On wireless, consider using WPA or WPA2 and providing the passphrase to guests or customers. Some businesses taking this approach display the passphrase on a placard in the lobby or waiting area, posted in a guest room, or provide it upon request. Also consider implementing Captive Portal on pfSense software (covered in *Captive Portal*). This helps prevent people in other offices and outside the building from using the wireless network even if it is open access.

Disable Intra-BSS communication

If the access point allows, disable intra-BSS communication. This option is also sometimes called "AP Client Isolation". This prevents wireless clients from communicating with other wireless clients directly, which protects users from intentional attacks from other wireless users as well as unintentional ones such as worms.

Intra-BSS communication may be required for certain functions such as wireless printers, Chromecast devices or similar cases when two wireless devices must talk directly to each other, but this is rarely if ever required in the context of a public hotspot.

Egress filtering

Consider what kind of egress policy to configure. The most basic, allowing access to the Internet without allowing access to the private network, is probably the most commonly deployed but consider additional restrictions.

To avoid having the public IP address of the firewall black listed because of infected visiting systems acting as spam bots, consider blocking SMTP. Several large ISPs already block SMTP outbound because clients have moved to using authenticated access on the submission port (587) rather than using port 25 directly. An alternative that still lets people use their SMTP e-mail but limits the effect of spam bots is to create an allow rule for SMTP and specify **Maximum state entries per host** under **Advanced Options** when editing the firewall rule. Ensure the rule is above any other rules that would match SMTP traffic, and specify a low limit. Because connections may not always be properly closed by the mail client or server, do not set this too low to prevent blocking legitimate users, but a limit of five connections should be reasonable. **Maximum state entries per host** can be set on all firewall rules, but keep in mind that some protocols will require dozens or hundreds of connections to function. HTTP and HTTPS may require numerous connections to load a single web page depending on the content of the page and the behavior of the browser, so don't set the limits too low.

Balance the desires of users against the risks inherent in providing Internet access for uncontrolled systems, and define a policy that fits the environment.

- *Wireless Status*
- *Using an External Wireless Access Point*
- *Troubleshooting Wireless Connections*

pfSense® software includes built in wireless capabilities that allow a firewall running pfSense software to be turned into a wireless access point, to use a wireless 802.11 connection as a WAN connection, or both. This chapter covers how to configure pfSense software for these roles as well as suggested means of securely accommodating external wireless access points and how to securely deploy a wireless hotspot. In-depth coverage of 802.11 in general is outside the scope of this documentation. For those seeking such information, see other works such as 802.11 Wireless Networks: The Definitive Guide.

Hangouts Archive to view the May 2015 Hangout on Wireless Access Points.

CHAPTER

THIRTYTHREE

CELLULAR WIRELESS

pfSense® software can use a supported cellular modem (3G/4G/LTE) as a WAN interface for connectivity. This can be used as a sole means of connectivity or as a backup.

33.1 Configuring Cellular Modems

To configure a cellular modem in pfSense® software on a current supported release, plug in a *Known Working Modem* and log into the firewall GUI to begin configuration.

See also:

PPP (Cellular Modem)

33.1.1 Example Cellular Configuration

- Navigate to **Interfaces > Assignments**, **PPPs** tab
- Click **+** to create a new entry
- Configure the settings as follows:

Link Type
PPP

Link Interface(s)
Select the port for the modem from the list. The list contains all available serial ports on the firewall.

Note: A modem may list several serial ports. Typically the correct choice is the last entry, but may require trial and error to identify.

Description
Text used to reference this PPP configuration in other parts of the GUI. For example, it could contain the service provider and/or modem model.

Country
Select the country in which this modem is operating.

The firewall populates the **Provider** list based on the value of this field.

Provider
Select the cellular network provider for the modem.

The firewall populates the **Plan** list based on the value of this field.

Plan
Select the cellular plan used by this modem. Check with the cellular provider to determine which choice is correct.

This populates the remaining fields where possible with values specific to the **Plan**.

Username / Password
Enter login credentials if the provider requires authentication.

The remaining settings can typically be left at their automatic or existing values. For more information on the available settings, see *PPP (Cellular Modem)*.

- Click **Save**.

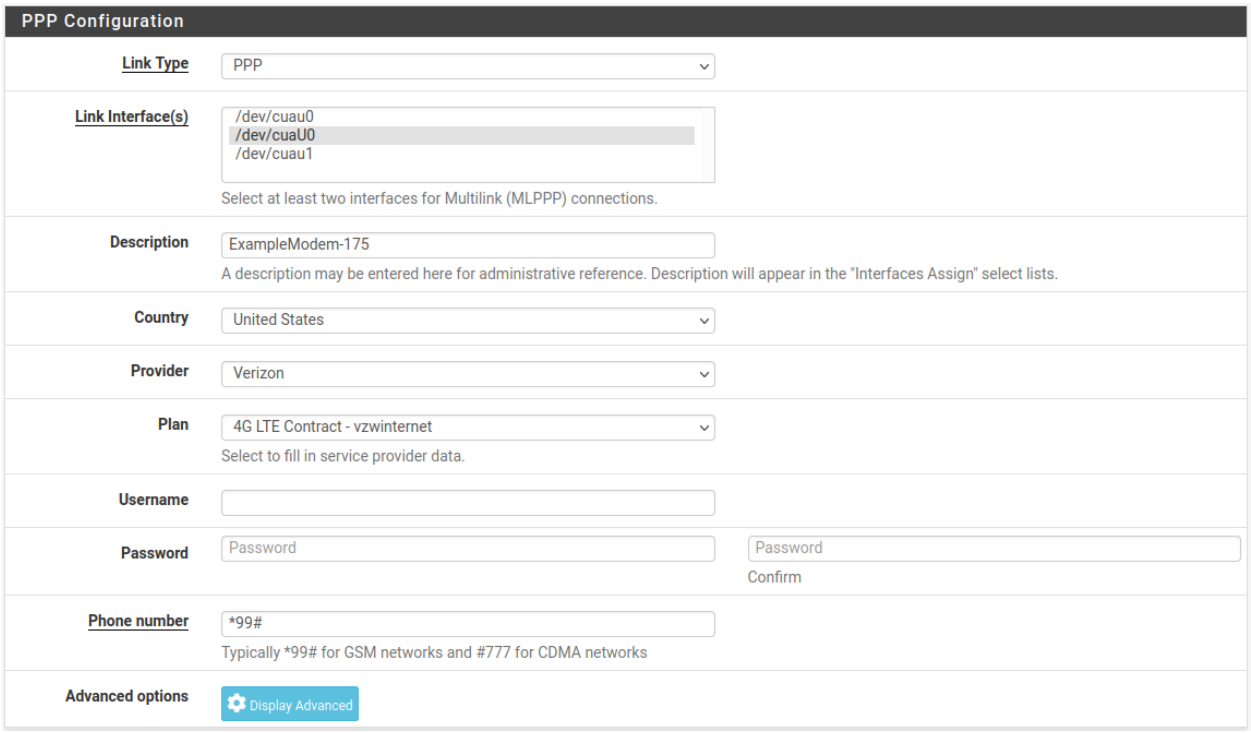

Fig. 1: Example modem configuration

The GUI lists the newly created PPP interface on the **PPPs** tab:

Fig. 2: PPP list entry for a modem

Assigning the PPP Interface

Next, assign the PPP instance to an interface.

- Navigate to **Interfaces > Assignments**
- Set the **Available network ports** field to the newly created PPP interface
- Click  **Add**

The firewall will assign the PPP interface as the next available OPTx interface, for example, OPT1.

Fig. 3: Assign the PPP interface

Enable the PPP Interface

- Navigate to the menu entry for the new interface name, e.g. **Interfaces > OPT1**
- Check **Enable Interface**
- Enter a new name for the interface in the **Description** field, e.g. `CellModem`
- Click **Save**
- Click **Apply changes**

Check the interface status

Navigate to **Status > Interfaces** and locate the entry for the new PPP interface in the list.

If the interface does not show connected, check the logs under **Status > System logs**, **PPP** tab to see if the firewall has log messages indicating why the connection is failing.

Note: Some connection problems are a lack of signal. If the cellular modem is in a location with poor reception, such as an equipment room, datacenter, rack, etc, then it use an antenna and/or longer USB cable to achieve a better signal.

33.2 Known Working 3G-4G Modems

This page lists 3G and 4G modem devices which are known to work with pfSense® software.

- 4G Systems XS Stick P14
- Alcatel Onetouch 4G L850V
- Anydata ADU-635 WA
- Verizon/Pantech UM175
- Verizon/Pantech UML290 and UML295 (see also: *UML290 config info*)
- Verizon USB727
- HP hs2340 HSPA+ Mini Card AMO Ericsson

- Huawei B970/B970B
- Huawei E122
- Huawei E153
- Huawei E156G
- Huawei E160
- Huawei E161
- Huawei E160E
- Huawei E169
- Huawei E172
- Huawei E173
  - It has been reported that some E173 modems are shipping labeled as E173 but have a different chip that is not supported. See below.
- Huawei E173U-1
- Huawei E176
- Huawei E180
- Huawei E220
- Huawei E226
- Huawei E272
- Huawei E352
- Huawei E353U-2
- Huawei E367
- Huawei E372
- Huawei E392
- Huawei E397u-53
  - Link interface: `/dev/cuaU0.0`
  - Init string: `&F`
- Huawei E398 (E398u-1)
- Huawei E960
- Huawei E1550
- Huawei E1552
- Huawei E1556
- Huawei E1612
- Huawei E1692
- Huawei E1750
- Huawei E1756
- Huawei E1762

- Huawei E1820
- Huawei E3372s LTE USB-stick
  - Link interface: `/dev/cuaU0.1`
  - Init string: `&F&C1&D2E0S0=0`
- Huawei E3372h LTE USB-stick
  - As an Ethernet device: see *Modems reported to work as Ethernet devices*
  - As a modem device: requires manual firmware changes, see this article
- Huawei E3531

  The command to switch to the correct mode depends on the hardware revision.

  Newer versions of the hardware may use this command:

  ```
  usb_modeswitch -v 12d1 -p 1f01 -c /usr/local/share/usb_modeswitch/12d1:1f01
  ```

  Older hardware revisions may use this ID instead:

  ```
  usb_modeswitch -v 12d1 -p 15e7 -c /usr/local/share/usb_modeswitch/12d1:15e7
  ```

  The command has to be executed every time it's detached and reattached, the interface has to be disabled and then enabled again.

  - Link interface: `/dev/cuaU0.0`
  - Init string: `&F0E1Q0 +CMEE=2`
- Huawei K3563
- Huawei E5372
- Huawei E5776
- Huawei VIK K3715 HSU by Vodafone
- Huawei K3765 by Vodafone
- Huawei ME909u-521 4G/LTE Mini-PCIe
  - Link interface: `/dev/cuaU0.0`
  - Init string: `&F0E1Q0 +CMEE=2`
- Huawei ME909s-120 4G/LTE Mini-PCIe
- Nokia Phone E72-1 connected via USB cable
- Sierra Wireless U305
- Sierra Wireless 320u usb LTE
- Sierra Wireless U330
- Sierra Wireless MC7354
- Sierra Wireless MC7355
- Sierra Wireless MC7710
  - May require usb-comp or ID change. See https://forum.netgate.com/post/556751 for more information.
- HP2300 (Sierra Wireless MC8775 3G) Mini-PCIe

- USB Connect Mercury (Sierra Wireless Compass 885 or C885)
- Sierra Wireless Compass 889
- Ovation U727 by Novatel on Sprint CDMA
- Nokia CS-17
- Turkey-TTNET Usb Stick 3G Modem. Label says Huawei E173 but its actually Huawei E1800.
- Telstra maxon bp3-usb (Benchmarked: 2500/350)
- ZTE MF656A
- Vodafone Mobile Connect K3565
- Huawei K4505 (Vodafone Mobile Broadband)
- LTE Yota LiTE LU 156 4G - NOTE: May need nudged in some way out of storage mode. (e.g. boot delay, unplug/replug)
- Novatel EU850D (Mini PCIe)
- ZTE MF683 (May need CD-ROM disabled using AT+ZCDRUN=8 on another system first)
- ZTE MF622
- Ericsson H5321G / Lenovo FRU 60Y3297
- Ericsson F5521GW Gobi3000 / Lenovo
- Ericsson N5321 / Lenovo
  - May need "AT+CFUN=1" in the init string. Serial port varies from `/dev/cuaU[0-3]`.
- ZTE MF915 LTE modem (T-Mobile)
- ZTE MF190 USB (1&1) using */dev/cuaU0.2*
- ZTE MF669 - May need "camcontrol eject da0" in shellcmd, uses `/dev/cuaU0.2`
- ZTE MF830 - Can be switched from Ethernet to Modem by accessing the device's web interface, depending on preference.
- ZTE MF861
- ZTE MF985 - Branded as AT&T Velocity 2
- D-Link DWM-157 (3.75HSPA+)
- ONDA MT503HSA Type MF636 (requires eject mode switch, see below)
- Netgear LB1120 (US)
- Netgear LB1121 (US)
- Netgear LB2120 (US)
- Netgear LB1110 (EU)
- Netgear LB1111 (EU)
- Netgear LM1200 (EU)
- And many others

If a modem **DOES WORK** but is not on the list - Please *submit a documentation update*.

If a modem **DOES NOT WORK** - post about it on the Netgate Forum for help, **do not contact Netgate asking for support or drivers**.

33.2.1 Modems reported to work as Ethernet devices

- Verizon (Pantech) 295 - Works, but fails if detached and reattached, must reboot.
- ZTE MF60 3g
- ZTE MF90
- ZTE MF823 - Defaults to 192.168.0.1, will need to be sure local system does not have an overlapping network.
- ZTE MF833R - Same
- ZTE MF833V - Same
- ZTE MF915 LTE modem (T-Mobile)
- ZTE MF975S
- ZTE MF79U - Requires Plus 23.01, CE 2.7.0, or later. USB Ethernet device appears after running `camcontrol eject cd0`.
- Huawei E3372-325
- Huawei E3372h - Command to switch to the correct mode:

  ```
  usb_modeswitch -v 12d1 -p 1f01 -c /usr/local/share/usb_modeswitch/12d1:1f01
  ```

  The command has to be executed every time it's detached and reattached, the interface has to be disabled and then enabled again.
- Huawei E5573 - Command to switch to the correct mode:

  ```
  usb_modeswitch -v 12d1 -p 1505 -c /usr/local/share/usb_modeswitch/12d1:1505
  ```

  The command has to be executed every time it's detached and reattached, the interface has to be disabled and then enabled again.
- Huawei E8372h – See *Mode Switching* and #6226
- TP-LINK M7350

33.2.2 Modem variations reported to NOT work

These have the same model numbers as the above, but have different chips and may not be supported.

- Huawei E173s

```
#Before switching (USB mass storage)
DefaultVendor= 0x12d1
DefaultProduct=0x1c0b
#After switching into modem mode
TargetVendor=  0x12d1
TargetProductList="1c05,1c08"
```

- mPCIe: Sierra Wireless Gobi2000

33.2.3 Mode Switching

Some devices show up as a media device, such as `cd0`, in this case it may be possible to switch modes by executing a command:

```
camcontrol eject cd0
```

If that does switch the modem to the proper mode, it may be added as a *Executing Commands at Boot* using the full path:

```
/sbin/camcontrol eject cd0
```

`usb_modeswitch` is required in order to make certain devices switch to the correct mode.

In some cases, switching to the correct mode is too late, resulting in an error "Network interface mismatch" on the console. In this case, the additional command `&& sleep 10` can be added. For example:

```
/usr/local/sbin/usb_modeswitch -v 12d1 -p 1f01 -c /usr/local/share/usb_modeswitch/
↪12d1:1f01 && sleep 10
```

This package is available in the pfSense software repository, but cannot be installed using the GUI package manager. It can be installed from a shell prompt using `pkg install usb_modeswitch`.

This method should not be used on a production firewall it has not been tested officially.

33.3 Verizon UML290 Cellular Modem

These instructions are specifically for the Verizon 4G modem Pantech UML290.

First, find the phone number associated with the device. One way to find it is to install the VZAccess Manager on a Windows PC and then plug in the device and let it detect the phone number. I also connected from the Windows PC to ensure it was activated but I'm not sure if that is necessary.

Follow the instructions here for how to configure the interface in pfSense® software: *Configuring Cellular Modems*.

Some setups may need to modify the instructions because `#777` may not work. Instead try `*99***3#`. Also for **username** try `devicephone#@vzw4g.com` and for **password** put `vzw`.

33.4 Configuring a Verizon UML295 USB Modem

Connect the UML295 to a computer to do the initial setup and remove the initial SIM PIN.

Test the connection from the computer to ensure that there is 4G connectivity.

If the test succeeded, remove the modem from computer and plug it into the firewall running pfSense® software. There should be no PPP configuration necessary for this device in the firewall as it will register as a USB Ethernet device in the interface list.

Note: Reboot the firewall if the device does not show in the list for assignment.

Assign **UE0** as a DHCP interface, and it should show an IP address in the `192.168.32.0/24` subnet which then should be accessible from the LAN after configuring the necessary rules.

The gateway on the new interface can also be used by the firewall for failover. See *Multiple WAN Connections* for details.

CHAPTER

THIRTYFOUR

TROUBLESHOOTING

34.1 Troubleshooting Asymmetric Routing

Asymmetric routing happens when traffic between two nodes takes a different path in each direction (e.g. A->B->C, C->D->A). This can pose a problem for TCP which has strict state tracking but often does not affect "stateless" protocols such as ICMP or UDP.

34.1.1 Common Scenario

What happens in most cases is this:

- Client sends a TCP SYN packet which arrives at the firewall
- The firewall creates a state table entry
- The firewall sends an ICMP redirect to the client letting it know to reach the target server through an alternate gateway on the same interface
- The target server sends a TCP SYN+ACK packet to the client by a different path that does not pass through the firewall
- The client sends its ACK and later responses to the server using the other gateway and they are not visible to the firewall
- After 30 seconds the firewall removes its state table entry as the firewall did not see the client and server fully establish a connection
- Some time later the route the client learned via ICMP redirect expires and the client sends another packet back to the firewall
- Since this packet is not starting a new connection the firewall drops the packet
- The client gets disconnected as it no longer knows how to reach the server

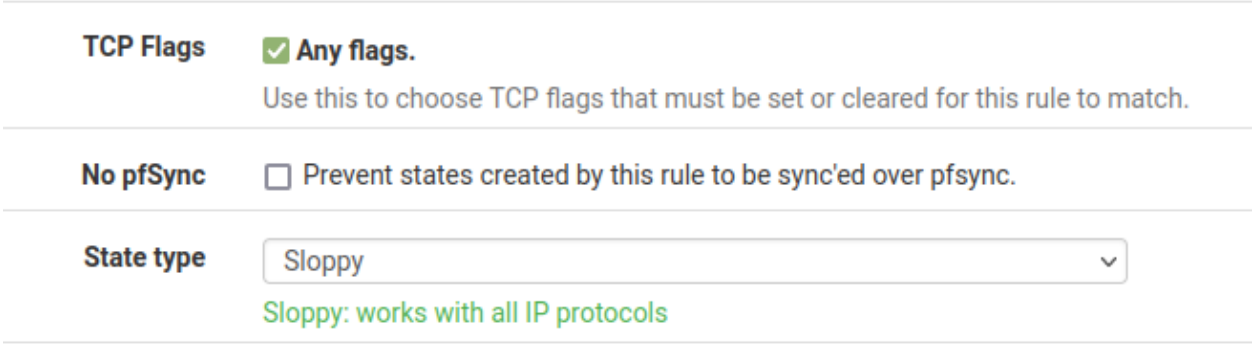
34.1.2 Automatic Fix

The **Bypass firewall rules for traffic on the same interface** option located under **System > Advanced** on the **Firewall & NAT tab** activates rules for traffic to/from the static route networks which are much more permissive when it comes to creating states for TCP traffic and allowing it to pass. The rules allow any TCP packets regardless of their flags to create a state, and also utilize "Sloppy" state tracking which performs a less strict state match.

34.1.3 Manual Fix

The same rules may be created manually by adding one on the affected **interface tab** (e.g. LAN), and a second rule on the **Floating tab** using the same interface (LAN again) to match the traffic in the *out* direction. The rule must be set for a protocol of *TCP*, under **TCP flags** check *Any Flags*, and use a **State Type** of *Sloppy*.

The options for **TCP flags** and **State Type** can be found in the **Advanced Options** when editing a firewall rule.



34.1.4 Alternate Causes

On occasion these issues can be caused by other factors that lead to asymmetric routing, such as issues with `route-to` or `reply-to`, both having to do with gateways on interface settings.

Defining gateways under **System > Routing** does not cause this, but rather these problems can come up when the gateway is improperly configured on the interface pages, **Interfaces > WAN**, **Interfaces > LAN**, and so on.

See also:

WAN vs LAN Interfaces

Gateway set when it should not be set

If a gateway is set on an internal interface, such as LAN, it can cause problematic behavior. Setting a gateway on an internal interface will tag outbound rule on that interfacewith `route-to`, and inbound rules with `reply-to` which will cause the firewall to forward packets to the defined gateway rather than following their natural path. For WANs this is typically a good thing! For LANs it is not. Among other ill effects, it can lead to a loop of sorts where packets bounce between the firewall and the defined gateway, eventually being blocked or dropped when their TTL expires.

Gateway not set when it should be set

A gateway should usually be set on a WAN or other external-type interface settings (MPLS, IP VPN, etc.) In these cases the `reply-to` and `route-to` behavior is desired and likely required. If it is missing the packets may be blocked or dropped as they attempt to leave the wrong interface. A packet could enter via the alternate WAN, but the reply would leave by the default gateway. Similar to the effect seen when improperly using an *Interface Group* for WAN interfaces.

34.2 Troubleshooting Authentication

Testing authentication servers is possible using the tool located at **Diagnostics > Authentication**.

See also:

- *Authentication Servers*
- *External User Authentication Examples*
- Hangouts Archive to view the August 2015 Hangout on RADIUS and LDAP.

34.2.1 Testing Authentication

Testing user authentication is a simple process:

- Navigate to **Diagnostics > Authentication**
- Select an **Authentication Server**
- Enter a **Username**
- Enter a **Password**
- Click the **Test** button.

Note: This only performs a basic authentication test. Some special use cases, such as EAP, cannot be tested in this manner and may still fail when this test succeeds.

The firewall will attempt to authenticate the user against the chosen server, then it prints the results. The best practice is to try this at least once before attempting to use the server.

If the server returned a set of groups for the user, and the groups exist locally with the same name, the GUI prints the names of the groups in the test results.

If the firewall receives an error when testing authentication, double check the credentials and the server settings, then make any necessary adjustments and try again.

Debug Option

The **Set debug flag** option enables additional logging for authentication attempts made from this page. Currently this is only recognized by the LDAP authentication code path.

When debugging is enabled for LDAP authentication, the authentication process will write messages to the main system log with much more detail about the LDAP query and results. This can be a great help for dialing in authentication containers, group membership, and extended query contents. This is especially useful when communicating with an LDAP server over TLS, where a packet capture cannot see those details.

34.2.2 RADIUS Authentication Server Troubleshooting

Missing/Incomplete RADIUS Reply Attributes

There is a limit to the maximum number of attributes the RADIUS client on pfSense® software can receive.

The radius client library in pfSense software does not support RFC 7499. This restricts the RADIUS request and response payloads to an upper limit of `4096` bytes. Large lists of attributes, such as numerous ACL entries, will be truncated to this limit.

34.2.3 LDAP Authentication Server Troubleshooting

Tip: When troubleshooting LDAP authentication, be sure to check the *Debug Option* for increased LDAP query and response logging.

LDAP DN and Related Settings

For LDAP authentication servers, first ensure the base DN and similar settings match those configured on the LDAP server. Check the LDAP server for more information.

For **Base DN**, it's common to use the root of the LDAP tree but in most cases **Entire Subtree** must also be selected for the **Search Scope**.

Authentication Containers vary by LDAP implementations and setup. On Windows, it is commonly `CN=Users,DC=example,DC=com`, but it may vary. Try using an LDAP browser or similar software to locate the correct container.

LDAP path components are not case sensitive, so `CN=Administrator` is equivalent to `cn=administrator`.

Bind Credentials

When using authenticated (Not anonymous) binds, the username can be the short name (e.g. `DOMAIN\User` for AD) or a full LDAP specification for a user (e.g. `CN=administrator,CN=Users,DC=example,DC=com`).

Tip: The full DN of a Windows AD bind user can be found by navigating to the user in **ADSI Edit** found under **Administrative Tools** on the Windows server.

For a production setup, an unprivileged user should be used for binding if possible, and not AD Administrator-level account. Such an unprivileged user may need sufficient permissions to attempt binding as other users and access the LDAP directory.

Another common mistake with group membership is not specifying *Entire Subtree* for the **Search Scope Level**.

Active Directory Group Membership

Depending on how the Active Directory groups were made, the way they are specified may be different for things like Authentication Containers and/or Extended Query. For example, a traditional user group in AD is exposed differently to LDAP than a separate Organizational Unit.

ADSI Edit found under **Administrative Tools** on the Windows server can locate the DN for a given group.

Extended Query

The most common mistake with **Extended Query** is that the given directive fails to include both the item to be searched as well as how, such as:

```
memberOf=CN=VPNUsers,CN=Users,DC=example,DC=com
```

Note that in the above example the DN of the group is given along with the restriction (`memberOf=`).

For users of RFC2307 groups, such as with OpenLDAP, an extended filter might look more like the following:

```
&(objectClass=posixGroup)(cn=VPNUsers)(memberUid=*)
```

Connection-Related Issues (non-SSL/TLS)

Make sure that the LDAP server is listening on the expected port, and that connectivity to the LDAP server network is functional.

Performing a packet capture filtered on the LDAP server IP address and port will help track down the problem. Tools such as **Wireshark** can interpret LDAP packets and help diagnose queries and failures. See *Troubleshooting via Packet Captures*.

Connection-Related Issues (SSL/TLS)

By far the most troublesome connection type is LDAP+SSL/TLS (ldaps) due to its strict security and validation standards.

Restart PHP and the GUI

When making configuration changes to LDAP server entries using SSL/TLS, in some cases PHP and the GUI must be restarted for it to fully utilize the changes. Therefore it's best to perform this step before others to ensure tests have the best chance to succeed.

To accomplish this, either reboot the device **or** connect to the console or SSH and run menu options 16 then 11. After restarting PHP and the GUI, run the test again to see if it succeeds.

Hostname Required

When connecting to LDAP with SSL/TLS, the hostname given for the server is also used to verify the server certificate. The server certificate SAN entries and/or CN **must include its hostname**, and that **hostname must resolve to the LDAP server IP address**, e.g. `CN=ldap.example.com`, and `ldap.example.com` is `192.168.1.5`.

If an IP address has been entered for the hostname of the LDAP server, it will not work unless that IP address happens to also be the CN or a SAN of the server certificate.

If this must be worked around, it is possible to create a DNS host override in the DNS forwarder for `<common name of the cert>.<firewall domain name>`. That assumes that the CN is in a format that could actually be a hostname, or that the hostname in question is present in a SAN entry on the server certificate.

Use the Correct Port

When using port `636` for SSL/TLS, the firewall uses an `ldaps://` URL, not STARTTLS. Ensure that the LDAP server is listening on the correct port with the correct mode. For STARTTLS, use port `389`.

Ensure CA Matches

The most important factor in making sure that it is possible to communicate with the LDAP server over SSL/TLS is that the correct CA certificate has been imported into the firewall, and is chosen on the LDAP settings. The key is not required, only the CA certificate.

Nested CAs

If the LDAP server certificate CA is part of a chain, or there is an intermediate CA, every CA certificate in the chain must imported into the Certificate Manager.

Other Cert/CA Issues

Confirm that the certificates are otherwise valid, for example they are not expired or set to be valid in the future.

Troubleshooting via Server Logs

Authentication failures are typically logged by the target server (FreeRADIUS, Windows Event Viewer, etc), assuming the request is making it all the way to the authentication host. Check the server logs for a detailed explanation why a request failed. The system log at **Status > System Logs** may also contain information that hints at a resolution.

Troubleshooting via Packet Captures

Packet captures (*Packet Capturing*) can be invaluable for diagnosing errors as well. If an unencrypted method (RADIUS, LDAP without SSL/TLS) is in use, the actual password being used may not be visible but enough of the protocol exchange can be seen to determine why a request is failing to complete. This is especially true when a capture is loaded in Wireshark, which can interpret the responses, as seen in Figure *Sample LDAP Failure Capture*.

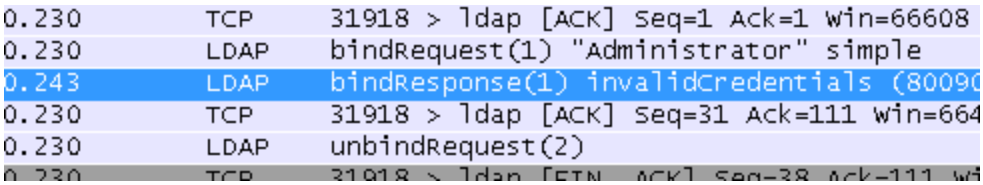


Fig. 1: Sample LDAP Failure Capture

34.3 Troubleshooting Boot Issues

The errors in this article would happen during bootup, typically the first boot either from the install media or immediately after installation. If the system was up and running but then developed a boot issue with no changes in the software/OS, it isn't likely to be related.

34.3.1 Booting with an alternate console

To boot a different console, first get to a loader prompt. Either choose the menu option from the boot menu, or when **Hit [Enter] to boot immediately, or any other key for command prompt.** is seen during the boot process, press space or another key.

Once at the loader prompt, type the following to boot with the serial console active:

```
set console=comconsole
boot -v
```

Similarly, if a serial memstick image is used that prefers the serial console, the video console can be used instead as follows:

```
set console=vidconsole
boot
```

34.3.2 ISA Serial Console not Fully Functional

Older devices with ISA-based serial console ports may not fully detect their console due to changes in how FreeBSD probes serial ports. The console may show boot and kernel messages, but will not show pfSense software boot output or an interactive console.

Devices affected by this are primarily older non-EFI hardware running pfSense CE software. This includes devices such as the APU (1), RCC-DFF 2220, and RCC-VE models such as the 2440, 4860, and 8860.

pfSense plus software attempts to detect known affected models of hardware from Netgate. Other devices may require manual intervention. One workaround is to *add a loader tunable* defining the location of an affected console port:

```
hint.uart.0.at="isa"
```

The value above assumes a standard console on the first serial port. If the device uses the second serial port instead, then change the `0` to `1`.

This value can also be `set` via the loader prompt to test for a single boot. Add the loader tunable after booting successfully so the setting will be present for future boots.

34.3.3 Booting from USB

If booting fails from a USB 3.0 port and the above does not help, try a USB 2.0 port with the same delay settings. Similarly, if it fails with a USB 3.0 thumb drive, try a USB 2.0 thumb drive. Drive capacity can also make a difference, where some older hardware may not be able to boot large capacity USB drives.

If the boot stops with a mountroot error while booting off the installation disc, usually with USB CD/DVD drives, escape to the loader prompt and run the following:

```
set kern.cam.boot_delay="10000"
boot
```

Note: pfSense® software applies this change already when it detects the need, but there may be some edge cases where it should be handled manually.

At which point the boot will continue normally and a normal installation will be possible.

If running permanently from a medium that requires this delay, add the following as a *Loader Tunable*:

```
kern.cam.boot_delay="10000"
```

34.3.4 Multiple Disk Boot Issues

If a system has multiple disks and pfSense software has been installed on both, it is possible they may conflict in one or more ways.

For details in troubleshooting this type of situation, including identifying which drive the operating system is using, see *Troubleshooting Multiple Disks*.

34.3.5 EFI Boot Issues

Occasionally certain devices or hypervisors may have issues booting pfSense software via EFI. There can be multiple issues here even if they preset using similar symptoms.

A few items to check are:

- Ensure the BIOS is up-to-date from the OEM
- For hypervisors, ensure the hypervisor OS/Software is up-to-date
- Ensure **Secure Boot** is disabled in the BIOS settings.
- For Virtual Machines on Proxmox® VE, check the recommended settings as described in *Booting UEFI*. In particular, adding a **Serial Port** to the VM hardware may improve EFI boot behavior. Shut down/power off the VM and start it back up after adding the port to ensure it's fully added.
- If the BIOS supports both Legacy and EFI booting, the boot selection menu may contain two entries for the installation media (Legacy and EFI), try the EFI entry first.
- If the system boots the ISO OK but not the installed OS, dismount the ISO image and/or remove the virtual optical drive from the VM and try again.
- Some EFI-capable BIOS implementations have a method to reset the boot list entries. Resetting or clearing this list may help, though in some rare cases resetting the list may require reinstalling pfSense software afterward.

If all else fails, fall back to booting using Legacy mode if possible. The BIOS may need to be adjusted to allow that behavior.

34.3.6 GPT Boot Issues

Some systems may fail to boot a 2.4 memstick because they do not fully support booting from GPT or they are particular about the layout or other attributes.

In these cases, the memstick can be modified using another firewall running pfSense software version 2.3 or later, or with a FreeBSD 10.x or later system.

Insert the memstick into the device with the pfSense or FreeBSD installation and check the system log or dmesg output to find the device name, such as `da1`.

First, try to set the partition on the memstick active:

```
gpart recover da1
gpart set -a active da1
```

Remove the memstick and attempt to boot the memstick on the target hardware. If it works, be sure to only use compatible options in the installer. In this case, if the BIOS requires an active GPT partition then either of the following installer choices will work:

- **Auto (UFS)** requires the Partition Scheme **BSD (BSD Labels)**
- **Auto (ZFS)** requires the Partition Scheme **GPT + Active (BIOS)**

Other platforms may need more changes to the memstick, including:

```
gpart bootcode -b /boot/pmbr -p /boot/gptboot -i 2 da1
gpart set -a bootme -i 2 da1
```

In this case the hardware may not be capable of booting ZFS, but use the same option above for UFS with BSD Labels which should work.

In either case, depending on the BIOS and hardware capabilities, similar modifications may be made to the installation target disk to use other partition schemes not listed above, but that has not been tested internally.

34.3.7 BIOS/Disk Errors

- If after installation, a "cannot load kernel" error is observed, or the firewall hangs at the spinner (`/`):
  - Make sure BIOS is up to date
  - Reinstall but do not check the packet mode option during boot block installation process
  - Set the HDD mode in BIOS to LBA (don't use "auto", the detected geometry is different if it is set to auto and it fails)
  - Set the HDD mode in BIOS to CHS if the above fails
  - Set AHCI mode in the BIOS
- Try using multiple partitions, one small one (~4GB) for `/` and another for `/usr` using the rest of the disk.
- If the installer fails to start correctly (system reboots), try the following (attempt each substep, then rerun the installer each time):
  - Make sure BIOS is up to date
  - Change the hard drive ribbon/SATA cable
  - Force a slower speed in the bios for the channel
  - Boot from another disk and run: (note that ad0 is the first ata hard drive):

```
# dd if=/dev/zero of=/dev/ad0 bs=8k count=16
# fdisk -I ad0
```

- If all those fail…
  - Partition from a FreeBSD Live CD or Linux
  - Different hard drive
  - Different hardware entirely that isn't prone to legacy booting issues

34.3.8 DVD Errors

- If the installer disc starts to boot but hundreds of errors are printed, try:
  - Make sure BIOS is up to date
  - Use a USB memstick instead
  - Burn the disc at a slower speed
  - Change the DVD drive cable
  - Different DVD drive

34.3.9 Boot Blocks/Loader Issues

- If a read error occurs during boot, please see this Boot Error.
- If FreeBSD will boot but not pfSense, try booting from a FreeBSD Live CD and running the following (More Info):

```
# fdisk -B -b /boot/boot0 /dev/ada0
# bsdlabel -B /dev/ad0as1
```

Note: `ada0` is the first hard drive in that example

34.3.10 Vendor-Specific Issues

- Certain Dell Blade servers may hang at boot if the system's virtual USB media is enabled. Disable the virtual media in the BIOS and then it should boot normally.
- Certain systems running Hyper-V on AMD processors may need to do the following:

  Escape to the loader prompt during bootup and run:

```
set hw.clflush_disable=1
boot
```

  At that point, boot the rest of the way and install pfSense software. After installation, add the following line as a *Loader Tunable*:

```
hw.clflush_disable=1
```

If all else fails, Netgate offers Netgate TAC and hardware through the Netgate Store that is pre-loaded with pfSense Plus software.

34.3.11 "Fake" RAID cards with a GRAID error

Certain "fake" RAID cards, driver/software-based RAID adapters that are not true hardware RAID, may fail to mount properly with the following error:

```
Root mount waiting for: GRAID
mountroot>
```

Another symptom can be that "Intel RAID" messages are shown during the boot sequence, and typing ? at the mountroot prompt it only shows the drive itself and no partitions:

```
Mounting from ufs:/dev/ada0s1a failed with error 19
mountroot> ?
[...]
ada0
```

- Escape to a loader prompt during bootup and run:

  ```
  set kern.geom.raid.enable="0"
  boot
  ```

- After a successful install/boot, add that settings permanently as a *Loader Tunable*:

  ```
  kern.geom.raid.enable="0"
  ```

34.3.12 Conflicting Hardware

If the system stops with an error such as:

```
run_interrupt_driven_hooks: still waiting after 60 seconds for xpt_action
```

Disable any Firewire/1394 controllers and built-in USB Card Readers in the BIOS.

34.4 Troubleshooting Multiple Disks

If a system has multiple disks and pfSense software has been installed on both, it is possible they may conflict in one or more ways. For example, this can happen if an older disk was left in place after adding a new disk of a different type and reinstalling to the new disk.

In these situations best practice is to remove the unused disk but that is not always possible. For example, if the original installation was using an embedded disk such as eMMC. If the disk cannot be removed, then the next best solution is to clear the metadata from the unused disk.

A common way multiple disks conflict is if they both use the same ZFS label. In that case it is unpredictable which ZFS pool will be used by the OS and it may change depending on the boot order. Another way is if the OS boots the kernel from one disk but mounts the other disk in the operating system, leading to a situation where the installed OS appears up-to-date but is booting with an outdated kernel.

34.4.1 Identify the Disk

To clear the metadata safely, first identify the unused disk. This may take some investigation, but typically disks are listed in the full boot log output in `/var/log/dmesg.boot`, the output of `sysctl kern.disks`, along with other OS commands such as `geom list disk`, `gpart list`, and `geom -t`. In some cases it's clear which is which, such as when using an add-on SSD instead of eMMC, where the eMMC disk is named `mmcsdX` and the SSD is `ndaX` or `adaX`.

It's also possible that the drive that loaded the kernel at boot time is different from the drive mounted as the root of the filesystem (`/`). Once booted, it's not possible to determine which drive loaded the kernel, but it is possible to determine which drive holds the root filesystem.

Note: If the unused disk cannot be definitively identified, take a backup, clear the data from *all* disks, and then reinstall.

When a system has multiple disks, odds are high that the disk holding the live root filesystem is the intended disk and whichever disk is *not* used for the root filesystem is the one that should be wiped to avoid conflicts.

UFS

On UFS systems, look at the output of `df /` in the first column (`Filesystem`):

- If it's a disk device (e.g. `/dev/ada0s2a`), then note it and move on. The filesystem device name will include a slice or partition identifier at the end (e.g. `s2a` in the previous example) but it should be possible to match the disk name against the list in `sysctl kern.disks`.

  In this case, it is located on `ada0s2a` which is the first filesystem in the second slice of the disk `ada0`.

- If it contains a label (e.g. `/dev/diskid/`, `/dev/gpt/`, or `/dev/ufs/`), look at the output of `glabel status` and match the start of the filesystem label with the `Name` column and find the disk device in the corresponding `Components` column.

  ```
  $ df /
  Filesystem                    1K-blocks    Used   Avail Capacity  Mounted on
  /dev/diskid/DISK-9D1CEC59s2a   7353532 1664148 5101104    25%    /
  $ glabel status
                  Name  Status  Components
  diskid/DISK-9D1CEC59     N/A  ada0
  ```

  In this case, the root filesystem is located on `/dev/diskid/DISK-9D1CEC59s2a` which is the first filesystem in the second slice of disk ID `DISK-9D1CEC59`, which corresponds to the disk `ada0`.

  Other label types may not always include a slice or partition identifier.

ZFS

For systems using ZFS, check output of `zpool status` and look at the disk names in the output:

```
$ zpool status
  pool: pfSense
 state: ONLINE
  scan: scrub repaired 0B in 00:00:17 with 0 errors on Wed Feb 22 11:03:52 2023
config:

    NAME        STATE     READ WRITE CKSUM
    pfSense     ONLINE       0     0     0
```

(continues on next page)

(continued from previous page)

```
       nda0p4    ONLINE       0     0     0

errors: No known data errors
```

In this output, the ZFS pool is located on `nda0p4` which is the fourth partition on the disk `nda0`.

Using the Geom Tree

If there is any doubt about the devices in question based on the filesystem device, run `geom -t`. That command outputs a tree style view of all disks and their components, such as slices/partitions. This can make it relatively simple to narrow down the disk which contains a given ID, partition, or slice with minimal searching through command output:

```
$ geom -t
Geom                                Class      Provider
nda0                                DISK       nda0
  nda0                              PART       nda0p1
    nda0p1                          LABEL      gpt/efiboot0
      msdosfs.gpt/efiboot0          VFS
      gpt/efiboot0                  DEV
    nda0p1                          DEV
  nda0                              PART       nda0p2
    nda0p2                          LABEL      gpt/gptboot0
      gpt/gptboot0                  DEV
    nda0p2                          DEV
  nda0                              PART       nda0p3
    swap                            SWAP
    nda0p3                          DEV
  nda0                              PART       nda0p4
    nda0p4                          DEV
    zfs::vdev                       ZFS::VDEV
  nda0                              DEV
mmcsd0                              DISK       mmcsd0
  mmcsd0                            DEV
  mmcsd0                            LABEL      diskid/DISK-9D1CEC59
    diskid/DISK-9D1CEC59            DEV
    diskid/DISK-9D1CEC59            PART       diskid/DISK-9D1CEC59s1
      diskid/DISK-9D1CEC59s1        DEV
      msdosfs.diskid/DISK-9D1CEC59s1 VFS
    diskid/DISK-9D1CEC59            PART       diskid/DISK-9D1CEC59s2
      diskid/DISK-9D1CEC59s2        DEV
      diskid/DISK-9D1CEC59s2        PART       diskid/DISK-9D1CEC59s2a
        diskid/DISK-9D1CEC59s2a     DEV
        ffs.diskid/DISK-9D1CEC59s2a VFS
mmcsd0boot0                         DISK       mmcsd0boot0
  mmcsd0boot0                       DEV
mmcsd0boot1                         DISK       mmcsd0boot1
  mmcsd0boot1                       DEV
```

34.4.2 Clear the Disk

In these examples the unused disk is `mmcsd0`.

The commands in these examples must be run from a console or SSH shell prompt. Do not attempt to execute these commands from the GUI. The best practice is to run them from the console and to have installation media on hand in case a reinstall is necessary.

Tip: If any of the commands generate an error, boot the *Netgate Installer* and perform the commands from a shell launched through the installer menu (AMD64 and AARCH64). When booted from install media, the disks in the device will not be mounted and can be safely cleared. For ARMv7 devices, boot the recovery installer and use `Ctrl-Z` to suspend the recovery process and reach a shell prompt to run the commands.

Wipe Metadata

The quickest and easiest way to wipe a disk is to clear its metadata.

The following commands clear the disk partition metadata, ZFS metadata, and also wipe the start of the disk to clear the partition table and other data at the beginning of the disk. Depending on the situation it may only be necessary to clear the ZFS metadata but it's safer to clear it all.

```
### Stop a legacy style GEOM mirror and clear its metadata from all disks
### Mirror name may vary, check "gmirror status" output.
# gmirror destroy -f pfSenseMirror

### Clear the ZFS label (exact partition may vary)
# zpool labelclear -f /dev/mmcsd0p4

### Clear the partition metadata
# gpart destroy -F mmcsd0

### Wipe the first 1MB of the disk
# dd if=/dev/zero of=/dev/mmcsd0 bs=1M count=1 status=progress
```

Note: Alternately, skip the first two commands and omit the `count=1` on `dd` to wipe the entire target disk from start to end.

Wipe Start and End of Disk

Another tactic is to wipe only the start and end of the disk. However, this approach is a much more complicated process as it involves calculations based on the sector size and number of sectors on the disk:

```
### Wipe the first 1MB of the disk
# dd if=/dev/zero of=/dev/mmcsd0 bs=1M count=1 status=progress

### Wipe the last 1MB of the disk
# dd bs=`diskinfo mmcsd0 | awk '{print $2}'` \
     if=/dev/zero \
     of=/dev/mmcsd0 \
     count=`diskinfo mmcsd0 | awk '{print ((1024 * 1024) / $2)}'` \
```

(continues on next page)

(continued from previous page)

```
    seek=`diskinfo mmcsd0 | awk '{print $4 - ((1024 * 1024) / $2)}'` \
    status=progress
```

Note: Be sure to replace **every** instance of the target disk in each command, as the disk is referenced numerous times to obtain the necessary calculation numbers.

34.5 Troubleshooting "No buffer space available" Errors

On occasion traffic on a NIC may have trouble getting out with an error similar to:

```
ping: sendto: No buffer space available
```

Or:

```
dpinger WANGW x.x.x.x: sendto error: 55
```

The most common causes of this are:

- No route to the target network (or no default route)
- Missing link route for a local target
- Stale state in pf sending the connection out an invalid path (reset states)
- Network memory buffer exhaustion

  See also:

  See *Hardware Tuning and Troubleshooting*

- Faulty NIC and/or driver issue

  Sometimes resetting the NIC can bring it back again:

  ```
  # ifconfig ix3 down; ifconfig ix3 up
  ```

- Faulty cable
- Traffic shaping (ALTQ or Limiters) dropping the packet
- Virtual NIC being throttled by the hypervisor or host, such as an AWS instance using more throughput than an instance size can support

  In this case, change the throttling in the host (not guest) or upgrade to a larger instance/higher tier on a hosted platform such as AWS.

- Virtual NIC being disconnected/disabled in certain hypervisors
- An otherwise overloaded NIC exhausting its send/recv buffers
- Other various switch/buffer/connectivity issues

Trying to bounce the NIC with `ifconfig` is the easiest thing to try first. After that, save/apply the interface settings on each interface (or at least WANs and the LAN in question). Check/(re)set the default route if it has been lost. *Reset States*. Replacing the cable may also help. Removing traffic shaping if it is enabled is also a good test.

Otherwise investigate the traffic on the NIC and look for other buffer-related causes. Seek help from Netgate TAC for assistance in diagnosing the issue, or post on the forum/mailing list.

34.6 Troubleshooting Captive Portal

This section contains troubleshooting tips for the most common problem with captive portal.

34.6.1 Authentication failures

Authentication failures are normally the result of users entering an incorrect username or password. In the case of RADIUS authentication, these can occur because of connectivity problems to the configured RADIUS server(s), or problems on the RADIUS server itself. Check the RADIUS server logs for indications of why access was denied, and ensure the firewall can communicate with the RADIUS server.

For local users, if the option to require the Captive Portal login privilege is enabled, ensure the users have the privilege directly or are members of a group with the privilege.

34.6.2 Captive Portal Does not Redirect

If clients are not being redirected to the portal page when attempting to browse on an interface with captive portal enabled, it's typically one of the following causes:

DNS resolution not functioning
: Clients on the captive portal interface must either be using the DNS resolver or forwarder on pfSense® software, on the IP address of the interface where the client resides (which is the default configuration), or if using another IP address for DNS, it must be in an allowed IP address entry. If DNS fails, the browser never issues the HTTP request, hence it cannot be intercepted and redirected.

Firewall rules on the captive portal interface do not allow the initial HTTP request
: If the user is trying to browse to google.com, but HTTP connections are not allowed to google.com, the HTTP request will be blocked and hence cannot be redirected. Under **Firewall > Rules**, on the interface where captive portal is enabled, the traffic to be redirected must be allowed to pass. This is most commonly HTTP to any destination.

The client has an HTTPS home page
: The request must be to an HTTP site in order for the portal to redirect the client. If HTTPS is enabled for the portal, this may still work but it depends upon the client browser or operating system automatic portal detection to work.

  Many modern browsers and operating systems detect portals now which makes this less of an issue.

Client is using IPv6
: Captive Portal does not currently support IPv6, so IPv6 traffic is not able to traverse the portal interface. If the interface has IPv6 configured and the client attempts to use it, it may encounter network timeouts.

34.6.3 Apple devices are unable to load the portal page or login

Certain versions of Safari on iOS do not properly handle the login form for the Captive Portal page. The most common resolution is to disable autofill for forms in Safari on iOS.

In some cases, Apple devices will not automatically prompt for a Captive Portal login or test for its presence if the wireless network uses encryption. In these cases, manually open a browser and navigate to an HTTP site to get the login redirect.

There have also been reports that on older version of macOS, a Mac would refuse to load any HTTPS sites, including an HTTPS portal, until it could load a CRL and OSCP URL for the certificate. This has been fixed in current versions of OS X.

Some users have had to add `www.apple.com` to their allowed hostnames so that Apple's call to their test page succeeds.

34.6.4 Port Forwards Behind Portal Only Work When Target Logs In

This is a side effect of how the portal operates. No traffic is allowed to reach a host behind the portal unless it has been authenticated or passed through the portal. If a port forward must always work to a device behind the portal, then it must be setup to bypass the portal with either a Pass-through MAC entry (*MAC Address Control*) or an Allowed IP Address entry (*Allowed IP Address*) to allow traffic *To* the target.

34.6.5 Captive Portal Rules

On pfSense Plus software version 22.05 or CE version 2.7.0 or later, Captive Portal uses `pf` features for L2 `ether` processing under the hood. When having issues with the captive portal, it is possible to inspect the rules for debugging purposes.

To see rules for Captive Portal look in `/tmp/rules.debug` at the multiple sections starting with a comment `# Captive Portal`.

Anchors

The entries for various client and other entries for Captive Portal are kept under special anchors in the ruleset.

The easiest way to see all of the anchors and rules is to use the script `pfanchordrill` playback script.

```
# pfSsh.php playback pfanchordrill
```

The relevant anchors are named: `cpzoneid_<id number>_<purpose>` and entries are nested underneath there in subordinate anchors.

The purpose names include:

cpzoneid_<id number>_auth
: Entries for authenticated clients in a zone.

cpzoneid_<id number>_allowedhosts
: Entries for permanently allowed hosts in a zone.

cpzoneid_<id number>_passthrumac
: Entries from the pass-through MAC list.

For example the output of the `pfanchordrill` script includes the following entry for an authenticated captive portal client on `10.7.0.10`:

```
cpzoneid_2_auth/10.7.0.10_32 rules/nat contents:
ether pass in quick proto 0x0800 from 5e:13:3b:ef:4d:24 l3 from 10.7.0.10 to any tag␣
↪cpzoneid_2_auth dnpipe 2000
ether pass out quick proto 0x0800 to 5e:13:3b:ef:4d:24 l3 from any to 10.7.0.10 tag␣
↪cpzoneid_2_auth dnpipe 2001
```

See `/etc/inc/captiveportal.inc` for information on other anchors and rules.

See also:

For assistance in solving problems, post on the Captive Portal category of the Netgate Forum.

34.7 Troubleshooting Cisco VPN Pass Through

If trouble is encountered when attempting a connection from an internal Cisco VPN client to an external host, (e.g. a workstation with the Cisco client is trying to get out through pfSense® software to connect to a remote site), then try the following.

34.7.1 Workaround

- In the Cisco VPN client software, Modify the connection and turn off transparent tunneling completely in the **Transport** tab.
- In the pfSense software GUI, under **Firewall > NAT** on the **Outbound** tab:
  - Enable **Manual Outbound NAT**.
  - Remove any NAT rules that perform static port NAT on udp/500.

34.8 Troubleshooting Network Connectivity

The following list covers most causes of outbound connectivity failure in common usage scenarios.

Each test assumes the items above it have been checked. This document assumes a single WAN but most of the advice is relevant to multiple WANs.

34.8.1 WAN Interface

- Check the WAN IP address (**Interfaces > WAN**)
  - This is only relevant to static WANs, dynamic WANs handle addresses automatically
  - Using the wrong address could prevent the ISP from delivering traffic to/from the firewall, among other issues
- Check that the WAN IP address has the correct subnet mask (**Interfaces > WAN**)
  - This is only relevant to static WANs, dynamic WANs handle subnet masks automatically
  - An improper subnet mask such as `/1` could cause connectivity issues to large portions of the Internet, using `/32` for a mask could prevent the firewall from contacting its gateway
- Check that WAN has a gateway and that the gateway IP address is correct (**Interfaces > WAN**)
  - This is only relevant to static WANs, dynamic WANs handle gateways automatically
  - This interferes with automatic outbound NAT and `route-to`/`reply-to`
- Check the default gateway configuration (**System > Routing**)
  - Without a default gateway traffic has no exit path
  - If it is set to *Automatic*, the automatic selection process may have chosen a non-viable gateway
- Check that the default gateway shows **Online** (**Status > Gateways**)
  - If it is not, verify the WAN settings and gateway settings, or use an alternate monitor IP address
- Check the default gateway in the routing table (**Diagnostics > Routes**)
  - Another source such as a VPN may have changed the default gateway

34.8.2 LAN Interface

- Check the LAN IP address (**Interfaces > LAN**)
  - Using an invalid IP address (e.g. `.0` or `.255` in a `/24`) will cause problems reaching addresses locally.
- Check the LAN subnet mask (**Interfaces > LAN**)
  - Using an incorrect subnet mask, such as `/32`, will prevent other hosts in the LAN subnet from finding the firewall LAN address to use as a gateway and vice versa
- Check that LAN does NOT have a gateway set (**Interfaces > LAN**)
  - This will interfere with automatic outbound NAT
- Check that LAN does NOT have **Block Private Networks** set (**Interfaces > LAN**)
  - If the LAN subnet is using a private network, this will block local traffic.
- Check that LAN does NOT have **Block Bogon Networks** set (**Interfaces > LAN**)
  - If the LAN subnet is using a private network, this will block local traffic.

34.8.3 Firewall/Rules

- Check the firewall log for blocked connections from hosts on LAN (**Status > System Logs**, **Firewall** tab)
  - If the log contains entries showing blocked connections, check the rule that triggered the block and adjust rules accordingly (**Firewall > Rules**, **LAN** tab)
- Check that the LAN rule allows all protocols, or at least TCP and UDP ports for reaching DNS and HTTP/HTTPS, and allows ICMP for testing. (**Firewall > Rules**, **LAN** tab)
  - Not allowing UDP would make DNS fail, among other things.
  - Similarly, on a DNS rule, using UDP only and not TCP/UDP will cause larger queries to fail.
  - Not allowing ICMP would cause ping to fail, but other protocols may work
  - Not allowing TCP would cause HTTP, HTTPS, and other protocols to fail.
- Check that the LAN rules allow to a destination of *any* (**Firewall > Rules**, **LAN** tab)
  - Using the wrong destination would not allow traffic to reach the Internet. For example, *WAN net* is only the subnet of the WAN interface, **NOT** the Internet, so typically the correct setting is *any*.
- Check that the LAN rule does not have an improper gateway set (**Firewall > Rules**, **LAN** tab)
  - If it is set to leave by another (possibly broken) non-WAN gateway it would cause the connections to fail

34.8.4 Outbound NAT

- Check **Outbound NAT**, ensure it is set for *Automatic* or *Hybrid* outbound NAT (**Firewall > NAT**, **Outbound** tab)
  - If the firewall requires manual outbound NAT, skip to the next test
  - Incorrect NAT settings will prevent traffic from reaching WAN
- Check manual outbound NAT rules, if in use, to ensure that they match local traffic sources
  - Incorrect NAT settings will prevent traffic from reaching WAN

34.8.5 Diagnostic Tests

- Check connectivity from the firewall itself: Try to ping `8.8.8.8` (**Diagnostics > Ping**)
  - If this does not work, ensure proper WAN settings, gateway, etc.
- Check DNS: Try to lookup `pfsense.org` (**Diagnostics > DNS Lookup**)
  - If this does not work, fix/change the DNS configuration (*Troubleshooting DNS Resolution Issues*)
- Test NAT: Try to ping `8.8.8.8` using *LAN* as the **Source Address** (**Diagnostics > Ping**)
  - If this fails but the other tests work, then the problem is likely outbound NAT (See the WAN/LAN gateway checks above)

34.8.6 Client Tests

- Test if the client can ping the LAN IP address of the firewall
  - If this fails, check the LAN rules, client IP address/subnet mask, LAN IP address/subnet mask, etc.
- Test if the client can ping the WAN IP address of the firewall
  - If this fails, check the client subnet mask and gateway
- Test if the client can ping the WAN Gateway IP address of the firewall
  - If this fails, check the client subnet mask and gateway, and double check outbound NAT on the firewall
- Test if the client can ping an Internet host by IP address (e.g. `8.8.8.8`)
  - If this fails, check the client subnet mask and gateway, and triple check outbound NAT on the firewall
- Test if the client can ping an Internet host by Host name (e.g. `www.google.com`)
  - If this fails, check the client DNS settings, and/or the DNS Resolver or Forwarder on the firewall (**Services > DNS Resolver**, **Services > DNS Forwarder**, **Diagnostics > DNS Lookup**)

34.8.7 Miscellaneous Additional Areas

- If Captive Portal is enabled, disable it temporarily (**Services > Captive Portal**).
  - See *Captive Portal Troubleshooting*.
- Check for packages such as pfBlockerNG, Snort, or Suricata, that might interfere with connectivity and disable them if necessary
  - Improperly configured packages could allow certain traffic such as ICMP ping to work but might prevent access to HTTP and/or HTTPS sites.

34.9 Troubleshooting GUI Connectivity

If the GUI is not accessible from the LAN, the first thing to check is cabling. If the cable is a hand-made cable or *shorter* than 3 feet/1 meter, try a different cable. If the client PC is directly connected to a network interface on the firewall, a crossover cable may be needed on older hardware that does not have Auto-MDIX support on its network cards. This is not a concern on gigabit or faster hardware.

Once there is a link light on both the client network card and the firewall LAN interface, check the TCP/IP configuration on the client PC. If the DHCP server is enabled on the firewall, as it is by default, ensure that the client is also set for

DHCP. If DHCP is disabled on the firewall, hard code an IP address on the client residing in the same subnet as the firewall LAN IP address, with the same subnet mask, and use the firewall LAN IP address as the gateway and DNS server.

If the cabling and network settings are correct, the client will be able to ping the LAN IP address of the firewall. If the client PC can ping, but not access the GUI, there are still a few more things to try. First, if the error on the client PC is a connection reset or failure, then either the server daemon that runs the GUI is not running or the client is attempting to use the wrong port. If the error is instead a connection timeout, that points more toward a firewall rule.

If the client receives a connection timeout, refer to *Troubleshooting Access when Locked Out of the Firewall*. With a properly configured network connection, this shouldn't happen, and that section offers ways to work around firewall rule issues.

Double check that WAN and LAN are not on the same subnet. If WAN is set for DHCP and is plugged in behind another NAT router, it may also be using `192.168.1.1`. If the same subnet is present on WAN and LAN, unpredictable results may happen, including not being able to route traffic or access the GUI. When in doubt, unplug the WAN cable, reboot the firewall, and try again.

If the client receives a connection reset, first try to restart the GUI server process from the system console, typically option 11, followed by option 16 to restart PHP-FPM. If that does not help, start a shell from the console (option 8), and type:

```
# sockstat | grep nginx
```

The firewall will return a list of all running `nginx` processes, and the port upon which they are listening, like this:

```
root     nginx      41948 5  tcp4   *:443                 *:*
root     nginx      41948 6  tcp6   *:443                 *:*
root     nginx      41948 7  tcp4   *:80                  *:*
root     nginx      41948 8  tcp6   *:80                  *:*
```

In that output, it shows that the process is listening on port 443 of each interface on both IPv4 and IPv6, as well as port 80 for the redirect, but that may vary based on the firewall configuration.

Try connecting to the firewall LAN IP address by using that port directly, and with both HTTP and HTTPS. For example, if the LAN IP address was `192.168.1.1`, and it was listening on port `82`, try `http://192.168.1.1:82` and `https://192.168.1.1:82`.

34.10 Troubleshooting OS Issues with a Debug Kernel

Starting with pfSense® Plus software version 23.01 there is a new package containing an operating system kernel and module set built with additional debugging enabled. This is known as a "Debug Kernel".

Note: In the past, there was a similar package which installed debug symbols but it did not include a full debug kernel or modules.

34.10.1 Installing the Debug Kernel

The debug kernel can be installed from the command line:

```
# pkg update
# pkg install -y pfSense-kernel-debug-pfSense
```

Warning: The debug kernel consumes a significant amount of disk space, ensure there is at least 1GB free.

Once installed, the debug kernel and associated module files are located in `/boot/kernel.debug` and debug symbols are under `/usr/lib/debug/boot/kernel/`.

34.10.2 Booting the Debug Kernel

After installing the debug kernel it can be activated in one of several ways:

Loader Menu

From the loader menu:

- Select menu option `6` until it says `kernel.debug`
- Select menu option `1` or press the `Enter` key to boot

This will boot the debug kernel one time and the next boot will revert back to the default kernel.

Loader Prompt

To reach a loader prompt, select menu option `3` from the loader menu or press the space bar during the kernel spinner on systems without a loader menu.

At the loader prompt, enter the following at the `OK` prompt:

```
boot kernel.debug
```

This will boot the debug kernel one time and the next boot will revert back to the default kernel.

Loader Configuration

To persistently boot from the debug kernel, add the following line as a *Loader Tunable*:

```
kernel="kernel.debug"
```

Save and exit, then reboot the firewall as usual from the GUI or console menu.

The next boot and all subsequent boots will use the debug kernel.

Warning: Do not leave the debug kernel persistently active when making a firmware upgrade. The upgrade process relies on booting from the default non-debug kernel. The package may remain installed, but it **must not be active** as a loader tunable during the upgrade process.

To temporarily switch back to the default non-debug kernel, use the loader menu or loader prompt as described in the previous sections, but boot `kernel` instead of `kernel.debug`.

To permanently switch back to the non-debug kernel, remove the `kernel` line from the *Loader Tunables*.

34.10.3 Removing the Debug Kernel

To remove the debug kernel, first boot from the non-debug kernel. Then, check for and remove any reference to the debug kernel in *Loader Tunables*.

Finally, remove the debug kernel package from the command line:

```
pkg delete pfSense-kernel-debug-pfSense
```

34.11 Troubleshooting Offline DHCP Leases

The **Status > DHCP Leases** page only reports clients as "online" if the MAC address for a given system appears in the ARP table on the firewall. This can be verified by checking **Diagnostics > ARP Table**.

Systems which have not communicated with or via the firewall in the past few minutes will appear as offline.

To check a system, try to ping it from **Diagnostics > Ping**. Even if the system does not respond to ping, that action will cause the system to appear in the ARP table if it is on the network, and would thus show online in the DHCP Leases list.

The *Arping Package* may also be of interest. It is available under **System > Packages**. The *Nmap package* can also be used to perform an ARP-based subnet scan to locate online hosts even if they don't respond to ICMP.

34.12 Troubleshooting DHCPv6 Client XID Mismatches

An IPv6 WAN configured to obtain is address via DHCPv6 can suddenly find itself without an IPv6 address if the transaction ID for the IPv6 DHCP client does not match.

When this happens, a log message similar to the following may appear in the DHCP and/or System logs:

```
dhcp6c[xxxxx]: client6_recvadvert: XID mismatch
```

When this happens, the most common cause is having multiple running copies of the DHCPv6 client (`dhcp6c`) on the same interface. Both clients send out a request with different transaction IDs and then get confused by the responses.

When this happens, the quickest way to ensure the clients are reset is to kill the duplicates and start the client again.

From the shell or from **Diagnostics > Command Prompt**, first check for duplicate clients:

```
# ps uxawww | grep dhcp6c
root xxxxx 0.0 0.0 5780 1488 ?? INs Sat09PM 0:00.90 /usr/local/sbin/dhcp6c -d -c /var/
↪etc/dhcp6c_wan.conf -p /var/run/dhcp6c_re1.pid re1
root xxxxy 0.0 0.0 5780 1524 ?? Is Tue07AM 0:00.30 /usr/local/sbin/dhcp6c -d -c /var/etc/
↪dhcp6c_wan.conf -p /var/run/dhcp6c_re1.pid re1
```

Once it has been confirmed that a duplicate client is running, `kill` them:

```
# killall -9 dhcp6c
```

Then navigate to **Interfaces > WAN**, click **Save**, then click **Apply Changes**.

The WAN should now have its IPv6 address once again.

34.13 Troubleshooting DMA and LBA Errors

34.13.1 Non-Fatal Errors

SETFEATURES Error

Newer snapshots and releases of pfSense® software attempt to setup APM for an ATA hard drive at boot. Sometimes the detection yields a non-fatal error when trying to find if the value is supported, or when the drive claims it's supported but can't set it. That error is:

```
ad0: FAILURE - SETFEATURES 0x85 status=41<READY,ERROR> error=4<ABORTED>
```

The error should only appear once at bootup on such systems, and can safely be ignored.

34.13.2 Fatal Errors

The following errors would indicate more serious problems such as a faulty HDD/SSD, faulty cable/controller, a faulty SATA/SD/IDE converter, a device out of space, or other similar condition.

```
ad0: FAILURE - READ_DMA status=51<READY,DSC,ERROR> error=40<UNCORRECTABLE> LBA=3919
```

```
ad0: WARNING - READ_DMA UDMA ICRC error (retrying request) LBA=207
ad0: WARNING - READ_DMA UDMA ICRC error (retrying request) LBA=207
ad0: FAILURE - READ_DMA status=51<READY,DSC,ERROR> error=84<ICRC,ABORTED> LBA=207
g_vfs_done():ad0s1a[READ(offset=65536, length=8192)]error = 5
```

```
ad0: FAILURE - WRITE_DMA status=51<READY,DSC,ERROR> error=4<ABORTED> dma=0x06 LBA=1129359
```

34.13.3 Other Errors

The following errors have been observed on certain hardware platforms running pfSense software. While they do not appear to be fatal, the cause appears to be a disk driver issue in FreeBSD (9.2 and later) and it may degrade performance. If these errors are encountered, attempt to reproduce the problem with a stock FreeBSD 10.1 or later installation and report the problem directly to FreeBSD.

```
(ada0:ata0:0:1:0): READ_DMA. ACB: c8 00 3f 95 07 40 00 00 00 00 08 00
(ada0:ata0:0:1:0): CAM status: ATA Status Error
(ada0:ata0:0:1:0): ATA status: ff (BSY DRDY DF SERV DRQ CORR IDX ERR), error: 00 ()
(ada0:ata0:0:1:0): RES: ff 00 46 95 07 00 00 00 00 00 00
(ada0:ata0:0:1:0): Retrying command
```

```
(ada0:ata0:0:1:0): WRITE_DMA. ACB: ca 00 ef e8 1a 40 00 00 00 00 08 00
(ada0:ata0:0:1:0): CAM status: ATA Status Error
(ada0:ata0:0:1:0): ATA status: ff (BSY DRDY DF SERV DRQ CORR IDX ERR), error: 00 ()
(ada0:ata0:0:1:0): RES: ff 00 ef e8 1a 00 00 00 00 08 00
(ada0:ata0:0:1:0): Retrying command
```

This appears to further be limited to onboard CF-to-SATA sockets. Using another disk type (mSATA, SATA, etc) may also be a viable workaround.

34.14 Troubleshooting DNS Resolution Issues

Working DNS resolution is critical for functional access to the Internet.

34.14.1 Test connectivity

Before diagnosing DNS issues with pfSense® software specifically, start with *Troubleshooting Network Connectivity* to ensure the firewall has a proper networking configuration and working connectivity. Specifically, ensure the firewall can reach hosts on the Internet by IP address and that clients can reach the both the firewall and hosts on the Internet by IP address.

34.14.2 Check DNS service

First check which DNS service is enabled on the firewall and how it is configured.

The default configuration uses the *DNS Resolver* in resolver mode (*DNS Resolver Mode*). This mode does not require specific *DNS Servers*, it queries the root DNS servers and other authoritative servers directly (*DNS Resolution Process*).

Installations upgraded from versions before the DNS Resolver became the default may be using the *DNS Forwarder*, which requires *DNS Servers* to be entered under **System > General Setup** or to be acquired from a dynamic WAN such as DHCP or PPPoE. The DNS Resolver can also operate in this manner if set to forwarding mode.

Whichever service is active, check if it is running under **Status > Services**.

If the DNS Resolver is active but the firewall is unable to resolve hostnames, the problem is usually a lack of working WAN connectivity. Aside from that, one possibility is that the WAN or upstream network gear does not properly pass DNS traffic in a way that is compatible with DNSSEC. Disable DNSSEC in the *DNS Resolver Configuration* to see resolution functions without DNSSEC. It is also possible that the ISP filters or rate limits DNS requests and/or requires the use of specific DNS servers. In that case, configure *DNS Servers* and then activate forwarding mode in the *DNS Resolver Configuration*.

34.14.3 Check DNS Servers

If the DNS Resolver is in forwarding mode, or the DNS Forwarder is active, then check if the firewall has DNS servers defined and ensure it can reach its DNS servers.

The firewall *DNS Server Settings* are under **System > General Setup**, and DNS servers obtained from dynamic WANs are also visible at **Status > Interfaces**. The best practice is to define at least two DNS servers. If there are multiple WANs, there should be at least one DNS server per WAN with an appropriate gateway set (*Interface and DNS Configuration*).

Perform a *Ping* test to check if the firewall can reach the DNS servers.

Note: Not all DNS servers respond to ICMP ping requests, so a failure here does not necessarily indicate a problem. Proceed to the next test to check if they respond to a DNS query.

34.14.4 Check Firewall DNS

Perform a *DNS Lookup* test to check if the firewall can resolve a hostname. The page will report the results of the query, which servers responded, and how fast they responded.

If using the DNS Resolver in resolver mode without DNS servers configured, then only `127.0.0.1` may be listed. So long as the query received the expected response, that is normal. If no response was received, ensure the DNS Resolver service is running. If it is running, disable DNSSEC and try again, or try forwarding mode. If either of those work, then the ISP may be restricting or redirecting DNS queries.

If DNS Servers are configured on the firewall or obtained from dynamic WANs, the DNS lookup page lists them and whether or not they responded.

If using the DNS Resolver in forwarding mode or the DNS Forwarder, the individual DNS server responses are important. If any of the servers did not respond, investigate them and potentially replace them with working servers.

If none of the servers respond, check the WAN connectivity (*Troubleshooting Network Connectivity*) and double check the DNS server IP addresses. If the firewall can reach the gateway address at the ISP, but not the DNS servers, double check the server IP addresses. If the DNS servers are obtained via DHCP or PPPoE and the firewall cannot reach them, contact the ISP. If all else fails, consider using a public DNS service such as Google public DNS, Quad9, or CloudFlare on the firewall instead of the DNS servers provided by the ISP. If those are already in use, The ISP may be restricting DNS queries so the only choice may be to use the ISP DNS servers.

34.14.5 Check Client DNS

If DNS works from the firewall but not from a client PC, it could be the DNS Resolver or Forwarder configuration on the firewall, the client configuration, or firewall rules.

Out of the box, the DNS Resolver handles DNS queries for clients behind the firewall. Older upgraded configurations may have the DNS Forwarder active in the same capacity.

If the client PCs are configured with DHCP, they will receive the IP address of the firewall interface to which they are connected as a DNS server, unless that is manually changed. For example, if a PC is on the LAN interface, and the firewall LAN IP address is `192.168.1.1`, then the client DNS server should also be `192.168.1.1`.

If the DNS Resolver and DNS Forwarder are disabled, adjust the DNS servers which get assigned to DHCP clients under **Services > DHCP Server**. Normally when the DNS Resolver and DNS Forwarder are disabled, the system DNS servers are assigned directly to the clients, but if that is not the case in practice for this setup, define them in the DHCP settings. If the client PC is not configured for DHCP, be sure it has the proper DNS servers set in its local configuration. This could be the LAN IP address of the firewall or an alternate set of working internal or external DNS servers.

Another possibility for DNS working from the firewall but not a local client is an overly strict firewall rule on the LAN. Check **Status > System Logs**, on the **Firewall** tab. If blocked connections appear in the log from the local client trying to reach a DNS server, then add a firewall rule at the top of the LAN rules for that interface which will allow connections to the DNS servers on **TCP and UDP** port `53`. If the client uses DNS over TLS, allow port `853` as well.

34.15 Troubleshooting the DNS Cache

34.15.1 DNS Resolver

To fully clear the DNS Resolver cache, restart the unbound daemon:

- Navigate to **Status > Services**
- Find unbound in the list

- Click  (restart) or click  (stop) then  (start)

Restarting the daemon will clear the internal cache, but client PCs may still have cached responses.

Alternately, issue a `reload` command using the CLI which will flush the cache without stopping the daemon:

```
unbound-control -c /var/unbound/unbound.conf reload
```

To selectively clear the DNS Resolver cache at the command line, run:

```
unbound-control -c /var/unbound/unbound.conf flush <name>
```

Where <name> is a domain name or hostname to be cleared.

Inspect the contents of the cache from the command line using:

```
unbound-control -c /var/unbound/unbound.conf dump_cache
```

34.15.2 DNS Forwarder

To clear the DNS Forwarder cache, restart the `dnsmasq` daemon:

- Navigate to **Status > Services**
- Find `dnsmasq` in the list
- Click  (restart) or click  (stop) then  (start)

Restarting the daemon will clear the internal cache, but client PCs may still have cached responses.

34.15.3 Client DNS Cache

The DNS cache on a Windows PC may be cleaned from a command prompt or **Start > Run**:

```
ipconfig /flushdns
```

This may need to be executed from an Administrator command prompt on Windows Vista and later.

Other operating systems will surely have other means to clear the DNS resolver cache. For example, Ubuntu-based distributions also use *dnsmasq*, and it may be restarted using:

```
sudo service network-manager restart
```

Browsers also have their own internal DNS caches separate from the OS. Close and re-open the browser if none of the above help.

As a last resort, rebooting/restarting a client will surely clear any locally cached data.

34.16 Troubleshooting DNS Queries

An administrator may need to troubleshoot issues with certain queries to the DNS Resolver (Unbound) or DNS Forwarder (dnsmasq). In such cases it can be helpful to view the queries received by the firewall and to see the responses generated.

For the DNS Resolver this can be accomplished by adding the following keyword to the **Custom Options** box on a new line:

```
server:
log-queries: yes
```

For the DNS Forwarder, add this line to the **Advanced Options** box:

```
log-queries
```

When saved, the DNS Resolver or Forwarder will begin logging the received queries and their replies, along with information about the result. The messages vary depending on the daemon. The DNS Forwarder logs whether an answer was pulled from the cache, but the DNS Resolver does not log extra data for queries answered from the cache.

Here are some examples of exchanges that might find in the query log:

A query using the DNS Resolver in forwarding mode to a system DNS server using DNS over TLS (not answered from the cache):

```
Oct  5 15:16:46 fw1 unbound[96103]: [96103:0] info: 192.168.1.100 daisy.ubuntu.com. A IN

↪215
Dec  3 08:49:21 dnsmasq[1068]: failed to send packet: Permission denied
```

34.17 Troubleshooting Disk and Filesystem Issues

pfSense® software will run a filesystem check (`fsck`) at boot when it detects an unclean UFS filesystem, typically from after a power outage or other sudden unclean reboot or shutdown. In rare cases, that isn't always enough, as a filesystem can become corrupted in other ways that may not always leave the drive marked unclean.

Note: This is not necessary for ZFS. There is no `fsck` equivalent for ZFS, and it is not prone to the issues for which UFS and other filesystem types require checks and repairs.

The command `zpool scrub <pool name>` can validate the contents of a pool, identify potential issues, and attempt to repair damage where possible. The scrub operation is not the same as `fsck`; it is not necessary in cases where `fsck` is typically needed and it does not require a read-only filesystem so it can be run at any time.

In these cases, perform one of the following repair methods.

34.17.1 Automatic Filesystem Check

These methods force a filesystem check during the boot sequence even if the drive is considered clean.

Note: This option is not present on all firewalls as it is not compatible with certain hardware. To run a manual check instead, see *Manual Filesystem Check*.

GUI

- Navigate to **Diagnostics > Reboot**
- Set **Reboot Method** to *Reboot with Filesystem Check*
- Click  Submit

The firewall will reboot and run the check. Monitor the console output for errors.

Console

- Connect to the console
- Choose the menu option to reboot from the console menu (`5`)
- Enter `F` (uppercase "f")

The firewall will reboot and run the check. Monitor the console output for errors.

34.17.2 Manual Filesystem Check

If an automatic filesystem check is not possible, run a manual check instead:

- Reboot the firewall into single user mode as described in *Entering Single User Mode*
- Press `Enter` when prompted for a shell
- Enter `fsck -fy /`
- Repeat the command at least **five** times, or until no errors are found nor fixed, even if the filesystem is reported clean.
- Exit single user mode as described in *Exiting Single User Mode*.

Example:

```
/boot/kernel/kernel data=0x19e4818+0x777e8 syms=[0x4+0x9a3b0+0x4+0xdc388]
|
Hit [Enter] to boot immediately, or any other key for command prompt.

Type '?' for a list of commands, 'help' for more detailed help.
loader> boot -s
[lots of boot output]
Enter full pathname of shell or RETURN for /bin/sh:
# fsck -fy /
[...]
# fsck -fy /
[...]
# fsck -fy /
[...]
# fsck -fy /
[...]
# fsck -fy /
[...]
# reboot
```

See also:

The Netgate Resource Library contains a video which walks through the process of running a filesystem check.

34.18 Troubleshooting Full Filesystem or Inode Errors

Error messages may appear on the console or main system log indicating that the hard drive in the firewall is full, such as:

```
/: write failed, filesystem is full
/: create/symlink failed, no inodes free
Warning: session_start(): open(/tmp/sess_XXXXXX, O_RDWR) failed: No space left on device
```

The typical cause of such errors is rarely that the drive is full, but that the operating system is unable to contact the drive. In short, the disk (HDD, SSD, CF, etc) is dead or dying.

In cases when the drive is dying, the OS tries to write to the drive, and receives back an error code that there aren't any inodes left. Typically other messages about the underlying problem are logged to the console but not passed back to PHP so they can be seen by the GUI. Usually those refer to things like g_vfs_done or *Troubleshooting DMA and LBA Errors*.

In order to eliminate the possibility that the drive is actually full, such as from a package that went crazy eating up space, try to get to a shell from the console or ssh, and run the following command:

```
: df -hi
```

The output shows disk space usage for both capacity and inodes, using human-readable numbers. The **System Information** widget on the Dashboard also shows the usage for all mounted partitions. The following output is from a system running with UFS:

```
Filesystem                     Size    Used   Avail Capacity iused ifree %iused  Mounted␣
↪on
/dev/ufsid/5ec430415d66e7cc     29G    1.9G     25G     7%     25k  4.0M    1%   /
devfs                          1.0K    1.0K      0B   100%       0     0  100%   /dev
/dev/md0                       3.4M    120K    3.0M     4%      43   979    4%   /var/run
devfs                          1.0K    1.0K      0B   100%       0     0  100%   /var/
↪dhcpd/dev
```

Note: The `devfs` lines do NOT indicate an actual problem; The `devfs` filesystem is virtual and used for housing device nodes not for files.

Of special concern is the space on `/var` and `/tmp` on systems configured to use RAM disks for those directories. Large files, such as an abnormally large DHCP leases file, can in fact fill up the `/var` memory disk and that is one way to encounter the problem.

If the root (`/`) slice has space and inodes remaining, and so do `/var` and `/tmp` and so on, then the problem is most likely a failing disk.

If disk space has been exhausted, find a way to free it up. This usually involves uninstalling or removing packages or changing the settings so they use less space.

If the disk is failing, swap it out as soon as possible.

Often when the drive is failing or full the system will continue routing packets indefinitely until it would need to access the hard drive, at which point it would quit. Users have reported firewalls running for months with a dead drive unnoticed before, though of course that is not advisable.

Another possible cause is mild filesystem corruption, which could be helped by *Troubleshooting Disk and Filesystem Issues*.

34.19 Troubleshooting Filesystem Capacity Shrinking

If the capacity of a ZFS dataset appears to shrink or reduce in size, the most likely reason is because the "missing" space is consumed by *ZFS Boot Environments* or ZFS snapshots created by the user manually.

ZFS Boot Environments/Snapshots consume space based on how different the current disk contents are compared to when the snapshot was taken. Rather than appear as filesystem usage like a traditional file, the apparent capacity of the filesystem is reduced instead. This allows traditional filesystem utilities to accurately account for space used by actual files vs filesystem data which is fundamentally different.

Tip: On systems with ZFS Boot Environments, use the ZFS Dashboard Widget to see the ZFS pool size as a total, rather than the size and consumption of individual filesystems.

Cleaning up older ZFS Boot Environments/snapshots will return the space they consumed and the capacity of the filesystem will increase accordingly.

See also:

Boot Environment Disk Space Usage

The ZFS Boot Environment list in the GUI displays a total amount of usage but it is possible to see a more detailed breakdown of usage with the `zfs list -t snapshot` command in the CLI:

```
: zfs list -t snapshot
NAME                                                    USED  AVAIL  REFER  MOUNTPOINT

```

34.20 Troubleshooting Disk Lifetime

An important part of keeping a firewall running reliably is to ensure its storage is in good condition.

If the disk in a firewall fails, it may continue to run in a reduced capacity until the system restarts. Exactly which parts may fail depends on the services and packages in use and what roles the firewall is performing. Packet filtering may continue to function indefinitely, but it may not be able to update rules, for example. Certain types of disks, such as SSD and eMMC disks, may fail into a read only state where disk writes fail or are discarded, but data can still be read.

34.20.1 Checking Disk Health & Lifetime

Contrary to popular rumors, the vast majority of modern flash storage found in SSD and eMMC drives is very resilient. Early SSDs were more prone to failure or only supported a comparatively small number of writes, but the technology has improved vastly over the years.

Traditional spinning platter hard drives have their own problems, such as failure of mechanical moving parts, which are harder to predict.

Over the lifetime of any disk, they typically will encounter failing spots and remap them to spares. This happens on traditional HDDs as well as SSDs. It's normal to see a small number of these over time, but if the pool of spares is almost consumed, the disk should be replaced.

Depending on the hardware it may be possible to query the disk for information about its health. Not all platforms support each method, and disk OEMs track data in different ways. When in doubt, contact the manufacturer of the disk for details.

SSD

Many SSDs can report their health through S.M.A.R.T. data as described in *S.M.A.R.T. Hard Disk Status* as well as perform disk tests. Disks connected using SATA, mSATA, M.2, and other similar methods can typically use the same methods as traditional HDDs, but may have SSD-specific health information in their S.M.A.R.T. data. For example, some SSDs will include a life time estimate or media wear indication level.

NVMe disks require special handling, but can also be queried through S.M.A.R.T., though the data they report may be in a different format from typical SSDs.

eMMC

eMMC disks are unique in that they do not support S.M.A.R.T. but hardware which supports the correct revisions of the eMMC specification are capable of reporting health in their own way.

Install MMC Utilities

The first step is to install the `mmc-utils` package from an SSH or console shell prompt:

```
# pkg install -y mmc-utils; rehash
```

Note: This package is currently only available on pfSense® Plus software and does not have a GUI component. It must be run from an SSH or console shell prompt.

Check MMC Health Status

To check the health of the first MMC disk, run the following command:

```
# mmc extcsd read /dev/mmcsd0rpmb
```

If the disk supports reporting its health, it should return output. For additional MMC disks, increase the device number in the command.

34.20.2 Interpreting MMC Health Data

The primary fields to look at in MMC health are the life time estimations and Pre-EOL estimation.

Note: Not all disks support all of these fields.

```
: mmc extcsd read /dev/mmcsd0rpmb | egrep 'LIFE|EOL'
eMMC Life Time Estimation A [EXT_CSD_DEVICE_LIFE_TIME_EST_TYP_A]: 0x01
eMMC Life Time Estimation B [EXT_CSD_DEVICE_LIFE_TIME_EST_TYP_B]: 0x02
eMMC Pre EOL information [EXT_CSD_PRE_EOL_INFO]: 0x01
```

Type A
An estimate for life time of SLC (and pseudo-SLC) eraseblocks in steps of 10%.

Type B
An estimate for life time of MLC eraseblocks in steps of 10%.

Type A and B Values
The values of the A and B life time estimations are in 10% increments based on the hexadecimal value returned by the disk. This is only an estimate and the value can exceed 100%.

Possible values include:

Value	Meaning
0x00	Not defined
0x01	The disk has used 0%-10% of its estimated life time
0x02	The disk has used 10%-20% of its estimated life time
0x03	The disk has used 20%-30% of its estimated life time
0x04	The disk has used 30%-40% of its estimated life time
0x05	The disk has used 40%-50% of its estimated life time
0x06	The disk has used 50%-60% of its estimated life time
0x07	The disk has used 60%-70% of its estimated life time
0x08	The disk has used 70%-80% of its estimated life time
0x09	The disk has used 80%-90% of its estimated life time
0x0a	The disk has used 90%-100% of its estimated life time
0x0b	The disk has used 100%-110% of its estimated life time

Warning: This is only an estimation. Though useful as a general guideline, it does not necessarily indicate that a disk will fail at a given time.

Pre-EOL
Pre EOL information is an overall status for reserved blocks on the disks.

Possible values are:

Value	Severity	Meaning
0x00		Not defined.
0x01	Normal	The disk has consumed less than 80% of its reserved blocks
0x02	Warning	The disk has consumed more than 80% of its reserved blocks
0x03	Urgent	The disk has consumed more than 90% of its reserved blocks

HDD

Most HDDs can report their health through S.M.A.R.T. data as described in *S.M.A.R.T. Hard Disk Status* as well as perform disk tests. S.M.A.R.T. may need to be enabled both in the system BIOS and on the disk, though in modern systems these tend to both be enabled by default.

USB Disks

Disks connected through USB controllers are unlikely to support health queries, no matter what type of disk they are.

34.20.3 Taking Action

If a disk is showing signs that it might be failing, the safest action is to replace the disk. If a device has a built-in disk like an eMMC disk that cannot be replaced, it may be capable of taking an additional drive using another means such as NVMe, M.2, mSATA, or SATA. When in doubt, contact the device OEM for guidance.

If the disk is showing some wear but still has a lot of life left, consider making changes to *reduce disk writes* to potentially extend its remaining lifetime.

34.21 Troubleshooting Disk Writes

Certain tasks can make the firewall write lots of data to the disk, which could impact the health of the hardware over time. This is not as large a concern on modern disks, even SSDs, but can still be a factor over long time spans.

There are ways to reduce the amount of writes which happen on the disk, depending on the needs of the firewall and its environment.

34.21.1 RAM Disks

The `/var` and `/tmp` directories on the firewall contain most of the files which are highly volatile. The firewall has an option to keep these volatile areas in RAM disks under **System > Advanced** on the **Misc** tab.

See also:

RAM Disk Settings

Enabling RAM disks for `/var` and `/tmp` does have some caveats, which are noted in *RAM Disk Settings*. For instance, it requires sufficient RAM to hold them comfortably without filling up, and it can potentially lead to loss of logging and monitoring data if the firewall suffers a power loss.

Overall, however, if there is enough RAM to spare, using RAM disks will drastically reduce disk writes over time.

34.21.2 Disable Write-Heavy Features

One method to limit writes is by disabling features which cause lots of disk writes.

Logging
: It is possible to disable local logging, and optionally use only remote logging (*Log Settings*). This eliminates all writing of logs to the local disk. Logging is one of the primary sources of disk writes on an ongoing basis.

  This can make troubleshooting on the firewall more difficult, so it's not a best practice.

RRD Graphs
: It is possible to disable the system monitoring RRD graphs which are frequently updated with new monitoring data (*Graph Settings*).

  Instead of monitoring this data locally, most of this data can be monitored remotely by an NMS using SNMP.

DHCP Server
: On a busy network the DHCP lease database can be large and is rewritten frequently. Disabling the *DHCP server* on all interfaces and moving DHCP service to another device will result in decreased load on the firewall disk.

  This tends to be prohibitively inconvenient in most deployments, so in practice this is rare.

Note that all of these features write data in `/var` so if `/var` is in a RAM disk, they can safely remain enabled.

34.21.3 Avoid Write-Heavy Packages

Another way to reduce disk writes is to minimize use of packages that can cause heavy disk writes.

pfBlockerNG, Snort, Suricata, HAProxy
: These can write a lot due to logging and rule updates.

nmap, darkstat, other monitoring
: These use lots of disk writes to maintain databases and reports.

See also:

The package list at *Package List* also notes when specific packages require or work better with an SSD or HDD.

34.21.4 Reinstall

If it has been a while since the firewall OS was installed, reinstalling and restoring from backup can help as well.

Filesystem properties are sometimes optimized in a new release, such as ZFS dataset layouts and attributes. Installing again will ensure the firewall is using the most optimal disk layout.

34.22 Troubleshooting Thread Errors with Hostnames in Aliases

If a large number of hostnames are present in aliases, the following error may appear in the system log:

```
filterdns: Unable to create monitoring thread for host myhost.example.com! It
will not be monitored
```

This error indicated that the `filterdns` daemon hit the limit of the number of concurrent threads it could launch in order to resolve and monitor the hostnames properly.

The cure for this is to raise the number of allowed threads per process. This can be done by navigating from the pfSense® software GUI to **System > Advanced** on the **System Tunables** tab. There, create an entry for `kern.threads.max_threads_per_proc` and set it to `4096`.

After raising that value, `filterdns` must be restarted. This can be done by any method that triggers a filter reload, such as navigating to **Status > Filter Reload** and clicking **Reload Filter**.

34.23 Troubleshooting Firewall Rules

This section provides guidance for troubleshooting issues with firewall rules.

34.23.1 Check The Firewall Logs

The first step when troubleshooting suspected blocked traffic is to check the firewall logs (**Status > System Logs**, on the **Firewall** tab).

By default pfSense® software logs all dropped traffic and will not log any passed traffic. Unless block or reject rules exist in the ruleset which do not use logging, all blocked traffic will be logged. If there are no log entries with a red  in the firewall logs which match the traffic in question, pfSense software is not likely to be dropping the traffic.

34.23.2 Check the State Table

Attempt a connection and immediately check the state table at **Diagnostics > States** and filter on the source or destination to see if a state exists. If a state table entry is present, the firewall has passed the traffic.

If the rule in question is a pass rule, the state table entry means that the firewall passed the traffic through and the problem may be elsewhere and not on the firewall.

If the rule is a block rule and there is a state table entry, the open connection will **not** be cut off. To see an immediate effect from a new block rule, the states must be reset. See *Firewall States* for more information.

34.23.3 Review Rule Parameters

Edit the rule in question and review the parameters for each field. For TCP and UDP traffic, remember the source port is almost never the same as the destination port, and should usually be set to *any*.

If the default deny rule is to blame, craft a new pass rule that will match the traffic to be allowed. If the traffic is still blocked, there may be some other special aspect of the packets which require additional handling in the rule configuration. For example, certain multicast traffic may need to have **Allow IP Options** enabled, or the log entries may be due to asymmetric routing, or the packets may have an invalid combination of parameters such as a fragmented packet with "Don't Fragment" set inside.

See also:

- *Bypass Firewall Rules for Traffic on Same Interface*
- *Static Route Filtering*
- *Troubleshooting Asymmetric Routing*
- *Troubleshooting Blocked Log Entries for Legitimate Connection Packets*

In such advanced cases, running a packet capture for the traffic in question can help diagnose the problem. Refer to *Packet Capturing* for more information on how to capture and analyze packets.

Protocol

The protocol to which the rule will apply must be specified. Most often, this is TCP, UDP, or ICMP, but other protocols such as ESP, AH, and GRE are regularly encountered when dealing with VPNs.

Confusion arises when a firewall administrator is unsure of what protocol to use. A rule set with TCP may not work because the application being filtered may actually use UDP instead. When in doubt, try using TCP/UDP.

34.23.4 NAT Confusion

When crafting rules for firewalls involving inbound NAT connections, remember to use the **private IP address** as the Destination. This applies for port forwards as well as 1:1 NAT

34.23.5 Port Forward *pass* action

When creating a port forward, the *pass* action will bypass firewall rules and pass the traffic directly through without filtering. Change the setting to create an associated rule and then arrange the block rule above the resulting pass rule.

34.23.6 Source and Destination Ports

When crafting rules, bear in mind that typically only a source *or* a destination port needs to be specified, and rarely both. In the majority of cases, the source port does not matter at all. For example, to allow ssh access to the firewall, only specify a **destination** port of `22`. The source port of the client will be random.

34.23.7 Review Rule Ordering

Firewall rules are generally processed as follows:

- Floating Rules
- Interface Group rules
- Interface tab rules

See also:

See *Ordering of NAT and Firewall Processing* for more details.

If a floating rule with **quick** checked passed the traffic, then a block rule on an interface would have no chance to match the traffic.

34.23.8 Rules and Interfaces

Ensure rules are on the correct interface to function as intended. Traffic is filtered only by the ruleset configured on the interface where the traffic is *initiated*. Traffic coming from a system on the LAN destined for a system on any other interface is filtered by **only** the LAN rules. The same is true for all other interfaces.

34.23.9 Enable Rule Logging

Determine which rule is matching the traffic in question. The hit counters in the rule list can help with this to some degree. By enabling logging on pass rules, the firewall logs will show an individual entry specifically to determine which rule passed the connection.

34.23.10 Troubleshooting with packet captures

Packet captures can be invaluable for troubleshooting and debugging traffic issues. With a packet capture, it is easy to tell if the traffic is reaching the outside interface or leaving an inside interface, among many other uses. See *Packet Capturing* for more details on troubleshooting with packet captures.

34.23.11 New Rules Are Not Applied

If a new rule does not appear to apply, there are a couple possible explanations.

First, If the rule is a block rule and there is a state table entry, the open connection will **not** be cut off. See *Check the State Table*.

Second, the ruleset may not be reloading properly. Check **Status > Filter Reload** to see if an error is displayed. Click the  **Reload Filter** button on that page to force a new filter reload. If an error is displayed, resolve the problem as needed. If the cause is not obvious, consult support resources for assistance.

If none of the above causes are to blame, it's possible that the rule is not matching at all, so review the traffic and the rule again.

34.23.12 Unfilterable Traffic

Certain traffic cannot be filtered. Not because the pfSense software isn't capable, but because they actually do not touch the firewall at all. A prime example of this is trying to keep one device on the LAN from accessing another device on the same LAN. This is not possible if both clients are on the same subnet and switch; In that case, the routing of packets is handled at the switch level (layer 2), and the firewall has no knowledge of the traffic. If there is a need to control access in this way, the devices in question must be on separate firewall interfaces. When on different "legs" of the network, their traffic will route through the firewall, the firewall will have full control of the flow.

34.23.13 UPnP IGD & PCP passed traffic

If *UPnP IGD & PCP* is enabled and a LAN device opens a port to the world, the traffic may still get in even if it appears it should otherwise be blocked.

34.23.14 Asymmetric Routing

If reply traffic such as `TCP:A`, `TCP:SA`, or `TCP:RA` is shown as blocked in the logs, the problem could be asymmetric routing. See *Troubleshooting Asymmetric Routing* for more info.

34.23.15 Ruleset Failing to Load

It is also possible that the rules are not being loaded properly. Typically this would result in a notification in the GUI, however manual tests can be performed to check.

From the GUI, visit **Status > Filter Reload**. Click  **Reload Filter** wait for the process to stop, then scroll to the bottom of the page to see if the last line says `Done.` or if it stops. If it stops, for example in a particular package, then there may be a problem with that package.

The ruleset can also be verified from the console or **Diagnostics > Command** in the **Shell Execute** box by running:

```
pfctl -f /tmp/rules.debug
```

If an error is displayed, it may have an obvious fix, or search for that error to find possible resolutions.

34.23.16 Other Causes

There are other pitfalls in firewall rules, NAT, routing, and network design that can interfere with connectivity. See *Troubleshooting Network Connectivity* for more suggestions.

See also:

Hangouts Archive to view the June 2016 hangout on Connectivity Troubleshooting which contains much more detailed troubleshooting procedures.

34.24 Troubleshooting Bogon Network List Updates

Make sure the firewall can resolve DNS host names and can reach the bogons host, otherwise the update will fail.

To ensure the firewall can resolve the bogon update host via DNS, perform a *DNS Lookup*:

- Navigate to **Diagnostics > DNS Lookup**
- Enter `files.pfsense.org` in the **Hostname** field
- Click **Lookup**

If that fails, *troubleshoot DNS resolution* for the firewall itself.

If that works, then perform a *port test* as demonstrated in Figure *Testing Connectivity for Bogon Updates*:

- Navigate to **Diagnostics > Test Port**
- Enter `files.pfsense.org` in the **Hostname** field
- Enter `80` in the **Port** field
- Click **Test**

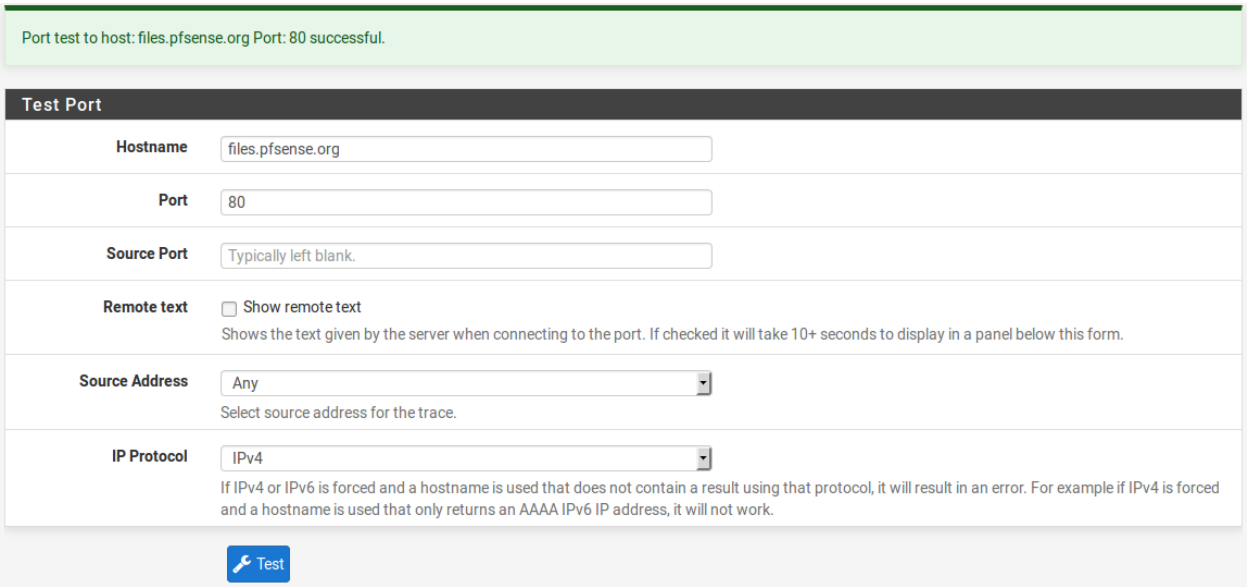

Fig. 2: Testing Connectivity for Bogon Updates

If that fails, *troubleshoot connectivity from the firewall*.

34.24.1 Forcing a Bogon Network List Update

With the relatively infrequent changes to the bogons list, and advance notice of new public IP assignments, a monthly bogons update is adequate. However there may be scenarios where a manual bogon update can help, such as if the bogon updates have been failing because of an incorrect DNS configuration. Execute an update via the GUI:

- Navigate to **Diagnostics > Tables**
- Select *bogons* or *bogonsv6* from the **Table** list
- Click  **Update**

34.25 Troubleshooting FTP Connections

pfSense® software does not have a built-in FTP proxy, but one is available as an add-on package.

See also:

- *Using NAT and FTP without a Proxy*

34.25.1 Rules to allow FTP

If problems are encountered with FTP, check the rules to/from FTP devices, ensure that both the control port and PASV range are allowed.

34.25.2 Troubleshooting/Alternatives

- Disable the FTP Proxy and attempt the connection again
- Use SCP/SFTP which only needs one port to traverse the firewall since it is wrapped in SSH (a safe AND simple way of traversing a firewall!)
- Don't use FTP (highly recommended option)

34.26 Troubleshooting Gateway Monitoring

In some cases, the dpinger gateway monitoring daemon will output numeric error codes in the Gateways log indicating a problem reaching the monitored target IP address. The errors on this page are the most common.

34.26.1 sendto error: 55

```
55 ENOBUFS
No buffer space available.
An operation on a socket or pipe was not performed because the system lacked sufficient␣
↪buffer space or because a queue was full.
```

Several possible conditions can cause this. For a list of possible causes and solutions, see *Troubleshooting "No buffer space available" Errors*.

34.26.2 sendto error: 64

```
64 EHOSTDOWN
Host is down.
A socket operation failed because the destination host was down.
```

In this case, the firewall is unable to reach a target host directly connected at layer 2 (No ARP response), or it received a similar error response from an upstream source. Generally this only happens due to remote problems, indicating that the target is actually down or the L1/L2 link to the target is down.

34.26.3 sendto error: 65

```
65 EHOSTUNREACH
No route to host.
A socket operation was attempted to an unreachable host.
```

Either there is no possible route to the target locally, or status information was received from an upstream router that indicated the same condition elsewhere along the path to the target.

This can happen due to a lack of default route, missing interface link route, or similar conditions.

34.27 Troubleshooting High Availability DHCP Failover

There are several potential scenarios that can cause problems with DHCP service for a high availability cluster. This document contains items to check as well as potentially problematic scenarios and workarounds.

The issues and limitations encountered here vary depending on which DHCP daemon backend is active.

34.27.1 Common Issues

These issues may affect high availability DHCP failover no matter which backend is active.

Time Not Synchronized

The system time on both cluster nodes must be within 90 seconds of each other. Otherwise the time difference is too large and the DHCP daemon processes will not communicate.

34.27.2 Kea DHCP Daemon

These issues may affect high availability DHCP failover when the Kea DHCP backend is active.

Kea High Availability Node Status

Check the DHCP Leases or DHCPv6 Leases to see the current status of failover for each daemon. The High Availability status for Kea DHCP operates identically for both DHCP and DHCPv6. For details on how the DHCP HA status operates, see *High Availability Status – Kea DHCP Only*.

If any of the peers are in a state other than `hot-standby` it may indicate a problem. The solution is likely in one of the other answers in this document.

Incorrect Failover Peer Address

The **Settings** tab for DHCP and DHCPv6 service defines the failover peers for HA in Kea.

The address in this field **must** be an actual **interface IP address** on the peer – **not** a CARP VIP, other shared address. Most often this is the IP address of the Sync interface on each node.

Note: The address family does not need to match the family of the DHCP daemon, for example, DHCPv6 HA can be performed using IPv4 peer addresses.

When XMLRPC synchronization is enabled the primary node will adjust this automatically when copying settings to the secondary node, swapping the local and remote values appropriately.

Failover Peer Unreachable

If the peers are both active but cannot communicate with each other, they may both consider the peer to be in an unreachable state. If this happens, both nodes may hand out addresses at the same time, causing a conflict. Double check the IP addresses and ports used for failover as well as the firewall rules on the interfaces involved.

Firewall Rules

For two DHCP peers to exchange failover data they must be able to reach each other on the configured ports through the interfaces containing the configured local and remote addresses. These addresses are typically on the Sync interface.

It may be necessary to add firewall rules to pass the sync traffic, for example when using strict firewall rules on the Sync interface.

The primary node must be allowed to reach the secondary node on the defined port (default `8765` for DHCPv4 and `8766` for IPv6) using the **Remote Address** defined in the DHCP settings, and vice versa. Check the firewall rules on the Sync interface and add rules as needed to pass this traffic.

Secondary Does Not Enter `partner-down` State

In certain cases with customized **Advanced** settings, a secondary node may not enter the `partner-down` state even when the primary is unreachable. Usually this happens because of the **Max Unacked Clients** setting, which instructs the daemon to wait for that many clients to send unanswered DHCP requests before it will take over.

While this setting can help prevent a secondary node from taking over too quickly in certain cases, a high value for **Max Unacked Clients** will prevent that number (minus 1) clients from getting addresses until another client also requests an address and goes unanswered. On a large and busy network this may not take long, but on a small or quiet network this could take a significant amount of time and leave some clients stranded. If too many clients are going unanswered for too long, lower the value until clients are served in a timely manner during a failure of the primary node.

The default value is `0` which causes the secondary to take over immediately after the primary has been unresponsive (default time: 60 seconds).

Mismatched TLS Settings

The TLS settings for Kea DHCP and DHCPv6 HA do not synchronize via XMLRPC as they may be different on each node. If the TLS settings are not configured in an appropriate way that aligns for both nodes, then the two nodes cannot communicate and DHCP HA will fail.

When using TLS transport, ensure each node has the **Server certificate** option set to use a **Server** type certificate signed by a CA trusted by both peers (e.g. both using the same CA).

When using mutual TLS, ensure each node is using an appropriate **User** certificate signed by the same CA in the **Client certificate** option.

34.27.3 ISC DHCP Daemon

These issues may affect high availability DHCP failover when the ISC DHCP backend is active.

Interface Order Mismatch

The interfaces must be assigned identically on both nodes, for example: wan=WAN, lan=LAN, opt1=Sync, opt2=DMZ. Check the `config.xml` contents directly to ensure a match. If the interface are not assigned in the same order, the automatically generated failover pool names will not match, which prevents DHCP failover from working.

Pool Status

Look at the pool status section at **Status > DHCP leases**. All defined pools (often 1 per interface) are listed at the top of that page.

If any of the pools are in a state other than "normal", then debug the problem further. The solution is most likely found in one of the other items in this document.

If the pool status on both nodes is "normal" for a given interface, then issues with clients obtaining leases on that interface is not likely a problem in the DHCP configuration or failover, but elsewhere. For example, an L2 or switch problem, client problem, etc.

Incorrect Failover Peer Address

Each interface tab in the DHCP server options has a separate field for the Failover Peer IP address. This field must be filled in for each interface participating in DHCP with HA. The address in this field **must** be the actual **interface IP address** on the peer corresponding to the chosen tab – **not** a CARP VIP, other shared address, or an address from an unrelated interface (e.g. The SYNC interface).

When XMLRPC synchronization is enabled the primary node will adjust this automatically when copying settings to the secondary node, filling in its own IP address for the interface.

Failover Peer Unreachable

If one failover peer cannot contact the other peer when it starts up, it will stop itself from handing out leases intentionally. It does this as a fail safe to prevent itself from handing out conflicting lease data.

This can happen if, for example, both nodes suffer a power loss and only one recovers. Another common scenario is if one node suffers a hardware failure and the working node must be rebooted before the failed node can be repaired.

Correcting this can be tricky. The simplest way to correct it is to bring the other peer online if possible. If that is not possible, then the only way may be to remove the failover peer IP addresses from each DHCP interface configuration so the node no longer believes it should be part of a failover pool. When the other node recovers, the configuration can be put back in place.

Firewall Rules

For two DHCP peers to exchange failover data, they must be able to reach each other on an interface. There are typically automatic firewall rules which handle this, but there have been issues in the past where these automatic rules did not cover every possible scenario.

If the firewall log shows this traffic being blocked, then it may be necessary to add manual rules to pass the traffic. Ensure the two nodes are allowed to communicate on every relevant interface. The primary node must be allowed to receive traffic on TCP port 519 from the secondary node and the secondary node must be allowed to receive traffic on TCP port 520 from the primary node.

Restart DHCP Daemons

Stop and restart the DHCP daemon from **Status > Services** on both nodes and check the status after a few moments. This may correct the issue or at least provide better detail in the logs during the startup procedure for the daemons.

Check CARP VIP Configuration

Check the CARP VIP configuration for VIPs on interfaces used for DHCP failover. The primary node must have an **Advertising Frequency Skew** value *below* `20`, the secondary node must have an **Advertising Frequency Skew** value *above* `20`.

Mismatched Versions

Both nodes must be running the same version of pfSense® software. Update both nodes to the newest available stable release if they do not match. Older versions may have problems with various aspects of DHCP failover that have already been corrected.

Reset Lease Database

If the two nodes cannot agree on the pool status, it may be due to the contents of the lease databases. This can sometimes happen when first setting up failover or after reinstalling an HA node without backing up and restoring its DHCP lease database.

If all else fails, perform the following:

- Stop the DHCP daemon on both nodes
- Remove the DHCP lease database files from `/var/dhcpd/var/db/dhcpd.leases*` on both nodes
- Start the DHCP daemon on both nodes

It's important to perform each step on both nodes individually and not do the whole procedure at once on each node; the important part is that they both start at the same time with a new empty lease database.

Inconsistent Client Hostnames

The DHCP servers on each node in a failover configuration work in coordination with one another. Each server will handle a portion of the total pool and relay lease information to the failover peer.

The lease information the nodes exchange, however, does not include client hostnames. This means that features which rely on DHCP hostnames, such as DNS resolution of DHCP client hostnames, will not work consistently when using DHCP failover.

This is a limitation of the ISC DHCP daemon and not something that can be changed or corrected in pfSense software.

Currently the most viable workaround is to define static DHCP mappings for each host that must be resolved via DNS.

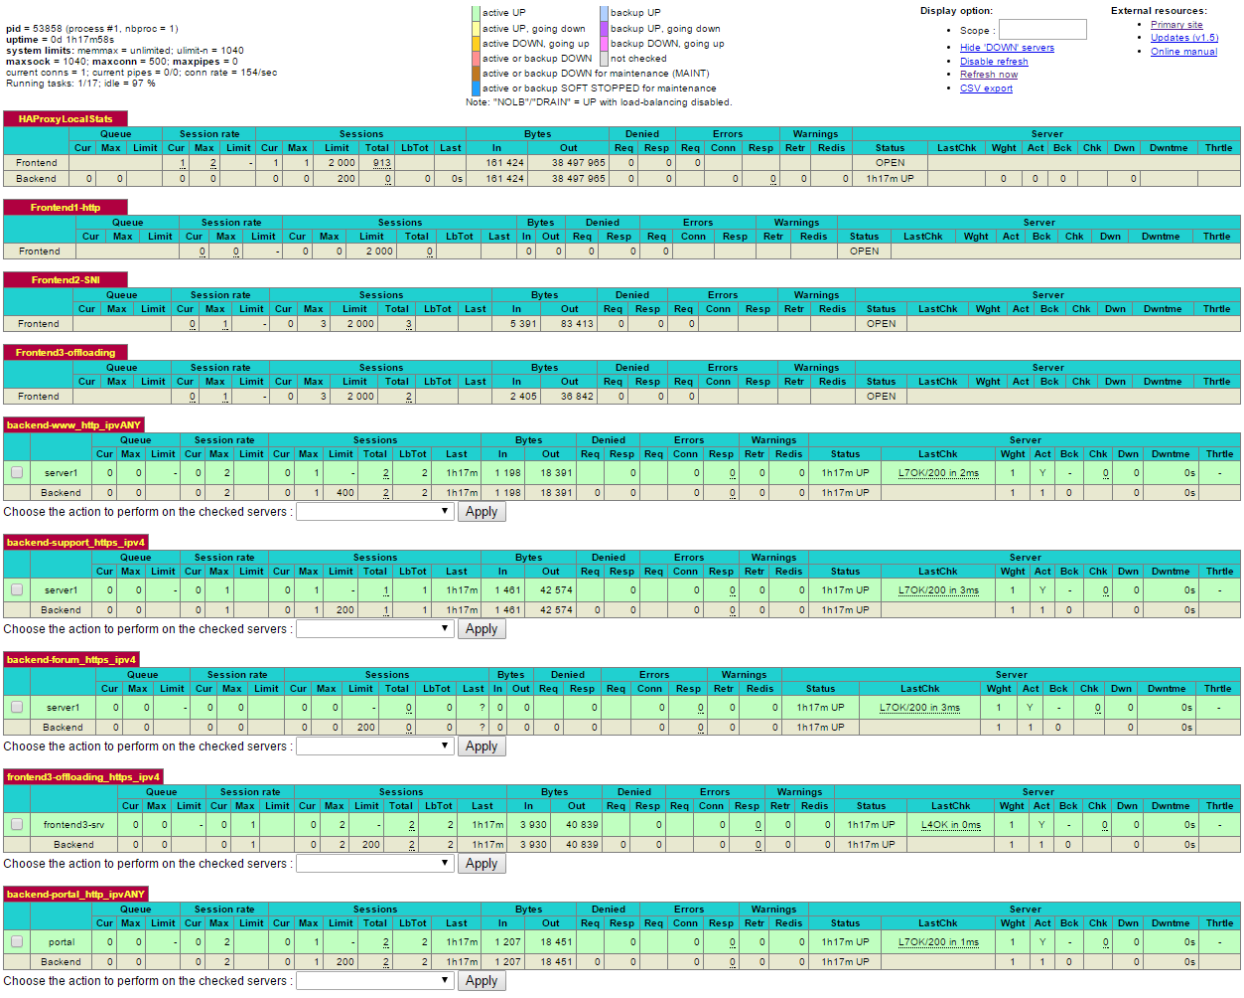
34.28 Troubleshooting the HAProxy Package

Troubleshooting steps for *HAProxy package*.

For troubleshooting there are 2 parts are helpful, depending on the issue:

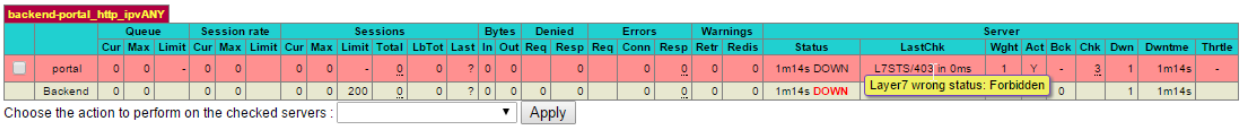
- Stats page
- Syslog logging

34.28.1 Stats

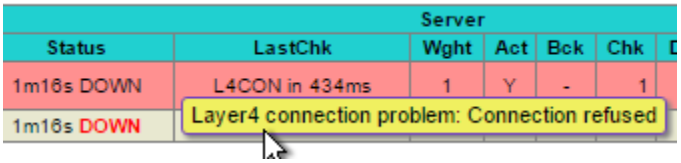


If health checks have been configured on the servers, the backend will show what servers are up or down. Layer 7 checks provide the most information about this, but a layer 6 or 4 check can also be useful.

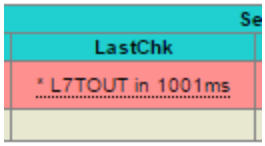
If a server is shown in red like here, hover over the check result for a second. It will tell what the short error code means in a more readable description:



There are different error codes that ask for different resolution.



or



A layer 4 issue might indicate that a wrong server ip or port was filled in, or that the server is not running / accepting connections. A firewall on the server itself, or a missing route could all cause these kinds of issues. A layer 6 issue indicates a problem with the SSL certificates. A layer 7 issue would generally be due to a unexpected or no status returned by the webserver, the webserver might take to long to present the checked url. Or the webserver does not support the configured check method/options.

For configuring the healthcheck, the following options should be accepted by most webserver, but are more difficult to filter out from normal webserver logs:

```
option httpchk GET / HTTP/1.1\r\nHost:\ www.yourdomain.com\r\nAccept:\ */*
```

If the backend requires authentication, another option could be to change the url to a different page that does not need authentication, perhaps specifically added to the webserver for this purpose:

```
option httpchk GET /healthcheck.php
```

Or accept that authentication error as the 'valid' result:

```
http-check expect status 401
```

34.28.2 Syslog

If all backend servers are 'up' in the stats, but 'sometimes' users are reporting problems, then logging is important to configure and collect.

Haproxy allows for configuring syslog server destination on the settings tab. The actual logging to files must by configured on that destination syslog server. The default log format is rather detailed if configured for the appropriate format. As such the 'Detailed logging' option in the frontend edit page should be checked. For mode HTTP servers the following will be configured in the config file:

```
option httplog
```

For mode TCP servers the following will be configured in the config file:

```
option tcplog
```

If needed, it's also possible to capture additional traffic headers which will be added into the syslog messages.

More information about these options can be found in the official documentation: Official HAProxy manual

34.29 Troubleshooting VPN Connectivity to a High Availability Secondary Node

If there is a VPN connection to a High Availability cluster (site-to-site or remote access/mobile), often remote devices can communicate with the active node but the backup node is unreachable.

The reason for this is that the VPN is configured and active on both firewalls. The packet from the client goes to the primary over the VPN tunnel that is up and connected, then goes from the primary to the secondary, and the secondary attempts to send it back over its own copy of the VPN which is down because it is the backup. The response never makes it back to the original client.

To address this situation, configure Hybrid or Manual outbound NAT and add rules such that the firewall performs NAT on the traffic from the VPN subnet going to IP addresses on the secondary node, and vice versa. that way these connections appear to originate from the opposing firewall and not the VPN, so the traffic returns as expected. Hybrid or Manual Outbound NAT is likely already enabled set since it is typically a requirement for HA using CARP VIPs.

For example, set the mode to **Hybrid Outbound NAT** and add an outbound NAT rule on the LAN interface. Configure the rule with the source being the VPN subnet, destination being an alias containing both the primary and secondary node LAN IP addresses. Translation would be **Interface Address** (NOT the CARP VIP!).

With the NAT rule present, when attempting to access the opposing node over the VPN the traffic will appear to originate from the node to which the VPN is currently connected and the return traffic will go back as expected.

34.30 Troubleshooting High Availability

High availability configurations can be complex, and with numerous different ways to configure a failover cluster, it can be tricky to get things working properly. This section discusses common problems and solutions for the majority of cases. If issues are still present after consulting this section, there is a dedicated HA/CARP/VIPs board on the Netgate Forum.

Before proceeding, take the time to check all members of the HA cluster to ensure that they have consistent configurations. Often, it helps to walk through the example setup, double checking all of the proper settings. Repeat the process on the secondary node, and watch for any places where the configuration must be different on the secondary. Be sure to check the CARP status (*Check CARP status*) and ensure CARP is enabled on all cluster members.

Errors relating to HA will be logged in **Status > System Logs**, on the **System** tab. Check those logs on each system involved to see if there are any messages relating to XMLRPC sync, CARP state transitions, or other related errors.

See also:

The issues on this page are for HA in general. For issues specific to using HA in virtual environments, see *Troubleshooting High Availability Clusters in Virtual Environments*

34.30.1 Common Misconfigurations

There are several common misconfigurations that happen which prevent HA from working properly.

Incorrect Interface Order

As mentioned on *pfSense Software XMLRPC Config Sync Overview*, the interface assignment order and internal identifiers must match identically on both nodes.

If the interface order does not match, the configuration synchronziation process will copy rules and other settings such as DHCP failover to different/unexpected interfaces on the secondary node.

Use a different VHID on each CARP VIP

Every CARP VIP on a given interface or broadcast domain must use a different VHID. The VHID determines the virtual MAC address used by a CARP IP address, thus different clusters attempting to use the same VHID on the same L2 segment cause a MAC address conflict.

Within a single HA pair, input validation prevents configuring duplicate VHIDs. Unfortunately, it isn't always that simple. CARP is a multicast technology, and as such anything using CARP on the same network segment must use a unique VHID, even if it is a different subnet. Other protocols such as VRRP and HSRP also use protocols similar enough to CARP that they can conflict, so ensure there are no other devices using similar VHIDs with other protocols, such as if the ISP or another router on the local network is using VRRP.

The best way around this is to use a unique set of VHIDs. If a known-safe private network is in use, start numbering at 1. On a network where VRRP or CARP are conflicting, consult with the administrator of that network to find a free block of VHIDs. Performing a packet capture on the segment an analyzing it with tools such as Wireshark may also reveal other hosts sending similar multicast messages with IDs to avoid.

Incorrect CARP VIP Settings

Inspect the settings for CARP VIPs (**Firewall > Virtual IPs**) to ensure they are correct and consistent on both nodes.

The **Advertising Frequency** values must be appropriate for each VIP and node:

Base
: Values should be the same on both nodes. In some situations where the secondary node is on a slow or non-local link, users have increased this value on only the secondary, but that can lead to problems with each node assuming their expected roles at the proper times.

Skew
: Values must be different on the primary and secondary nodes. The primary is typically `1` or `0`, and the secondary is typically `100`.

Incorrect Times

Check that all nodes involved are properly synchronizing their clocks using NTP and have valid time zones, especially if running in a Virtual Machine. If the clocks are too far apart, some synchronization tasks like DHCP failover will not work properly.

Incorrect Subnet Mask

The real subnet mask **must** be used for a CARP VIP, **not** `/32`. This **must** match the subnet mask for the IP address on the interface to which the CARP VIP is assigned.

Both Nodes in Maintenance Mode

If both nodes have activated **Persistent CARP Maintenance Mode** at **Status > CARP (failover)**, they each will advertise a skew of `254` and the actual status will be unpredictable. Ensure only one node is in maintenance mode at a time.

34.30.2 Incorrect Hash Error

There are a few reasons why this error turns up in the system logs, some more worrisome than others.

If CARP is not working properly when this error is present, it could be due to a configuration mismatch. Ensure that for a given VIP, that the VHID, password, and IP address/subnet mask all match.

If the settings appear to be proper and CARP still does not work while generating this error message, then there may be multiple CARP instances on the same broadcast domain. Disable CARP and monitor the network via packet capturing to check for other CARP or CARP-like traffic (*Packet Capturing*), then adjust VHIDs appropriately.

If CARP is working properly and this message is in the logs when the node boots up, it may be disregarded. It is normal for this message to be seen during boot, as long as CARP continues to function properly (primary shows **MASTER** status, secondary shows **BACKUP** status).

34.30.3 Both Nodes Appear as MASTER

This will happen if the secondary node cannot see the CARP hearbeat advertisements from the primary. Check the firewall rules, connectivity between the nodes on that segment, and switch configurations. Also check the system logs for any relevant errors that may lead to a solution. If this is encountered in a Virtual Machine (VM) hypervisor environment such as VMWare ESX, see *Troubleshooting High Availability Clusters in Virtual Environments*.

34.30.4 Primary Node is Stuck as BACKUP

In some cases this may happen normally for a short period after a node comes back online. However, certain hardware failures or other error conditions can cause a server to silently take on a high advskew of `240` in order to signal that it still has a problem and should not become master. This can check be checked from the GUI, or via the shell or **Diagnostics > Command**.

In the GUI, this condition is printed in an error message on **Status > CARP**.

From the shell or **Diagnostics > Command**, run the following command to check for a demotion:

```
#  sysctl net.inet.carp.demotion
net.inet.carp.demotion: 240
```

If the value is greater than `0`, the node has demoted itself.

In that case, isolate the firewall, check its network connections, and perform further hardware testing.

If the demotion value is `0` and the primary node still appears to be demoting itself to BACKUP or is flapping, check the network to ensure there are no layer 2 loops. If the firewall receives its own heartbeats back from the switch, it can also trigger a change to BACKUP status.

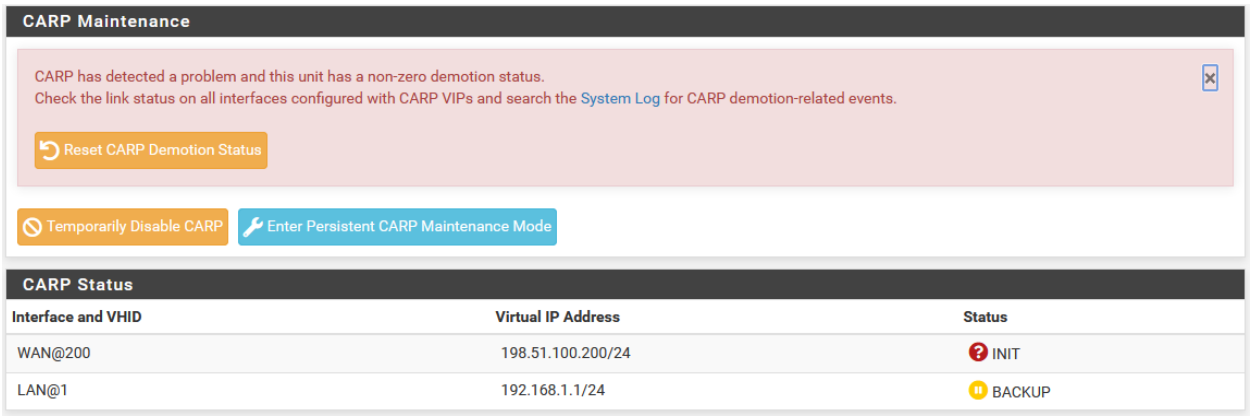


Fig. 3: CARP Status when Primary is demoted

34.30.5 Other Switch and Layer 2 Issues

- If the nodes are plugged into separate switches, ensure that the switches are properly trunking and passing broadcast/multicast traffic.
- Some switches have broadcast/multicast filtering, limiting, or "storm control" features that can break CARP.
- Some switches have broken firmware that can cause features like IGMP Snooping to interfere with CARP.
- If a switch on the back of a modem/CPE is use, try a dedicated switch instead. Switches built into routers and other similar CPE devices often do not properly handle CARP traffic. In these cases, plugging the firewalls into a proper switch and then uplinking to the CPE will eliminate problems.

34.30.6 Configuration Synchronization Problems

Double check the following items when problems with configuration synchronization are encountered:

- The XMLRPC synchronization user must be configured properly in the user manager. The account must have the "System - HA node sync" privilege. If users are synchronized, the account must be added on both nodes initially, once the first synchronization happens, the primary will copy its entry the secondary.
- The password in the configuration synchronization settings on the primary node must match the synchronization user password on the secondary node.
- The GUI must be on the same port on all nodes.
- The GUI must be using the same protocol (HTTPS or HTTP) on all nodes.
- Traffic must be permitted to the GUI port on the interface which handles XMLRPC synchronization traffic.
- Verify that only the primary node has configuration synchronization options enabled.
- Ensure no IP address is specified in the **Synchronize Config to IP** on the secondary node.
- Ensure the clocks on both nodes are current and are reasonably accurate.

34.30.7 State Synchronization Problems (pfsync)

If the State Creator Host IDs do not line up under **Status > CARP** in the **State Synchronization Status** section, that can indicate that the states have not been synchronized. The status should include the **Filter Host ID** of both nodes if states are synchronizing correctly. If the filter host ID has been changed recently, additional values may be in the list until the older states expire.

- Ensure that **Synchronize States** is enabled on **both** nodes.
- Ensure both nodes have the correct **Synchronize interface** selected.
- Ensure the two nodes can communicate directly on the chosen synchronize interface (e.g. Verify with `ping` that they can both reach each other.)
- Check the firewall logs for blocked traffic using the `pfsync` protocol. If the traffic is blocked, make sure it is present on the correct interface. If the interface is correct, then adjust the firewall rules to allow the traffic to pass.
- Ensure the interface assignment order matches.
- If state synchronization does not work with **Synchronize Peer IP** left empty, fill in the Sync interface IP address of each peer on both nodes.

34.30.8 HA and Multi-WAN Troubleshooting

If clients have trouble reaching CARP VIPs when using with Multi-WAN, double check that a rule is present like the one mentioned in *Firewall Configuration*.

34.31 Troubleshooting High Availability Clusters in Virtual Environments

34.31.1 Hypervisor users (Especially VMware ESX/ESXi)

The below settings are specifically for VMware ESX/ESXi but similar settings may be present on Hyper-V, VirtualBox, and other similar hypervisors.

Note: These notes all apply to CARP VIPs in multicast mode. Unicast mode CARP on pfSense Plus software may not require these settings, but experiences may vary by hypervisor and environment.

- Enable promiscuous mode on the vSwitch
- Enable **MAC Address changes**
- Enable **Forged transmits**
- If multiple physical ports exist on the same vswitch, the `Net.ReversePathFwdCheckPromisc` option must be enabled to work around a vswitch bug where multicast traffic will loop back to the host, causing CARP to not function with “link states coalesced” messages. (See below)

ESX VDS Promisc Workaround

If a Virtual Distributed Switch is in use, a port group can be made for the firewall interfaces with promiscuous mode enabled, and a separate non-promiscuous port group may be used for other hosts. This has been reported to work by users on the forum as a way to strike a balance between the requirements for letting CARP function and for securing client ports.

ESX VDS Upgrade Issue

If a VDS (Virtual Distributed Switches) is used in ESX 4.0 or 4.1 and an **upgrade** from 4.0 to 4.1 or 5.0 is performed, the VDS will not properly pass CARP traffic. If a new VDS is **created** on 4.1 or 5.0, it will work, but the upgraded VDS will not.

It is reported that disabling promiscuous mode on the VDS and then re-enabling it will resolve the issue.

ESX VDS Port Mirroring Issue

If port mirroring is enabled on a VDS, it will break promiscuous mode. To fix it, disable promiscuous mode, then re-enable promiscuous mode.

Client Port Issues

If a bare metal HA cluster is connected to a switch with an ESX host using multiple ports on the ESX host (lagg group or similar), and only certain devices or IP addresses are reachable by the target VM, then the port group settings in ESX may need adjusted to set the load balancing for the group to hash based on IP address, not the originating interface.

Side effects of having that set incorrectly include:

- Traffic only reaching the target VM in promisc mode on its NIC
- Inability to reach the CARP VIP from the target VM when the "real" IP address of the primary firewall is reachable
- Port forwards or other inbound connections to the target VM work from some IP addresses and not others.

Changing Net.ReversePathFwdCheckPromisc

Login to the VMware vSphere Client

For each VMware host

- Click on host to configure and select the **Configuration** Tab
- Click **Software Advanced Settings** in left pane
- Click on **Net** and scroll down to **Net.ReversePathFwdCheckPromisc** and set to 1
- Click **OK**

Promiscuous Mode interfaces need to be set now or toggled off and then back on. This is done per host by clicking **Networking** in the **Hardware** section

- For each vSwitch and/or Virtual Machine Port Group:

> **Note:** If Promiscuous is already enabled it must be disabled, saved and then re-enabled and saved again.

  - Click on **Properties** of the vSwtich

    By Default Promiscuous Mode is **Reject**.
  - Click the **Edit > Security** Tab
  - Select **Accept** from the drop down
  - Click **OK**
- However, this setting is usually applied per Virtual Machine Port Group (More Secure) where the VSwitch is left at default to Reject.
  - Navigate to **Edit > Security > Policy Exceptions**
  - Uncheck Promiscuous Mode
  - Click **OK**
  - Navigate to **Edit > Security > Policy Exceptions**
  - Check Promiscuous Mode and select **Accept**.

More information available from VMware

ESX Physical NIC Failure Fails to Trigger Failover

Self-demotion of a CARP VIP relies on the loss of link on a switch port. As such, if a primary and secondary node instance are on separate ESX host and the primary ESX host loses a switch port link and does not expose that to the VM, CARP will stay MASTER on all of its VIPs and the secondary will also believe it should be MASTER. One way around this is to script an event in ESX that will take down the switch port on the VM if the physical port loses link. There may be other ways around this in ESX as well.

VMware Workstation

If using VMware workstation on Linux for testing/modeling and CARP failover does not function, it is likely because VMware workstation is running non-root and cannot set the vmnet adapter in Promiscuous mode.

The permissions on `/dev/vmnet*` should be changed such that the user running VMware workstation is allowed to modify the `/dev/vmnet*` devices. See the VMware KB for details.

To make the change permanent, edit `/etc/init.d/vmware`, and in function `vmwareStartVmnet()`, add commands to `chgrp` and `chown` the `vmnet` devices to a group which contains user running VMware Workstation.

34.31.2 ProxMox VE, KVM, and QEMU Issues

Use VirtIO (`vtnet(4)`) or e1000 NICs (`em(4)`), not the `ed(4)` NICs or CARP VIPs will never leave the INIT state.

34.31.3 VirtualBox Issues

From this thread:

Setting **Promiscuous mode: Allow All** on the relevant interfaces of the VM allows CARP to function on any interface type (Bridged, Host-Only, Internal)

34.32 Troubleshooting High CPU Load

First, open a shell from SSH or the serial/VGA console (option 8).

Typically one of these commands will include some obvious consumer of large amounts of system resources. For example, if the system CPU usage is high, it may be the packet filter. If a VPN process is using lots of CPU, the hardware may not be able to process more VPN traffic. If it is a NIC, see *Hardware Tuning and Troubleshooting*, etc.

If the solution is not obvious based on the output, post the collected information on the forum or contact support for further assistance.

34.32.1 View CPU Processes

To view the top processes, including interrupt processing CPU usage and system CPU:

```
top -aSH
```

34.32.2 View Interrupt Counters

To view the interrupt counters and other system usage:

```
systat -vmstat 1
```

34.32.3 View mbuf Usage

To view the mbuf usage:

```
netstat -m
```

Note: Alternately, check the dashboard mbuf counter, and the graph under **Status > Monitoring** on the **System** tab.

34.32.4 View I/O Operations

To view I/O operations:

```
systat -iostat 1
```

Or:

```
top -aSH
```

Then press `m` to switch to **I/O mode** to view disk activity.

34.33 Troubleshooting Installation Issues

The vast majority of the time, installations of pfSense® software finish with no problems. The following sections describe the most common problems and the steps to resolve them.

See also:

Troubleshooting Boot Issues

34.33.1 Installer Network Connectivity Problems

As the installer requires network connectivity getting the WAN settings correct is critical to its success.

If the installer is unable to contact Netgate servers it will display an error saying "Cannot verify the eligibility of this system, please try again." This could be due to a network configuration or connectivity issue, for example. Double check the WAN settings before attempting the installation again.

If the installer is still unable to achieve outbound connectivity, it may need to be relocated behind a different connection or on a different network through which it can directly reach the Internet.

34.33.2 Errors During Installation

Errors may occur during the installation, for example if the network connection is interrupted or if the installer encounters a problem with the hardware.

The installer saves a log containing all of the installation output to a file named `/tmp/install-log.txt`.

After the installer encounters an error, it displays a notice stating the installation failed and then exits to a shell prompt.

From that shell prompt, it's possible to copy that log file off either over the network with scp or by copying it to a USB drive, for example.

34.33.3 Boot from Install Media Fails

Due to the wide array of hardware combinations in use, it is not uncommon for a memstick or CD to boot incorrectly (or not at all). Given the unpredictable nature of commodity hardware support, using hardware from the Netgate Store is the only guaranteed path to success.

That said, the most common problems and solutions are:

USB Memstick Support
: Some BIOS implementations can be picky about USB memstick support. If booting from one stick fails, try a different one.

USB 3 Ports
: Certain combinations of USB sticks and ports, especially USB 3.0 ports, may not work correctly. Try a USB 2.0 memstick and/or a USB 2.0 port.

BIOS Issues
: Update to the most recent BIOS, and disable any unneeded peripherals such as Firewire, Floppy Drives, and Audio.

Dirty Optical Drive
: Clean the drive with a cleaning disc or a can of compressed air, try another drive, or use USB media instead.

Bad Optical Media
Burn another disc and/or burn the disc at a lower speed. Perhaps try another brand of optical media or use USB media instead.

SATA/IDE Cable Issues
Try a different cable between the DVD drive and the controller or motherboard or use USB media instead.

34.33.4 Boot from hard drive after installation fails

After the installation completes and the firewall restarts, there are conditions which may prevent the operating system from fully booting. The most common reasons are typically BIOS-related. For example, a BIOS implementation may not boot from a disk using GPT or ZFS, or may require UEFI.

Some of these may be worked around by choosing different options for the partition layout during the installation process. Upgrading the BIOS to the latest version available may also help.

Altering the SATA options in the BIOS has improved booting in some situations as well. If a SATA hard drive is being used, experiment with changing the SATA options in the BIOS for settings such as AHCI, Legacy, or IDE. AHCI is the best mode to use with current versions of pfSense software.

See also:

For additional troubleshooting techniques, see *Troubleshooting Boot Issues*.

34.33.5 Interface link up not detected

If the firewall complains that it did not detect an interface link up event during automatic assignment, first make sure that the cable is unplugged and that the interface does not have a link light prior to choosing the link detection option. After selecting the option, plug the cable back into the interface and ensure it has a link light prior to pressing `Enter`. Test or replace the cable in question if it does not show a link light on the switch and/or NIC port once it is connected.

If a network cable is connected directly between two computers and not to a switch, and one of those pieces of hardware is older (e.g. 10/100 NIC) ensure that a crossover cable is being used. Gigabit adapters all support Auto-MDIX and will handle this internally, but many older 10/100 adapters do not. Similarly, if connecting a firewall running pfSense software to a switch that does not support Auto-MDIX, use a straight-through patch cable.

If the interface is properly connected but the firewall still does not detect the link event, the network interface may not properly detect or report link status to the operating system or driver. In this case, manually assigning the interfaces is necessary.

34.33.6 Hardware Troubleshooting

the following suggestions will help resolve general hardware issues.

Booting from USB

If the boot stops with a `mountroot>` prompt while booting off the installer image, usually with USB CD/DVD drives, escape to the loader prompt from the boot menu and run the following:

```
set kern.cam.boot_delay=10000
boot
```

At which point the boot will continue normally.

If the firewall is running permanently from a medium that requires this delay, add the following line as a *Loader Tunable*:

```
kern.cam.boot_delay=10000
```

Remove unnecessary hardware

If the firewall contains hardware that will not be used, remove or disable it. This normally isn't an issue, but can cause problems and has the potential to reduce performance. If an unused piece of hardware is removable, take it out of the firewall or disable it in the BIOS.

Upgrade the BIOS

The second most common fix for hardware problems is upgrading the BIOS to the latest revision. People seem to have a hard time believing this one, but trust us, do it. BIOS updates commonly fix bugs in hardware. It isn't uncommon to hit problems induced by hardware bugs on systems that have been stable running Windows for long periods of time. Either Windows doesn't trigger the bug, or has a work around, as Netgate TAC has encountered this on multiple occasions. Things that BIOS updates can fix include: Failing to boot, time keeping problems, general instability, and other issues like hardware compatibility.

Reset BIOS settings to factory defaults

Recycled systems may have an atypical BIOS configuration. Most contain an option allowing factory default options to be loaded. Use this option to get a fresh start on the BIOS settings.

Other BIOS settings

If the BIOS allows power management configuration, try toggling that option. Look for anything else that seems relevant to whichever aspect of the installation is failing. If it gets to this point, the target hardware is probably a lost cause and alternate hardware may be necessary. Also check to see if the BIOS has an event log that may list hardware errors such as memory test failures.

If the hardware uses a new or recent chipset, a development version of pfSense software may work. Depending on the development cycle of pfSense software, snapshots may be available via upgrade or potentially for installation from within the installer.

Other Hardware Issues

The target hardware may be faulty, which testing with diagnostic software may reveal. Test the hard drive with diagnostic software from the OEM, and test the memory with a program such as memtest86+. These and more tools are available on the "Ultimate Boot CD", which is preloaded with many free hardware diagnostic tools.

Also ensure that all of the fans are spinning at speed, and that no components are overheating. If this is older reused hardware, compressed/canned air cleaning of the fans and heat sinks can work wonders.

34.34 Troubleshooting IPsec VPNs

Due to the finicky nature of IPsec it is not unusual for trouble to arise with tunnels when creating them initially or over time.

Follow the troubleshooting advice in this section to diagnose and solve most common problems with IPsec tunnels on pfSense® software.

34.34.1 Troubleshooting IPsec Connections

IPsec connection names

IPsec tunnels follow a consistent naming pattern when forming connection names used in the strongSwan configuration. These names are printed in the IPsec status and can also be found in the IPsec configuration file (`/var/etc/ipsec/swanctl.conf`), the IPsec log, and the output of various `swanctl` commands.

Non-mobile tunnels all use an IKE connection named `conX` where `X` is the phase 1 IKE ID.

Phase 2 child definitions use slightly different names based on the tunnel settings:

For normal IKEv2 tunnels without **Split Connections** enabled all phase 2 entries are combined into a single child definition. In this case the connections are named `conX` where `X` is the phase 1 IKE ID and this is identical to the name of the IKE portion of the connection.

For IKEv1 tunnels and for IKEv2 tunnels with **Split Connections** enabled each phase 2 entry is defined as a separate child. In this case the child definitions are named `conX_Y` where `X` is the phase 1 IKE ID and `Y` is the phase 2 reqid.

Note: The phase 1 IKE ID and phase 2 reqid are printed in the IPsec tunnel list and on the page when editing those entries.

To see a list of current connections, run the following command from the shell:

```
# swanctl --list-conns
```

The output of that command lists the IKE connection name first (e.g. `con1`) with no indentation. Child definitions are listed at the end of a tunnel entry and are indented.

Manually connect IPsec from the shell

Connections can be manually initiated and terminated from the shell using the `swanctl` command.

Tip: When initiating a tunnel in this way, `swanctl` will output only the relevant logs to the terminal. This is much easier than attempting to follow the log file contents in other ways.

The connection name for a tunnel must be used in this case, such as `con1` or `con2_1`.

Note: To locate the correct `con` identifier, see *IPsec connection names*.

The following command will attempt to initiate the IKE portion of a tunnel (phase 1):

```
# swanctl --initiate --ike conX
```

The following command will attempt to initiate the child SA portion of a tunnel (phase 2) as well as IKE if it is not already connected:

```
# swanctl --initiate --child conX
```

Terminating a tunnel uses similar syntax.

Terminate IKE connection (also terminates all child connections):

```
# swanctl --terminate --ike conX
```

Terminate a child connection:

```
# swanctl --terminate --child conX
```

Tunnel does not establish

First check the service status at **Status > Services**. If the IPsec service is stopped, check if there is at least one configured and enabled IPsec tunnel (*IPsec Tunnels Tab*).

If the service is running, check the firewall logs at **Status > System Logs**, **Firewall** tab. Look for entries that indicate that the connection is being blocked. If the tunnel is not establishing, check for UDP entries for ports `500` and `4500`. Rules are normally added automatically for IPsec (*IPsec and firewall rules*), but that feature can be disabled or there may be edge cases where the firewall cannot identify the remote IPsec gateway. Add rules to pass traffic if needed.

The single most common cause of failed IPsec tunnel connections is a configuration mismatch. Often it is something small, such as a DH group set differently, or perhaps a subnet mask of /24 on one side and /32 on the other in the phase 2 networks. Some routers (Linksys, for one) also like to hide certain options behind "Advanced" buttons or make assumptions. A lot of trial and error may be involved, and a lot of log reading, but ensuring that both sides match precisely will help the most.

Depending on the Internet connections on either end of the tunnel, it is also possible that a router involved on one side or the other does not properly handle IPsec traffic. This is a larger concern with mobile clients and networks where NAT is involved outside of the actual IPsec endpoints. The problems are generally with the ESP protocol and problems with it being blocked or mishandled along the way. NAT Traversal (NAT-T) encapsulates ESP in UDP port `4500` traffic to work around these issues. Typically this situation is detected automatically but in some edge cases it can help to force NAT traversal for IKEv1 tunnels.

"Random" tunnel disconnects/DPD failures on low-end routers

If IPsec tunnels are dropped on low-end hardware that is pushing the limits of its CPU, DPD on the tunnel may need disabled. Such failures tend to correlate with times of high bandwidth usage. This happens when the CPU on a low-power system is tied up with sending IPsec traffic or is otherwise occupied. Due to the CPU overload it may not take the time to respond to DPD requests or see a response to a request of its own. As a consequence, the tunnel will fail a DPD check and be disconnected. This is a clear sign that the hardware is being driven beyond its capacity. If this happens, consider replacing the firewall with a more powerful model.

Tunnels establish and work but fail to renegotiate

In some cases a tunnel will function properly but once the phase 1 or phase 2 lifetime expires the tunnel will fail to renegotiate properly. This can manifest itself in a few different ways, each with a different resolution.

DPD is unsupported and one side drops while the other remains

Consider this scenario, which DPD is designed to prevent, but can happen in places where DPD is unsupported:

- A tunnel is established from Site A to Site B, from traffic initiated at Site A.
- Site B expires the phase 1 or phase 2 before Site A
- Site A will believe the tunnel is up and continue to send traffic as though the tunnel is working properly.
- Only when the Site A phase 1 or phase 2 lifetime expires will it renegotiate as expected.

In this scenario, the likely things resolutions are:

- Check to make sure all of the settings match on both sides, especially the phase 1 **DH Group** and phase 2 **PFS** values.
- Enable DPD, or Site B must send traffic to Site A which will cause the entire tunnel to renegotiate. The easiest way to make this happen is to enable a keep alive mechanism on both sides of the tunnel.
- Enable the periodic check keep alive method on one end (*Configuring IPsec Keep Alive*)

Tunnel establishes when initiating but not when responding

If a tunnel will establish sometimes, but not always, generally there is a settings mismatch. The tunnel may still establish because if the settings presented by one side are more secure the other may accept them, but not the other way around.

Lifetime mismatches do not cause a failure in phase 1 or phase 2.

To track down these failures, configure the logs as shown in *Troubleshooting IPsec Logs* and attempt to initiate the tunnel from each side, then check the logs.

Tunnel establishes at start but not when disconnected

An IPsec tunnel can be disconnected for a variety of reasons. For example, connectivity being interrupted to the far side, the remote being down or offline for an extended time, or even a manual or policy action on the far side.

Note: This is not the same scenario as a rekey or reauthentication event, which will rebuild the appropriate parts of the tunnel and remain active.

A tunnel mode IPsec instance will connect at start and when it disconnects, will connect again on demand. This happens due to trap policies which trigger initiation when traffic attempts to use the tunnel. A tunnel mode IPsec connection can be reconnected without manual intervention by the automatic ping keep alive function on a phase 2 entry.

VTI mode IPsec cannot support trap policies so it is not capable of using this tactic. As such, a VTI tunnel may need help to stay up and running at all times.

There are a two workarounds that may help in this case:

Keep Alive - Periodic Check

The *IPsec phase 2 Keep Alive option* to perform a periodic IPsec status check is ideally suited to this case. When enabled, if a given phase 2 is down it will trigger an initiation directly.

This works with VTI because it does not rely on trap policies.

Note: This feature is new in pfSense® Plus software version 22.01 and CE 2.6.0.

Child SA Actions

Another tactic to keep a tunnel up is to set it to initiate immediately at start and automatically reconnect if it gets disconnected. This should only be set on **one** side of a tunnel.

Child SA Start Action

Set the start action to *Initiate at start*. This will trigger a tunnel initiation when the IPsec daemon starts, such as at boot time.

Note: This does not trigger when the IPsec configuration is changed and reloaded, only when the daemon loads the configuration the first time at startup.

Child SA Close Action

Set the close action to *Restart/Reconnect* which will attempt to immediately reconnect the child SA if it gets disconnected.

Depending on the reason the tunnel was disconnected, this may or may not be helpful. For example, if the reason the tunnel disconnected was a local cause, these events may not trigger. The periodic check keep alive method is much more reliable, but only available on current versions of pfSense software.

Tunnel stops attempting connections after timeout

If the remote end of an IPsec tunnel is down when the tunnel attempts to initiate at start, but fails, it may eventually times out and stop trying to connect.

The solution here is similar to the previous scenario above, which is to enable keep alive options for the tunnel which will trigger a fresh initiation periodically if the tunnel is down.

34.34.2 Troubleshooting IPsec Traffic

Tunnel establishes but no traffic passes

The first place to look if a tunnel comes up but will not pass traffic is the IPsec firewall rules tab. If Site A cannot reach Site B, check the Site B firewall log and rules. Conversely, if Site B cannot contact Site A, check the Site A firewall log and rules.

Inspect the firewall logs at **Status > System Logs**, on the **Firewall** tab. Check for log entries indicating traffic is blocked involving the subnets used in the IPsec tunnel. Also check for traffic on the WAN interface used by the tunnel for the protocol **ESP** or UDP port `4500` both of which could be used to carry encapsulated IPsec traffic. If there are log entries which match either case, continue on to check the rules. If there are no log entries indicating blocked packets, revisit the section on IPsec routing considerations in *Client Routing and Gateway Considerations*.

Blocked packets on the IPsec or `enc0` interface indicate that the tunnel itself has established but traffic is being blocked by firewall rules. Blocked packets on the LAN or other internal interface may indicate that an additional rule may be needed on that interface ruleset to allow traffic from the internal subnet out to the remote end of the IPsec tunnel. Blocked packets on WAN type interfaces would prevent a tunnel from establishing. Typically this only happens when the automatic VPN rules are disabled. Adding a rule to allow the **ESP** protocol along with UDP ports `500` and `4500` from that remote IP address will allow the tunnel to establish and pass traffic. In the case of mobile tunnels, allow traffic from any source to connect to those ports. See *IPsec and firewall rules* for more details.

Rules for the IPsec interface can be found under **Firewall > Rules**, on the **IPsec** tab. Common mistakes include setting a rule to only allow *TCP* traffic, which means things like ICMP ping and DNS would not work across the tunnel. See *Firewall* for more information on how to properly create and troubleshoot firewall rules.

In some cases it is possible that a setting mismatch can also cause traffic to fail passing the tunnel. In one instance, a subnet defined on a third-party firewall was `192.0.2.1/24`, and on the firewall running pfSense® software it was `192.0.2.0/24`. The tunnel established, but traffic would not pass until the subnet was corrected.

Routing issues are another possibility. Running a traceroute (tracert on Windows) to an IP address on the opposite side of the tunnel can help track down these types of problems. Repeat the test from both sides of the tunnel. Check *Client Routing and Gateway Considerations* for more information. When using traceroute , traffic which enters and leaves the IPsec tunnel will seem to be missing interim hops. This is normal and part of how IPsec works. Traffic which does not properly enter an IPsec tunnel will appear to leave the WAN interface and route outward across the Internet, which would point to either a routing issue such as the firewall running pfSense software not being the gateway (as in *Client Routing and Gateway Considerations*), policy routing rules matching the traffic, an incorrectly specified remote subnet on the tunnel definition, a tunnel which has been disabled.

Some hosts work but not all

If traffic between some hosts over the VPN functions properly, but some hosts do not, this is commonly one of four things:

Missing, incorrect or ignored default gateway

If the device does not have a default gateway or has one pointing to something other than the firewall running pfSense software, it does not know how to properly get back to the remote network on the VPN (see *Client Routing and Gateway Considerations*).

Some devices, even with a default gateway specified, do not use that gateway. This has been seen on various embedded devices, including IP cameras and some printers. There isn't anything that can be done about that other than getting the software on the device fixed. This can be verified by running a packet capture on the inside interface of the firewall connected to the network containing the device. Troubleshooting with tcpdump is covered in *Using tcpdump on the command line*, and an IPsec-specific example can be found in *IPsec tunnel will not connect*.

If traffic is observed leaving the inside interface of the firewall, but no replies return, the device is not properly routing its reply traffic or could potentially be blocking it via a local client firewall.

Incorrect subnet mask
If the subnet in use on one end is `10.0.0.0/24` and the other is `10.254.0.0/24`, and a host has an incorrect subnet mask of `255.0.0.0` or `/8`, it will never be able to communicate across the VPN because it thinks the remote VPN subnet is part of the local network and hence routing will not function properly. The system with the broken configuration will attempt to contact the remote system via ARP instead of using the gateway.

Host firewall
If there is a firewall on the target host, it may not be allowing the connections. Check for things like Windows Firewall, iptables, or similar utilities that may be preventing the traffic from being processed by the host.

Firewall rules on pfSense software
Ensure the rules on both ends allow the desired network traffic.

Connection hangs

IPsec does not gracefully handle fragmented packets. Many of these issues have been resolved over the years, but there may be lingering problems and edge cases. If hangs or packet loss are seen only when using specific protocols (SMB, RDP, etc.), MSS clamping for the VPN may be necessary. MSS clamping can be activated under *Firewall & NAT*. A good starting point for MSS clamping is `1400`. If that works slowly increase the MSS value until the breaking point is hit, then back off a little from there.

Disappearing traffic

If IPsec traffic arrives but never appears on the IPsec interface (`enc0`), check for conflicting routes/interface IP addresses. For example, if an IPsec tunnel is configured with a remote network of `192.0.2.0/24` and there is a local OpenVPN server with a tunnel network of `192.0.2.0/24` then the ESP traffic may arrive, strongSwan may process the packets, but they never show up on `enc0` as arriving to the OS for delivery.

Resolve the duplicate interface/route and the traffic will begin to flow.

34.34.3 Troubleshooting IPsec Logs

Note: Examples presented in this document contain logs edited for brevity but significant messages remain.

Logging for IPsec can provide useful information. To configure IPsec logging for diagnosing tunnel issues with pfSense® software, the following procedure yields the best balance of information:

- Navigate to **VPN > IPsec** on the **Advanced Settings** tab
- Set **IKE SA**, **IKE Child SA**, and **Configuration Backend** to *Diag*
- Set all other log settings to *Control*
- Click Save

Note: Changing logging options is not disruptive to IPsec tunnels.

Tip: Though this section assumes log messages are obtained from the IPsec log, using a manual connection attempt (*Manually connect IPsec from the shell*) can yield more focused results when initiating. When initiating manually using a shell command the messages are printed to the console and not mixed with logs from other connections, making it much simpler to find relevant log messages.

IPsec log interpretation

The IPsec logs available at **Status > System Logs**, on the **IPsec** tab contain a record of the tunnel connection process and some messages from ongoing tunnel maintenance activity. Some typical log entries are listed in this section, both good and bad. The main things to look for are key phrases that indicate which part of a connection worked. If "IKE_SA … established" is present in the log, that means phase 1 was completed successfully and a Security Association was negotiated. If "CHILD_SA … established" is present, then phase 2 has also been completed and the tunnel is up.

In the following examples, the logs have been configured as listen in *Troubleshooting IPsec Logs* and irrelevant messages may be omitted. Bear in mind that these are samples and the specific ID numbers, IP addresses, and so forth will vary.

Successful connections

When a tunnel has been successfully established both sides will indicate that an **IKE SA** and a **Child SA** have been established. When multiple phase 2 definitions are present with IKEv1, a child SA is negotiated for each phase 2 entry.

Log output from the initiator:

```
charon: 09[IKE] IKE_SA con2[11] established between 192.0.2.90[192.0.2.90]...192.0.2.
↪74[192.0.2.74]
charon: 09[IKE] CHILD_SA con2{2} established with SPIs cf4973bf_i c1cbfdf2_o and TS 192.
↪168.48.0/24|/0 === 10.42.42.0/24|/0
```

Log output from the responder:

```
charon: 03[IKE] IKE_SA con1[19] established between 192.0.2.74[192.0.2.74]...192.0.2.
↪90[192.0.2.90]
charon: 16[IKE] CHILD_SA con1{1} established with SPIs c1cbfdf2_i cf4973bf_o and TS 10.
↪42.42.0/24|/0 === 192.168.48.0/24|/0
```

Failed connection examples

These examples show failed connections for varying reasons. In most cases it is clear from the examples that the initiator does not receive messages about specific items that do not match, so the responder logs are much more informative. This is done to protect the security of the tunnel, it would be insecure to provide messages to a potential attacker that would give them information about how the tunnel is configured.

Phase 1 main / aggressive mismatch

In this example, the initiator is set for Aggressive mode while the responder is set for Main mode.

Log output from the initiator:

```
charon: 15[IKE] initiating Aggressive Mode IKE_SA con2[1] to 203.0.113.5
charon: 15[IKE] received AUTHENTICATION_FAILED error notify
charon: 13[ENC] parsed INFORMATIONAL_V1 request 1215317906 [ N(AUTH_FAILED) ]
charon: 13[IKE] received AUTHENTICATION_FAILED error notify
```

Log output from the responder:

```
charon: 13[IKE] Aggressive Mode PSK disabled for security reasons
charon: 13[ENC] generating INFORMATIONAL_V1 request 2940146627 [ N(AUTH_FAILED) ]
```

Note that the logs on the responder state clearly that Aggressive mode is disabled, which is a good clue that the mode is mismatched.

In the reverse case, if the side set for Main mode initiates, the tunnel to a firewall running pfSense software will establish since Main mode is more secure.

Phase 1 identifier mismatch

When the identifier does not match the initiator only shows that the authentication failed, but does not give a reason. The responder states that it is unable to locate a peer, which indicates that it could not find a matching phase 1, which implies that no matching identifier could be located.

Log output from the initiator:

```
charon: 10[ENC] parsed INFORMATIONAL_V1 request 4216246776 [ HASH N(AUTH_FAILED) ]
charon: 10[IKE] received AUTHENTICATION_FAILED error notify
```

Log output from the responder:

```
charon: 12[CFG] looking for pre-shared key peer configs matching 203.0.113.5...198.51.
↪100.3[someid]
charon: 12[IKE] no peer config found
charon: 12[ENC] generating INFORMATIONAL_V1 request 4216246776 [ HASH N(AUTH_FAILED) ]
```

Phase 1 pre-shared key mismatch

A mismatched pre-shared key can be a tough to diagnose. An error stating the fact that this value is mismatched is not printed in the log, instead this messages is shown:

Log output from the initiator:

```
charon: 09[ENC] invalid HASH_V1 payload length, decryption failed?
charon: 09[ENC] could not decrypt payloads
charon: 09[IKE] message parsing failed
```

Log output from the responder:

```
charon: 09[ENC] invalid ID_V1 payload length, decryption failed?
charon: 09[ENC] could not decrypt payloads
charon: 09[IKE] message parsing failed
```

When the above log messages are present check the Pre-Shared Key value on both sides to ensure they match.

Phase 1 encryption algorithm mismatch

Log output from the initiator:

```
charon: 14[ENC] parsed INFORMATIONAL_V1 request 3851683074 [ N(NO_PROP) ]
charon: 14[IKE] received NO_PROPOSAL_CHOSEN error notify
```

Log output from the responder:

```
charon: 14[CFG] received proposals: IKE:AES_CBC_128/HMAC_SHA1_96/PRF_HMAC_SHA1/MODP_1024
charon: 14[CFG] configured proposals: IKE:AES_CBC_256/HMAC_SHA1_96/PRF_HMAC_SHA1/MODP_
↪1024
charon: 14[IKE] no proposal found
charon: 14[ENC] generating INFORMATIONAL_V1 request 3851683074 [ N(NO_PROP) ]
```

In this case, the log entry shows the problem exactly: The initiator was set for AES 128 encryption, and the responder is set for AES 256. Set both to matching values and then try again.

Phase 1 hash algorithm mismatch

Log output from the initiator:

```
charon: 10[ENC] parsed INFORMATIONAL_V1 request 2774552374 [ N(NO_PROP) ]
charon: 10[IKE] received NO_PROPOSAL_CHOSEN error notify
```

Log output from the responder:

```
charon: 14[CFG] received proposals: IKE:AES_CBC_256/MODP_1024
charon: 14[CFG] configured proposals: IKE:AES_CBC_256/HMAC_SHA1_96/PRF_HMAC_SHA1/MODP_
↪1024
charon: 14[IKE] no proposal found
charon: 14[ENC] generating INFORMATIONAL_V1 request 2774552374 [ N(NO_PROP) ]
```

The hash algorithm is indicated by the `HMAC` portion of the logged proposals. As can be seen above, the received and configured proposals do not have matching HMAC entries. Set them both to match and try again.

Phase 1 DH group mismatch

Log output from the initiator:

```
charon: 11[ENC] parsed INFORMATIONAL_V1 request 316473468 [ N(NO_PROP) ]
charon: 11[IKE] received NO_PROPOSAL_CHOSEN error notify
```

Log output from the responder:

```
charon: 14[CFG] received proposals: IKE:AES_CBC_256/HMAC_SHA1_96/PRF_HMAC_SHA1/MODP_8192
charon: 14[CFG] configured proposals: IKE:AES_CBC_256/HMAC_SHA1_96/PRF_HMAC_SHA1/MODP_
↪1024
charon: 14[IKE] no proposal found
charon: 14[ENC] generating INFORMATIONAL_V1 request 316473468 [ N(NO_PROP) ]
```

DH group is indicated by the `MODP` portion of the listed proposal. As indicated by the log messages, the initiator was set for 8192 (Group 18) and the responder was set for 1024 (Group 2). This error can be corrected by setting the DH group setting on both ends of the tunnel to a matching value.

Phase 2 network mismatch

In the following example, the phase 2 entry on the initiator side is set for `10.3.0.0/24` to `10.5.0.0/24`. The responder is not set to match as it lists `10.5.1.0/24` instead.

Log output from the initiator:

```
charon: 08[CFG] proposing traffic selectors for us:
charon: 08[CFG] 10.3.0.0/24|/0
charon: 08[CFG] proposing traffic selectors for other:
charon: 08[CFG] 10.5.0.0/24|/0
charon: 08[ENC] generating QUICK_MODE request 316948142 [ HASH SA No ID ID ]
charon: 08[NET] sending packet: from 198.51.100.3[500] to 203.0.113.5[500] (236 bytes)
charon: 08[NET] received packet: from 203.0.113.5[500] to 198.51.100.3[500] (76 bytes)
charon: 08[ENC] parsed INFORMATIONAL_V1 request 460353720 [ HASH N(INVAL_ID) ]
charon: 08[IKE] received INVALID_ID_INFORMATION error notify
```

Log output from the responder:

```
charon: 08[ENC] parsed QUICK_MODE request 2732380262 [ HASH SA No ID ID ]
charon: 08[CFG] looking for a child config for 10.5.0.0/24|/0 === 10.3.0.0/24|/0
charon: 08[CFG] proposing traffic selectors for us:
charon: 08[CFG] 10.5.1.0/24|/0
charon: 08[CFG] proposing traffic selectors for other:
charon: 08[CFG] 10.3.0.0/24|/0
charon: 08[IKE] no matching CHILD_SA config found
charon: 08[IKE] queueing INFORMATIONAL task
charon: 08[IKE] activating new tasks
charon: 08[IKE] activating INFORMATIONAL task
charon: 08[ENC] generating INFORMATIONAL_V1 request 1136605099 [ HASH N(INVAL_ID) ]
```

The responder logs lists both the networks it received (`child config` line in the log) and what it has configured locally (`proposing traffic selectors for...` lines in the log). By comparing the two, a mismatch can be spotted. The `no matching CHILD_SA config found` line in the log will always be present when this mismatch occurs and that directly indicates that it could not find a phase 2 definition to match the values received from the initiator.

Phase 2 encryption algorithm mismatch

Log output from the initiator:

```
charon: 14[CFG] configured proposals: ESP:AES_CBC_128/HMAC_SHA1_96/NO_EXT_SEQ
charon: 14[ENC] generating QUICK_MODE request 759760112 [ HASH SA No ID ID ]
charon: 14[NET] sending packet: from 198.51.100.3[500] to 203.0.113.5[500] (188 bytes)
charon: 14[NET] received packet: from 203.0.113.5[500] to 198.51.100.3[500] (76 bytes)
charon: 14[ENC] parsed INFORMATIONAL_V1 request 1275272345 [ HASH N(NO_PROP) ]
charon: 14[IKE] received NO_PROPOSAL_CHOSEN error notify
```

Log output from the responder:

```
charon: 13[CFG] selecting proposal:
charon: 13[CFG] no acceptable ENCRYPTION_ALGORITHM found
charon: 13[CFG] received proposals: ESP:AES_CBC_128/HMAC_SHA1_96/NO_EXT_SEQ
charon: 13[CFG] configured proposals: ESP:AES_CBC_256/HMAC_SHA1_96/NO_EXT_SEQ
charon: 13[IKE] no matching proposal found, sending NO_PROPOSAL_CHOSEN
charon: 13[IKE] queueing INFORMATIONAL task
charon: 13[IKE] activating new tasks
charon: 13[IKE] activating INFORMATIONAL task
charon: 13[ENC] generating INFORMATIONAL_V1 request 1275272345 [ HASH N(NO_PROP) ]
```

In this case the initiator receives a message that the responder could not find a suitable proposal (`received NO_PROPOSAL_CHOSEN`), and from the responder logs it is obvious this was due to the sites being set for different encryption types, AES 128 on one side and AES 256 on the other.

Phase 2 hash algorithm mismatch

Log output from the initiator:

```
charon: 10[CFG] configured proposals: ESP:AES_CBC_256/HMAC_SHA2_512_256/NO_EXT_SEQ
charon: 10[ENC] generating QUICK_MODE request 2648029707 [ HASH SA No ID ID ]
charon: 10[NET] sending packet: from 198.51.100.3[500] to 203.0.113.5[500] (188 bytes)
charon: 10[NET] received packet: from 203.0.113.5[500] to 198.51.100.3[500] (76 bytes)
charon: 10[ENC] parsed INFORMATIONAL_V1 request 757918402 [ HASH N(NO_PROP) ]
charon: 10[IKE] received NO_PROPOSAL_CHOSEN error notify
```

Log output from the responder:

```
charon: 11[CFG] selecting proposal:
charon: 11[CFG] no acceptable INTEGRITY_ALGORITHM found
charon: 11[CFG] received proposals: ESP:AES_CBC_256/HMAC_SHA2_512_256/NO_EXT_SEQ
charon: 11[CFG] configured proposals: ESP:AES_CBC_256/HMAC_SHA1_96/NO_EXT_SEQ
charon: 11[IKE] no matching proposal found, sending NO_PROPOSAL_CHOSEN
charon: 11[IKE] queueing INFORMATIONAL task
charon: 11[IKE] activating new tasks
charon: 11[IKE] activating INFORMATIONAL task
charon: 11[ENC] generating INFORMATIONAL_V1 request 757918402 [ HASH N(NO_PROP) ]
```

Similar to a phase 1 hash algorithm mismatch, the `HMAC` values in the log entries do not line up. However the responder also logs a clearer message `no acceptable INTEGRITY_ALGORITHM found` when this happens in phase 2.

Phase 2 pfs mismatch

Log output from the initiator:

```
charon: 06[ENC] generating QUICK_MODE request 909980434 [ HASH SA No KE ID ID ]
charon: 06[NET] sending packet: from 198.51.100.3[500] to 203.0.113.5[500] (444 bytes)
charon: 06[NET] received packet: from 203.0.113.5[500] to 198.51.100.3[500] (76 bytes)
charon: 06[ENC] parsed INFORMATIONAL_V1 request 3861985833 [ HASH N(NO_PROP) ]
charon: 06[IKE] received NO_PROPOSAL_CHOSEN error notify
```

Log output from the responder:

```
charon: 08[CFG] selecting proposal:
charon: 08[CFG] no acceptable DIFFIE_HELLMAN_GROUP found
charon: 08[CFG] received proposals: ESP:AES_CBC_256/HMAC_SHA1_96/MODP_2048/NO_EXT_SEQ
charon: 08[CFG] configured proposals: ESP:AES_CBC_256/HMAC_SHA1_96/NO_EXT_SEQ
charon: 08[IKE] no matching proposal found, sending NO_PROPOSAL_CHOSEN
charon: 08[ENC] generating INFORMATIONAL_V1 request 3861985833 [ HASH N(NO_PROP) ]
```

Perfect Forward Secrecy (PFS) works like DH groups on phase 1, but is optional. When PFS options do not match a clear message is logged indicating this fact: `no acceptable DIFFIE_HELLMAN_GROUP found`.

Note: In some cases, if one side has PFS set to *off* , and the other side has a value set, the tunnel may still establish and work. The mismatch shown above may only be seen if the values mismatch, for example `1` vs. `5`.

Note: Due to the way IPsec negotiates the first child SA will not use the PFS value from phase 2, but the DH group value from phase 1. Subsequent child SA entries or rekeys will use the value from phase 2. Thus, if a tunnel connects OK at first but fails at rekey, ensure the phase 2 PFS values match.

Mismatched identifier with nat

In this case, pfSense software is configured for a **Peer Identifier** of *Peer IP address*, but the remote device is actually behind NAT. In this case strongSwan expects the actual private before-NAT IP address as the identifier.

Log output from the responder:

```
charon: 10[IKE] remote host is behind NAT
charon: 10[IKE] IDir '192.0.2.10' does not match to '203.0.113.245'
[...]
charon: 10[CFG] looking for pre-shared key peer configs matching 198.51.100.50...203.0.
↪113.245[192.0.2.10]
```

To correct this condition, change the **Peer Identifier** setting to *IP Address* and then enter the pre-NAT IP address, which in this example is `192.0.2.10`.

34.34.4 Troubleshooting Duplicate IPsec SA Entries

In certain cases an IPsec tunnel may show what appear to be duplicate IKE (phase 1) or Child (phase 2) security association (SA) entries.

Lengthy testing and research uncovered that the main way this starts to happen is when both sides negotiate or renegotiate simultaneously. If both peers initiate, reauthenticate, or rekey phase 1 at the same time, it can result in duplicate IKE SAs. If both peers rekey phase 2 at the same time, it can result in duplicate child SAs.

Mitigating this problem involves ensuring that the chance of simultaneous negotiation is minimized or eliminated. The easiest way to reach that goal is to set higher phase 1 and phase 2 lifetimes on one peer, or at least make sure both sides are **not** set identically.

Specific values vary but the settings below are the best general advice. Using the suggested values may not be possible due to peer constraints, such as third party vendors which do not support these settings or insist upon other settings. Variations are mentioned which should accommodate most situations, however, use as many strategies as possible.

Note: The values in this document take precedence over default recommendations in other IPsec examples and recipes.

Current version (2.5.0 and later)

The values in this section can be found in the current GUI. Older versions may have different values or some settings may not be available. Always run the most recent released version to ensure the best experience.

Peer A

Phase 1 (IKE SA)

Key Exchange Version
IKEv2 if supported by both peers.

Life Time
The total IKE SA lifetime as a hard upper limit (e.g. `28800`)

Rekey Time
90% of total IKE SA lifetime (e.g. `25920`).

Reauth Time
`0` to disable reauthentication.

If the peer requires IKEv1 or only supports IKEv2 reauthentication, set this as mentioned in **Rekey Time** above and also enable **Make Before Break** on the **Advanced Settings** tab.

Rand Time
Defaults to 10% of IKE SA **Life Time** (e.g. `2880`). A larger **Rand Time** will decrease the chances of both peers renegotiating simultaneously.

Child SA Close Action
Restart/Reconnect so that this side will reconnect child SA entries when they expire or fail.

Phase 2 (Child SA)

Life Time
Total Child SA lifetime (e.g. `3600` for 1 hour). This peer will attempt to rekey the Child SA before it reaches this limit.

Rekey Time
Leave blank to automatically use 90% of the **Life Time**, or choose a lower amount.

Rand Time
Defaults to 10% of Child SA **Life Time** (e.g. `360`). A larger **Rand Time** will decrease the chances of both peers renegotiating simultaneously.

Peer B

Phase 1 (IKE SA)

Key Exchange Version
IKEv2 if supported by both peers.

Life Time
The total IKE SA lifetime as a hard upper limit, but use a higher lifetime than Peer A by at least 10% (e.g. `31680`). With this peer set higher, Peer A will primarily manage IKE SA renegotiation, reducing the chance of conflicts.

Note: If the remote peer insists their lifetime be set to a specific value, then set peer A lower instead by a similar margin.

Rekey Time
90% of total IKE SA **Life Time**

Reauth Time
Blank (disabled) to disable reauthentication.

If the peer requires IKEv1 or only supports IKEv2 reauthentication, set this as mentioned in **Rekey Time** above and also enable **Make Before Break** on the **Advanced Settings** tab.

Rand Time
Defaults to 10% of IKE SA **Life Time** (e.g. `3168`). A larger **Rand Time** will decrease the chances of both peers renegotiating simultaneously. If using the same **Life Time** as Peer A, then increase this value further. If using a larger **Life Time** for Peer B, then leave this at the default or disable it (`0`).

Responder Only
Checked so that this side **will not** automatically initiate IKE SA negotiation.

Note: This peer can still manually initiate a connection from **Status > IPsec**, but it won't happen automatically.

Child SA Close Action
Close connection and clear SA so that when a Child SA expires, this side will remove the SA and not attempt to renegotiate a new entry.

Phase 2 (Child SA)

Life Time
A larger value than the **Life Time** set on Peer A by at least 10%. For example, if Peer A is set to `3600`, set this to `5400`. That way Peer A will primarily manage Child SA renegotiation.

Note: If the remote peer insists their lifetime be set to a specific value, then set peer A lower instead by a similar margin.

Rekey Time
Leave blank to automatically use 90% of the **Life Time**, or choose a lower amount.

Rand Time
Defaults to 10% of Child SA **Life Time** (e.g. `540`). A larger **Rand Time** will decrease the chances of both peers renegotiating simultaneously. If using the same **Life Time** as Peer A, then increase this value further. If using a larger **Life Time** for Peer B, then leave this at the default or disable it (`0`).

Advanced IPsec Settings (both)

Make Before Break
Checked if phase 1 uses IKEv2 and reauthentication, not relevant otherwise.

Version 2.4.5-p1 and older

The settings are almost all the same as the section above, with a couple changes. The primary difference is in the GUI settings for rekey and reauth. Only the differences are noted below, so follow the previous section except for the values noted here.

Warning: On 2.4.5-p1, setting **Responder Only** in the phase 1 options requires an extra patch, `9a69dd4b8ff6eeeaf5779b7388a10743afae8e91`, which can be applied using the *System Patches Package*.

Peer A

Lifetime
The total time at which this peer will renegotiate the IKE SA (e.g. `28800`)

Margin Time
An amount of time, in seconds, before the **Life Time** is reached when renegotiation begins. Defaults to `540`, but larger values can help reduce the chance of simultaneous renegotiation. Due to the default behavior of the IPsec daemon, this time can be randomly increased up to twice its value to further help avoid both sides choosing the same time. A larger value will help avoid potential collisions.

Disable Rekey
Unchecked

Disable Reauth
Checked

Peer B

Lifetime
A higher time than the same field on Peer A by at least 10%. (e.g. `32400`)

Margin Time
If using the same **Life Time** as Peer A, use a larger value to help avoid simultaneous renegotiation. If using a larger **Life Time** value, then leave this blank or set to the same value as Peer A.

Disable Rekey
Unchecked

Disable Reauth
Checked

Other notes

The strongSwan daemon introduces randomness into the renegotiation process which can help mitigate the problem, but still leaves it up to chance if both peers are using the exact same lifetime values. That is why setting one peer higher, beyond the randomness threshold, is a better practice. The randomness also explains why the problem can take a while to manifest in certain environments as the duplicates do not happen until both peers happen to land on the same random rekey time.

34.35 Troubleshooting L2TP

This section covers troubleshooting steps for the most common problems users encounter with L2TP.

34.35.1 Cannot connect

Check that firewall rules have been added to the external interface where the L2TP traffic enters the firewall. Also make sure the client is connecting to the interface IP address chosen on the L2TP settings.

34.35.2 Connected to L2TP but cannot pass traffic

Ensure firewall rules have been added to the **L2TP VPN** interface as described in *Configure firewall rules for L2TP clients*.

Also ensure the remote subnet across the VPN is different from the local subnet. It is not possible to reach a 192.168.1.0/24 network across the VPN when the local subnet where the client resides is also 192.168.1.0/24, traffic destined for that subnet will never traverse the VPN because it is on the local network. This is why it is important to choose a relatively obscure LAN subnet when using a VPN.

34.35.3 Connection Fails with a Windows Client

If the IPsec layer appears to complete, but no L2TP traffic passes, it is likely a known incompatibility between Windows and the strongSwan daemon used on pfSense® software. There is currently no known workaround except to move the Windows client out from behind NAT, or to use a different style VPN such as IKEv2.

34.35.4 L2TP Traffic Blocked Outbound

In some cases, such as when combined with IPsec, L2TP traffic may also require special handling via floating rules. This appears as blocked traffic in the *outbound* direction in the firewall logs, showing an L2TP server interface.

If this happens, add a floating rule as follows:

- Navigate to **Firewall > Rules**, **Floating** tab
- Click  **Add** to add a new rule to the top of the list

- Set **Action** to *Pass*
- Check **Quick**
- Select *L2TP VPN* for the **Interface**
- Set **Direction** to *Out*
- Set **Protocol** to *TCP*
- Set **Source/Destination** as needed, or set to *any*
- Advanced Features:
  - Set **TCP Flags** to *Any flags*
  - Set **State Type** to *Sloppy State*

34.36 Troubleshooting Access when Locked Out of the Firewall

Under certain circumstances an administrator can be locked out of the GUI. There are a number of ways to regain control, so it is not necessarily a major cause for concern. Some methods are a little tricky, but it is nearly always possible to recover access. The worst-case scenarios require physical access, as anyone with physical access can bypass security measures.

Danger: Let the tactics in this document be a lesson: Physical security of a firewall is **critical**, especially in environments where the firewall is physically located in a common area accessible to people other than authorized administrators.

Before taking any of these steps, try the *Default Username and Password*.

34.36.1 Forgotten Password

The firewall administrator password can easily be reset using the firewall console if it has been lost. Access the physical console (*Connect to the Console*) and use option `3` to change the password for the `admin` account. This option can also reset the `admin` account if it is disabled or expired.

See also:

See *3) Reset admin account and password* for details on how this console menu option works.

34.36.2 Forgotten Password with a Locked Console

If the console is password protected, all is not lost. It takes two reboots to accomplish, but the password can be reset with physical access to the console:

- Connect to the console
- Reboot the firewall
- Choose the *Boot Single User* option (`2`) from the loader menu with the ASCII logo
- Press `Enter` when prompted to start `/bin/sh`
- Remount all partitions as rewritable:

  The specific commands vary based on the filesystem.

  - For devices installed using UFS, see *Re-mount UFS Volumes as Read/Write*.
  - For devices installed using ZFS, see *Re-mount ZFS Volumes as Read/Write*.
- Run the built-in `admin` account reset command:

```
# /etc/rc.initial.password
```

- Follow the prompts to change the password
- Run `/sbin/reboot` to reboot.

See also:

See *3) Reset admin account and password* for details on how this console menu option works.

34.36.3 HTTPS Certificate Problems

If the browser refuses to connect due to the certificate itself, or if the GUI web server refuses to run due to the certificate, then the easiest method to regain access is to generate a new self-signed certificate from the console or SSH:

```
# pfSsh.php playback generateguicert
```

That will create a new self-signed GUI certificate, activate it, and restart the GUI web server.

See also:

SSL/TLS Certificate

34.36.4 HTTP vs HTTPS Confusion

Ensure the client is connecting with the proper protocol, either HTTP or HTTPS. If one doesn't work, try the other. If the GUI has not been configured correctly, the firewall may be running the GUI on an unexpected port and protocol combination, such as:

- `http://<hostname>:443`
- `https://<hostname>:80`

To reset this from the console, reset the LAN interface IP Address, enter the same IP address, and the script will prompt to reset the GUI back to HTTP.

Warning: If the browser previously connected to the GUI using HTTPS, it may refuse to connect using HTTP for security reasons (e.g. HSTS).

34.36.5 Blocked Access with Firewall Rules

If a remote administrator loses access to the GUI due to a firewall rule change, then access can still be obtained from the LAN side. The LAN rules cannot prevent access to the GUI unless the anti-lockout rule is disabled. The anti-lockout rule ensures that hosts on the LAN are able to access the GUI at all times, no matter what the other rules on the LAN interface block.

Having to walk someone on-site through fixing the rule from the LAN is better than losing everything or having to make a trip to the firewall location!

34.36.6 Locked Out by Too Many Failed Login Attempts

Attempting to login to the GUI or SSH and failing many times will cause the connecting IP address to be added to the lockout table.

To regain access, login successfully from another IP address and then manually remove the entry as follows:

- Navigate to **Diagnostics > Tables**
- Select *sshguard*
- Click  by the entry or entries for workstations to allow again.

The lockout table may also be cleared by the console or ssh in the shell:

```
pfctl -T flush -t sshguard
```

34.36.7 Remotely Circumvent Firewall Lockout with Rules

There are a few ways to manipulate the firewall behavior at the shell to regain access to the firewall GUI. The following tactics are listed in order of how easy they are and how much impact they have on the running system.

Add a rule with EasyRule

The easiest way, assuming the administrator knows the IP address of a remote client PC that needs access, is to use the `easyrule` shell script to add a new firewall rule. In the following example, the `easyrule` script will allow access on the WAN interface, from `x.x.x.x` (the client IP address) to `y.y.y.y` (presumably the WAN IP address) on TCP port `443`:

```
# easyrule pass wan tcp x.x.x.x y.y.y.y 443
```

Once the `easyrule` script adds the rule, the client will be able to access the GUI from the specified source address.

Add an allow all WAN rule from the shell

Another tactic is to temporarily activate an "allow all" rule on the WAN to let a client in.

> **Warning:** An "allow all" style rule is dangerous to have on an interface connected to a public or untrusted network, such as a WAN interface connected to the Internet. **Do not forget to remove the rule added by this script**

To add an "allow all" rule to the WAN interface, run the following command at a shell prompt:

```
# pfSsh.php playback enableallowallwan
```

Once the administrator regains access and fixes the original issue preventing them from reaching the GUI, remove the "allow all" rule from the WAN.

Disable the Firewall

An administrator can (very temporarily) disable firewall rules by using the physical console or SSH.

> **Warning:** This completely disables `pf` which disables firewall rules and NAT. If the network run by this firewall relies on NAT to function, which most do, then running this command will disrupt connectivity from the LAN to the Internet.

To disable the firewall, connect to the physical console or ssh and use option `8` to start a shell, and then type:

```
# pfctl -d
```

That command will disable the firewall, including all NAT functions. Access to the GUI is now possible from anywhere, at least for a few minutes or until a process on the firewall causes the ruleset to be reloaded (which is almost every page save or **Apply Changes** action). Once the administrator has adjusted the rules and regained the necessary access, turn the firewall back on by typing:

```
# pfctl -e
```

Manual Ruleset Editing

The loaded ruleset is retained in `/tmp/rules.debug`. If the administrator is familiar with PF ruleset syntax, they can edit that file to fix the connectivity issue and reload those rules:

```
# pfctl -f /tmp/rules.debug
```

After getting back into the GUI with that temporary fix, the administrator must perform whatever work is required in the GUI to make the fix permanent. When the rules are saved in the GUI, the temporary edit to `/tmp/rules.debug` will be overwritten.

34.36.8 Remotely Circumvent Firewall Lockout with SSH Tunneling

If remote access to the GUI is blocked by the firewall, but SSH access is allowed, then there is a relatively easy way to get in: SSH Tunneling.

If the GUI is on port `443`, set the SSH client to forward local port `443` (or `4443`, or another port) to remote port `localhost:443`. If the firewall GUI is on another port, use that as the target instead. Then point the browser to `https://localhost`. Add the port to the end of the URL if it differs from the default 443, for example `https://localhost:4443`. If the GUI is using HTTP, change the protocol on the URL to `http://`.

Fill out the options as shown in Figure *Setting Up a Port 443 SSH Tunnel in PuTTY*, then click **Add**.

Once the client connects and authenticates, the GUI is accessible from the redirected local port.

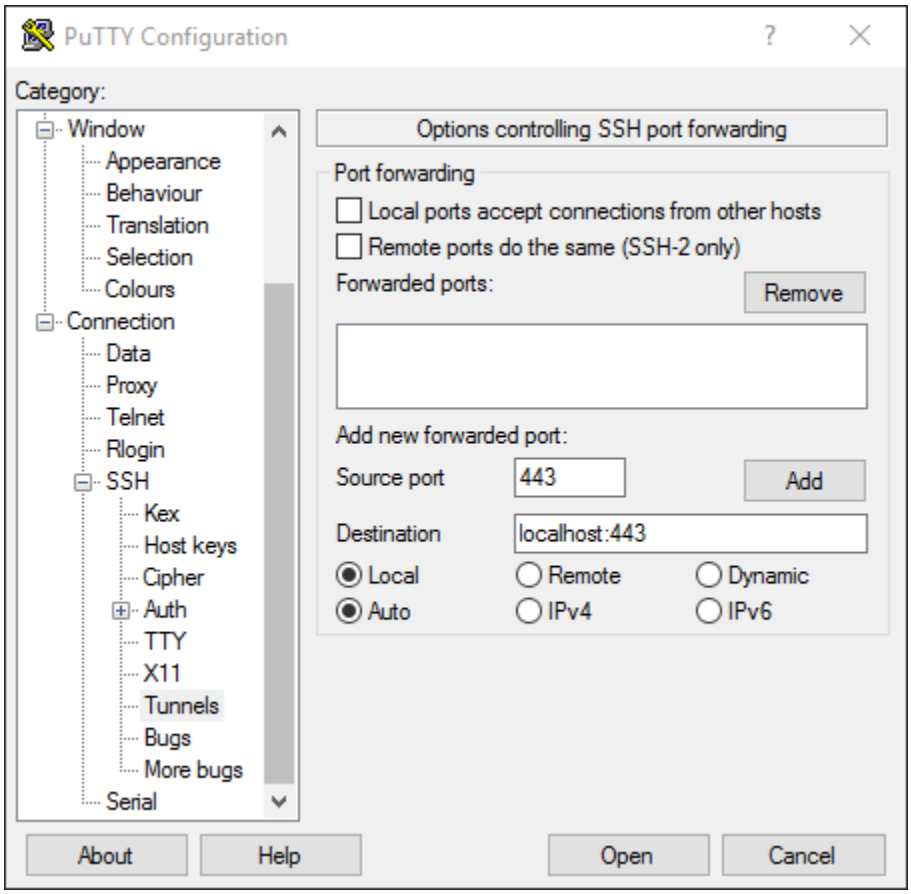

Fig. 4: Setting Up a Port 443 SSH Tunnel in PuTTY

34.36.9 Authentication Server Failure

LDAP and RADIUS authentication for the GUI automatically fall back to the local database if they fail. If the authentication server fails and all local accounts are disabled, locked out, passwords are not known, etc., then to get back in, regain access to the local `admin` account.

Connect to the console (*Connect to the Console*) or ssh and run option `3` to reset the credentials to the *Default Username and Password*.

34.37 Troubleshooting Blocked Log Entries for Legitimate Connection Packets

Sometimes log entries will be present that appear to be blocking legitimate traffic, while labeled with the "Default deny" or even sometimes a pass rule. There are several possible causes for this behavior.

34.37.1 Out-of-State Web Server Packets

The most common example is seeing a connection blocked involving a web server.

Action	Time	Interface	Rule	Source	Destination	Protocol
✕	Apr 17 06:28:59	LAN	Default reject instead of block for multi-WAN (1647375041)	17 :42888	142.251.32.14:443	TCP:PA
✕	Apr 17 06:28:59	LAN	Default reject instead of block for multi-WAN (1647375041)	17 :42888	142.251.32.14:443	TCP:FA
✕	Apr 17 06:34:44	LAN	Default reject instead of block for multi-WAN (1647375041)	17 :55402	142.250.112.95:443	TCP:FA
✕	Apr 17 06:34:50	LAN	Default reject instead of block for multi-WAN (1647375041)	17 :40816	35.244.164.0:443	TCP:FPA
✕	Apr 17 06:41:56	LAN	Default reject instead of block for multi-WAN (1647375041)	17 :48278	216.239.38.57:443	TCP:PA
✕	Apr 17 06:41:56	LAN	Default reject instead of block for multi-WAN (1647375041)	17 :48278	216.239.38.57:443	TCP:FA

Fig. 5: Log entries for blocked out-of-state TCP packets

This is likely due to a TCP FIN packet arriving after firewall has removed the connection state. This happens because on occasion a packet will be lost, and the retransmits will be blocked because the firewall has already closed the connection. Another possible reason for the messages is if a packet arrived too slowly and was outside of its expected arrival window. It can also happen when web servers attempt to reuse connections.

In each case, the log entries are harmless and do not indicate a blocked connection. All stateful firewalls do this, though some do not generate log messages for this blocked traffic even if all blocked traffic is logged.

These blocked packets will occur even if rules exist which look as though they should match the traffic, such as an "Allow All" rule. Pass rules for TCP only allow **TCP SYN** packets to create a state. These rules assume TCP traffic with other flags will either be part of an existing state in the state table, or packets with spoofed TCP flags.

See also:

TCP Flags

34.37.2 Packets with IP Options

PF will drop packets containing IP options unless pass rules specifically allow them using the "Allow IP Options" checkbox in the Advanced section when editing a firewall rule (*IP Options*).

Since this is a special case, the firewall always logs when it drops these packets. However, the rule ID shown in this case is the rule the packet would have otherwise matched.

Action	Time	Interface	Rule	Source	Destination	Protocol
✕	Apr 16 14:33:31	WAN	Allow IGMP (1670603678)	[redacted].202	224.0.0.22	IGMP
✕	Apr 16 14:33:36	WAN	Allow IGMP (1670603678)	[redacted].201	224.0.0.22	IGMP
✕	Apr 16 14:33:37	WAN	Allow IGMP (1670603678)	[redacted].201	224.0.0.22	IGMP
✕	Apr 16 14:39:09	WAN	Allow IGMP (1670603678)	[redacted].24	224.0.0.22	IGMP
✕	Apr 16 14:39:11	WAN	Allow IGMP (1670603678)	[redacted].24	224.0.0.22	IGMP
✕	Apr 16 14:42:33	WAN	Allow IGMP (1670603678)	[redacted].24	224.0.0.22	IGMP

Fig. 6: Log entries for packets blocked due to the presence of IP options

To resolve this, ensure any rules which should pass packets containing IP Options (e.g. IGMP) are configured to allow IP options.

See also:

IP Options

34.37.3 Asymmetric Routing

Blocked packets are also common for legitimate-looking traffic where routed networks and/or Multi-WAN are involved when *Asymmetric Routing* or other related causes are present in the network.

See also:

- *Bypass Firewall Rules for Traffic on Same Interface*
- *Static Route Filtering*
- *Troubleshooting Asymmetric Routing*

34.37.4 Clustering and Load Balancing

In a clustered environment, traffic arriving via the primary and leaving an internal interface can appear to be blocked on the secondary if the destination is a broadcast or multicast address like those used for Microsoft Network Load Balancing. The traffic appears to be blocked on the internal interface of the secondary from a public IP address source. Capturing the traffic on the secondary and inspecting the destination address in Wireshark will reveal the nature of the destination MAC address.

34.38 Troubleshooting ARP Move Log Messages

Log entries on pfSense® software may appear in the system log showing something similar to the following:

```
pfsense kernel: arp: 192.168.1.50 moved from c4:0c:5c:69:6c:05 to 62:1e:3e:43:04:0c on␣
↪em1
```

This indicates that the firewall saw the specified IP address move between the first MAC address and the second. This can happen for several reasons.

IP address conflict
: Two hosts are configured with the same IP address

ARP poisoning
: Someone on the network is ARP poisoning hosts

NIC teaming
: Some NIC teaming or bonding configurations will routinely log messages such as this because of the way they function. In these cases, this message is normal.

IP address moved to a different host or NIC
: If an actively used IP address is reassigned to a different device or different NIC, this message will be logged. This will only occur when an active IP is moved, for instance an expired DHCP lease that later is assigned to a different host will not trigger this as the IP must have an active ARP table entry on the firewall for this to occur.

Apple Bonjour sleep proxy
: Apple's Bonjour sleep proxy will cause these logs to appear because of its network behavior. If both of the listed MAC addresses are Apple vendor MACs, this is likely why and can be disregarded as normal behavior.

This logging can be disabled by setting the tunable `net.link.ether.inet.log_arp_movements` to value `0` under **System > Advanced**, **System Tunables** tab.

34.39 Troubleshooting "login on console as root" Log Messages

Occasionally, the following messages may appear in the system log:

```
login: login on console as root
```

or:

```
login: login on ttyv0 as root
```

This is normal. It means that the console menu stopped and restarted, or someone pressed `Enter` (didn't choose a menu option) at the console menu. To suppress these messages, enable password protection for the console login and then it will only login after authentication. If console logins are already enabled, then this means someone logged into the console.

To password protect the console:

- Click **System > Advanced**
- Find the **Console Options** section near the end of the page
- Check **Password protect the console menu**
- Click **Save**

34.40 Troubleshooting "promiscuous mode enabled" Log Messages

The following log messages are recorded when a utility has placed the network card into promiscuous mode:

```
Feb 10 01:41:58    kernel: igc0: promiscuous mode disabled
Feb 10 01:41:57    kernel: igc0: promiscuous mode enabled
Feb 10 01:41:54    kernel: igc0: promiscuous mode disabled
Feb 10 01:41:54    kernel: igc0: promiscuous mode enabled
Feb 10 01:41:50    kernel: igc0: promiscuous mode disabled
```

Promiscuous mode is a mode where the network card will receive every packet on the interface, regardless of the target MAC address, in order to monitor traffic. This is normal for utilities such as `tcpdump`.

34.41 Troubleshooting Low Interface Throughput

In situations where the firewall is not transferring as much data as desired. There are many potential causes for this condition, most of which are listed here along with possible resolutions

34.41.1 Insufficient Hardware

The first thing to check is that the hardware is capable of pushing the expected amount of traffic. In some cases this is more obvious, such as a newer multi-core server being unable to transfer small amounts of packets, or an older firewall not being able to transfer high loads. Other cases are more subtle and require some testing and verification.

The most obvious test is to watch the firewall CPU load while transferring data. This can be observed from **Diagnostics > System Activity** or from the shell by running:

```
top -aSH
```

If an IRQ process for a network card is using a significant amount of CPU on a core, then either the hardware is being fully (or over) utilized, or the driver may need adjustments to work as expected. If the firewall is not under any stress whatsoever while transferring data, the problem likely lies elsewhere.

If the amount of "System" CPU is high and the amount of interrupts is low, the problem may be in the amount of packet processing happening in pf or being used for encryption. If pf is pushing the CPU as high as it can, it may require a faster CPU.

If the CPU is being used for encryption, a faster cipher may be chosen, or in some cases a cryptographic accelerator may be utilized.

34.41.2 Hardware/Driver Tuning Required

If a CPU core is fully utilized by interrupts, the network card driver may need tuning. Most of these tweaks are covered on *Tuning and Troubleshooting Network Cards*. Some cards, such as `igb`, are able to use more queues for processing packets which will spread the load across multiple cores and result in higher throughput, but not every workload is helped by these options, so less queues may also help.

Another item to check is under **System > Advanced** on the **Networking** tab. Ensure that the boxes are checked for **Disable hardware TCP segmentation offload** and **Disable hardware large receive offload**. If they are already checked, try toggling **Disable hardware checksum offload**. If no difference is observed, toggle it back.

34.41.3 Duplex Mismatch

A duplex mismatch is also possible, though this is more common on circuits 100Mbit/s or less. Some providers are stuck in the stone age and still insist on hard-coding ports on CPEs such as fiber converters at *100Mbit/s full-duplex*. If the CPE is hard-coded but the firewall is not, it would show as using 100Mbit/s half-duplex on **Status > Interfaces**. The duplex mismatch will lead to interface errors, collisions, and low throughput. Setting the speed and duplex is covered on *Forcing Interface Speed or Duplex Settings*.

34.41.4 Traffic Shaping

If the traffic shaping wizard was run previously before an increase in upstream bandwidth, the old limits may still be in effect. Visit **Firewall > Traffic Shaper** and check the root interface queues, and *qInternet* queues to ensure that any listed interface bandwidths are appropriately specified and current.

Also check the **Limiters** tab under the traffic shaper settings, verify that any configured limiters are set for appropriate speeds. Limiters may also need increased queue lengths to handle higher throughput volumes.

34.41.5 MTU Issues

Issues with upload speed frequently end up being issues with the MTU. If the MTU on pfSense® software (default 1500), is higher than the MTU of the upstream link, it can result in packets being fragmented, lost, or otherwise mishandled. Setting MSS clamping on the WANs or changing the MTU of the interface may help.

VPN + MTU Issues

Similar to the above, if large packets or high-throughput seems to break over a VPN, enable MSS Clamping for VPN Networks under **System > Advanced**, **Firewall & NAT** tab in the **VPN Packet Processing** section. The default value for the option is `1400`, but try lower values such as `1350`, `1300`, `1250`, etc.

34.41.6 WAN Connection

There could also be issues between the WAN and the Modem/CPE. It could be a cable, or a quirk in how the two interfaces talk to each other. Place a small switch between the firewall and the Modem/CPE as a test.

34.41.7 Client/Testing Method

The slowness may not be from any cause on the firewall. It could be the client itself or how it connects. Testing a 100Mbit/s WAN over 802.11g wireless, for example, would never show full speed. Testing a 300Mbit/s WAN from a 100Mbit/s LAN connection would likewise not be a valid test.

Ensure the client is connected to the firewall through a connection at least as fast as the WAN supports.

34.41.8 ISP Issues

If every other factor has been eliminated, test the modem without the firewall involved. If the speed is still low, it may be the ISP to blame, or the Modem/CPE.

34.42 Troubleshooting Multi-WAN

This section describes some of the most common problems with multi-WAN and how to troubleshoot them.

34.42.1 Verify Firewall Rule Configuration

The most common error when configuring multi-WAN is improper firewall rules. Remember, the first matching rule wins and any further rules are ignored. If a policy routing rule is below the default LAN rule in the list, no traffic will ever match that rule because it will match the default LAN rule first. Review *Policy Routing Configuration* and verify the rules are correct.

If the rule ordering and configuration appears correct, it may help to enable logging on the rules. See *Troubleshooting Firewall Rules* for more information. Ensure the appropriate policy routing rule is passing the traffic.

34.42.2 Policy routing does not work for web traffic or all traffic

When a package that can proxy traffic is used, it overrides any policy routes that are defined for client traffic on that port. So no matter which gateway is set in firewall rules, traffic that uses a proxied connection will still go through the proxy.

34.42.3 Failover not working

If problems occur when an Internet connection fails, typically it is because the monitor IP address is still answering, so the firewall thinks the connection is still available. Check **Status > Gateways** to verify. An IP address on the modem may be used as a monitor IP address, which will still be accessible even if the Internet connection is down.

34.42.4 Load balancing not working

- Check that the Gateway Group is properly configured for load balancing, with at least two gateways on the same tier.
- Check that the firewall rules being matched direct traffic to the correct load balancing gateway group.
- Check that all of the gateways in the group show as Online under **Status > Gateways**. Connections marked as Offline will not be used.
- Check the testing methodology. Rather than testing with a web browser, try testing with curl or similar utilities which do not retain session data.
- Check that the traffic is not using a proxy or otherwise being initiated from a daemon on the firewall itself.

34.42.5 A gateway is incorrectly marked offline

If a gateway is listed as offline, but the WAN is actually up, several things could be at fault:

- First, test to see if the monitor IP address responds to a ping from a client device on the LAN, and again from **Diagnostics > Ping**.
- If the device with the monitor IP address or other intermediate hop drops ICMP echo request packets without a payload, manual pings would work but the gateway monitoring would fail. See *Advanced Gateway Settings* and set the payload to a value of `1` or higher.
- If the gateway or monitor IP address does not respond to ICMP echo requests, enter a different monitor IP address to use instead.
- If the monitor IP address is configured as a DNS server for a different WAN, the static routes could be causing a conflict and the echo requests to the gateway may not be following the expected path. Set a non-conflicting monitor IP address on the gateway.
- If there is an outbound NAT rule on the WAN with a **Source** of *any*, it can cause problems with traffic on the firewall, including monitoring traffic, because that will also NAT traffic from the firewall itself. This can be especially problematic if the source address is changed to a CARP VIP. Fix the outbound NAT.

If all else fails, it's possible the circuit really is down, but the testing methodology appears to show it up. Verify the Interface and Gateway settings and run the test again, and try `traceroute` to make sure the traffic is leaving using the expected path.

34.42.6 Ping works by IP address, but web browsing fails

In this case, the most likely cause is DNS. If the firewall DNS settings do not match those in *Interface and DNS Configuration*, clients may not be able to resolve DNS when a WAN is down. Review the settings and fix any problems that are found.

34.42.7 Services on the firewall do not use multiple connections

Services on the firewall itself do not understand load balancing; They will use only the WAN connection with the default gateway. Configuring default gateway switching (*Managing the Default Gateway*) can allow such services to use failover.

Check the Netgate Forum for package-specific alternate techniques.

34.43 Troubleshooting NAT

NAT can be a complex animal and in all but the most basic environments there are bound to be issues obtaining a good working configuration. This section will go over a few common problems and suggestions on how they can potentially be solved.

See also:

Hangouts Archive to view the May 2016 hangout for NAT on pfSense® software version 2.3, The June 2016 hangout on Connectivity Troubleshooting, and the December 2013 Hangout on Port Forward Troubleshooting, among others.

34.43.1 Port Forward Troubleshooting

Port Forwards in particular can be tricky, since there are many things to go wrong, many of which could be in the client configuration and not pfSense software.

For information on diagnosing these problems, see *Troubleshooting NAT Port Forwards*,

34.43.2 NAT Reflection Troubleshooting

For detailed information about troubleshooting NAT reflection, see *Troubleshooting NAT Reflection*.

34.43.3 Outbound NAT Troubleshooting

When manual outbound NAT is enabled and there are multiple local subnets, an outbound NAT entry is required for each. This applies especially if traffic must exit with NAT after coming into pfSense software through a VPN connection.

One indication of a missing outbound NAT rule would be seeing packets leave the WAN interface with a source address of a private network. See *Packet Capturing* for more details on obtaining and interpreting packet captures.

34.43.4 1:1 NAT Troubleshooting

For information about troubleshooting 1:1 NAT, see *Troubleshooting 1:1 NAT*.

34.44 Troubleshooting 1:1 NAT

If 1:1 NAT (or even Outbound NAT) is properly configured, but the system still appears to access sites like https://www.pfsense.org/ip and https://ifconfig.me/ from the main WAN IP Address on the firewall, then a web proxy or similar may be in use.

With a proxy involved, even though 1:1 NAT is in place the web requests are still proxied, and thus originate from the firewall itself or the proxy.

To proxy the web traffic and verify the 1:1 mapping is working properly, find a different service to verify against, such as:

- Login to a remote system and watch the firewall logs or `tcpdump`.
- Initiate some traffic from the system and verify the traffic is originating from the proper IP Address.
- Access an HTTPS site that does not flow through the proxy.

34.45 Troubleshooting NAT Port Forwards

If problems are encountered while attempting a port forward using pfSense® software, try the following.

34.45.1 Port Forward Testing Procedures

Follow the Guide

If the *Port Forwarding* guide was not followed exactly, delete anything that has been tried and start from scratch with those instructions.

NAT Reflection

Port forwards do not work internally unless *NAT reflection* has been enabled. Always test port forwards from outside the network, such as from a client in another location, or from a 3G/4G device.

Setup Logging

Edit the firewall rule that passes traffic for the NAT entry and enable logging. Save and Apply Changes. Then try to access it again from the outside. Check the firewall logs (**Status > System Logs**, **Firewall** tab) to see if the traffic shows as being permitted or denied.

Check States

Check the states table under **Diagnostics > States**, filter on the source, destination, or port number to see if any entries are present. If entries are present that appear to match the NAT performed by the port forward, then the firewall is accepting and translating the traffic properly, so look at internal issues (e.g. client firewalls, etc, see below.)

Check Packet Capture

Use a **Packet Capture** or `tcpdump` to see what is happening on the wire.

See also:

Packet Capturing

This is the best means of finding the problem, but requires the most networking expertise. Navigate to **Diagnostics > Packet Capture** to capture traffic, or use `tcpdump` from the shell.

Start with the WAN interface, and use a filter for the appropriate protocol and port. Attempt to access from outside the network and see if it shows up. If not, the ISP may be blocking the traffic, or if Virtual IPs are involved they may have an incorrect configuration.

If the traffic is seen on the WAN interface, switch to the inside interface and perform a similar capture. If the traffic is not leaving the inside interface, there is a NAT or firewall rule configuration problem.

If packets leave the internal interface, but no traffic is coming back from the destination host, the target host default gateway may be missing or incorrect, it may not be listening on that port, or it may have a local firewall (Windows Firewall, iptables) blocking the traffic.

For certain types of packets return traffic may be seen indicating the host is not listening on that port. For TCP, this would be a TCP RST. For UDP, it may be an ICMP Unreachable message.

34.45.2 Check for Common Problems

Aside from the testing procedures outlined above, this section contains common problems with port forwards and how to resolve them.

Missing or incorrect firewall rule

After checking the port forward settings, double check that the firewall rule has the proper settings. An incorrect firewall rule would also be apparent by viewing the firewall logs (*Viewing the Firewall Log*). Remember, the destination for the firewall rule is the internal IP address of the target system and not the address of the interface containing the port forward. See *Rules for NAT* for more details.

Firewall is enabled on the target machine

Another thing to consider is that pfSense software may be forwarding the port properly, but a firewall on the target machine may be blocking the traffic. If there is a firewall on the target system, check its logs and settings to confirm whether or not the traffic is being blocked at that point.

Incorrect Gateway on Target

For pfSense software to properly forward a port for a local system, pfSense software **must** be the default gateway for the target host.

If pfSense software is not the gateway, the target host will attempt to send replies to port forward traffic out whatever router the target has for its gateway, and then one of two things will happen: It will be dropped at that point since there would be no matching connection state on that router or it would have NAT applied by that router and then be dropped by the system originating the request since the reply is from a different IP address than the one to which the request was initially sent.

Target system has no gateway or cannot use pfSense software as its gateway

A subset of the larger problem of the target machine gateway is when the device has no gateway, or is incapable of having a gateway. In these cases, work around that problem by switching to Hybrid or Manual Outbound NAT and crafting a rule on the LAN or other internal interface facing the local device. This rule would translate traffic from any source going to the target host on the target port.

For example, if there is a file server that does not support a gateway located at `10.3.0.6`, switch to Hybrid Outbound NAT and create a rule like Figure *Manual Outbound NAT Rule for LAN Device with Missing Gateway* to reach it from outside the network. The file server will see the LAN IP address of the firewall as the source of the traffic, and since that is "local" to the server, it will respond properly.

Target machine is not listening on the forwarded port

If the request is rejected instead of timing out when the connection is tested, in all likelihood pfSense software is forwarding the connection properly and the connection is rejected by the target host. This can happen when the target host has no service listening on the port in question, or if the port being forwarded does not match the port on which the target host is listening.

For example, if the target host is supposed to listen for SSH connections, but the port forward was entered for port `23` instead of `22`, the server would most likely reject the request. The difference can typically be detected by trying to connect to the port in question using `nc` or `telnet`. A message such as "Connection refused" indicates something, frequently the inside host, is actively rejecting the connection.

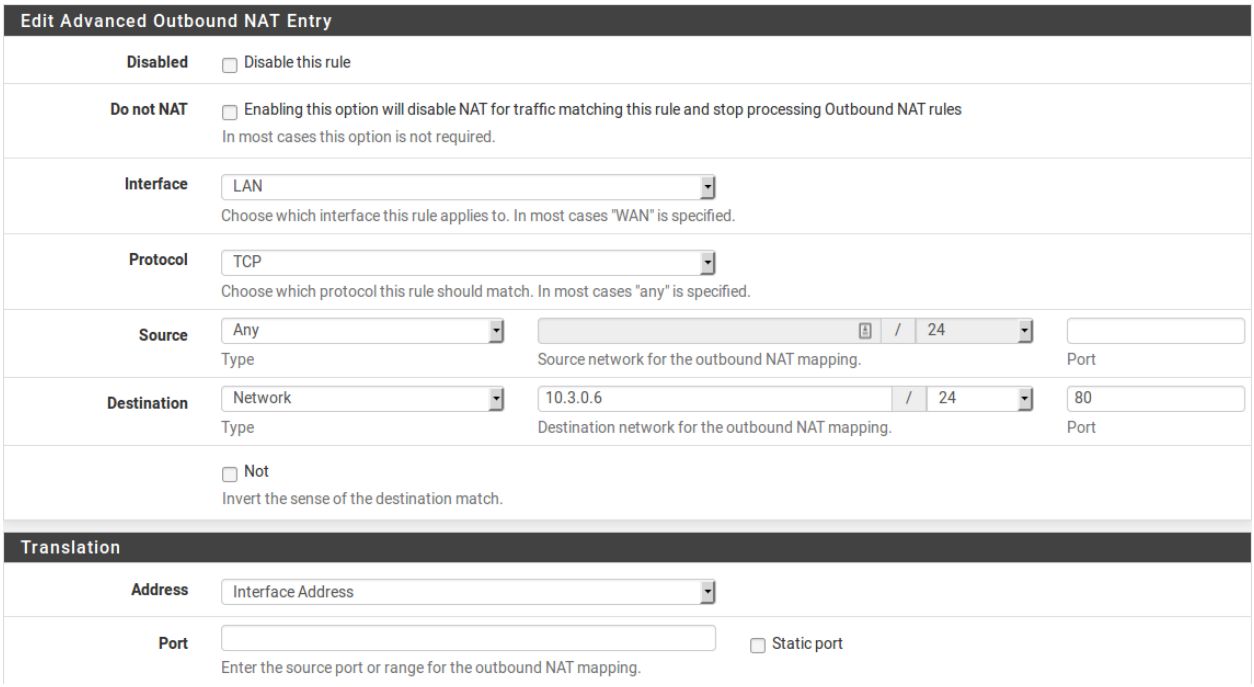

Fig. 7: Manual Outbound NAT Rule for LAN Device with Missing Gateway

See also:

Using **Diagnostics > Test Port** can also help, see *Testing a TCP Port*.

ISP is blocking the port

Some ISPs filter incoming traffic to well-known ports. Check the Terms of Service (ToS) from the ISP to see if there is a clause about running servers. Such restrictions are more common on residential connections than commercial connections. When in doubt, a call to the ISP may clear up the matter.

If ports are being filtered by the ISP, moving the services to a different port may work around the restriction. For example, if the ISP disallows servers on port `80`, try `8080` or `18080`.

Before attempting to work around a filter, consult the ISP ToS to ensure that running a server is not a violation of their rules.

Testing from inside the network instead of outside

By default, port forwards will only work when connections are made from outside of the local network. This is a frequent mistake when testing port forwards.

If port forwards are not required to work internally, see *NAT Reflection*. However, Split DNS (*Split DNS*) is a more proper and elegant solution to this problem without needing to rely on NAT reflection or port forwards, and it would be worth the time to implement that instead.

Even with NAT reflection, testing from inside the network isn't necessarily indicative of whether it will work from the Internet. ISP restrictions, restrictions on devices upstream from the firewall, amongst other possibilities are not possible to see when testing from within the network.

Incorrect or missing Virtual IP address

When using IP addresses that are not the actual IP addresses assigned to an interface, a Virtual IP address must be used (VIPs, see *Virtual IP Addresses*). If a port forward on an alternate IP address is not working, a different type of VIP may be required. For example, a Proxy ARP type may be necessary instead of an "Other" type VIP.

When testing, also make sure that the client is connecting to the proper VIP.

pfSense software is not the border/edge router

In some scenarios pfSense software is acting as an internal router and there are other routers between it and the Internet also performing NAT. In such a case, a port forward must also be entered on the edge router forwarding the port to pfSense software, which will then use another port forward to get it to the local target host.

Note: Some upstream gear may also be able to change to a bridge mode to eliminate double NAT, or use a half bridge or DMZ/1:1 NAT mode to forward all traffic to the firewall running pfSense software.

Forwarding ports to a host behind Captive Portal

Forwarding ports to a host behind a captive portal needs special consideration. See *Port Forwards Behind Portal Only Work When Target Logs In* for details.

Return Routing

There are a few possible issues with return routing on WANs, particularly with multiple WANs.

- If the port forward is on a WAN that is not the default gateway, make sure there is a gateway chosen on the corresponding WAN interface, or the firewall rules for the port forward would not reply back via the correct gateway.

  The firewall will not add `reply-to` on the rules unless the interface is configured with a gateway.

- If this is on a WAN that is not the default gateway, ensure the traffic for the port forward is **NOT** passed in via Floating Rules or an Interface Group.

  Only rules present on the WAN interface tab under Firewall Rules will have the `reply-to` keyword to ensure the traffic responds properly via the expected gateway.

- If this is on a WAN that is not the default gateway, make sure the firewall rule(s) allowing the traffic in **do not** have the box checked to disable `reply-to`.

- If this is on a WAN that is not the default gateway, make sure the master `reply-to` disable switch is not checked under **System > Advanced**, on the **Firewall/NAT** tab.

Gateways on Firewall Rules

WAN rules **should NOT** have a gateway set, so make sure that the rules passing traffic for the port forward do NOT have a gateway configured.

Check UPnP IGD & PCP

If the traffic appears to be forwarding in to an unexpected host, it may be happening due to UPnP IGD & PCP. Check **Status > UPnP IGD & PCP** to see if an internal host has configured a port forward unexpectedly. If so, disable UPnP IGD & PCP on either that host or on the firewall.

34.46 Troubleshooting NAT Reflection

NAT Reflection (*NAT Reflection*) is complex, and as such may not work in some advanced scenarios. The best practice is to use Split DNS instead (*Split DNS*) in most cases. However, NAT Reflection on current pfSense software releases works reasonably well for nearly all scenarios, and any problems are usually a configuration mistake. Ensure that it was enabled the right way, and make sure a large range of ports is not being forwarded unnecessarily.

NAT Reflection rules are also duplicated for each interface present in the system, so if a lot of port forwards and interfaces are in use, the number of reflectors can easily surpass the limits of the firewall. If this happens, an entry is printed in the system logs. Check the logs for any errors or information.

34.46.1 Web Access is Broken with NAT Reflection Enabled

If an improperly specified NAT Port Forward is present on the firewall, it can cause problems when NAT Reflection is enabled. The most common way this problem arises is with a local web server, and port `80` is forwarded there with an improperly specified **External Address**.

If NAT Reflection is enabled and the **External Address** is set to *any* , any connection made on the firewall comes up as the local web server. To fix this, edit the Port Forward for the offending port, and change **External Address** to *Interface Address* instead.

If an external address of *any* is required, then NAT Reflection will not work, and Split DNS must be used instead.

34.47 Troubleshooting OpenVPN

This section describes several troubleshooting techniques for OpenVPN, as well as common issues users encounter with OpenVPN along with their solutions.

34.47.1 Check OpenVPN Status

The first place to check is **Status > OpenVPN**, which displays the connection status for each OpenVPN instance.

If a VPN is connected, waiting, reconnecting, etc, it is indicated on that screen.

See also:

For more information, see *OpenVPN Server and Client Status*.

34.47.2 Check Firewall Log

If a VPN connection does not establish, or establishes but does not pass traffic, check the firewall logs under **Status > System Logs** on the **Firewall** tab.

If traffic for the tunnel itself is being blocked, such as traffic to the WAN IP address on port `1194`, then adjust the WAN firewall rules accordingly.

If traffic is blocked on the OpenVPN interface, add rules to the **OpenVPN** tab (or assigned OpenVPN interface tab, if present) to allow traffic there.

34.47.3 Some hosts work, but not all

If traffic between some hosts functions over OpenVPN, but some hosts do not, this is commonly one of four things:

Firewall rules
: Ensure the rules in the firewall GUI on both sides allow the desired network traffic. This may be on the **OpenVPN** tab in **Firewall > Rules** or an assigned OpenVPN interface tab.

Missing, incorrect or ignored default gateway
: If the host that cannot be reached across the VPN does not have a default gateway, or has one pointing to something other than the firewall running OpenVPN, the host does not know how to properly get back to the remote network on the VPN.

  Additionally, some devices, even with a default gateway specified, do not use that gateway. This has been seen on various embedded devices, including IP cameras and printers. In this case, there is no proper firewall-based solution. The software on the device must be fixed.

  This behavior can be verified by running a packet capture on the inside interface of the firewall connected to the network containing the host. If the packet capture contains traffic leaving the inside interface on the firewall, but not replies to that traffic, the device is not properly routing its reply traffic or potentially blocking it via local firewall on the device.

  See also:

  Troubleshooting with tcpdump is covered in *Using tcpdump on the command line*.

Incorrect subnet mask
: If the subnet in use on one end is `10.0.0.0/24` and the other is `10.254.0.0/24`, and a host has an incorrect subnet mask of `255.0.0.0` or `/8`, it will never be able to communicate across the VPN because it thinks the remote VPN subnet is part of the local network and hence routing will not function properly.

  Fix the incorrect subnet mask and then two-way communication is possible.

Host firewall
: If there is a firewall on the target host, it may not be allowing the connections. The Windows firewall, for example, will not allow connections from outside of its local subnet in certain configurations.

34.47.4 Check the OpenVPN logs

The OpenVPN logs contain details about the OpenVPN processes, including log messages relating to connections attempts, remote access login records, and other related messages. These logs are in the GUI under **Status > System Logs**, **OpenVPN** tab.

When an OpenVPN instance connects it will log messages similar to the following:

```
openvpn[32194]: UDPv4 link remote: 1.2.3.4:1194
openvpn[32194]: Peer Connection Initiated with 192.168.110.2:1194
openvpn[32194]: Initialization Sequence Completed
```

Note: The number following `openvpn` will differ, it is the process ID of the OpenVPN process handling the connection.

If the `link remote` and `Peer Connection Initialized` messages are not shown when trying to connect, the cause is likely either incorrect client configuration, so the client is not attempting to connect to the correct server, or incorrect firewall rules blocking the client's connection.

34.47.5 Overlapping IPsec connections

The way IPsec configures security policies in the kernel, any enabled IPsec connection matching the local and remote subnets pairs will restrict the firewall to only passing traffic for that pair through IPsec. The traffic will not pass through any other interface, including OpenVPN. Disable any IPsec connections which specify the same local and remote networks as another VPN.

If an IPsec tunnel has been recently disabled or removed, check if the security policy database (SPD) entries are still present at **Status > IPsec** on the **SPD** tab.

If the SPD entries for a disabled tunnel are still active, stop the IPsec daemon and then start it again.

34.47.6 Check the system routing table

Browse to **Diagnostics > Routes** and review the contents of the routing table. For site-to-site VPNs, routes will be present for the remote network(s) to the appropriate *tun* or *tap* interface. If the routes are missing or incorrect, the **Local Network**, **Remote Network**, or custom options are not configured correctly.

If a peer-to-peer setup is in use (shared key or SSL/TLS with `/30` tunnel network) and not client/server, ensure that the custom options do not contain any "push" commands. In a peer-to-peer setup, the peers cannot push settings to each other. Both sides must contain appropriate remote network configurations.

34.47.7 Test from different vantage points

If the connection appears to be up according to the logs, but it does not work from a host on the LAN, try it from the firewall itself. These tests may be easily performed by the **Diagnostics > Ping** page in the GUI.

See also:

- *Ping Host*
- *OpenVPN Adapter Address ICMP Behavior*

First test using the inside interface involved in handling OpenVPN internal traffic as the ping source. This is typically the LAN interface. If that does not work, try again using the *default* source address so that the firewall will source the ping from the OpenVPN interface itself.

If the *default* source ping works but the internal network ping does not, check the firewall rules and routes on the far side.

34.47.8 Trace the traffic with packet captures

Using packet captures to determine traffic flow is one of the most helpful troubleshooting techniques.

Start with the internal interface (commonly LAN) on the side where hosts initiate the traffic. Next, progress to the *tun* interface on that firewall, then the *tun* interface on the remote firewall. Finally, check the inside interface on the remote firewall. Determining which interfaces contain the traffic which do not can help greatly in narrowing down the location of the problem.

See also:

Packet Capturing

34.47.9 Routes will not push to a client

If a client does not receive routes for networks from the **Local Network** settings or a `push` statement, a couple things could be happening:

- Check that an SSL/TLS server setup is used with a **Tunnel Network** larger than a `/30`. The `server` mode in OpenVPN only takes effect when using a subnet large enough to contain multiple clients, such as a `/24`.
- If the client is running on Windows 10 or similar, try running the client as Administrator. Some versions of the OpenVPN client require Administrator mode to apply routes to the client PC routing table.

  Note: This should not be a factor on modern versions of the OpenVPN client for Windows, so another step is to uninstall the OpenVPN client on the end user device and install the most current available client.

- Peer-to-peer setups (shared key, SSL/TLS with a `/30` tunnel network) are not capable of pushing routes. Use the **Remote Network** boxes or `route` statements on each side (both client and server) to direct traffic to subnets on the far end of the tunnel.

34.47.10 Why do multiple OpenVPN clients get the same IP address?

If all clients use the same certificate then OpenVPN will assign all clients the same IP address when they connect. To work around this, create separate certificates for each client, which is the best practice.

Another workaround is to check **Duplicate Connections** on the server configuration. This is a bad practice, however, as it is less secure than using unique certificates for each client.

34.47.11 Importing OpenVPN DH Parameters

When importing an existing OpenVPN setup into pfSense, there is no need to import DH Parameters. DH parameters are not specific to a given setup in the way that certificates or keys are.

See also:

DH Parameters Length

34.48 Troubleshooting Windows OpenVPN Client Connectivity

Historically, OpenVPN client software on Windows had issues with routing due to a lack of privileges. Current versions of the OpenVPN client software for Windows run as a service which only requires administrative privileges during the installation process and **not** when the client software runs afterward.

Older legacy client software versions may still need such privileges, but in nearly all cases the correct course of action is to upgrade the software.

See also:

- *Installing the OpenVPN Client on Windows*
- *Routes will not push to a client*
- *OpenVPN Client Export Package*

When installing OpenVPN client software using the *OpenVPN Client Export Package*, the installer will not upgrade an existing installation of OpenVPN client software. To ensure the client software is updated properly, uninstall the old client software first, reboot, then install the new copy.

34.49 Troubleshooting OpenVPN Internal Routing (iroute)

For a site-to-site PKI (SSL) OpenVPN setup with a tunnel network larger than `/30`, OpenVPN must have an internal route for the client subnet. Without the internal route, the firewall will forward traffic into OpenVPN but OpenVPN will drop the traffic as it has no way to determine the proper destination. There are a couple common scenarios where this may have difficulties.

The **Remote Network** (`route`) definitions on the server settings inform the firewall operating system that the networks must be routed to an OpenVPN instance. The **Remote Network** (`iroute`) options on the **Client Specific Override** inform OpenVPN internally which networks are associated with a specific client certificate.

See also:

- *Client Specific Overrides*
- *OpenVPN Site-to-Site Configuration Example with SSL/TLS*

34.49.1 Check Internal Route Configuration

Internal routes are set by a **Client Specific Overrides** entry which matches the client certificate **common name**. In the override, the **IPv4/IPv6 Remote Network/s** boxes can setup this internal routing, or it can be performed manually using an `iroute` statement in the advanced settings.

The firewall creates `iroute` statements automatically for each network listed in the **IPv4** and **IPv6 Remote Network/s** fields of an override.

Next, ensure that the **common name** matches and that OpenVPN is learning the internal route as it should be. Log verbosity in OpenVPN may need increased to see if this is working. On **Status > OpenVPN** the internal routing for the OpenVPN server may also be viewed while the client is connected.

For each network that needs an `iroute` statement, the **server** definition must also have the same network(s) listed as **IPv4/IPv6 Remote Networks** or as `route` statements in the **Custom options** box.

34.49.2 Example Configuration

This is a basic example which demonstrates routing a single subnet to a specific client.

- Server1 custom options:

```
push "route a.a.a.0 255.255.255.0";
route b.b.b.0 255.255.255.0;
```

- Client Specific Overrides for **Common Name** `client1`:
  - **IPv4 Remote Network/s** set to `b.b.b.0/24` **OR**
  - Advanced options:

```
iroute b.b.b.0 255.255.255.0;
```

client1 custom options:

```
(blank -- no route statements needed)
```

34.49.3 Single Client Strategy Without Internal Routing

For a site-to-site setup between only two locations, the tunnel network can be a `/30` so that OpenVPN uses peer-to-peer mode and does not require `iroute` statements to reach client networks. In this case, use the **IPv4/6 Remote Network/s** on both sides to setup the routes and there is no need for an override.

See also:

See the note at *IPv4/IPv6 Tunnel Network* for more information.

34.50 Troubleshooting Lost Traffic or Disappearing Packets

If there are issues with traffic being lost, or packets that seem to disappear or never show up (or leave) an interface, there are a few potential causes to consider.

See also:

Troubleshooting Network Connectivity contains procedures to diagnose and analyze these sort of problems in great detail.

34.50.1 IPsec (Tunnel Mode)

If a packet matches the traffic selectors set in tunnel mode IPsec phase 2 entries exactly (matches both source and destination), then the kernel will attempt to inject that packet into IPsec even if the IPsec tunnel is down.

This is commonly observed by users who setup an alternate VPN (e.g. WireGuard or OpenVPN) for the same networks previously handled by IPsec without fully removing the IPsec configuration.

Check the contents of the Security Policy Database (SPD) at **Status > IPsec** on the **SPDs** tab to see if one of the policies there overlaps. If it does, remove or disable the IPsec configuration and stop the IPsec daemon, then start it again. In some rare cases it may require a reboot to fully clear the old policy.

34.50.2 Captive Portal

If a host is on a network segment in an active Captive Portal zone, then it must be authenticated to the portal or setup as a bypass (e.g. Allowed IP/Host/MAC address) to pass traffic through the tunnel. This includes traffic from inbound NAT such as port forwards or 1:1 NAT.

34.50.3 Firewall Rules

Firewall rules, including floating rules, could be blocking and not logging the block action. Check the floating tab for matching rules (e.g. from packages such as pfBlockerNG) and also look at the content of block tables maintained by packages such as Snort and Suricata.

34.50.4 Routing Problems

If the firewall has a packet but nowhere to deliver the packet, then the firewall can drop that packet. The most common way this happens is from a lack of default route on the firewall itself.

If a packet arrives for a network that is not on a directly connected interface and the firewall has no default route, then the firewall has no idea where it should send that packet. This, it has no choice but to drop.

This can be sidestepped in certain cases by policy routing, which can make it tricky to diagnose at first. For example if the pass rules on LAN all have a gateway set then traffic from LAN might work, but traffic from the firewall itself (e.g. DNS resolution) would fail.

34.50.5 Hardware Checksum Offloading

It's possible that a problem in hardware checksum offloading is leading to the packets being rejected by various parts of the network (e.g. OS, NIC, switch, peers, etc.)

Try disabling Checksum Offloading as follows:

- Navigate to **System > Advanced**, **Networking** tab
- Check **Disable hardware checksum offload** under **Network Interfaces**
- Click **Save**

Then try to reproduce the problem.

Note: A reboot may be desired after applying this option, but it should not be necessary.

This has historically been an issue with Realtek NICs, some Via Rhine NICs, and some specific Intel `fxp` chips, as well as virtualized/emulated NICs in some hypervisors, especially those that use VirtIO.

The problem may also manifest as a PPPoE connection that will establish a login and bring up the interface, but will not pass traffic.

34.51 Troubleshooting a Broken pkg Database

In rare edge cases it is possible for the pkg database in `/var/db/pkg/` to become corrupted. In the unlikely event this happens to a firewall, it can usually be corrected by running a few commands to re-create the database.

Note: The following commands only account for the base system of a typical CE installation.

- Ensure that the package database directory exists:

```
/bin/mkdir -p /var/db/pkg/ /root/var/db/pkg/
```

- Force an update of the package repository data:

```
/usr/local/sbin/pkg-static update -f
```

- Force a reinstall of the pfSense® software base package and kernel:

```
/usr/local/sbin/pkg-static install -yf pkg pfSense pfSense-kernel-pfSense
```

- Refresh the `php.ini` and other files to ensure they are loading the correct modules:

```
/etc/rc.php_ini_setup
```

- If any additional packages were installed, reinstall them manually using the GUI if possible, or by using `pkg-static install` as above:

```
/usr/local/sbin/pkg-static install -yf <additional-package> <another-additional-
↪package>
```

34.52 Troubleshooting Routes

When diagnosing traffic flow issues, one of the first things to check is the routes known to the firewall.

34.52.1 Viewing Routes

Viewing the routing table is described in detail at *Route Table Contents*. For routed destinations, check the contents of the table and see if the destination is listed as expected.

It is also possible to check how the operating system will route a specific destination at the CLI. For example, to see how the firewall will reach `8.8.8.8`:

```
$ route -n get 8.8.8.8
   route to: 8.8.8.8
destination: 0.0.0.0
       mask: 0.0.0.0
    gateway: 198.51.100.1
        fib: 0
  interface: igb0
      flags: <UP,GATEWAY,DONE,STATIC>
 recvpipe  sendpipe  ssthresh  rtt,msec    mtu        weight    expire
       0         0         0         0      1500         1         0
```

In that example, there isn't a specific static route in place for the destination, so it uses the default route.

In the next example, there is a specific route for `8.8.4.4` using an alternate gateway:

```
: route -n get 8.8.4.4
   route to: 8.8.4.4
destination: 8.8.4.4
    gateway: 10.0.14.1
        fib: 0
  interface: igb5
      flags: <UP,GATEWAY,HOST,DONE,STATIC>
 recvpipe  sendpipe  ssthresh  rtt,msec    mtu        weight    expire
       0         0         0         0      1500         1         0
```

While viewing the routing table as a whole is helpful, sometimes querying the OS in this way is faster and easier when a specific destination is known.

34.52.2 Using traceroute

Traceroute is a useful tool for testing and verifying routes and multi-WAN functionality, among other uses. It shows each "hop" along the path a packet travels from one end to the other, along with the latency encountered in reaching that intermediate point. On pfSense® software, a traceroute can be performed by navigating to **Diagnostics > Traceroute**, or by using `traceroute` at the command line. From clients running Windows, the program is available under the name `tracert`.

See also:

For details on how traceroute works and how to perform a traceroute using the GUI, see *Traceroute*.

34.52.3 Routes and VPNs

Depending on the VPN being used, the firewall may not have routes in the table for the remote side. IPsec in tunnel mode does not use the routing table, it is instead handled internally in the kernel using IPsec security policy database (SPD) entries. Static routes will never cause traffic to be directed across a tunnel mode IPsec connection. VTI mode IPsec, OpenVPN, and WireGuard use the system routing table and as such entries are present for networks reachable via those types of VPNs.

For example, the following output includes an OpenVPN tunnel:

```
#netstat -rWn
Routing tables

Internet:
Destination        Gateway            Flags       Use    Mtu      Netif Expire
default            198.51.100.1       UGS       92421   1500        em0
10.6.0.0/16        10.6.203.1         UGS           0   1500     ovpnc2
10.6.203.0/24      10.6.203.2         UGS           0   1500     ovpnc2
10.6.203.1         link#9             UH            0   1500     ovpnc2
10.6.203.2         link#9             UHS           0  16384        lo0
10.7.0.0/24        link#2             U       1260771   1500        em1
10.7.0.1           link#2             UHS           0  16384        lo0
127.0.0.1          link#7             UH          866  16384        lo0
198.51.100.0/24    link#1             U       1251477   1500        em0
198.51.100.7       link#1             UHS           0  16384        lo0
```

The OpenVPN interface is `10.6.203.2`, with a gateway of `10.6.203.1` and the interface is `ovpnc2`. The network reachable using OpenVPN in this example is `10.6.0.0/16`.

With tunnel mode IPsec, traceroute is not as useful as with routed setups, because a tunnel mode IPsec connection does not have an interface or IP addresses. When running traceroute to a destination across tunnel mode IPsec, the client will experience a timeout when crossing the IPsec tunnel.

34.53 Troubleshooting in Single User Mode

Warning: This option must only be used under the guidance of a support representative or a FreeBSD user with advanced knowledge.

Single user mode is a special boot mode in which only the operating system kernel is loaded and a bare minimum of functions are available. For example, networking is not configured, the GUI is not available, and no system services are started. The root filesystem defaults to read-only and other filesystems are not mounted. In single user mode, commands must be entered into a shell prompt on the primary system console.

Warning: This action **requires** access to the primary system console, which depending on hardware and configuration may be a video console or serial console. Ensure console access is available and working before attempting to enter single user mode.

34.53.1 Entering Single User Mode

There are multiple ways to enter single user mode:

Next Boot Configuration
From the console or SSH menu, choose option `5` *Reboot System* and then enter `S` (capital `s`) to reboot and automatically enter single user mode.

> **Warning:** ZFS systems will not automatically clear this configuration when exiting single user mode. See *Re-mount ZFS Volumes as Read/Write*.

Choose Single User Mode on Boot Menu
From the loader menu with the ASCII logo, choose the menu option to enter single user mode, typically option `2`

Use the Loader Prompt
Enter the loader directly, either by using option `3` from the ASCII loader menu or if the boot menu is unavailable, press the `Space` bar while the kernel is loading at boot time, which will start the boot loader with an `OK` or `loader>` prompt.

Note: The correct moment to hit `Space` varies by hardware.

The OS may display prompt such as "Hit [Enter] to boot immediately, or any other key for command prompt." at the proper moment to press `Space`. If that message is not present, press `Space` when "Loading kernel…" and/or the kernel loading spinner are visible.

Do not press a key at the `Hit any key to stop autoboot` prompt as that is too early. That prompt is for U-Boot or similar and is before the OS boot process starts.

Enter the following command at the loader prompt:

```
boot -s
```

Warning: Check the prompt again before typing this command. It must say either `loader>` or `OK`. If the prompt shows a different string such as `Marvel>>` that is not the correct prompt for this action. Reboot and try again.

After invoking one of those options, the kenel will load and then immediately after, the operating system will prompt for a shell:

```
Enter full pathname of the shell or RETURN for /bin/sh:
```

At that point, press `Enter` and the resulting shell prompt is now running in single user mode.

Tip: Redminder: At this point, all filesystems are still read-only.

34.53.2 Exiting Single User Mode

There are two ways to exit single user mode, and the method to use depends on the changes made.

Reboot
Run `/sbin/reboot` or an equivalent command to force an operating system reboot. This is the safest choice as it will ensure the system is fully reinitialized. This method is required when making boot-time changes such as those in *Managing Loader Tunables*.

Continue Boot
Exiting the single user mode shell via `exit`, `logout`, or `^D` (Ctrl-D) will terminate the single user mode shell and then continue to boot the system into its regular multi-user mode. This may be OK for simple changes such as `config.xml` alterations, but will not activate changes which must be present before the kernel loads.

34.53.3 Working in Single User Mode

Mounting Filesystems

In single user mode the root filesystem defaults to read-only and other filesystems are not mounted.

Re-mount UFS Volumes as Read/Write

To mount all UFS type filesystems in read-write mode, run the following command:

```
# /sbin/mount -a -t ufs
```

Re-mount ZFS Volumes as Read/Write

For ZFS the procedure to mount the all filesystems as read-write in single user mode requires several commands.

First, remount the root slice as read-write:

```
# /sbin/mount -u /
```

If that produces an error, try:

```
# /sbin/zfs set readonly=off pfSense/ROOT/default
```

Next, mount all ZFS filesystems, datasets, etc:

```
# /sbin/zfs mount -a
```

On newer versions, such as pfSense® plus software installations with ZFS boot environment support, this may not mount all of the ZFS datasets as a few are marked not to mount automatically. In this case, mount them manually:

```
# /sbin/zfs mount pfSense/ROOT/default/cf
# /sbin/zfs mount pfSense/ROOT/default/var_db_pkg
```

Finally, if the system was put into single user mode using the reboot menu `S` option, the `nextboot` configuration **must** be cleared manually:

```
# /sbin/nextboot -D
```

Warning: Failing to clear the `nextboot` configuration will result in the system booting back into single user mode on every boot.

Tip: It is safe to run this command even if the system was not booted in that way, so always run this command on ZFS systems before exiting single user mode.

Running Commands

Be aware that when running commands single user mode, their behavior may be unexpected as the system does not have a full traditional terminal setup, and some default shell environment variables and console/terminal settings are not available. For example, using `vi`, the arrow keys on the keyboard may not work or the dimensions of the terminal may be incorrect.

Some commands may be run without typing the full pathname to the binary, but it is safest to use the full path where possible.

34.54 Troubleshooting Snort Rule Updates

34.54.1 MD5 Signature Mismatch

Periodically, Sourcefire redesigns their site or updates the engine and rules, and the snort package needs an update to accommodate this change. Removing and then installing the snort package again is required to restore proper functionality, assuming the package has been updated to match the upstream rule format.

34.54.2 Upstream Issues

Rule problems can almost always be solved by waiting 20-30 minutes and then trying the download again. Failing that, uninstall the package completely and then reinstall the package to ensure the snort binaries are the latest/correct ones.

34.54.3 Space Issues

If the `/tmp` slice is small, because the firewall is running with `/tmp` on a RAM disk, current rulesets can easily fill the slice up and cause numerous rule-related errors.

If there is sufficient RAM, increase the size of `/tmp` using the options on **System > Advanced**, **Miscellaneous** tab.

34.55 Troubleshooting the Squid Package

Danger: The add-on packages Squid, SquidGuard and Lightsquid are deprecated in pfSense Plus and pfSense CE software due to a large number of unfixed upstream security vulnerabilities. Netgate **STRONGLY** recommends that users uninstall these packages. The packages will no longer function in the next major release of pfSense Plus and pfSense CE software.

34.55.1 Disk Usage Issues

The `swap.state` from Squid file can grow large and consume all available drive space. See *Tuning the Squid Package* for more details.

34.55.2 Sites not loading with splice / Error 409 in access log

As a security measure, squid will not allow a user to connect to a site that has a hostname that does not match its IP address. This prevents clients from hardcoding or altering DNS responses to evade access controls. The side effect of this, however, is that sites which employ round-robin DNS or other DNS optimizations can cause squid to block or drop connections those sites unintentionally. The squid access log will have a `409 (Conflict)` error code when a connection is dropped for this reason.

This happens with sites such as Google or Facebook when the client and squid use different sources for DNS, and thus get different DNS results for the same query because the results are randomized. Even though the address for the server is valid, the disparity causes squid to drop the connection.

The solution is to have the clients use the firewall as their DNS server, so that both squid and clients use the same DNS source and the results will match.

34.55.3 Clear Cache

Resetting the cache in squid can often clear up issues without performing a more complicated procedure. Before performing a full reset, try clearing and resetting the cache:

```
mv /var/squid/cache /var/squid/cache.old
squid -z
rm -rf /var/squid/cache.old
```

The old cache should be moved, then reset, and then the old cache should be removed, as above, because removing the cache directory can be time consuming, and if it is moved first, then its removal will not prevent squid from being run while it is happening.

34.55.4 Complete Reset

When troubleshooting squid/squidGuard there are some procedures that may be followed to ensure things are completely reset.

- **Remove** the packages from **System > Packages** on the **Installed Packages** tab in the proper order:
  1. Lightsquid
  2. squidGuard
  3. Squid
- Remove the contents of the squid directory and cache:

```
rm -rf /var/squid
```

- Remove the Squid and related package include files:

```
rm /usr/local/pkg/*squid*
rm -rf /usr/local/etc/squid/
```

- Ensure any leftover PBI symlinks are removed:

```
find / -type l -lname '/usr/pbi/*' -delete
```

- [Optional] Remove the settings from inside `config.xml` using one of the following methods:
  - From **Diagnostics > Command Prompt** in the **PHP Execute** box:

```
$squid_sections = array("squid", "squidnac", "squidcache", "squidauth",
 "squidextauth", "squidtraffic", "squidupstream", "squidusers");
foreach ($squid_sections as $sec) {
 if (is_array($config['installedpackages'][$sec]))
        unset($config['installedpackages'][$sec]);
}
write_config("Removed Squid");
```

  - Or to remove squid, squidguard, lightsquid, and anything else with 'squid' in its package name from **Diagnostics > Command Prompt** in the **PHP Execute** box:

```
foreach (array_keys($config['installedpackages']) as $sec) {
 if (strpos($sec, "squid") !== false)
```

(continues on next page)

(continued from previous page)

```
        unset($config['installedpackages'][$sec]);
}
write_config("Removed all squid-related settings");
```

  - Or backup `config.xml`, edit the settings out, then restore.

- Navigate to **System > Packages** and on the **Available Packages** tab, reinstall the following packages in order:
  1. Squid
  2. squidGuard
  3. Lightsquid

For assistance in solving problems, post on the Cache/Proxy category of Netgate Forum.

34.56 Troubleshooting Hardware Shutdown and Power Off

If a firewall device does not automatically power itself off, this is typically a case of FreeBSD and ACPI not working well together on a particular hardware combination.

As a test, enter this at the CLI then attempt a power-down:

```
sysctl hw.acpi.disable_on_reboot=1
```

For a more permanent solution, add an entry under **System > Advanced** on the **Tunables** tab to set:

```
hw.acpi.disable_on_reboot=1
```

34.57 Troubleshooting Clock Issues

Time and clock issues are relatively common on hardware, but on firewalls they are critical, especially if the firewall is performing tasks involving validating certificates as part of a PKI infrastructure.

Proper time synchronization is an absolute necessity on systems which do not have a battery onboard to preserve their date and time settings when power is removed.

Not only will getting this all in line help with critical system tasks, but it also ensures that the log files on the firewall are properly timestamped, which aids with troubleshooting, record keeping, and general system management.

34.57.1 Time Keeping Problems

Hardware can have significant problems keeping time, though such problems are generally isolated to older, low-quality hardware. All PC clocks will drift to some extent, but some hardware can drift as much as one minute for every couple minutes that pass and rapidly get out of sync. NTP is designed to periodically update the system time to account for normal drift. It cannot reasonably correct clocks that drift significantly. This is very uncommon, but there are a few methods that can potentially work around these problems.

The best way to avoid time keeping problems is to use quality hardware that has been tested and does not experience these issues, such as official appliances found in the Netgate Store.

There are several items to check if hardware has significant time keeping problems.

Network Time Protocol

By default, pfSense software attempts to synchronize its time using the ntp.org Network Time Protocol (NTP) server pool. This ensures an accurate date and time on the firewall, and will accommodate normal clock drift. If the firewall date and time are incorrect, ensure NTP synchronization is functioning. The most common problem preventing synchronization is the lack of proper DNS configuration on the firewall. If the firewall cannot resolve hostnames, NTP synchronization will fail. The results of synchronization are shown at boot time in the system log, and the status of the NTP clock synchronization can be viewed at **Status > NTP**. The **NTP Status** widget for the Dashboard also offers basic information about the NTP server selected for use by the firewall.

BIOS Updates

Netgate has observed older hardware that ran fine for years on Windows encounter major timekeeping problems once redeployed on FreeBSD (and by consequence, pfSense software). The systems were running a BIOS version several revisions out of date. One of the revisions addressed a timekeeping issue that apparently never affected Windows. Applying the BIOS update fixed the problem. The first thing to check is to make sure the hardware in question has the latest available BIOS.

PNP OS settings in BIOS

Other hardware might have time keeping difficulties in FreeBSD and pfSense software unless **PNP OS** in the BIOS was set to *No*. If the BIOS does not have a **PNP OS** configuration option, look for an **OS** setting and set it to *Other*.

Disable ACPI

A few BIOS vendors have produced ACPI (Advanced Configuration and Power Interface) implementations which are buggy at best and dangerous at worst. On more than one occasion Netgate has encountered hardware that would not boot or run properly while ACPI support is active.

While ACPI support can be disabled in the BIOS, and in the OS, this is not a best practice and as such hardware that requires such changes should be replaced.

Adjust Timecounter Hardware Setting

On rare systems, the `kern.timecounter.hardware` sysctl value may need to be changed to correct an inaccurate clock. This is known to be an issue with older versions of VMware such as ESX 5.0 in combination with an amd64-based pfSense software or FreeBSD image. That special case was a bug in the hypervisor that is fixed in ESX 5.1 and later.

On these systems the default timecounter will eventually stop the clock from ticking, causing problems with encryption, VPNs, and services in general. On other systems, the clock may skew by large amounts with the wrong timecounter.

To change the timecounter, browse to **System > Advanced**, on the **System Tunables** tab and add an entry to set `kern.timecounter.hardware` to `i8254`

This will make the system use the i8254 timecounter chip, which typically keeps good time but may not be as fast as other methods. The other timecounter choices will be explained later in this section.

If the system keeps time properly after making this change, leave the tunable entry in place to make this change permanent. If the change did not help, remove the tunable or try another value.

Depending on the platform and hardware, there may also be other timecounters to try. For a list of available timecounters found on a firewall, execute the following command:

```
# sysctl kern.timecounter.choice
```

The firewall will print a list of available timecounters and their "quality" as reported by FreeBSD:

```
kern.timecounter.choice: TSC-low(1000) ACPI-safe(850) i8254(0) dummy(-1000000)
```

Try any of those four values for the sysctl `kern.timecounter.hardware` setting. In terms of "quality" in this listing, the larger the number the better, but the actual usability varies from system to system.

TSC
: A counter on the CPU, but is tied to the clock rate and is not readable by other CPUs. It can be used in bare metal SMP systems but it requires that TSCs on all CPUs be synchronized. It cannot be used reliably on systems with variable-speed CPUs or virtualized system with multiple CPUs.

i8254
: A clock chip found in most hardware, which tends to be safe but can have performance drawbacks.

ACPI-safe
: If it is properly supported by the hardware, this is a good choice because it does not suffer from the performance limitations of i8254, but in practice its accuracy and speed vary widely depending on the implementation.

ACPI-fast
: A faster implementation of the ACPI timecounter available on hardware that does not suffer from known ACPI issues.

HPET
: High Precision Event Timer available in some hardware. When available, it is generally considered a good source of accurate time counting.

This and more information on FreeBSD Timecounters can be found in the paper Timecounters: Efficient and precise timekeeping in SMP kernels by Poul-Henning Kamp of the FreeBSD Project, and in the FreeBSD source code.

Adjust the Kernel Timer Frequency

In rare cases adjusting the kernel timer frequency, or `kern.hz` kernel tunable, can help performance or stability. This is especially true on virtualized environments. The default is `1000`, but in some cases `100`, `50`, or even `10` will be a better value depending on the system. When pfSense software is installed in VMware, it detects it and automatically sets this tunable to `100`, which should work fine in nearly all cases with VMware products.

To adjust this setting, add the following line, with the new value, as a *Loader Tunable*:

```
kern.hz=100
```

34.57.2 GPS Time Synchronization

To aid in maintaining an accurate clock, GPS time synchronization is also provided by pfSense software on supported hardware. Certain serial or USB GPS devices are supported, and in combination with external time servers, they can help keep the clock accurate. For more detail, see *NTPD*.

34.58 Troubleshooting Time Zone Configuration

34.58.1 Processes use different time zones

Processes on FreeBSD (and thus pfSense® software) only pick up time changes when they are started. If the firewall has not been rebooted since the last time zone change, doing so will ensure that all running processes are using the correct time zone.

34.58.2 Clock does not use the expected zone offset

If the clock is several hours off, but accurate to the minute, it is most likely a time zone setting issue. If using a GMT offset time (e.g. *-0500*), change to a more specific **geographic** time zone such as *America/New_York* instead.

Using geographic zones is the best practice as they use an accurate offset, include local Daylight Saving Time behavior, and also consider historical changes in time zones.

The following text from the time zone database explains the behavior of the GMT zones further:

```
# We use POSIX-style signs in the Zone names and the output abbreviations,
# even though this is the opposite of what many people expect.
# POSIX has positive signs west of Greenwich, but many people expect
# positive signs east of Greenwich.  For example, TZ='Etc/GMT+4' uses
# the abbreviation "GMT+4" and corresponds to 4 hours behind UTC
# (i.e. west of Greenwich) even though many people would expect it to
# mean 4 hours ahead of UTC (i.e. east of Greenwich).
```

This behavior is also noted on the Wikipedia page for the time zone database.

34.59 Troubleshooting Traceroute Output

When `traceroute` is run from LAN to a destination on the Internet, the firewall itself may be missing from the `traceroute` output depending on the configuration.

This happens on Multi-WAN due to the way that `route-to` and `reply-to` work. policy routing (`route-to`/`reply-to`) does not decrease the IP TTL when forwarding packets, so the firewall does not appear as a hop.

This may also happen with IPsec due to the way IPsec traffic is handled in the kernel. The traffic is not "routed" in a traditional sense.

See also:

This behavior may change in future versions of pfSense® software, see Redmine issue #932.

34.60 Troubleshooting Traffic Shaping

Traffic Shaping/QoS is a tricky topic, and can prove difficult to get right the first time. This section covers several common pitfalls.

34.60.1 Bittorrent traffic not using the P2P queue

Bittorrent is known for not using standard ports. Clients are allowed to declare which port other clients use to reach them, which means chaos for network administrators trying to track the traffic based on port alone. Clients can also choose to encrypt their traffic. Regular shaper rules don't have any way to examine the packets to tell what program the traffic appears to be, so it is forced to rely on ports. This is why it may be a good idea to use the P2P Catchall rule, and/or make rules for each type of desirable traffic and treat the default queue as low priority.

34.60.2 UPnP IGD & PCP traffic shaping

Out of the box, traffic allowed in by the UPnP IGD & PCP daemon will end up in the default queue. This happens because the rules generated dynamically by the UPnP IGD & PCP daemon do not have any knowledge of queues unless UPnP IGD & PCP is configured to send traffic into a specific queue.

The nature of the traffic depends on what the client devices utilizing UPnP IGD & PCP on a network are doing. This could be low priority traffic like Bittorrent, or high priority traffic such as videoconferencing or online gaming.

To configure UPnP IGD & PCP to use a specific ALTQ queue:

- Setup ALTQ shaping and decide which queue to use for UPnP IGD & PCP
- Navigate to **Services > UPnP IGD & PCP**
- Enter the chosen ALTQ queue name into the **Traffic Shaping** field
- Click **Save**

This trick only works with the ALTQ shaper. At this time, the firewall is not capable of assigning UPnP IGD & PCP traffic to a limiter.

34.60.3 ACK queue bandwidth calculations

This is a complex topic and most users gloss over it and guess a sufficiently high value. For more detailed explanations with mathematical formulas, check the Traffic Shaping section of the Netgate forum. There is a sticky post in that board which describes the process in great detail, and there is also a downloadable spreadsheet which can be used to help ease the process.

34.60.4 Why is <x> not properly shaped?

The reason is nearly always one of these choices:

- The traffic matched a different rule than expected
- The traffic did not match any rule

As with other questions in this section, this tends to happen because of rules entered either internally or by other packages that do not have knowledge of queues. Since no queue is specified for a rule, it ends up in the default or root queue, and not shaped.

Working around the limitation may require altering the rules to better match the traffic, or disabling internal rules that are matching the traffic in unexpected ways. Another tactic is to identify all other traffic and then use different shaping options on the default queue.

In rare cases, such as bittorrent, it may be impossible to accurately identify all traffic of a given type. One workaround is to isolate the traffic to one specific device on the network and then match based on that client device address.

34.60.5 WAN connection speed changes

To update the speed of a WAN if it changes, edit the appropriate queues under **Firewall > Traffic Shaper** to reflect the new speed.

The queues that need updating are:

- The root queue for each WAN interface for the upload speed
- The root queue for each LAN interface for the download speed
- qInternet queue for each LAN interface for the download speed

If this firewall has multiple WANs, the LAN root and qInternet queue must use the total download speed of **all** WANs.

Alternately, if the wizard created all of the queues and rules and these have not been changed, then complete the wizard again and update the speed using the wizard.

34.61 Troubleshooting Traffic Shaping Graphs

The RRD for traffic shaping graphs must be reset when a change is made to the traffic shaper settings. The RRD files are in a very specific format and refer to the number and name of the queues as they exist in the shaper configuration. Should this data change, the RRD file data becomes invalid and must be reset.

Therefore any time a traffic shaper setting is changed, the *queue* and *queuedrops* graphs are reset in order to ensure that the RRD schema matches up with the current shaper configuration.

34.62 Troubleshooting Unexpected Reboots

Unexpected reboots are caused by one of two things – hardware problems, or FreeBSD kernel panics. The vast majority of the time it is hardware problems. Hardware diagnostics should be run before trying anything else.

If the reboot was caused by a kernel panic and the firewall has swap space available, the GUI will display a prompt asking to *view the crash report*. If there is no kernel panic, then the cause is most likely a hardware problem.

For hardware issues, check on:

- Failing power supply
- Flaky electricity in general
- Overheating CPU
- Overheating or faulty RAM
- Faulty hard drive/SSD/other storage
- Faulty drive cables
- and many others…

If the firewall does panic, and the panic message contains a backtrace that mentions things like memory allocation, `mbuf`, `uma_zalloc_arg`, or similar, then it may be crashing due to mbuf exhaustion. See *Tuning and Troubleshooting Network Cards* for information on how to overcome that problem.

Devices with eMMC or small disks may not have any swap space and thus may not be able to recover panic information. In these cases they will typically print the panic information on the console when it occurs. If the device has a serial console, record the output there.

See also:

See *Obtaining Panic Information for Developers* for details.

34.63 Troubleshooting Upgrades

This document describes methods of troubleshooting problems firewalls may encounter when attempting to run a pfSense® software upgrade.

34.63.1 Check Disk Space and ZFS Boot Environments

Running out of space during an upgrade can lead to a variety of failure states that are difficult to fully document. The upgrade process attempts to estimate the amount of disk space it will need but the calculations are not always accurate enough to prevent problems during the upgrade process itself.

If there are any problems with an upgrade one of the best places to start is by cleaning up disk usage where possible. On systems running pfSense Plus software on ZFS, ZFS Boot Environments can consume significant disk space over time if they are not cleaned up. See *Check and Clean Up ZFS Boot Environments* for details. Additionally, if there are packages installed, package logs and data in particular may be consuming large amounts of disk space.

34.63.2 Low Memory Hardware and AWS/Azure Instances

Hardware with **1 GiB or less** available memory may have issues upgrading depending on which features, services, or packages are running. This includes some Netgate hardware such as the Netgate 1100 when running with ZFS and/or certain services/packages. For the best chance of success in these cases, temporarily disable any non-critical services before starting the upgrade.

Tip: A *Pre-Upgrade Reboot* can also temporarily reduce memory used for ZFS caching, which can help in this situation as well.

---

pfSense Plus software can no longer run on AWS ".nano" size instances as they lack sufficient RAM to upgrade properly. Attempting to upgrade a ".nano" instance to pfSense Plus software version 24.03 will fail before the upgrade is performed. Migrate the instance to a ".micro" or larger size **before** attempting to upgrade, or redeploy instead.

Similar to the above, pfSense Plus software can no longer run on Azure A0 instances. Migrate to instances with more memory.

34.63.3 Remove / Dismount any Installation Media

Some users leave an installation disk plugged in or mounted for various reasons, but this can interfere with the upgrade process. Be sure to dismount and remove any installation media such as a USB thumb drive, optical disk, or ISO in a virtual drive.

A particularly problematic case is when a non-UEFI system has UEFI boot media inserted, the upgrade process may attempt to upgrade the boot loader on the installer and fail:

```
Number of packages to be reinstalled: 1
[1/1] Reinstalling pfSense-boot-23.09...
[1/1] Extracting pfSense-boot-23.09: .......... done
mount_msdosfs: /dev/msdosfs/EFISYS: Read-only file system
pkg-static: POST-INSTALL script failed
 failed.
__RC=1 __REBOOT_AFTER=10
```

34.63.4 Cosmetic Problems Post-Upgrade

If cosmetic problems occur after performing an upgrade, this is nearly always due to stale browser cache entries for CSS, JavaScript, or other files where the browser does not pull the updated version. Force a refresh of the page in the browser (e.g. Shift+Reload or Ctrl+F5) or clear the browser cache to resolve the issues.

34.63.5 Upgrade Log

`pfSense-upgrade` keeps a log of the last update attempt, which may contain additional useful information. This log is located at `/conf/upgrade_log.latest.txt`. Please include the contents of this log with any post or support request when requesting assistance with upgrade problems.

34.63.6 Upgrade not Offered / Library Errors

If the update system does not offer an upgrade to the most recent version, the upgrade will not proceed, or the upgrade process encounters errors with shared libraries, take the following steps:

- Navigate to **System > Updates**
- Set **Branch** to *Previous stable version*
- Wait a few moments for the upgrade check to complete
- Optional: Confirm that the latest version of *pfSense-upgrade* is present using `pkg-static info -x pfSense-upgrade`.

  If the correct version is not present, wait a bit longer and check again as that package may be updating in the background.
- Set **Branch** to *Latest stable version*
- Wait a few moments for the upgrade check to complete

If the upgrade is still not offered, refresh the repository configuration and upgrade script by running the following commands from the console or shell:

```
# pkg-static clean -ay; pkg-static install -fy pkg pfSense-repo pfSense-upgrade
```

If that procedure results in an error, or the upgrade is still not offered, then attempt to update to an intermediate version. For example, to get from Plus 2.4.5-p1 to Plus 21.05 or later, upgrade to Plus 21.02.x before proceeding to later versions if a direct upgrade does not succeed. In these cases, the appropriate version will be visible as a branch to select.

34.63.7 Repository Metadata Version Errors

If `pkg` is unable to update and complains about the repository metadata version, the `pkg` utility may need to be updated manually to version 1.13.x or later.

Example metadata version error:

```
>>> Updating repositories metadata...
Updating pfSense-core repository catalogue...
pkg-static: repository meta /var/db/pkg/pfSense-core.meta has wrong version 2
pkg-static: Repository pfSense-core load error: meta cannot be loaded No error: 0
```

To correct the problem, manually bootstrap `pkg` from an ssh or console shell:

```
# pkg-static bootstrap -f
```

Warning: Do not run the above command from **Diagnostics > Command** as it requires interactive input. If ssh and console shells are unavailable, use this variation instead:

```
env ASSUME_ALWAYS_YES=yes pkg-static bootstrap -f
```

34.63.8 Rewrite Repository Information

In some cases the repository information may need to be rewritten:

- Navigate to **System > Updates**
- Set the **Branch** to *Latest Development Snapshots*
- Wait for the page to refresh
- Set the **Branch** to *Latest stable version*

If the update still does not appear, run the commands above from the console or shell.

34.63.9 CLI Troubleshooting

If the GUI update is not functioning as expected, there are a handful of shell commands that can help gather information or resolve problems.

Force pkg Metadata Update

Often times DNS or connectivity problems will prevent the firewall from finding updates. A quick way to verify this is to force a *pkg* metadata update:

```
# pkg-static update -f
```

This command forces an update and will print errors if problems are found, a few potential errors include:

No address record
: The firewall cannot resolve the update server hostname. This could be a problem with DNS from the firewall itself, or connectivity from the firewall to the Internet in general, such as a missing or incorrect default route.

No route to host
: The firewall cannot reach the update server because it cannot find a route there. Most likely, the firewall is missing its default route or the WAN with the default route is down.

Operation timed out
: The firewall was unable to download a file in a timely manner. This is most likely due to degraded connectivity between the firewall and the update servers. It could also be a routing issue, or a problem with IPv6 on the firewall (See *IPv6 Connectivity Problems*).

An error occured while fetching package
: A general error that could have a few different causes. It may indicate that `pkg` does not trust the package servers. Try running `certctl rehash` from the console, a root shell prompt, or via **Diagnostics > Command Prompt**. This will allow `pkg` to utilize the system certificates until the next reboot.

Authentication error
: There is a proxy between the firewall and the update servers and it requires authentication. Move the firewall so it is not behind a proxy, or configure the proxy under **System > Advanced**, **Miscellaneous** tab.

No trusted public keys found
: The firewall is attempting to update from the wrong repository. Ensure the correct branch is selected as mentioned in *Rewrite Repository Information*. May require a reinstall to resolve. For CE installations, try the following command:

```
# fetch -qo /usr/local/share/pfSense/keys/pkg/trusted/ \
 https://raw.githubusercontent.com/pfsense/pfsense/RELENG_2_4_5/src/usr/local/share/
↪pfSense/keys/pkg/trusted/pkg.pfsense.org.20160406
```

Debug pkg Metadata Update

If the previous command does not yield any meaningful information, try running the command in debug mode:

```
: pkg-static -d update
```

The output may yield additional useful messages, as in the following example:

```
DBG(1)[69233]> pkg initialized
Updating pfSense-core repository catalogue...
DBG(1)[69233]> PkgRepo: verifying update for pfSense-core
DBG(1)[69233]> PkgRepo: need forced update of pfSense-core
```

(continues on next page)

(continued from previous page)

```
DBG(1)[69233]> Pkgrepo, begin update of '/var/db/pkg/repo-pfSense-core.sqlite'
DBG(1)[69233]> Request to fetch pkg+https://pkg.pfsense.org/pfSense_v2_7_1_amd64-core/
↪meta.conf
DBG(1)[69233]> curl_open
DBG(1)[69233]> Fetch: fetcher used: pkg+https
DBG(1)[69233]> curl> fetching https://pkg.pfsense.org/pfSense_v2_7_1_amd64-core/meta.conf
DBG(1)[69233]> CURL> attempting to fetch from , left retry 3

DBG(1)[69233]> CURL> attempting to fetch from , left retry 2
```

That error suggests a problem with `pkg-static` trusting the package server, so in this case, try running `certctl rehash` from the console, a root shell prompt, or via **Diagnostics > Command Prompt** to allow `pkg` to utilize the system certificates until the next reboot.

Manual Update Check

To run a manual update check from the CLI:

```
# pfSense-upgrade -d -c
```

When run successfully, this command will print a line stating that a new version is available, and the version number of the available update. Errors displayed during that process are likely to be the same as those covered in *Force pkg Metadata Update*.

34.63.10 packages.netgate.com Has no A/AAAA Record

`pkg` does not use A/AAAA records. It uses service (SRV) records. The update server meta names such as `packages.netgate.com` are not meant to be accessed directly using a browser.

To find the actual update servers, lookup the SRV record for the host:

```
$ host -t srv _https._tcp.packages.netgate.com
_https._tcp.packages.netgate.com has SRV record 10 10 443 pkg01-atx.netgate.com.
_https._tcp.packages.netgate.com has SRV record 10 10 443 pkg00-atx.netgate.com.

$ host pkg01-atx.netgate.com
pkg01-atx.netgate.com has address 208.123.73.209
pkg01-atx.netgate.com has IPv6 address 2610:160:11:18::209

$ host pkg00-atx.netgate.com
pkg00-atx.netgate.com has address 208.123.73.207
pkg00-atx.netgate.com has IPv6 address 2610:160:11:18::207
```

Accessing the hosts using their direct hostnames will work with a browser:

```
$ curl --output /dev/null --silent --head --fail \
  "https://pkg00-atx.netgate.com/pfSense_v2_6_0_amd64-core/meta.txz"
$ echo $?
0
```

34.63.11 IPv6 Connectivity Problems

If IPv6 is configured on the firewall, the pfSense software will prefer to use it when performing an update. There are cases when a firewall may have broken IPv6 connectivity, however, that contribute to problems updating. This could manifest as a timeout or routing error when upgrading.

Typically the operating system will attempt to fall back to IPv4, but the extra time this takes could also lead to a timeout.

The firewall can be configured to prefer IPv4 to eliminate this as a potential cause. See *Controlling IPv6 Preference for traffic from the firewall itself* for details.

Alternately, from ssh or a console shell, force the upgrade to use IPv4 manually:

```
# pfSense-upgrade -4
```

34.63.12 Segmentation Fault in pkg

Certain cryptographic hardware can have a software-induced race condition which leads to a problematic state. In this state, `pkg` will crash with a segmentation fault:

```
1085486128:error:14099044:SSL routines:ssl3_send_client_verify:internal error:
Child process pid=30149 terminated abnormally: Segmentation fault
```

In this case, the device must be powered off and back on to recover. A warm reboot is not sufficient to reset the hardware.

- Navigate to **Diagnostics > Halt System**
- Click  **Halt**
- Wait for the device to shut down. Monitor the console to ensure that the shutdown completes.
- Unplug the power adapter
- Plug the power adapter back in

34.63.13 Forced pkg Reinstall

Forcing a reinstallation of all packages may resolve problems that otherwise may require a full reinstall. This is not ideal, as a clean install is more likely to have a positive result, but that is not always an option in every situation (e.g. remote install with no console access).

To forcefully reinstall all packages, take the following steps:

- Make a backup
- Clean the repository and forcefully reinstall pkg, repo data, and the upgrade script:

  ```
  # pkg-static clean -ay; pkg-static install -fy pkg pfSense-repo pfSense-upgrade
  ```

- Force a reinstall of everything:

```
# pkg-static upgrade -f
```

- Review the list of changes and enter `y` to proceed
- Manually reboot the firewall

34.63.14 Last Resort

If nothing else works then a reinstall will eliminate any possibility of problems related to the upgrade itself.

pfSense software supports multiple options to easily restore the configuration. The fastest method is `Recover config.xml` as discussed in *Automatically Restore Configuration During Installation*. Using that method, the pfSense software installation can pick up the existing configuration from the existing install and use it, eliminating the need for any manual restore process. The firewall will boot up after installation with the old settings and reinstall packages as needed.

34.64 Troubleshooting Upgrades on Netgate 1100 and Netgate 2100 Devices

34.64.1 Low Available RAM

Hardware with **1 GiB or less** available memory may have issues upgrading depending on which features, services, or packages are running. This includes some Netgate hardware such as the Netgate 1100 when running with ZFS and/or certain services/packages. For the best chance of success in these cases, temporarily disable any non-critical services before starting the upgrade.

Tip: A *Pre-Upgrade Reboot* can also temporarily reduce memory used for ZFS caching, which can help in this situation as well.

34.64.2 EFI Partition Size

Some older installations of pfSense Plus software on **Netgate 1100**, **Netgate 2100**, and **Netgate 2100 MAX** devices contain an EFI partition which does not have sufficient space to accommodate the new EFI loader for version 23.01 and later. This primarily affects UFS-based systems **initially** installed with pfSense Plus software version 21.02-p1 or before.

Upgrade Notice

Users of affected devices will see a warning about the EFI partition when attempting to upgrade.

When the upgrade check runs, it inspects the system for this problem and files a notice if it identifies a problem:

A similar notice is printed at the command line when checking for updates there:

```
: pfSense-upgrade -c
ERROR: Cannot update the EFI loader on this device. Contact TAC at
https://www.netgate.com/tac-support-request for assistance upgrading this device.
```

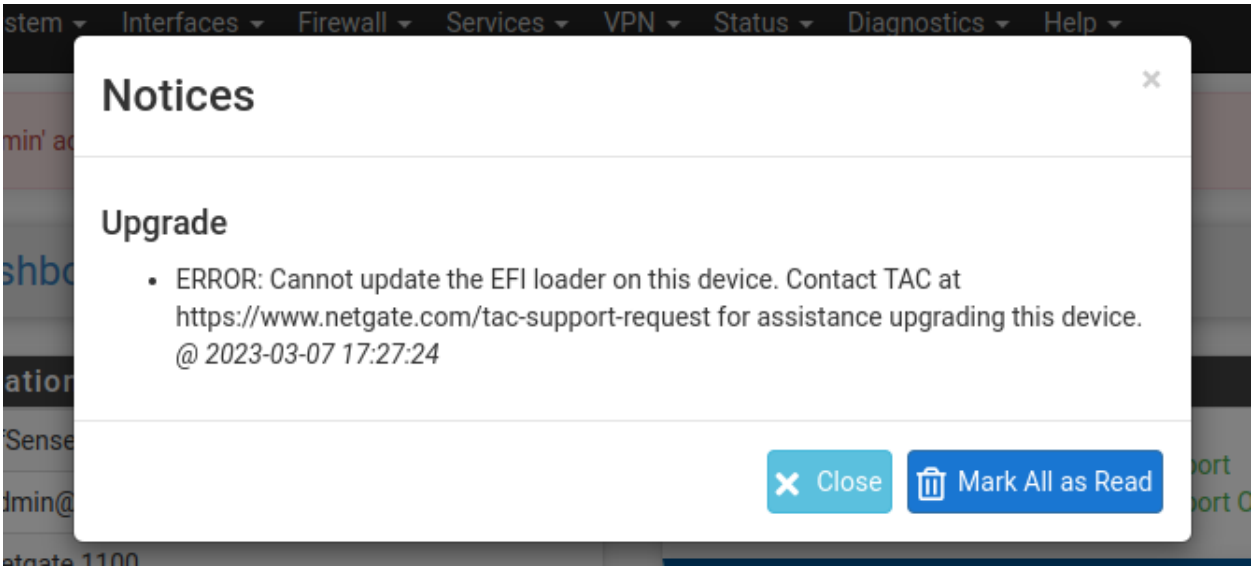

Fig. 8: Notice in the GUI after upgrade check

Check if the Device is Affected

Users can inspect the EFI partition size by checking the output of `gpart show`.

If the EFI partition size is small (`800K`), then the device must be reinstalled. Larger EFI partition sizes (`64M` or larger) are OK.

This example is a device with an undersized EFI partition:

```
: gpart show
=>       1  15269887  diskid/DISK-B1C82821  MBR  (7.3G)
         1      1600                       1  efi  (800K)
      1601     70012                       2  fat32  (34M)
     71613  15198275                       3  freebsd  (7.2G)
```

Note the size of the `efi` type partition, which is `800K`.

This example is a device with an EFI partition which **can** be upgraded:

```
: gpart show
=>       1  15269887  mmcsd0  MBR  (7.3G)
         1    409600       1  efi  (200M)
    409601     70012       2  fat32  (34M)
    479613  14790275       3  freebsd  [active]  (7.1G)
```

Take a Backup

Before altering the system, *take a local backup*. This backup can be restored at the end of the procedure to retain all current settings.

Tip: Use the *AutoConfigBackup* (ACB) service to store a remote backup, but be sure to note the current device key in ACB as reinstalling will result in the system having a different key unless a backup containing the previous SSH key data is restored.

While AutoConfigBackup is convenient for off-site backups, local file backups can optionally hold and restore much more data including SSH keys, RRD files, and DHCP lease data. Backing up and restoring all of the extra data is not strictly necessary but it makes for a much smoother transition during this kind of reinstallation. Additionally, a local backup can be used with a function such as the External Configuration Locator (ECL) to automatically restore the configuration on the first boot after reinstalling.

Reinstall to Upgrade

Users with affected units **must** reinstall pfSense Plus software to run version 23.01 or later.

To perform this procedure:

- Download the *Netgate Installer* for AARCH64 (*Download Installation Media*).
- Follow the reinstallation instructions in the product manual for the device:
  - Netgate 1100 Reinstallation Procedure
  - Netgate 2100 Reinstallation Procedure

Tip: This is a perfect opportunity to change filesystems from UFS to ZFS!

ZFS is more reliable and has more features than UFS (e.g. ZFS Boot Environments), however ZFS can be memory hungry. Either filesystem will work, but if RAM usage is critical to other tasks that will run on this firewall, UFS can be a more conservative choice. ZFS memory usage can be tuned, however, so that shouldn't be the only deciding factor. See *ZFS Tuning* for details.

Restore the Backup

Restore a backup file after completing the installation using a local file, *Automatic Configuration Backup Service*, or another method such as ECL.

See *Restoring from Backups* for information on the various methods available to restore configuration data.

34.65 Troubleshooting Website Access

If some sites will load, but other sites will not, there are a few possible causes.

- Check all of the items listed on *Connectivity Troubleshooting* before proceeding
- Ensure the WAN gateway is reachable and set to the proper address
- Ensure the subnet mask on the WAN interface of the firewall is correct
- Ensure the subnet mask on the client stations and on every interface (and VPN) in the pfSense® software configuration is correct
- Ensure the WAN MTU is properly set (See http://www.dslreports.com/faq/695 to determine the MTU), use MSS to lower the MTU if necessary
- Use `traceroute` to determine where the traffic stops. It may be an upstream connectivity issue and not the firewall or ISP.
- *Disable hardware checksums* and see if the problem disappears
- Check **Clear invalid DF bits instead of dropping the packets** on **System > Advanced**, **Firewall/NAT** tab.
- Check **Disable Firewall Scrub** on **System > Advanced**, **Firewall/NAT** tab.

34.66 Troubleshooting Wireless Connections

When it comes to wireless, there are a lot of things that can go wrong. From faulty hardware connections to radio interference to incompatible software or drivers, or simple settings mismatches, anything is possible, and it can be a challenge to make it all work on the first try. This section will cover some of the more common problems that have been encountered by users and developers of pfSense® software.

34.66.1 Check the Antenna

Before spending any time diagnosing an issue, double and triple check the antenna connection. If it is a screw-on type, ensure it is fully tightened. For mini-PCI cards, ensure the pigtail connectors are properly connected and snapped in place. Pigtails on mini-PCI cards are fragile and easy to break. After disconnecting and reconnecting pigtails a few times, they may need to be replaced.

34.66.2 Check Wireless Status

The status of connected wireless clients and nearby access points can be viewed by navigating to **Status > Wireless**. This menu option only appears when a wireless interface is present and enabled.

On this page, click **Rescan** and then refresh the page after 10 seconds to see other nearby access points. If they are on the same or a nearby channel, there could be interference.

In the list of associated clients, several flags are listed that explain the capabilities of the connected client. For example if the client has an “H” flag, this indicates High Throughput used by 802.11n. If a client is connected without that flag, they may be using an older lower standard. A full list of wireless flags is contained in *Wireless Status*, including access point capability descriptions.

34.66.3 Try with multiple clients or wireless cards

To eliminate a possible incompatibility between wireless functions on pfSense software and a wireless client, be sure to try it with multiple devices or cards first. If the same problem is repeatable with several different makes and models, it is more likely to be a problem with the configuration or related hardware than the client device.

34.66.4 Signal Strength is Low

If the signal is weak even when nearby the access point antenna, check the antenna again. For mini-PCI or mini-PCIe cards, if only one pigtail in use and there are two internal connectors, try hooking the pigtail up to the other internal connector on the card. Also try changing the **Channel** or adjusting the **Transmit Power**, or the **Antenna Settings** on the wireless interface configuration. For mini-PCI and mini-PCIe cards, check for broken ends on the fragile pigtail connectors where they plug into the card. If the **Regulatory Domain** settings have not been configured, set them before testing again.

34.66.5 Stuck Beacon Errors

If a "Stuck Beacon" error is found in the system or wireless log, it is usually an indication that the chosen wireless channel is too noisy:

```
kernel: ath0: stuck beacon; resetting (bmiss count 4)
```

The sensitivity of this behavior can be tuned by adding a System Tunable entry for `hw.ath.bstuck` with a value of `8` or higher.

If the errors persist, use a WiFi survey app or program to determine an open or less-used channel to use instead of the current channel.

34.66.6 Interface Unavailable for Assignment

If a wireless interface does not appear in the list of interfaces **Interfaces > Assignments** there are two possibile issues:

If the wireless card is supported, a wireless instance must first be created as described in *Creating and Managing Wireless Instances*. Once the instance is created, it will be available for assignment.

If the wireless card is not supported, it will not be available for selection as a parent interface when creating a wireless instance.

CHAPTER

THIRTYFIVE

PFSENSE® SOFTWARE CONFIGURATION RECIPES

The recipes in this section walk administrators through configuring various aspects of pfSense software.

35.1 WAN Connectivity with 802.1X Authentication Bridging and VLAN 0 PCP Tagging

Some Internet Service Providers require their customers to utilize the ISP modem in conjunction with an Optical Network Terminal (ONT) to be granted access to their fiber network. AT&T is one major example of such a provider. However, in some cases it is possible to bypass the modem and connect a firewall directly.

This guide covers the process of configuring a firewall to accommodate this type of authentication.

Note: This guide primarily applies to the AT&T Residential Fiber Network in North America, but can be adapted to any ISP utilizing a similar configuration.

Warning: The configuration options used in this guide are only present on pfSense® Plus software version 23.05-RELEASE and later.

35.1.1 Use Case

The purpose of this configuration is to provide authentication for access to the fiber network. Some ISP modems offer an "IP-Passthrough" mode which enables end users to have their public IPv4 and IPv6 addresses/blocks assigned directly to the equipment behind it (i.e. the firewall). However, this comes with a few drawbacks:

Modem Memory Limitations
: The fiber modem may still track states even in IP-Passthrough mode. Some modems have a hard limit on the number of states that they can handle at a time, becoming unstable under significant load.

Limitations in IPv6 Implementation
: In IP-Passthrough mode the modem is usually provisioned with an IPv6 prefix (`/60` for AT&T, for example), but will only hand out a single `/64` prefix out of the larger allocation via DHCP-PD to the firewall. This means that only a single LAN on the firewall can be provisioned with IPv6 by default. It is possible to request multiple `/64` networks out of the IPv6 prefix block, but that is an ugly workaround.

Multiple Points of Failure
: Having an ONT, a modem, and a firewall all needing to be powered at all times and available at all times introduces unnecessary additional points of potential hardware failure that can bring down connectivity even if the physical fiber link is in working order.

Bypassing the ISP equipment and attaching directly to the ONT with a pfSense Plus firewall eliminates or reduces the above limitations, allowing for greater control and flexibility.

Warning: The best practice when bypassing the ISP modem is to disable the Wi-Fi Access Point in the ISP equipment. This scenario requires an alternate means of Wi-Fi and switch connectivity behind the firewall to ensure connectivity parity with the ISP-provided all-in-one solution for Wi-Fi connectivity.

35.1.2 Requirements

Authenticating the firewall and allowing it to connect to the provider requires the following:

1. A firewall with at least **three** unique, discrete interfaces: One for the modem, one for the WAN/ONT connection, and one for the inside network(s).
2. The modem must be able to authenticate access using 802.1X EAP-TLS authentication. ISP modems using this type of 802.1X authentication have a "burned in" certificate and will initiate authentication when attached to a physical network on the red "ONT" port. This is handled on boot-up of the modem normally when it is in-line between the ONT and the local equipment and it will periodically retry authentication.
3. All traffic after authentication must be 802.1Q tagged on VLAN `0` with a Priority Code Point (PCP) of `1`. PCP is a means of defining traffic priority. A PCP of `1` is "Best Effort" and is how most ISPs, including AT&T, expect traffic to be marked. Configuring a PCP on a non-VLAN interface in pfSense Plus will tag the traffic on VLAN `0` and include the PCP value.
4. The WAN interface on pfSense Plus software must have the MAC address spoofed to match the WAN interface of the fiber modem. This MAC address may be printed on sticker attached to the modem, or it may be visible in the web interface on the modem.
5. The pfSense Plus software interface attached to the modem must be set to operate in promiscuous mode.
6. The firewall must send all IPv6 DHCP requests with a defined and expected DUID. A DUID is a unique identifier a device uses when requesting a DHCPv6 lease. Normally pfSense software will use an automatically generated random identifier, but ISPs such as AT&T expect a DUID-EN (DUID Enterprise Number) of `3561` and an identifier tied to the serial number of the modem. The identifier for a modem can be generated using an open source script.

   See also:

   To learn more about DUIDs, see *DHCP6 DUID*.
7. The firewall must send a prefix hint when requesting a DHCPv6 Prefix Delegation. Typically this is `/60` for AT&T. A `/60` prefix allows for 16 interfaces to each have a unique /64 subnet assigned from this block.

35.1.3 Modem Bypass Configuration

Physical Connections

Setup the physical connections as shown in *Diagram of Auth Bridge Wiring Layout*:

- Connect the ONT device LAN/Modem port to the NIC on the firewall which will be the **WAN** interface
- Connect the ISP modem ONT/WAN port (may be marked in red) to the NIC on the firewall which will be the **MODEM** interface
- Connect the NIC on the firewall which will be the **LAN** interface to a switch or other means of local connectivity

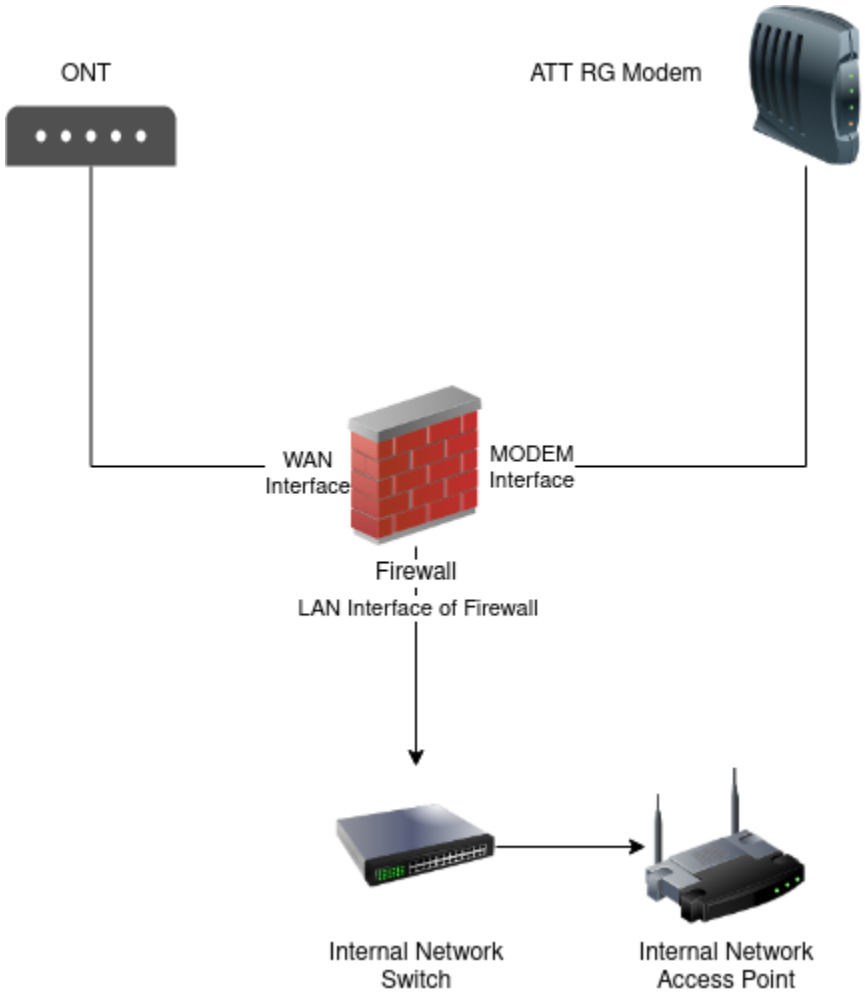

Fig. 1: Diagram of Auth Bridge Wiring Layout

Configure Firewall Interfaces

The next step is to configure the interfaces in the pfSense Plus software GUI.

Modem Interface

Assign and configure a new interface for the ISP Modem:

- Navigate to **Interfaces > Assignments**
- Set **Available network ports** to the physical interface attached to the ISP Modem
- Click  **Add**
- Note the name of the new interface (e.g. **OPT1**)
- Navigate to the newly added OPT interface using the **Interfaces** menu (e.g. **Interfaces > OPT1**)
- Configure the interface options as follows:

  Enable interface
  Checked

  Description
  `MODEM`

  IPv4 Configuration Type
  None

  IPv6 Configuration Type
  None

  Enable Promiscuous Mode
  Checked

- Click **Save**
- Click **Apply Changes**

The interface will now be available at **Interfaces > MODEM** and will appear as a choice with that name in various interface fields in the GUI.

WAN/ONT Interface

Now configure the WAN interface to send traffic that the ONT and ISP will accept:

- Navigate to the interface attached to the ONT (e.g. **Interfaces > WAN**)
- Configure the options as follows:

  Enable interface
  Checked

  Description
  `WAN` or another similarly descriptive name

  IPv4 Configuration Type
  DHCP

  IPv6 Configuration Type
  DHCP6

MAC Address
Enter the MAC address of the WAN interface on the **ISP Modem**

Priority Tag
1

DHCPv6 Prefix Delegation size
Set to match the value provided by the ISP, e.g. `60` for AT&T

Send IPv6 prefix hint
Checked

Do not wait for a RA
Checked

- Click **Save**
- Click **Apply Changes**

LAN Interface

Finally, configure the LAN and other local interfaces:

- Navigate to **Interfaces > LAN** or its equivalent
- Configure the options as follows:

  Enable interface
  Checked

  Description
  `LAN` or another similarly descriptive name

  IPv4 Configuration Type
  Static IPv4 using whichever private LAN subnet is already in place.

  IPv6 Configuration Type
  Track Interface

  Track IPv6 Interface

    IPv6 Interface
    WAN or whichever interface is attached to the ONT

    IPv6 Prefix ID
    1

- Click **Save**
- Click **Apply Changes**

Repeat this for any remaining inside interfaces. For each additional interface, increment the **IPv6 Prefix ID** value by `1` in **hexadecimal**. On AT&T or other providers who delegate a `/60` prefix size, the maximum ID value is `f`. The help text under the **IPv6 Prefix ID** field is automatically adjusted to show the minimum and maximum allowed values for the ID.

Configure IPv6 DUID

Set the custom DUID to send to the ISP:

- Navigate to **System > Advanced**, **Networking** tab
- Configure the options on the page as follows, leaving other unmentioned options at their current values:

  DHCP6 DUID
  DUID-EN: Assigned by Vendor based on Enterprise Number

  DUID-EN

  IANA Private Enterprise Number
  `3561`

  Identifier
  Enter the DUID value generated by the gen-duid.sh script

- Click **Save**

Configure Authentication Passthrough

Passing through the authentication traffic between the modem and ISP requires two Ethernet rules to bridge the appropriate traffic.

Enable Ethernet Rules

The Ethernet rules feature is disabled by default and must be manually enabled before use:

- Navigate to **System > Advanced**, **Firewall & NAT** tab
- Check **Enable Ethernet Filtering** in the **Advanced Options** section
- Click **Save**

See also:

Ethernet (Layer 2) Rules

Add WAN-Modem Bridge Rule

Add a rule to bridge 802.1X authentication traffic from the WAN/ONT to the MODEM interface:

- Navigate to **Firewall > Rules**, **Ethernet** tab
- Click  **Add**
- Configure the rule as follows:

  Action
  Pass

  Quick
  Checked

  Interface
  WAN or whichever interface is attached to the ONT

Direction
in

Protocol
IEEE 802.1X

Source
any

Destination
any

- Click **Display Advanced** and set:

Bridge To
MODEM

- Click **Save**

Add Modem-WAN Bridge Rule

Add a rule to bridge anything sent by the ISP Modem to the WAN interface:

- Navigate to **Firewall > Rules**, **Ethernet** tab
- Click  **Add**
- Configure the rule as follows:

Action
Pass

Quick
Checked

Interface
MODEM

Direction
in

Protocol
Any

Source
any

Destination
any

- Click **Display Advanced** and set:

Bridge To
WAN or whichever interface is attached to the ONT

- Click **Save**
- Click **Apply Changes**

35.1.4 Finish Up

The modem bypass configuration is now complete. Reboot the firewall to ensure the settings are applied completely. During the boot sequence, the modem should detect the link change and begin transmitting 802.1X authentication requests across the Layer 2 filter to the WAN interface, and the WAN interface should be able to acquire a DHCP and DHCPv6 lease.

35.2 Authenticating Users with Google Cloud Identity

Google Cloud Identity LDAP service can be used to authenticate users on pfSense® software installations.

The method varies depending on the version of pfSense software installed on the firewall. This is due to the fact that Google Cloud Identity requires a client certificate to make a secure LDAP connection.

- Firewalls running pfSense Plus software can use a client certificate directly on LDAP authentication sources.
- Firewalls running pfSense CE software or older unsupported versions require the stunnel package to make a secure LDAP connection.

Configuring a firewall running pfSense software to use G Suite LDAP authentication requires a number of steps, all of which are covered in this document.

35.2.1 Configure the LDAP Application on the G Suite admin portal

Follow the instructions from Google for configuring and enabling the G Suite LDAP application.

> **Warning:** **Follow these directions exactly**. No special provisions are required for pfSense, but please note that the LDAP application credentials (username and password) **are required**.

35.2.2 Download the certificate, key, username and password

Download the certificate, key, username and password from G Suite to a local directory on a workstation.

35.2.3 Import the certificate and key

From the web interface of a firewall running pfSense:

- Navigate to **System > Certificates**, **Certificates** tab
- Click  **Add/Sign** to display the certificate import interface
- Configure the entry as follows:

  Method
  Import an existing certificate

  Descriptive name
  `G Suite LDAP`

  Certificate data
  Copy and paste the contents of the downloaded certificate

Private Key data
Copy and paste the contents of the downloaded key

- Click **Save**

The certificate is now available for use by the firewall.

The next step depends on the version of pfSense software installed on the firewall.

For pfSense CE software the stunnel package is necessary to make a secure LDAP connection. For these environments, proceed to *Install the stunnel package (pfSense CE software)*.

For users of pfSense Plus software, LDAP authentication sources can use a client certificate directly. Skip ahead to *Configure LDAP authentication on pfSense software*.

35.2.4 Install the stunnel package (pfSense CE software)

From the web interface on pfSense:

- Navigate to **System > Package manager**, **Installed Packages** tab
- Check the list for **stunnel** and if it is listed as installed
- If the package is installed and up-to-date, with a version of **5.37** or later, no action is required
- If the package is installed but out of date
  - Update the package by clicking  for the **stunnel** entry
  - Click  **Confirm** to confirm the package update
- If **stunnel** is not installed
  - Navigate to the **Available packages** tab
  - Locate the **stunnel** package in the list, or use the search bar
  - Click  **Install** for the **stunnel** package entry
  - Click  **Confirm** to confirm the package installation

35.2.5 Configure the stunnel package (CE or 2.4.4-RELEASE)

From the web interface on pfSense:

- Navigate to **Services > STunnel**
- Click  **Add** to create a new profile
- Configure the profile as follows:

Description
Text describing this connection, such as `G Suite`

Client Mode
Check

Listen on IP
`127.0.0.1`

Listen on port
`1636`

Certificate
The entry imported previously, in this case *G Suite LDAP*

Redirects to IP
`ldap.google.com`

Redirects to port
`636`

- Click **Save**

35.2.6 Configure LDAP authentication on pfSense software

From the web interface on pfSense:

- Select **System > User manager**, **Authentication servers** tab
- Click  **Add** to create a new entry
- Enter a **Descriptive name** for this LDAP server, such as `G Suite`
- Configure the basic settings for the server as follows:

Type
LDAP

Protocol version
3

Server timeout
`25`

Search scope
Entire tree

The remaining settings depend on which version of pfSense software is installed:

For pfSense Plus:

Hostname or IP address
`ldap.google.com`

Port value
`636`

Transport
SSL - Encrypted

Peer Certificate Authority
Global Root CA List

Client Certificate
The entry imported previously, in this case *G Suite LDAP*

For pfSense CE or when using stunnel:

Hostname or IP address
`127.0.0.1`

Port value
`1636`

Transport
TCP-Standard

The next few settings are **UNIQUE TO THE DOMAIN**. For this example, assume that is `example.com`.

Warning: Substitute the actual domain when entering these values!

Base DN
The domain name in DN format, for example``dc=example,dc=com``

Authentication containers
Base DN prepended by the `Users` organizational unit, for example: `ou=Users,dc=example,dc=com`

Bind anonymous
Unchecked to show the **Bind Credentials** fields

Bind credentials
The G Suite LDAP username and password that were created with the certificate and key

The remaining attributes are not specific to the domain, or are defaults

User naming attribute
`uid`

Group naming attribute
`cn`

Group member attribute
`memberOf`

35.2.7 Create a Group

Using a remote authentication server to manage administrative logins to services on pfSense software requires a matching group to be present on both the authentication source server and on the firewall. The existing `admins` group could be used, but since the name is so general it may conflict with other desired permissions in G Suite.

This example uses a new group called `fwadmins`.

First, create the `fwadmins` group in G Suite and assign users to the group. The exact details will vary based on the domain and its organization.

Next, create a group on the firewall running pfSense software. This does not require local users, only a group entry. The group entry must have appropriate permissions.

To create the group on pfSense:

- Navigate to **System > User Manager**, **Groups** tab
- Click  **Add** to make a new group
- Configure the group as follows:

Group name
Name of the group, in this example: `fwadmins`

Scope
Remote

Description
Remote Firewall Administrators

- Click **Save**

Now the group needs privileges:

- Click  on the row for the newly created group
- Click  **Add** in the **Assigned Privileges** section
- Select the desired permissions for the group, for example: `WebCfg - All pages`

> **Warning:** **Do not select every item** in this list! Doing so will also select the `User - Config: Deny Config Write` privilege which will prevent users in this group from making changes to the firewall configuration.

- Click **Save** to store the privileges

35.2.8 Test G Suite Authentication

With the complete configuration described above, it is now possible to authenticate against Google G Suite LDAP. First, test the authentication to ensure it is working properly.

- Navigate to **Diagnostics > Authentication**
- Set the **Authentication server** to the name used for the LDAP Server entry, such as *G Suite*
- Enter a known username and password on the domain that G Suite controls

---

Note: By default only the username part of the login is checked against the configured LDAP base DN. If a username is submitted with a domain part, for example `user@example.com`, the `@example.com` part is ignored.

- Click  **Test**

The user should show as authenticating successfully, and if the user entered is a member of the `fwadmins` group in G Suite, that should also be reflected in the test output.

If the test succeeds, the service is ready for use. pfSense software can use it as an authentication source for the GUI, for VPNs, or anywhere the user manager authentication servers work.

If the test fails, check the main system log for error messages from LDAP. Start from the beginning of this document and compare all settings between this document, G Suite, and pfSense software. Most common problems are with parameters being input incorrectly, such as selecting the wrong certificate, using an incorrect LDAP attribute name, or not using correct bind credentials.

35.2.9 Use G Suite for Administrative Logins

If all is well and the user authenticated as expected:

- Navigate to **System > User manager**, **Settings**
- Set the **Authentication server** to *G Suite*
- Click **Save**

After saving, firewall users will be authenticated against Google Cloud Identity.

Note: pfSense software automatically falls back to local authentication if it cannot authenticate using the chosen LDAP server.

35.3 Configuring BIND as an RFC 2136 Dynamic DNS Server

If the DNS for a domain is directly controlled on a BIND server, RFC 2136 Dynamic DNS support can be setup for use by pfSense®. This section shows how to configure BIND to support this feature.

The exact location of the configuration directory for BIND will vary by operating system. It could be in `/usr/local/etc/namedb/`, `/etc/namedb/`, or elsewhere.

See also:

See *Configuring RFC 2136 Dynamic DNS updates* for more information on RFC 2136 Dynamic DNS.

35.3.1 Configure the BIND Server

On the server in `named.conf`, add the following block:

```
include "/etc/namedb/dns.keys.conf";
zone "dyn.example.com" {
     type master;
     file "dynamic/dyn.example.com";
     update-policy { grant *.dyn.example.com. self . A AAAA; };
};
```

Then create the initial zone file. BIND requires read/write access to this file and the directory in which it resides so that the zone and its journal may be updated.

Warning: BIND will rewrite this zone file, which is why a subdomain is used in the example.

From there, create the zone file for the new dynamic zone, `dynamic/dyn.example.com`

```
$ORIGIN      .
$TTL 30      ; 30 seconds
dyn.example.com             IN SOA  ns.example.com. hostmaster.example.com. (
                            2016062801 ; serial
                            3600       ; refresh (1 hour)
                            600        ; retry (10 minutes)
                            2600       ; expire (43 minutes 20 seconds)
```

(continues on next page)

(continued from previous page)

```
                            30         ; minimum (30 seconds)
                            )
                    NS      ns.example.com.
                    NS      ns2.example.com.
```

Reload the named service using `rndc reload` or a similar command, and then if any slave name servers are in place, add a zone to those servers as well:

```
zone "dyn.example.com" {
     type slave;
     file "dynamic/dyn.example.com";
     masters{ 192.0.2.5; };
};
```

For BIND 9.16+ create an entry using `tsig-keygen`:

```
# tsig-keygen -a hmac-sha256 myhost.dyn.example.com
key "myhost.dyn.example.com" {
     algorithm hmac-md5;
     secret "/0/4bxF9A08n/zke/vANyQ==";
};
```

Add that key to `dns.keys.conf` manually or by redirecting command output:

```
# tsig-keygen -a hmac-sha256 myhost.dyn.example.com >> /etc/namedb/dns.keys.conf
```

For BIND version < 9.16, follow the next steps.

On the master name server, make the keys directory:

```
# mkdir -p /etc/namedb/keys
```

And now generate a host key. The second line is the output of the command, *not* part of the command itself.

```
# /usr/sbin/dnssec-keygen -K /etc/namedb/keys -a HMAC-MD5 -b 128 -n HOST myhost.dyn.
↪example.com.
Kmyhost.dyn.example.com.+157+32768
```

The output `Kmyhost.dyn.example.com.+157+32768` is the first part of the filename for the key, it will append `.private` to one file and `.key` to another. Both contain the same data in different formats.

Now read the key from the new key file:

```
# /usr/bin/grep ^Key: /etc/namedb/keys/Kmyhost.dyn.example.com.+157+32768.private | /usr/
↪bin/awk '{ print $2; }'
/0/4bxF9A08n/zke/vANyQ==
```

And then add that key to `dns.keys.conf`:

```
key "myhost.dyn.example.com" {
     algorithm hmac-md5;
     secret "/0/4bxF9A08n/zke/vANyQ==";
};
```

This can be automated with a simple script, `make-ddns-host.sh`:

```
#!/bin/sh
KEY_NAME=${1}
KEY_DIR=/etc/namedb/keys
KEYS_CONFIG=/etc/namedb/dns.keys.conf
/bin/mkdir -p ${KEY_DIR}
cd ${KEY_DIR}
KEY_FILE_NAME=`/usr/sbin/dnssec-keygen -K ${KEY_DIR} -a HMAC-MD5 -b 128 -n HOST ${KEY_
↪NAME}.`
KEY_TEXT=`/usr/bin/grep "^Key:" ${KEY_DIR}/${KEY_FILE_NAME}.private | /usr/bin/awk '{␣
↪print $2; }'`
echo "key ${KEY_NAME}. {" >> ${KEYS_CONFIG}
echo "       algorithm hmac-md5;" >> ${KEYS_CONFIG}
echo "       secret \"${KEY_TEXT}\";" >> ${KEYS_CONFIG}
echo "};" >> ${KEYS_CONFIG}
echo "Key for ${KEY_NAME} is: ${KEY_TEXT}"
```

After making the file, make it executable:

```
# chmod u+x make-ddns-host.sh
```

To use the script:

```
# ./make-ddns-host.sh mynewhost.dyn.example.com
# rndc reload
```

35.3.2 Configuring a Client in pfSense Software

To add a DynDNS entry in the pfSense software GUI:

- Navigate to **Services > Dynamic DNS**, **RFC 2136** tab
- Click  **Add** to create a new entry with the following settings:

  Enable
  Checked

  Interface
  WAN

  Hostname
  The fully qualified hostname, e.g. `xxxxx.dyn.example.com`

  TTL
  `30`

  Key Name
  The fully qualified hostname again, exactly: `xxxxx.dyn.example.com`

  Key algorithm
  HMAC-SHA256

  Key
  Secret key for this hostname

  Server
  The IP address or hostname of the BIND server

Protocol
Unchecked

Description
`My DynDNS Entry`

- Click **Save**

Assuming the firewall has connectivity to the name server, and there are no other access policies that would prevent the update, RFC 2136 DynDNS service is now working. If the update does not work, check the BIND log and the system log on the firewall.

35.4 Blocking Web Sites

There are several options for blocking websites with pfSense® software, some of which are described on this article. This is not an exact science, but these solutions typically function well enough for a majority of use cases.

See also:

The pfBlockerNG package (*pfBlocker-NG Package*) offers mechanisms which can be useful in this area, such as DNSBL, geographic IP address blocking, and automation of AS lookups.

35.4.1 Using DNS

If the built in DNS Resolver or Forwarder are active an override can be entered there to resolve the unwanted website to an invalid IP address such as `127.0.0.1`.

> **Warning:** Do not use DNS override functionality as the only means of blocking access to sites.
>
> Blocking via DNS requires that local clients utilize the firewall as their only DNS source. See *Redirecting Client DNS Requests* and *Blocking External Client DNS Queries* for suggestions on ensuring clients get their DNS responses from the firewall. It will stop non-technical users, but it is easy to circumvent for those with more technical aptitude.

With the DNS Resolver, additional methods are possible via custom options.

This first example will prevent any host under the given zone from being resolved by clients:

```
server:
local-zone: "movie.edu" static
```

When the firewall enforces DNS resolution in this way, the firewall must also force clients to resolve DNS using the firewall. Otherwise, clients could bypass the restrictions by using alternate DNS servers. See *Redirecting Client DNS Requests* for details.

This can be limited in scope using custom views. This example is similar to the above, but only blocks access for `10.6.0.100`:

```
server:
access-control-view: 10.6.0.100/32 blocksites

view:
name: "blocksites"
local-zone: "movie.edu" static
```

35.4.2 Using Firewall Rules

If a website rarely changes IP addresses, then it can be blocked by an alias. Create an alias containing its IP addresses and then use this alias in firewall rules.

> **Warning:** This is not a feasible solution for sites that return low TTLs and spread the load across many servers and/or datacenters, such as Google and similar large sites. Most small to mid sized websites can be effectively blocked using this method as they rarely change IP addresses.

A hostname can also be inside a network alias. The firewall will resolve the hostname periodically and update the alias as needed. This is more effective than manually looking up the IP addresses, but will still fall short if the site returns DNS records in a way that changes rapidly or randomizes results from a pool of servers on each query, which is common for large sites.

Another option is finding all of the IP subnet allocations for a site. Create an alias with those networks and block traffic to those destinations. This is especially useful with sites such as Facebook that spread large amounts of IP space, but are constrained within a few net blocks. Using regional registry sites such as ARIN can help track down those networks. For example, all of the networks used by Facebook in the region covered by ARIN can be found at http://whois.arin.net/rest/org/THEFA-3.html under "Related Networks". Companies may have other addresses in different regions, so check other regional sites as well, such as RIPE, APNIC, etc.

As an alternative to looking up the IP blocks manually, locate the BGP Autonomous System (AS) number for the target company by doing a `whois` lookup on one of their IP addresses. For example, the AS number for Facebook is `AS32934` and the following command will locate all of their allocations:

```
# whois -h whois.radb.net -- '-i origin AS32934' | awk '/^route:/ {print $2;}' | sort |␣
↪uniq
```

Copy the results of that command into a new alias and it will cover all of their currently allocated networks. Check the results periodically for updates.

35.4.3 Using a Proxy

In modern environments a client proxy is not effective. HTTPS can sometimes be filtered via peek/splice to inspect SNI and similar aspects of connections, but even that fails with modern security practices like encrypted SNI. Using proxies for these tasks is no longer a recommended practice.

35.4.4 Prevent Bypassing Restrictions

With any of the above methods, there are many ways to get around the defined blocks. The easiest and likely most prevalent is using any number of proxy websites. Finding and blocking all of these individually and keeping the list up to date is impossible. The best way to ensure these sites are not accessible is using an external proxy or content filtering capable of blocking by category.

To further maintain control, use a restrictive egress ruleset and only allow traffic out to specific services and/or hosts. For example, only allow DNS access to the firewall or the DNS servers specifically used for LAN clients (*Redirecting Client DNS Requests*). Also, if a proxy is in use on the network, make sure to disallow direct access to HTTP and HTTPS through the firewall and only allow traffic to and/or from the proxy server.

35.5 Changing Credentials and Keys

Organizations may have guidelines about how often to change credentials such as passwords and encryption keys. Different types of credentials and keys are stored in various places in the configuration, and changing them can range from trivial or cumbersome depending on the type and how the firewall uses them.

These types of guidelines can vary widely based on various industry recommendations, certification standards, and other criteria. Due to these variations, this document won't make any specific commentary on timing of such changes.

See also:

- *Password Storage Security Policies*
- *Caveats and Gotchas*

35.5.1 User Manager Accounts

Administrators can change the password for their own account and for accounts of other users in the User Manager:

- Navigate to **System > User Manager**
- Find the user account in the list
- Click  at the end of the row to edit the user account
- Enter a new **Password** and enter it again in the **Confirm Password** field.
- Click **Save**

See also:

User Management and Authentication

Unprivileged Users

Non-administrator users with accounts in the user manager who have the "WebCfg - System: User Password Manager" privilege can login to the GUI with their existing username and password and change the password for their own account to a new value in the same place (**System > User Manager**).

The GUI displays a simplified form for these users with only the password change fields.

Warning: Do not expose the GUI to the Internet. Only allow users to reach the firewall GUI from a local interface or using a secure VPN.

35.5.2 Authentication Servers

User authentication may be handed off to external authentication servers. In this case the user credentials must be changed on then authentication server. However, there may be credentials the firewall itself uses when communicating with the authentication servers.

LDAP

LDAP servers may have two items to update, depending on the configuration:

TLS Certificate

If communication with the LDAP server users TLS (STARTTLS or dedicated TLS port) then there may be occasions when the server CA expires or needs changed. If there is a new server CA, replace the CA data in the *Certificate Manager*:

- Navigate to **System > Certificates**, **CAs** tab
- Find the LDAP server CA in the list
- Click  to edit the CA
- Paste in the new CA certificate and/or private key data in PEM format
- Click **Save**

Alternately, import a new CA entry, then edit the LDAP authentication server entry and switch to the new CA.

Bind Credentials

LDAP authentication servers may use authenticated or anonymous binds when validating LDAP users. If the entry uses bind credentials, these may change over time.

To update the bind credentials:

- Navigate to **System > User Manager**, **Authentication Servers** tab
- Find the LDAP server entry in the list
- Click  to edit the LDAP server entry
- Enter the new **Bind credentials** (**User DN**, **Password**)
- Click **Save**

RADIUS

RADIUS authentication servers have a **Shared Secret** (sometimes called a NAS password) which allows the firewall to perform authentication requests. If the shared secret for the firewall is changed on the RADIUS server, update the RADIUS authentication server entry on the firewall to match:

- Navigate to **System > User Manager**, **Authentication Servers** tab
- Find the RADIUS server entry in the list
- Click  to edit the RADIUS server entry
- Enter the new **Shared Secret**
- Click **Save**

35.5.3 Interfaces

A few interface types can have credentials as well. For WANs, these should be changed with the ISP first and then updated on the firewall to match.

PPP type WANs

These types of WANs (e.g. PPPoE, L2TP, PPP/Cellular) can be changed in either of two places: The interface configuration or the PPPs configuration.

Choose **one** of the following methods and update the credentials there.

Interface Method

- Navigate to **Interfaces > <Name>** for the interface in question
- Enter the new **Username**, **Password**, and **Confirm Password**
- Click **Save**
- Click **Apply Changes**

PPPs Configuration Method

- Navigate to **Interfaces > Assignments**, **PPPs** tab
- Find the entry in the list
- Click  to edit the entry
- Enter the new **Username**, **Password**, and **Confirm Password**
- Click **Save**

Wireless WANs

If the upstream wireless provider changes the pre-shared key or 802.x/EAP passphrase, a wireless WAN must change to match the new value(s):

- Navigate to **Interfaces > <Name>** for the interface in question
- Enter the new **WPA Pre-Shared Key** and/or **Inner Authentication Passphrase**
- Click **Save**
- Click **Apply Changes**

Wireless APs

WPA2

Access Points using WPA/WPA2 should periodically change the pre-shared key:

- Navigate to **Interfaces > <Name>** for the interface in question
- Enter the new **WPA Pre-Shared Key**
- Click **Save**
- Click **Apply Changes**

Clients will need to enter the new key to reconnect.

802.1x

Access Points using 802.1x/EAP may need to update the RADIUS shared secret if it changes on the RADIUS server.

- Navigate to **Interfaces > <Name>** for the interface in question
- Enter the new **Shared Secret** for the **Primary 802.1x server** and/or **Secondary 802.1x server**
- Click **Save**
- Click **Apply Changes**

35.5.4 Certificate Data and Private Keys

CA and Certificate entries have built-in expiration dates and can be easily renewed in the GUI. On occasion it may be necessary to change the private key for a CA or certificate as well.

Warning: When renewing a CA, changing the private key or serial number will invalidate any certificate signed by the CA as these are part of the data used to validate the trust chain.

To renew a CA or certificate and generate a new private key:

- Navigate to **System > Certificates**, **CAs** or **Certificates** tab
- Find the entry to renew
- Click  to start the renewal process

- Uncheck **Reuse Key**

  With this option unchecked, the renewal process will generate a brand new private key for the certificate. This is generally safe for server and user certificates but can be problematic for CAs as mentioned previously.

- Inspect the **Certificate Properties**

  If any are considered weak, consider checking **Strict Security** to use the recommended properties for stronger security.

- Click **Renew/Reissue**

If the entry is a CA, send the new CA to clients that need it. Assuming the key and serial were reused they can continue using the old CA until it expires but they will need to replace their local copy of the CA before that date arrives.

Note: When renewing the self-signed GUI certificate, it is safe to replace the key and using a new serial number is required.

35.5.5 VPNs

For optimal security, changing VPN keys periodically is a good practice. The practicality of doing so largely depends on the size of the VPN (e.g. a simple two-site point-to-point link vs a remote access setup with dozens of users)

In any case, the most important thing is to coordinate the change with the remote peer(s) so all parties are using the correct keys.

IPsec Pre-Shared Keys

Changing pre-shared key values is fairly simple but must be done in a coordinated fashion. As soon as one side changes the key, the other side will fail to negotiate the tunnel the next time it attempts to authenticate.

Tunnels

- Navigate to **VPN > IPsec**
- Locate the VPN tunnel in the list
- Click  to edit the tunnel Phase 1 entry
- Enter a new **Pre-Shared Key**
- Click **Save**
- Click **Apply Changes**

Remote Access (PSK and EAP)

- Navigate to **VPN > IPsec**, **Pre-Shared Keys** tab
- Locate the key entry in the list
- Click  to edit the entry
- Enter a new **Pre-Shared Key**
- Click **Save**
- Click **Apply Changes**

IPsec Certificates

An IPsec tunnel using certificate-based authentication will have two certificates that may need changed: **My Certificate** which is used by this firewall to identify itself, and **Peer Certificate Authority** which this firewall uses to authenticate the peer.

If the CA or certificate was created on this firewall, the entry can be renewed as described in *Certificate Data and Private Keys*.

To update a CA or Certificate entry in-place with data from a remote source:

- Navigate to **System > Certificates**, **CAs** or **Certificates** tab
- Find the entry in the list
- Click  to edit the entry
- Paste in the new certificate and/or private key data in PEM format
- Click **Save**

Alternately, renew, create, or import a new CA/Certificate, then select the new entry:

- Navigate to **VPN > IPsec**
- Locate the VPN tunnel in the list
- Click  to edit the tunnel Phase 1 entry
- Select the new **My Certificate** and/or **Peer Certificate Authority** entries
- Click **Save**
- Click **Apply Changes**

WireGuard

To update a new key for a tunnel:

- Navigate to **VPN > WireGuard**, **Tunnels** tab
- Find the entry in the list
- Click  to edit the entry
- Enter a new private key

  Alternately, click  **Generate** to automatically generate a new key pair.
- Click **Save Tunnel**

Warning: The tunnel will be down until the remote peer(s) update their configurations with the new public key.

If a peer changes their key, edit the peer and update:

- Navigate to **VPN > WireGuard**, **Peers** tab
- Find the entry in the list
- Click  to edit the entry
- Enter a new **Public Key**
- Click **Save Tunnel**

Another strategy for remote access setups is to make a new tunnel with settings similar to the old one. It must have a unique port number and interface addresses but it can otherwise use the same settings. Place the new keys on the new server and exchange new keys with clients. Once all clients are on the new server, retire the old entry and remove all of its contents.

OpenVPN

Warning: Shared Key mode is deprecated, move to certificate-based tunnels.

OpenVPN tunnels using certificates can, for the most part, be handled by methods already covered in this document. For example, if the CA or certificate was created on this firewall, the entry can be renewed as described in *Certificate Data and Private Keys* and the warnings there still apply.

Consider generating a new TLS auth/encryption key periodically as well:

- From an SSH or console shell prompt, or **Diagnostics > Commands**, run the following shell command:

```
$ openvpn --genkey secret
#
# 2048 bit OpenVPN static key
#
-----BEGIN OpenVPN Static key V1-----
```

(continues on next page)

(continued from previous page)

```

c1f8a7cc57cfb60a5adda5a3287d128c
f0a29f14cb4e1e7fda8174c4a7226252
-----END OpenVPN Static key V1-----
```

- Copy the resulting text including the # header lines and --- armor lines.
- Navigate to **VPN > OpenVPN**, **Servers** tab
- Find the entry in the list
- Click  to edit the entry
- Erase the existing TLS key
- Paste in the new TLS key
- Click **Save**

Warning: Coordinate with all clients as changing it on the server will require clients to use the new key immediately!

Another popular strategy for remote access setups is to make a new VPN server with settings similar to the old one. It must have a unique port number and tunnel network but it can otherwise use the same settings. Place the new TLS key, CA, and certificates on this new server and deliver the new files to clients. Once all clients are on the new server, retire the old entry and remove all of its contents.

PPPoE Server Users

If the firewall is acting as a PPPoE server, it has a separate configuration for users and/or RADIUS authentication.

Local Users

- Navigate to **Services > PPPoE Server**
- Locate the server entry in the list
- Click  to edit the server
- Locate user in the **User table**
- Set a new **Password**
- Click **Save**

RADIUS

- Navigate to **Services > PPPoE Server**
- Locate the server entry in the list
- Click  to edit the server
- Set and confirm a new **Primary RADIUS Server Shared Secret** and/or **Secondary RADIUS Server Shared Secret**
- Click **Save**

L2TP Server Users

If the firewall is acting as an L2TP server, it has a separate configuration for users and/or RADIUS authentication.

Local Users

- Navigate to **VPN > L2TP Server**, **Users** tab
- Locate the entry in the list
- Click  to edit the entry
- Set and confirm a new **Password**
- Click **Save**

RADIUS

- Navigate to **VPN > L2TP Server**
- Set and confirm a new **Secret** in the **RADIUS** section
- Click **Save**

35.5.6 Notification Services

Remote notification types frequently require credentials to contact the remote server and deliver messages. If the credentials change on the server, the firewall needs the new credentials to continue delivering remote notifications.

SMTP

- Navigate to **System > Advanced**, **Notifications** tab
- Enter a new **Notification E-mail auth password** in the **SMTP** Section
- Click **Save**
- Click **Test SMTP Settings**

Telegram

- Navigate to **System > Advanced**, **Notifications** tab
- Enter a new **API key** in the **Telegram** Section
- Click **Save**
- Click **Test Telegram Settings**

Pushover

- Navigate to **System > Advanced**, **Notifications** tab
- Enter a new **API key** and/or **User Key** in the **Pushover** Section
- Click **Save**
- Click **Test Pushover Settings**

Slack

- Navigate to **System > Advanced**, **Notifications** tab
- Enter a new **API key** in the **Slack** Section
- Click **Save**
- Click **Test Slack Settings**

35.5.7 Upstream Proxy

If the firewall must authenticate to an upstream proxy for its own outgoing HTTP/HTTPS requests and those credentials change, the firewall will need the new password for outbound connectivity:

- Navigate to **System > Advanced**, **Miscellaneous** tab
- Enter a new **Proxy Password**
- Click **Save**

35.5.8 Captive Portal

Uses the *User Manager* for local users, *Authentication Servers* for remote users, and *certificates from the certificate manager*. See those respective sections for information on updating credentials.

35.5.9 DHCP Server

OMAPI

To change the OMAPI key:

- Navigate to **Services > DHCP Server**
- Paste in a new **OMAPI Key** or check **Generate New Key** to create a new key automatically
- Click **Save**

Dynamic DNS Key

If the DHCP server securely sends dynamic DNS updates to an upstream DNS server, those credentials can be changed if the server updates the key:

- Navigate to **Services > DHCP Server**
- Paste in a new **DNS Domain key secret** from the DNS server
- Click **Save**

35.5.10 DNS Resolver

Uses *certificates from the certificate manager* when acting as a DNS over TLS server. See that section for information on updating credentials.

35.5.11 Dynamic DNS

Dynamic DNS Service Clients

The type and format of credentials for Dynamic DNS clients vary by provider.

- Navigate to **Services > Dynamic DNS**, **Dynamic DNS Clients** tab
- Find the entry in the list
- Click  to edit the entry
- Enter the new **Password** or equivalent credential
- Click **Save**

  Alternately, click **Save and Force Update** to also force an update to test the new settings.

RFC 2136 Clients

- Navigate to **Services > Dynamic DNS**, **RFC 2136 Clients** tab
- Find the entry in the list
- Click  to edit the entry
- Pick a new **Key algorithm** if it changed
- Enter the new **Key**
- Click **Save**

  Alternately, click **Save and Force Update** to also force an update to test the new settings.

35.5.12 NTP

If NTPv3 authentication is enabled and the server key changes, the firewall must be changed to match.

- Navigate to **Services > NTP**
- Enter a new **Authentication Key**
- Pick a new **Digest Algorithm** if it changed
- Click **Save**

35.5.13 Packages

Add-on packages can have their own sets of credentials. This section is not comprehensive. Check each add-on package individually.

ACME

Certificates

These certificates generally only have a 90-day lifetime and thus it's unusual to need to renew them sooner as their relatively short life is quite secure on its own.

To forcefully renew an ACME certificate:

- Navigate to **Services > ACME Certificates**, **Certificates** tab
- Locate the entry in the list
- Click **Issue/Renew**

Private Keys

Changing a private key for a certificate isn't a common need, the package does not currently have a good method to forcefully generate a new private key of the same type and size.

- Navigate to **Services > ACME Certificates**, **Certificates** tab
- Locate the entry in the list
- Click  to edit the entry
- Change the **Private Key** selection to a different length or type (RSA vs ECDSA)

  Alternately, generate a new private key externally and then choose *Custom* and paste the private key data in PEM format.
- Click **Save**
- Locate the entry in the list
- Click **Issue/Renew**

When the package renews the certificate it will change the private key to the new size and/or type.

Account Keys

The account key identifies a particular ACME user, but it can be changed if needed.

- Navigate to **Services > ACME Certificates**, **Account Keys** tab
- Locate the entry in the list
- Click  to edit the entry
- Click  **Create new account key**
- Click  **Register ACME account key**
- Click **Save**
- Navigate to **Services > ACME Certificates**, **Certificates** tab
- Locate each entry in the list using this account key
- Click **Issue/Renew** on each entry using the key

FRR

The FRR package can optionally store credentials used to communicate with peers.

Global

The master password is only used internally by FRR. Changing it is typically unnecessary but simple to do as it does not need to be updated anywhere else.

- Navigate to **Services > FRR Global/Zebra**
- Enter a new **Master Password**

BGP

- Navigate to **Services > FRR BGP**, **Neighbors** tab
- Locate the entry in the list
- Click  to edit the entry
- Enter a new **Password**
- Click **Save**

OSPF

- Navigate to **Services > FRR OSPF**, **Interfaces** tab
- Locate the entry in the list
- Click  to edit the entry
- Enter a new **Password**
- Click **Save**

FreeRADIUS

The FreeRADIUS package contains credentials for users as well as for its clients and other servers.

Note: If using a database, change data there instead.

Users

- Navigate to **Services > FreeRADIUS**, **Users** tab
- Locate the entry in the list
- Click  to edit the entry
- Enter a new **Password**
- Enter a new One-Time Password **Init-Secret** and/or **PIN** if needed
- Click **Save**

NAS / Clients

- Navigate to **Services > FreeRADIUS**, **NAS / Clients** tab
- Locate the entry in the list
- Click  to edit the entry
- Enter a new **Client Shared Secret**
- Click **Save**

EAP Certificates

EAP uses certificates from the *Certificate Manager*. To change those, see that section instead.

SQL

If this FreeRADIUS configuration pulls its data from an SQL server, it will have stored credentials for communicating with the SQL server. To update those credentials:

- Navigate to **Services > FreeRADIUS**, **SQL** tab
- Enter a new **Database Password** in the section for server 1 and optionally for server 2.
- Click **Save**

LDAP

If this FreeRADIUS configuration passes authentication requests to an LDAP server, it may have stored credentials for communicating with the LDAP server. To update those credentials:

- Navigate to **Services > FreeRADIUS**, **LDAP** tab
- Enter a new **Password** in the section for server 1 and optionally for server 2.
- Click **Save**

If communication with the LDAP server uses certificates, they are stored in the *Certificate Manager*. To change those, see that section instead.

NET-SNMP

NET-SNMP SSL/TLS options use entries from the *Certificate Manager*. To change those, see that section instead.

Users

- Navigate to **Services > NET-SNMP**, **Users** tab
- Locate the entry in the list
- Click  to edit the entry
- Enter a new **Password** and/or **Passphrase**
- Click **Save**

Communities

- Navigate to **Services > NET-SNMP**, **Communities** tab
- Locate the entry in the list
- Click  to edit the entry
- Enter a new **Community Name**
- Click **Save**

HAProxy

HAProxy SSL/TLS options use entries from the *Certificate Manager*. To change those, see that section instead.

Stunnel

HAProxy SSL/TLS options use entries from the *Certificate Manager*. To change those, see that section instead.

Zabbix

- Navigate to **Services > Zabbix Agent** or **Services > Zabbix Proxy**
- Paste a new **TLS PSK** value from the server

SSL/TLS options use entries from the *Certificate Manager*. To change those, see that section instead.

Others

The contents of the package system change on an ongoing basis. There may be additional third party packages with credentials not mentioned in this document. Check the settings of any other installed package for local or remote credentials.

35.6 Diagnostic Data for Support

pfSense® software includes a function to gather diagnostic data for support purposes. The data collected by this function can be useful when diagnosing issues, especially when working with Netgate TAC or community members on the Netgate Forum. This information may also be referred to as "Status Output".

This function is handled by an unlinked script at `/usr/local/www/status.php`. The script produces output and an optional archive containing a wide array of information from an installation.

Warning: Though the script makes an effort to remove private information such as passwords, keys, and other secrets, the output may still contain sensitive data. This is especially true when it comes to packages which may use non-standard names for items in the configuration.

Always inspect the output data to ensure it does not contain any private information.

There are multiple ways to invoke the script, both in the GUI and through the shell.

35.6.1 View and Download Diagnostic Data in the GUI

This script is not linked from any menu as it's not a function users would need to access on a regular basis.

To load the script, first *connect to the GUI* and then add `/status.php` to the end of the URL.

For example: `https://x.x.x.x/status.php`

Note: The page can take a while to load depending on the hardware.

The script will create an archive with the diagnostic data along with a  **Download** button to easily download the archive file.

By default the script also outputs all of the diagnostic data to the browser which can make it easy for users to inspect. This output can be suppressed, see *Script Options* for details.

35.6.2 Generate Diagnostic Data Archive in the Shell

The script can also be invoked from the shell if the GUI is unavailable. Additionally, in some cases the script may fail to run in the GUI but succeed from the shell. The script can be run from the console (video or serial) or via SSH.

To start, *connect to the firewall console* or *enable SSH* and *connect using an SSH client*.

Note: This script requires `admin` or `root` privileges, so use either of those usernames or use the *Sudo Package* to run the script from another user.

When connected to the console or SSH use option `8` from the menu to load a shell prompt and then execute the script:

```
php -f /usr/local/www/status.php
```

The script will gather the data and create an archive file at `/tmp/status_output.tgz`. This file can then be copied off the firewall using one of the methods covered later in this document.

35.6.3 Script Options

When invoking the script there a couple options that control its behavior:

archiveonly
: When set, suppresses the output of the script in the GUI so that it only generates an archive for download purposes.

  This option is only valid in the GUI as the console method only supports archive output.

nocleanup
: When set, the script leaves behind all of the individual diagnostic data files in `/tmp/status_output/` which is handy for inspecting the data directly in the shell without using the archive file.

To use the options in the GUI, they must be passed as query parameters, for example:

- `https://x.x.x.x/status.php?archiveonly`
- `https://x.x.x.x/status.php?nocleanup`
- `https://x.x.x.x/status.php?archiveonly&nocleanup`

When running the script in the shell, pass the option the script filename:

```
php -f /usr/local/www/status.php nocleanup
```

35.6.4 Copying the Diagnostic Data Archive

After using the script users can copy the archive file (`/tmp/status_output.tgz`) off the firewall in a variety of ways.

Download from the GUI

The easiest way to download the archive from the GUI is to use `/status.php` directly in the GUI. If that is not viable, use the *Download function* on **Diagnostics > Command Prompt** to download the `/tmp/status_output.tgz` archive file after generating it in the shell.

Download Using SCP

If the SSH daemon is *enabled on the firewall*, then an SCP client can copy files from the firewall remotely. Alternately, SCP can copy files from the firewall to a remote SSH server from the shell.

See *Accessing the Firewall Filesystem with SCP* for information on setting up and using SCP.

Copy to a USB Drive

Alternately, bypass the network and copy the archive file to a USB drive by following the procedure in *Copy Files to a USB Drive*.

35.7 Blocking External Client DNS Queries

This procedure configures the firewall to block DNS requests from local clients to servers outside the local network. With no other accessible DNS servers, clients are forced to send DNS requests to the DNS Resolver or DNS Forwarder on pfSense® software for resolution.

Note: Blocking is effective but does not gracefully handle the situation. Clients must manually adjust their configuration to use the firewall for DNS. Redirecting DNS requests to the firewall is a more seamless solution. See *Redirecting Client DNS Requests* for details.

- Navigate to **Firewall > Rules**, **LAN** tab
- Create the block rule as the first rule in the list:
  - Click  **Add** to create a new rule at the top of the list
  - Fill in the following fields on the rule:

    Action
    Reject

    Interface
    LAN

    Protocol
    TCP/UDP

    Destination
    Any

    Destination Port Range
    DNS (53)

    Description
    `Block DNS to Everything Else`

- Create the pass rule to allow DNS to the firewall, above the block rule:
  - Click  **Add** to create a new rule at the top of the list
  - Fill in the following fields on the rule:

    Action
    Pass

    Interface
    LAN

    Protocol
    TCP/UDP

    Destination
    LAN Address

    Destination Port Range
    DNS (53)

    Description
    `Pass DNS to the Firewall`

- Click  **Apply Changes** to reload the ruleset

When complete, there will be two rule entries that look like the following picture:

	States	Protocol	Source	Port	Destination	Port	Gateway	Queue	Schedule	Description	Actions
✓	0 /0 B	IPv4 TCP/UDP	*	*	LAN address	53 (DNS)	*	none		Pass DNS to the Firewall	
	0 /0 B	IPv4 TCP/UDP	*	*	*	53 (DNS)	*	none		Block DNS to Everything Else	

Certain local PCs could be allowed to use other DNS servers by placing a pass rule for them above the block rule.

35.7.1 DNS over TLS

Another concern is that clients could use DNS over TLS to resolve hosts. DNS over TLS sends DNS requests over an encrypted channel on an alternate port, `853`.

This traffic can be blocked with a firewall rule for port `853` using the same procedure used for `53`. Though if the firewall will not be providing DNS over TLS service to clients, do not add the pass rule.

35.7.2 DNS over HTTPS

Similar to DNS over TLS, clients may also use DNS over HTTPS (DoH). This is harder to block as it uses port `443`. Blocking port `443` on common public DNS servers may help (e.g. `1.1.1.1`, `8.8.8.8`).

Some browsers automatically attempt to use DNS over HTTPS because they believe it to be more secure and better for privacy, though that is not always the case. Each browser may have its own methods of disabling this feature. Firefox uses a "canary" domain `use-application-dns.net` by default if the user has not manually enabled DNS over HTTPS. If Firefox cannot resolve this name, Firefox disables DNS over HTTPS.

To prevent Firefox from using DNS over HTTPS, add the following to the DNS Resolver custom options:

```
server:
local-zone: "use-application-dns.net" always_nxdomain
```

35.8 Configuring DNS over TLS

Several popular public DNS providers provide encrypted DNS service using DNS over TLS. This prevents intermediate parties from viewing the content of DNS queries and can also assure that DNS is being provided by the expected DNS servers.

35.8.1 Requirements

This feature is only supported by the *DNS Resolver*. If the firewall is currently using the *DNS Forwarder*, convert to the DNS Resolver before starting this procedure.

Pick a DNS over TLS upstream provider, such as a private upstream DNS server or a public service like Cloudflare, Quad9, or Google public DNS. Note the addresses of the servers and their associated hostnames.

35.8.2 Configure DNS Servers

First, configure the DNS servers on the firewall.

Warning: When the firewall uses DNS over TLS, every DNS server used by the firewall **must** support DNS over TLS.

- Navigate to **System > General**
- Locate the **DNS Server Settings** Section
- Add or replace entries in the **DNS Servers** section such that only the chosen DNS over TLS servers are in the list

  Address
  : IP address of an upstream DNS Server providing DNS over TLS service (e.g. `1.1.1.1`).

  Hostname
  : Hostname of the same upstream DNS Server in the **Address** field, used for TLS certificate validation (e.g. `cloudflare-dns.com`).

  Warning: The hostname is technically optional but dangerous to omit. The DNS Resolver must have the hostname to validate that the correct server is providing a given response. The response is still encrypted without the hostname, but the DNS Resolver has no way to validate the response to determine if the query was intercepted and answered by a third party server (Man-in-the-Middle attack).

- Click  **Add DNS Server** and repeat the previous step as needed for each available DNS server
- Uncheck **Allow DNS server list to be overridden by DHCP/PPP on WAN**

  This could add DNS servers to the configuration which do not support DNS over TLS.

- Set **DNS Resolution Behavior** to *Use local DNS (127.0.0.1), ignore remote DNS Servers*

  This makes the firewall itself use only the DNS Resolver and it will not attempt to contact the DNS servers directly. This prevents DNS requests from the firewall being leaked unencrypted on port `53` if the resolver is temporarily unavailable (*DNS Resolution Behavior*).

- Click **Save**

Use *Example DNS Server list for DNS over TLS from Cloudflare* as a reference for the settings on the page.

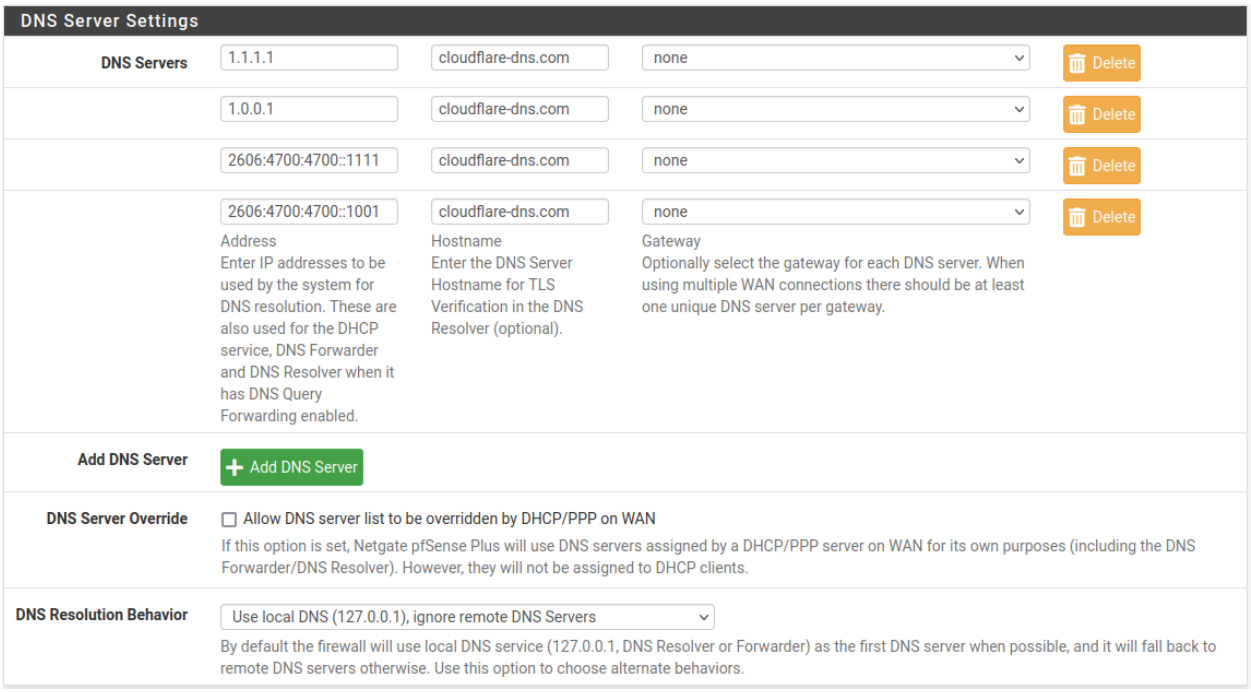

Fig. 2: Example DNS Server list for DNS over TLS from Cloudflare

35.8.3 Enable DNS over TLS for Forwarded Queries

Next, configure the DNS Resolver to use DNS over TLS for outgoing queries.

- Navigate to **Services > DNS Resolver**
- Uncheck **Enable DNSSEC Support**

> **Note:** DNSSEC is not generally compatible with forwarding mode, with or without DNS over TLS.

- Check **Enable Forwarding Mode**
- Check **Use SSL/TLS for outgoing DNS Queries to Forwarding Servers**
- Click **Save**
- Click **Apply Changes**

Use *Example DNS Resolver configuration for outgoing DNS over TLS* as a reference for the settings on the page.

The DNS Resolver will now send queries to all upstream forwarding DNS servers using SSL/TLS on the default port of `853`.

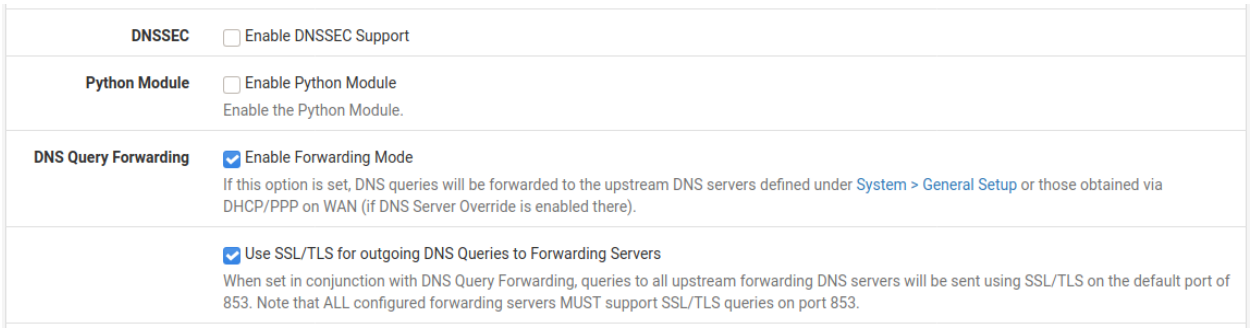

Fig. 3: Example DNS Resolver configuration for outgoing DNS over TLS

35.8.4 Testing DNS over TLS

There are several ways to validate that outbound queries are using DNS over TLS.

- Test via **Diagnostics > DNS Lookup** (*DNS Lookup*) and ensure the results from `127.0.0.1` are correct.
- Check for states using port `853` going to the DNS servers in the configuration (*Firewall States*) like those in *Example State Table contents for DNS over TLS queries*.
- Packet capture port `853` (*Packet Capturing*) and inspect the capture in Wireshark. The contents of the query are not visible, but the TLS exchange is, and any TLS errors in negotiation should be visible in the capture.

States

Interface	Protocol	Source (Original Source) -> Destination (Original Destination)	State	Packets	Bytes
WAN	tcp	198.51.100.23:51344 -> 1.0.0.1:853	FIN_WAIT_2:FIN_WAIT_2	11 / 9	952 B / 4 KiB
WAN	tcp	198.51.100.23:31300 -> 1.1.1.1:853	FIN_WAIT_2:FIN_WAIT_2	11 / 9	947 B / 4 KiB

Fig. 4: Example State Table contents for DNS over TLS queries

35.8.5 Enable DNS over TLS Server (optional)

The DNS Resolver can also act as a DNS over TLS server, though this function **does not** affect outbound/forwarded queries, so this section is optional.

Enable this feature only when *local clients* may need to communicate with the *DNS Resolver* using DNS over TLS queries.

- Navigate to **Services > DNS Resolver**
- Check **Respond to incoming SSL/TLS queries from local clients**
- Select a valid server certificate in **SSL/TLS Certificate**

> **Note:** Clients may reject this certificate if it is self-signed, consider using a certificate from *ACME*.

- Leave **SSL/TLS Listen Port** at the default (empty or `853`)
- Click **Save**
- Click **Apply Changes**

Use *Example DNS Resolver configuration for acting as a DNS over TLS Server* as a reference for the settings on the page.

Now the DNS Resolver will listen for DNS over TLS queries from local clients on TCP port 853.

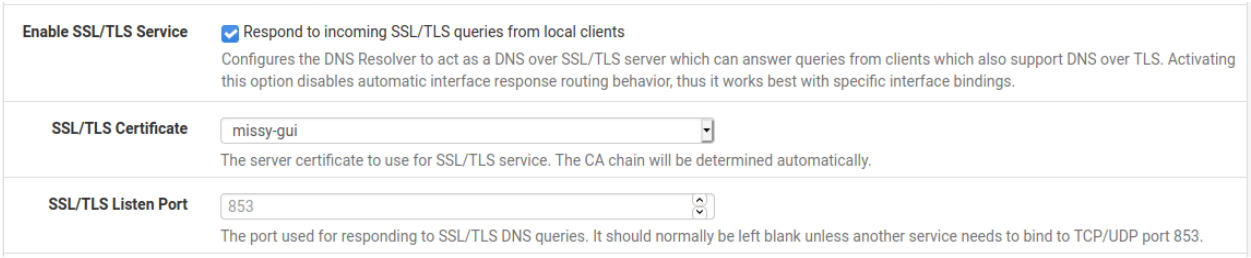

Fig. 5: Example DNS Resolver configuration for acting as a DNS over TLS Server

35.8.6 Caveats

Clients can make their own connections to DNS over TLS servers, so block them on TCP/UDP ports 53 and 853 to ensure they only query the DNS Resolver (*Blocking External Client DNS Queries*).

Redirecting DNS over TLS queries to the DNS Resolver may or may not work, depending on the clients. Setup the *DNS over TLS server* and add port forward redirects for TCP/UDP ports 53 and 853 to redirect DNS queries to the firewall (*Redirecting Client DNS Requests*).

Note: Though clients may reject the DNS over TLS server certificate since it would not match their intended server, this could still have the intended result. The client may fall back to traditional DNS queries if DNS over TLS validation fails.

35.9 Redirecting Client DNS Requests

To restrict client DNS to only the DNS Resolver or Forwarder on pfSense® software, use a port forward to capture all client DNS requests.

Note: Either The DNS Resolver or DNS Forwarder must be active and it must bind to and answer queries on *Localhost*, or *All* interfaces.

See also:

- *Blocking External Client DNS Queries*
- *Blocking Web Sites Using DNS*

The following example uses the LAN interface but the same technique will work with any local interface.

- Navigate to **Firewall > NAT**, **Port Forward** tab
- Click  **Add** to create a new rule
- Fill in the following fields on the port forward rule:

Interface
LAN

Protocol
TCP/UDP

Destination
Invert Match *checked*, *LAN Address*

Destination Port Range
DNS (53)

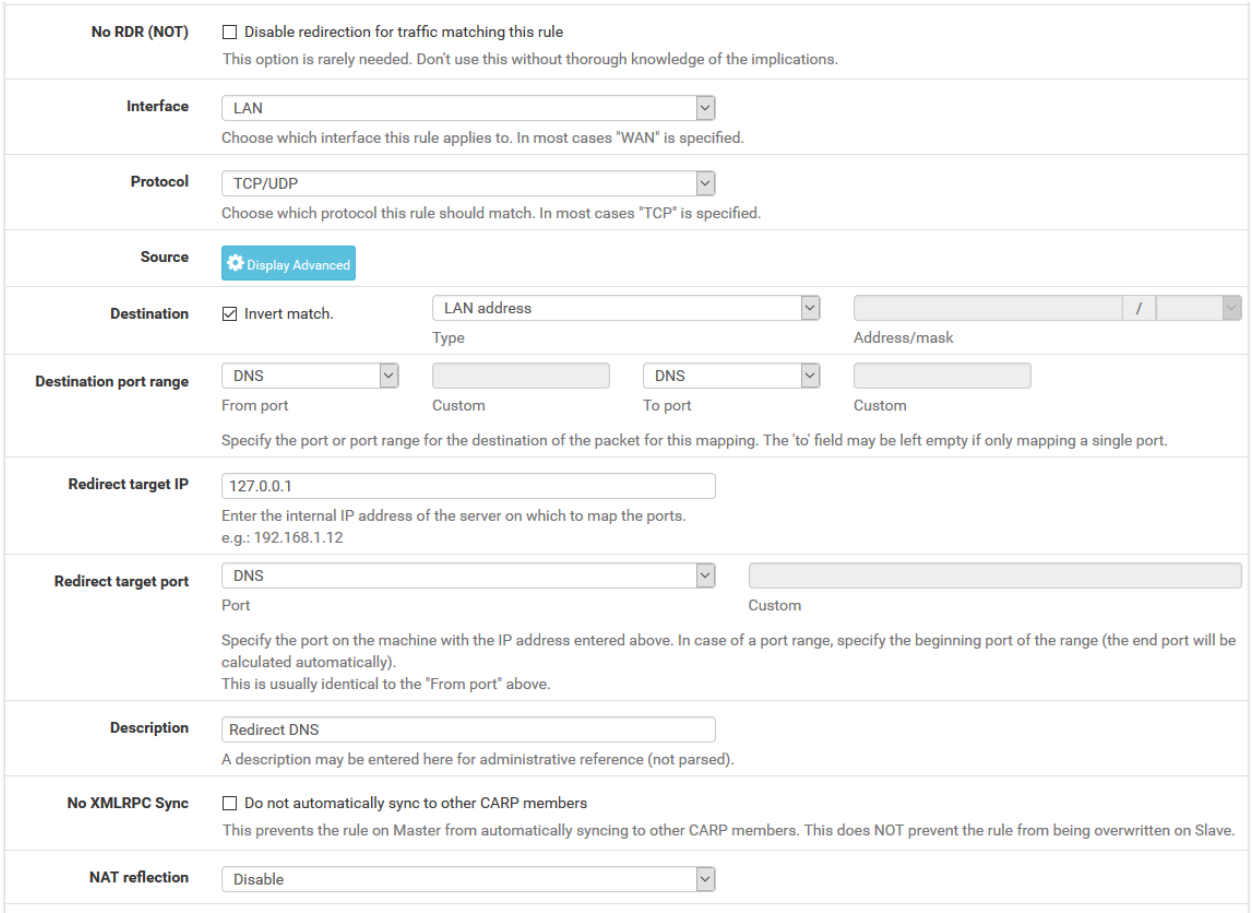
Redirect Target IP
`127.0.0.1`

Redirect Target Port
DNS (53)

Description
`Redirect DNS`

NAT Reflection
Disable

When complete, the port forward must appear as follows:



Note: If DNS requests to other DNS servers are blocked, such as by following *Blocking External Client DNS Queries*,

ensure the rule to pass DNS to `127.0.0.1` is above any rule that blocks DNS.

With this port forward in place, DNS requests from local clients to **any** external IP address will result in the query being answered by the firewall itself. Access to other DNS servers on port 53 is impossible.

Tip: This can be adapted to allow access to only a specific set of DNS servers by changing the Destination network from "LAN Address" to an alias containing the allowed DNS servers. The **Invert match** box should remain checked.

Warning: Clients using DNS over TLS or DNS over HTTPS could circumvent this protection. Redirecting or blocking port `853` may help with DNS over TLS, depending on the clients.

See *Blocking External Client DNS Queries* for additional advice.

35.10 Dynamic Routing Protocol Basics

Three routing protocols are supported in pfSense® software using the FRR package:

- *BGP* (Border Gateway Protocol)
- *OSPF* (Open Shortest Path First v2, for IPv4).
- *OSPF6* (Open Shortest Path First v3, for IPv6).

An in depth discussion of routing protocols is outside the scope of this documentation.

All of the supported dynamic routing protocols are handled by the *FRR package*. To install FRR:

- Navigate to **System > Package Manager**
- Click **Available Packages**
- Locate **FRR** in the list, or search for it
- Click the  **Install** to the right of the **FRR** package entry.
- Click  **Confirm**
- Wait for the installation to complete
- Navigate to **Services > FRR Global/Zebra**

35.10.1 BGP

The *FRR package documentation* contains a basic *BGP example* which can be used as the basis for most common configurations.

The general form of configuration for FRR BGP is:

- Add a route map to allow routes to be filtered
- Configure the BGP options for the local AS
- Add neighbors

35.10.2 OSPF

The *FRR package documentation* contains a basic *OSPF example* which can be used as the basis for most common configurations.

The general form of configuration for OSPF in FRR is:

- Add interfaces as needed, with local interfaces being marked passive, and those facing other OSPF routers as active.
- Configure the general settings as needed with the router ID, area ID, and so on.

See also:

OpenVPN Site-to-Site with Multi-WAN and OSPF contains an example configuration of OSPF.

35.10.3 OSPF6

The *FRR package documentation* contains a basic *OSPF6 example* which can be used as the basis for most common configurations.

The general form of configuration for OSPF6 in FRR is:

- Add interfaces as needed, with local interfaces being marked passive, and those facing other OSPF6 routers as active.
- Configure the general settings as needed with the router ID, area ID, and so on.

35.11 Basic Firewall Configuration Example

This article is designed to describe how pfSense® software performs rule matching and a basic strict set of rules. The approach described in this document is not the most secure, but will help show how rules are setup.

Rules on the **Interface** tabs are matched on the **incoming** interface.

See also:

Read the *Aliases* article as it will make management of rules easier.

35.11.1 Basic lock down of the LAN and DMZ outgoing rules

Outbound LAN

Make sure the **Default LAN > any** rule is either disabled or removed.

1. Allowing DNS access:
   - If pfSense is the DNS server:
     - Allow **TCP/UDP 53** (DNS) from LAN subnet to **LAN Address**.
   - If using Upstream DNS Servers:
     - Allow **TCP/UDP 53** (DNS) from LAN subnet to **Upstream DNS Servers**.
   - Otherwise:
     - Allow **TCP/UDP 53** (DNS) from LAN subnet to **anywhere**.
2. Allowing all users to browse web pages anywhere:

- Allow **TCP 80** (HTTP) from LAN subnet to **anywhere**.

3. Allowing users to browse secure web pages anywhere:
   - Allow **TCP 443** (HTTPS) from LAN subnet to **anywhere**.
4. Allowing users to access FTP sites anywhere:
   - Allow **TCP 21** (FTP) from LAN subnet to **anywhere**.
5. Allowing users to access SMTP on a mail server somewhere:
   - Allow **TCP 25** (SMTP) from LAN subnet to **anywhere**.
6. Allowing users to access POP3 on a mail server somewhere:
   - Allow **TCP 110** (POP3) from LAN subnet to **anywhere**.
7. Allowing users to access IMAP on a mail server somewhere:
   - Allow **TCP 143** (IMAP) from LAN subnet to **anywhere**.
8. Allowing remote connections to an outside windows server for remote administration:
   - Allow **TCP/UDP 3389** (Terminal server) from LAN subnet to **IP address of remote server**.
9. Allowing LAN to access windows shares on the DMZ, via NETBIOS/Microsoft-DS:
   - Allow **TCP/UDP 137** from LAN subnet (NETBIOS) to **DMZ subnet**.
   - Allow **TCP/UDP 138** from LAN subnet (NETBIOS) to **DMZ subnet**.
   - Allow **TCP/UDP 139** from LAN subnet (NETBIOS) to **DMZ subnet**.
   - Allow **TCP 445** from LAN subnet (NETBIOS) to **DMZ subnet**.

Outbound DMZ

By default, there are no rules on **OPT** interfaces.

1. Allowing servers to use Windows update or browse the **WAN**:
   - Allow **TCP 80** from DMZ subnet (HTTP) to **anywhere**.
   - Allow **TCP 443** from DMZ subnet (HTTP) to **anywhere**.
2. Allow users to connect to an external DNS server:
   - Allow **TCP/UDP 53** from DMZ subnet (DNS) to **IP address of the upstream DNS server(s)**
3. Allowing servers to use a remote time server:
   - If using an upstream remote time server:
     - Allow **UDP 123** from DMZ subnet (NTP) to **IP address of remote time server**.
   - Otherwise:
     - Allow **UDP 123** from DMZ subnet (NTP) to **any**.

35.11.2 Setup isolating LAN and DMZ, each with unrestricted Internet access

The following setup can be used instead if outbound access is more lenient, but still controlled between local interfaces. This assumes all local networks are privately numbered, and that interfaces have already been configured.

Create an alias, **Firewall > Aliases** from the main menu, called `RFC1918` containing `192.168.0.0/16`, `172.16.0.0/12`, and `10.0.0.0/8`.

LAN Configuration

1. For DNS from the firewall:
   - Allow **TCP/UDP** from LAN subnet to **LAN Address port 53**.
2. For accessing the GUI:
   - Allow **TCP** from LAN subnet to **LAN address port 443**.
3. To ping the firewall from the LAN:
   - Allow **ICMP** from LAN subnet to **LAN address**.
4. If there is any traffic required from LAN to DMZ:
   - Allow any traffic required from **LAN** to **DMZ**.
5. Do not allow LAN to reach DMZ or other private networks:
   - Reject **Any** from LAN subnet to **RFC1918**.
6. For internet access:
   - Allow **Any** from LAN subnet to **any**.

DMZ Configuration

1. For DNS from the firewall:
   - Allow **TCP/UDP** from DMZ subnet to **DMZ Address port 53**.
2. For accessing the GUI (optional):
   - Allow **TCP** from DMZ subnet to **DMZ address port 443**.
3. To ping the firewall from the DMZ:
   - Allow **ICMP** from DMZ subnet to **DMZ address**.
4. If there is any traffic required from DMZ to LAN:
   - Allow any traffic required from **DMZ** to **LAN**.
5. Do not allow DMZ to reach LAN or other private networks:
   - Reject **Any** from DMZ subnet to **RFC1918**.
6. For Internet access:
   - Allow **Any** from DMZ subnet to **any**.

Additional Interfaces

Repeat the above pattern as needed.

35.12 External User Authentication Examples

There are countless ways to configure the user manager to connect to an external RADIUS or LDAP server, but there are some common methods that can be helpful to use as a guide. The following are all tested/working examples, but the server setup will likely vary from the example.

See also:

Authentication Servers

35.12.1 RADIUS Server Example

This example was made against FreeRADIUS but doing the same for Windows Server would be identical. See *Authenticating from Active Directory using RADIUS/NPS* for info on setting up a Windows Server for RADIUS.

This assumes the RADIUS server has already been configured to accept queries from this firewall as a client with a shared secret.

Descriptive Name
`ExCoRADIUS`

Type
Radius

Hostname or IP Address
`192.2.0.5`

Shared Secret

35.12.3 Active Directory LDAP Example

In this example, the firewall connects to an Active Directory structure in order to authenticate users for a VPN. The results are restricted to the **VPNUsers** group. Omit the **Extended Query** to accept any user.

Descriptive Name
`ExCoADVPN`

Type
LDAP

Hostname or IP Address
`192.0.2.230`

Port
`389`

Transport
TCP - Standard

Protocol Version
3

Search Scope
Entire Subtree , `DC=domain,DC=local`

Authentication Containers
`CN=Users,DC=domain,DC=local`

Extended Query
memberOf=CN=VPNUsers,CN=Users,DC=example,DC=com

Bind Credentials
Anonymous binds *Unchecked*

User DN
`CN=binduser,CN=Users,DC=domain,DC=local`

Password
`secretsecret`

Initial Template
Microsoft AD

User Naming Attribute
`samAccountName`

Group Naming Attribute
`cn`

Group Member Attribute
`memberOf`

This example uses plain TCP, but if the Certificate Authority for the AD structure is imported under the Certificate Manager, the connection can also use SSL as well by selecting that option and choosing the appropriate CA from the **Peer Certificate Authority** drop down, and setting the **Hostname** to the match the server certificate.

35.13 Using an External Wireless Access Point

Most SOHO-style wireless routers can be used as an access point if a true Access Point (AP) is not available. If pfSense® software replaced an existing wireless router, the old router can still be used to handle the wireless portion of the network.

This type of deployment is popular for wireless because it is easier to keep the access point in a location with better signal and take advantage of more current wireless hardware without relying on driver support in pfSense software. This way a network supporting 802.11ac or later wireless standards may still be used and secured by pfSense software at the edge, even though pfSense software does not yet have support for newer standards.

This technique is also common with wireless equipment running *WRT, Tomato, or other custom firmware for use as dedicated access points rather than edge routers.

35.13.1 Turning a wireless router into an access point

To convert the wireless router into a wireless access point, follow these generic steps for any device. To find specifics for a particular wireless router, refer to its documentation.

Disable the DHCP server

Disable the DHCP server on the wireless router to prevent a conflict. pfSense software will handle this function for the network, and having two DHCP servers on the same broadcast domain will not function correctly.

Change the LAN IP address

A functional, unique, IP address on the access point is required for management purposes.

Change the LAN IP address on the wireless router to an unused IP address in the subnet where it will reside (commonly LAN). If the firewall running pfSense software replaced this wireless router, then the wireless router was probably using the same IP address now assigned to the firewall LAN interface, which conflicts.

Plug in the LAN interface

Most wireless routers bridge their wireless network to an internal LAN port or switch ports. This means the wireless segment will be on the same broadcast domain and IP subnet as the wired ports. For routers with an integrated switch, any of the LAN switch ports will typically work.

Note: Do not plug in the WAN or Internet port on the wireless router!

This will put the wireless network on a different broadcast domain from the rest of the network and the wireless router will perform NAT on the traffic between the wireless and LAN. This also results in double NAT of traffic between the wireless network and the Internet. This is an ugly design, and will lead to problems in some circumstances, especially if communication must occur between wireless and wired LAN clients.

Deciding where to connect the LAN interface from the wireless router depends on the chosen network design. The next sections cover options and considerations for selecting the best deployment style.

35.13.2 Bridging wireless to the LAN

One common means of deploying wireless is to plug the access point directly into the same switch as the LAN hosts, where the AP bridges the wireless clients onto the wired network. This works well, but offers limited control over the ability of the wireless clients to communicate with internal hosts.

See also:

See *Choosing Routing or Bridging* for details on bridging in this role.

35.13.3 Bridging wireless to an OPT interface

To keep wireless and wired networks on the same IP subnet and broadcast domain while also increasing control over wireless clients, add an OPT interface to the firewall for the access point and bridge the OPT interface to the LAN interface.

Warning: Though bridging offers increased control over traffic, it also results in lower performance as all wireless traffic must pass through and be processed by the firewall. Typically, wireless speeds are low enough that this is not a major concern, but as wireless speeds improve the severity of the problem also increases.

This scenario is functionally equivalent to plugging the access point directly into the LAN switch, except pfSense software can filter traffic from the wireless network to provide protection to LAN hosts and vice versa.

Note: A configuration with the bridge assigned as LAN is optimal here, rather than only having the OPT bridged to the existing wired LAN.

35.13.4 Routed segment on an OPT interface

The wireless network can also be placed on a separate IP subnet if desired. This is done without bridging the OPT interface on pfSense, instead assigning it with an IP address in a separate subnet different from the LAN. This enables routing between internal and wireless networks, as permitted by the firewall ruleset. This is commonly done on larger networks, where multiple access points are plugged into a switch that is then plugged into the OPT interface on pfSense software. It is also preferable when wireless clients will be forced to connect to a VPN before allowing connections to internal network resources.

35.14 Using Software from FreeBSD

pfSense® software is based on FreeBSD, thus many familiar FreeBSD packages are available for use by veteran FreeBSD system administrators.

Warning: Installing software this way **will** have unintended side effects.

This action is not recommended or supported by Netgate.

Many parts of FreeBSD are not included in the base installation of pfSense software, so library and other issues can occur when attempting to use software installed in this manner. The pfSense software base installation does not include a compiler in the base system for many reasons, and as such software cannot be built locally. However, packages can be installed from FreeBSD the package repository.

35.14.1 Concerns/Warnings

Several important concerns must be considered by any administrator before deciding to install additional software, especially software that is not obtained from Netgate package repositories.

Security Concerns

Any extra software added to a firewall is a security problem, and must be evaluated fully before installation. If the need outweighs the risk, it may be worth taking. Official packages for pfSense software are not immune to this problem either. Any additional service is another potential attack vector.

Performance Concerns

Most hardware running pfSense software can handle the traffic load with which it is tasked. If the firewall hardware has horsepower to spare, it may not hurt performance to add additional software. That said, be mindful of the resources consumed by the added software.

Conflicting Software

If an installed package duplicates functionality found in the base system, or replaces a base system package with a newer version, it could cause unpredictable system instability. Ensure that the software does not already exist in pfSense.

Lack of Integration

Any extra software installed will not have GUI integration. For some, this is not a problem, but there have been people who expected to install a package and have a GUI magically appear for its configuration. These packages must be configured by hand. If this is a service, that means also making sure that any startup scripts accommodate the methods used by pfSense software.

Software can also install additional web pages that are not protected by the pfSense software authentication process. Test any installed software to ensure that it protects and filters access appropriately.

Lack of Backups

Packages installed in this manner must have any configuration or other needed files backed up manually.

These files will not be backed up during a normal backup and could be lost or changed during a firmware update. The add-on package described in *Backup Files and Directories with the Backup Package* is capable of backing up arbitrary files such as these.

35.14.2 Installing Packages

To install a package, the proper package site must be used. pfSense software is compiled against a specific FreeBSD branch, and has only a specific set of packages hosted on Netgate servers.

Packages located in the Netgate package repository, including some FreeBSD software packages that are not a part of the pfSense software distribution, can be installed using `pkg install` directly:

```
# pkg install screen
```

Or use a full URL to a `pkg add` to add them from the FreeBSD package servers:

```
# pkg add http://pkg.freebsd.org/FreeBSD:11:amd64/latest/All/tshark-3.2.6.txz
```

The pkg utility will download and install the package, along with its required dependencies.

Additionally, the full set of FreeBSD packages can be made available by editing /usr/local/etc/pkg/repos/pfSense.conf and changing the first line to:

```
FreeBSD: { enabled: yes }
```

Next, edit /usr/local/etc/pkg/repos/FreeBSD.conf and make the same change there:

```
FreeBSD: { enabled: yes }
```

It must be enabled in both places to function.

Warning: Adding software from FreeBSD package repositories **will** introduce problems with package dependencies, especially if a package depends on another piece of software that already exists on the firewall which may have been built with conflicting options. Take extreme caution when adding packages in this way.

Custom packages can also be built on another computer running FreeBSD and then the package file can be copied and installed on a firewall running pfSense software. Due to the complexity of this topic, it will not be covered here.

35.14.3 Maintaining Packages

The following command prints a list of all currently installed packages, including packages and components of the base system of pfSense software:

```
# pkg info
```

To delete an installed package, pass its full name or use a wildcard:

```
# pkg_delete iftop-1.0.p4
# pkg_delete pstree-\*
```

35.15 Using EAP and PEAP with FreeRADIUS

35.15.1 General EAP configuration

The default EAP settings will work in most situations (EAP-MD5, EAP-TLS, EAP-TTLS, EAP-PEAP) so there is no need to change them without any need. If EAP-TTLS or EAP-PEAP is used with VLAN assignment then set **Use Tunneled Reply** to *yes*:

To make the use of certificates more secure, check the **Common Name** of the client certificate against the username entered in **FreeRADIUS > Users**. For this set **Check Client Certificate CN** to *yes*:

Another option to increase security with certificates is to check the issuer of the client certificate against the CA certificate. This can be enabled with **Check Cert Issuer** but then it is necessary to enter country, state, province and organization - case sensitive - to match the CA.

FreeRADIUS by default allows many EAP types for authentication. In some environments only some strong EAP types (TLS, TTLS, PEAP, MSCHAPv2) may be allowed or weak types (MD5, GTC, LEAP) may be disallowed. Disable

the weak EAP types in FreeRADIUS using **Disable weak EAP types** so that FreeRADIUS rejects users which try to authenticate using such a weak method. If these types are disabled it does **not** affect the inner tunnel session in EAP-TTLS and EAP-PEAP. Further it is no problem to use a weak or cleatext method in the inner tunnel because if the outer tunnel uses one of the above call strong encryption types.

FreeRADIUS is multitalented. It can handle almost all authentication types hosts send. So if weak encryption types such as MD5 and others are not disabled then the following will happen:

```
a client wants to authenticate using MD5 => freeradius will do that
a client wants to authenticate using LEAP => freeradius will do that
a client wants to authenticate with TLS or TTLS or PEAP or MSCHAPv2 or ... => freeradius␣
↪will do that
```

So **disable weak encryption** is checked then this disables MD5, GTC and LEAP. This will happen:

```
a client wants to authenticate using MD5 -> freeradius will not do that because that was␣
↪disabled
a client wants to authenticate using LEAP -> freeradius will not do that because that␣
↪was disabled
a client wants to authenticate with TLS or TTLS or PEAP or MSCHAPv2 or... -> freeradius␣
↪will do that.
```

35.15.2 PEAP and MSCHAPv2

- FreeRADIUS package configuration in the pfSense® software GUI:
  - Configure an interface in **FreeRADIUS > Interfaces**
  - Create a **CA-Certificate** and a **Server-Certificate**. Choose pfSense Cert-Manager or FreeRADIUS Cert-Manager but **never** use the default certificates which come with FreeRADIUS after package installation!
  - Select the certificates in **FreeRADIUS > EAP**. If FreeRADIUS as Cert-Manager is selected then nothing needs changed. If pfSense Cert-Manager was chosen, then it must be enabled there and the certs must be chosen from the pulldown menu. Click **Save**.
  - Add the WLAN-AccessPoint in **FreeRADIUS > NAS/Clients**
  - Add a username/password in **FreeRADIUS > Users**
- WLAN Access-Point Configuration:
  - Change the wireless encryption to **WPA-Enterprise** or better **WPA2-Enterprise** with **TKIP** or better **AES/CCMP**
  - Do **not** use a passphrase but select **RADIUS** or **802.1X**. Enter the IP-Address of the FreeRADIUS-Server on pfSense software and the shared secret according to that what was entered in **FreeRADIUS > NAS/Clients**
- WLAN Device (Supplicant) Configuration:
  - Some devices can autoconfigure the Authentication and Encryption Method. If not choose **PEAP as encryption** and **MS-CHAPv2 as Authentication**. 1
  - Connect to WLAN AccessPoint and the client will be prompted for username and password
  - Some devices auto-accept the CA-Certificate as valid. Often this CA-Certificate will first need to be accepted. This is the certificate created on pfSense software.

The most part of the "command line action" which is done in these tutorials can be done from FreeRADIUS GUI.

See also:

How-to with screenshots in German.

35.15.3 EAP-TLS

- pfSense software configuration:
  - Create a **CA**, a **Server-Certificate** and a **Client-Certificate**. Using **System > Certificates** is recommended.
- FreeRADIUS configuration:
  - Create an **interface**, add a **NAS/Client** and create a **user**. For this example, use *myuser* as username and *mypass* as password.
  - The EAP default options are working - read *FreeRADIUS package*.
  - Using **pfSense Cert-Manager** and selecting the CA and the server certificate is recommended.
  - Leave the password field empty
  - Download the `CA.crt` - **not the key** - from **System > Certificates**, **CAs** tab and Client `.p12` from **System > Certificates**, **Certificates** tab
- Client Requires password on `.p12`

  If a client will not load the `.p12` without a password (and space does not work), then export the archive with a password as described in *Export Password-Protected Files or Use Different Encryption Options*.

35.16 Using Mobile One-Time Passwords with FreeRADIUS

Using Mobile-One-Time-Password (mOTP) with the *FreeRADIUS package*.

35.16.1 Enable Mobile-One-Time-Password (OTP) support

This documentation will cover many parts from installation, configuration, modification, and more from here.

A one time password is a password which can be only used one time and will be only usable within a short time period (10s). So it can be compared with the handling of tokens from RSA SecureID.

This kind of password generation makes sense in some scenarios but not in all. It probably makes no sense to use these passwords in the office - there shouldn't be any attacker. But the mOTP could make sense for Road Warriors. Most of them use an state of the art mobile phone and a notebook to connect to the company VPN. For more take a look at the chapter below: *Miscellaneous configuration and hints*

pfSense® software configuration:

- Enable Mobile-One-Time-Password in **FreeRADIUS > Settings**

This will install the script in `/usr/local/etc/raddb/scripts/otpverify.sh`. To execute the script it needs the additional package `bash`. This will be installed automatically.

FreeRADIUS configuration:

- Create a user in **FreeRADIUS > Users**
- Enter a **username** but **do not** enter any password!
- Check **Enable Mobile-One-Time-Password For This User**
- Enter the **Init-Secret**. The init-secret will be created on the client (mobile device, mobile phone)

- Enter the **PIN**. Every time the user wants to generate a new password with his mobile token then he has to enter the PIN and then the token generates a one-time-password.
- The **Offset** should be zero by default. If the mobile token is on another time zone than the FreeRADIUS server then correct the offset. If the mobile device changes its time zone automatically than there is no need to do this.

Miscellaneous configuration and hints:

- The configuration for different mobile devices can be found here.
- And here is the software for mobile devices.
- Please read the limitations to make sure how secure this is.
- mOTP will probably not work with EAP, CHAP, MSCHAP.
- A generated one-time-password can be used for ~20 seconds. For example the Windows token generator generates new tokens every ~10 seconds. Perhaps other token generators use other timespans for generating tokens. FreeRADIUS and the OTP script accept tokens which were generated within the last 20 seconds.

35.17 Using NAT and FTP without a Proxy

Firewalls running pfSense® software do not include an FTP Proxy, but this does not affect clients and servers as much as one might think.

Important: Use of FTP is strongly discouraged. It is an outdated protocol that transmits credentials and other data openly without encryption which is very insecure.

35.17.1 Client Behind pfSense Software

FTPS, or encrypted FTP, is not affected. The proxy could not have affected its traffic before.

A client on a LAN or other internal interface behind pfSense software will likely not notice any difference. Most clients, aside from the Microsoft command line FTP program, default to passive (PASV) FTP, where clients make outbound connections to servers.

Passive mode on the client will require access to random/high ports outbound, which could run afoul of a strict outbound ruleset. Environments with a security policy that requires strict outbound firewall rules likely would not be using FTP anyhow, as it transmits credentials without encryption.

Active mode FTP through NAT will not function as that relies on a proxy or similar mechanism. Use Passive mode instead. Another option is the recently added FTP Client Proxy package which leverages in FreeBSD to allow clients on local interfaces to reach remote FTP servers with active FTP.

Active mode FTP for a client that does not involve NAT (Client has a public IP address) should work so long as WAN rules pass the appropriate traffic back to the client. The client may have a configurable active port range to make that simpler.

35.17.2 Server Behind pfSense Software

FTPS, or encrypted FTP, is not affected. The proxy could not have affected its traffic before.

A server behind pfSense software would work fine with active mode, there would be no difference here. In active mode the server would make outbound connections back to the client, so as long as the firewall rules on the interface containing the server allow outbound connections, it will work.

A server behind pfSense software running in Passive mode will function but requires a few items to be configured:

- Port forwards or 1:1 NAT to forward not only port 21, but also the passive port range in to the server
- The passive port range must be configured on the server, corresponding to the range of ports forwarded in the previous step.
- The server may also need to be configured to account for NAT. Some clients will ignore private addresses in passive responses so this may not be necessary.

Sample Configuration for vsftpd

In `vsftpd.conf`:

```
# Do not allow the client to use PORT
port_enable=NO
# Use the hostname in the PASV response (DNS must be setup and match!)
pasv_addr_resolve=YES
# Enable Passive Mode
pasv_enable=YES
# Set the passive port range (1000 ports)
pasv_min_port=20000
pasv_max_port=20999
```

35.18 Configuring pfSense Software for Online Gaming

This page provides information on using pfSense® software with online games.

First, many games will require the use of *Static Port* or *UPnP IGD & PCP*.

See also:

The Netgate Forum often has a wide array of threads for specific games and consoles. Search there for games if they are not listed here.

Note: There was a bug with UPnP IGD and multiple client devices on the same network. This bug was fixed in pfSense Plus software version 22.05 and pfSense CE software version 2.7.0.

There is a patch available through the *System Patches Package* which can correct this bug on some older versions as well.

35.18.1 Specific Game/Console Information

This section contains recommendations for specific consoles types and games. If a game or console requires special handling but is not listed here, please *submit a documentation update*. Include a link to manufacturer documentation when possible.

> **Warning:** What works to make a single console/device work from behind a firewall may not work for multiple consoles/devices behind the same firewall.
>
> What works to allow a client to play an online game may not work for hosting an online game.
>
> Hosting an online game and connecting a client to the same online game from behind the same firewall may not work, but as with everything else, it varies by game/console.

Nintendo Switch and Switch 2

Nintendo Switch and Switch 2 consoles require a Static Port setup for IPv4 NAT. See *Static Port*. Static port NAT enables the console to achieve NAT type "B" and work with most games.

Switch 2 also supports IPv6, but how well that works depends on the game and whether or not peers also have IPv6.

Nintendo Wii/Wii U/3DS

These consoles do not require any special configuration, though some cases may require UPnP IGD (*UPnP IGD & PCP*).

Steam / Steam Deck

Varies by game, but typically *UPnP IGD & PCP* or manual port forwards are sufficient. Some games may require *Static Port*.

Xbox

Modern Xbox consoles, including multiple consoles, work well with *UPnP IGD & PCP* in many cases.

Some games or situations may require Static Port, See *Static Port*.

See also:

Xbox Support

Playstation

Single consoles work well with *UPnP IGD & PCP* though multiple consoles can be problematic. When multiple consoles are on the same network, Playstation devices do not automatically attempt to use a different port if they cannot use their preferred port.

Tip: In a mixed environment with Playstation and other console types, start the game on Playstation first so it can get the port it wants, then start other clients which will properly notice the port is in use and shift to alternate ports.

Some games or situations may require Static Port, See *Static Port*.

Gunz Online

To play on multiple machines behind a firewall running pfSense software, configure each Gunz Online client with a different port. Visit **NAT > Outbound** and setup a custom static port entry for each machine using the appropriate custom port.

35.19 High Availability Configuration Example

This recipe describes a typical pfSense® software high availability (HA) cluster configuration with two nodes (primary and secondary) containing three interfaces: WAN, LAN, and Sync. This is logically equivalent to a deployment with two interfaces (WAN and LAN), with the Sync interface carrying synchronization data between the primary and secondary nodes.

Note: This example covers both IPv4 and IPv6 configuration.

If static IPv6 assignments are not available, set IPv6 to *None* on all interfaces and skip any configuration tasks specific to IPv6.

See also:

Review *High Availability* before following this recipe.

For help diagnosing issues with HA, see:

- *Troubleshooting High Availability*
- *Troubleshooting High Availability Clusters in Virtual Environments*
- *Troubleshooting VPN Connectivity to a High Availability Secondary Node*

35.19.1 Determine IP Address Assignments

The first task is to plan IP address assignments. A good strategy is to number the addresses as follows:

- Lowest usable IP address in the subnet as the CARP VIP address.
- The next IP address as the primary node interface IP address.
- The next IP address as the secondary node interface IP address.

This specific suggestion is optional. The best practice is to use a consistent and logical scheme to make design and administration simpler, but it is ultimately a matter of preference. For example, some network designers prefer to place routers at the end of a subnet instead of the beginning.

WAN IP Addresses

Select the WAN IP addresses from those assigned by the ISP. For this example, the assignments are listed in Table *WAN Interface IP Address Assignments*.

For IPv4, the WAN subnet for the HA pair is `198.51.100.0/24`. The WAN IPv4 addresses for the cluster are `198.51.100.200` through `198.51.100.202`.

For IPv6, the WAN prefix is `2001:db8::/64` and the ISP is routing a prefix of `2001:db8:1:df30::/60` for local networks. The WAN IPv6 addresses for the cluster are `2001:db8::200/64` through `2001:db8::202/64`.

Note: Though there is a whole `/64` to utilize, this example uses the same ending values in both IPv4 and IPv6 for consistency and to make similarities more apparent.

Table 1: WAN Interface IP Address Assignments

IP Address	Usage
`198.51.100.0/24`	WAN IPv4 subnet
`198.51.100.1`	WAN ISP IPv4 Gateway
`198.51.100.200/24`	CARP shared IPv4 address
`198.51.100.201/24`	Primary node WAN IPv4 address
`198.51.100.202/24`	Secondary node WAN IPv4 address
`2001:db8::/64`	WAN IPv6 Prefix
`2001:db8::1`	WAN ISP IPv6 Gateway
`2001:db8:1:df30::/60`	Routed IPv6 Prefix
`2001:db8::200/64`	CARP shared IPv6 address
`2001:db8::201/64`	Primary node WAN IPv6 address
`2001:db8::202/64`	Secondary node WAN IPv6 address

Note: In this case the ISP would route the IPv6 prefix (`2001:db8:1:df30::/60`) to the IPv4 WAN CARP VIP, `2001:db8::200`. Requirements vary by ISP. If the ISP prefers to route to a link-local address, add a CARP VIP on the WAN interface using a link-local address for this purpose.

LAN IP Addresses

The LAN IPv4 subnet is `192.168.1.0/24` and the LAN IPv6 prefix is `2001:db8:1:df30::/64`. For this example, the LAN IP addresses will be assigned as shown in Table *LAN Interface IP Address Assignments*.

Table 2: LAN Interface IP Address Assignments

IP Address	Usage
`192.168.1.1/24`	CARP shared IPv4 address
`192.168.1.2/24`	Primary node LAN IPv4 address
`192.168.1.3/24`	Secondary node LAN IPv4 address
`2001:db8:1:df30::1/64`	CARP shared IPv6 address
`2001:db8:1:df30::2/64`	Primary node LAN IPv6 address
`2001:db8:1:df30::3/64`	Secondary node LAN IPv6 address
`fe80::1:1/64`	CARP shared IPv6 Link-Local Address

Note: The CARP IPv6 link-local address in this example uses `fe80::1:1/64` as the `fe80::1/64` address is reserved for use by pfSense software in certain scenarios and can conflict. Using a different address avoids any potential problems.

Sync Interface IP Addresses

The IP addresses on the Sync interface are used only for communication between the firewalls. As there are no other devices on the Sync network, there is no need for a shared CARP VIP on the Sync interface, so it is not necessary to add a VIP on that interface.

This example uses the IPv4 subnet `172.16.1.0/24` and IPv6 prefix `2001:db8:1:df31::/64` for the Sync interface. The example only uses two IP addresses, but the IPv4 subnet uses a `/24` to be consistent with the other internal interface (LAN). For the last octet of the IP addresses, use the same last octet as the LAN IP addresses for consistency.

Table 3: Sync Interface IP Address Assignments

IP Address	Usage
`172.16.1.2/24`	Primary node Sync IPv4 address
`172.16.1.3/24`	Secondary node Sync IPv4 address
`2001:db8:1:df31::2/64`	Primary node Sync IPv6 address
`2001:db8:1:df31::3/64`	Secondary node Sync IPv6 address

35.19.2 Example Cluster Diagram

Figure *Example High Availability Cluster Network Diagram* shows the layout of this example HA cluster. The primary and secondary nodes each have identical connections to the WAN and LAN, and a crossover cable between them to connect the Sync interfaces.

See also:

In this basic example, the WAN switch and LAN switch are still potential single points of failure. Switching redundancy is covered in *Layer 2 Redundancy*.

35.19.3 Cluster Configuration Basics

Both nodes requires a few basic configuration steps before they are ready to be configured as a high availability cluster.

Danger: Do not connect both nodes to the same LAN (switch/layer 2) before both nodes have a non-conflicting LAN configuration.

Installation, interface assignment, and basic configuration

Install pfSense software on both nodes and assign the interfaces **identically** on both nodes.

Warning: Interfaces **must** be assigned in the same order on all nodes **exactly**. If the interface order is not identical, configuration synchronization and other tasks will not behave correctly. If any adjustments have been made to the interface assignments in the future, they **must** be replicated **identically** on both nodes.

After installation, connect to the GUI and use the Setup Wizard to configure each node with a unique hostname and non-conflicting static IP addresses.

See also:

Setup Wizard

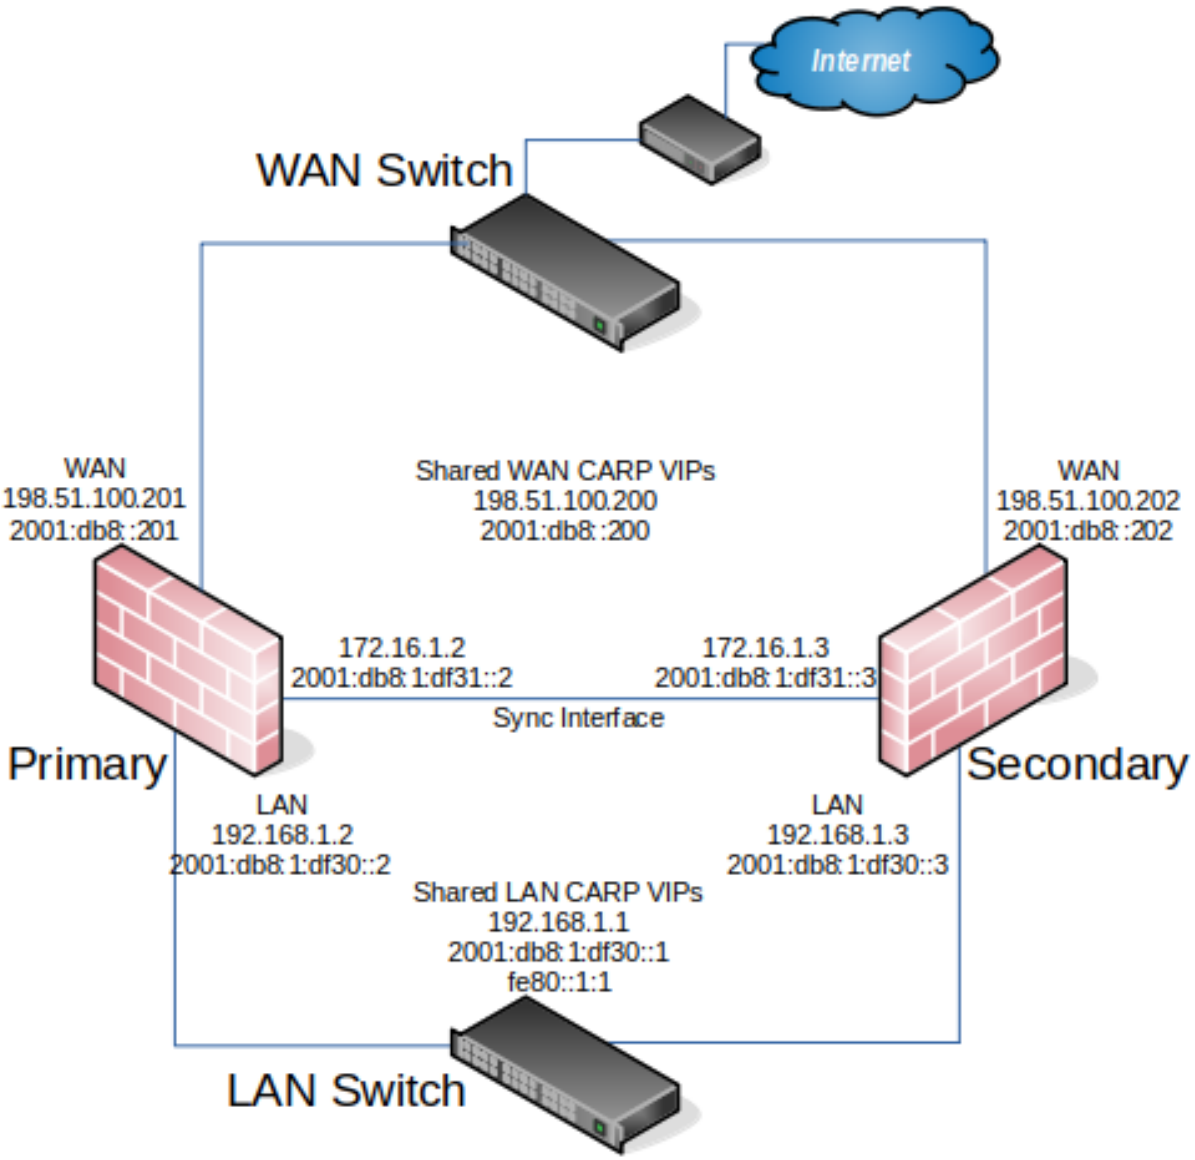

Fig. 6: Example High Availability Cluster Network Diagram

For example, the primary node could be `firewall-a.example.com` and the secondary could be `firewall-b.example.com`, or a more personalized pair of names.

Note: Avoid naming the nodes `master` or `backup` since those are *states*, not *roles*. Consider naming them `primary` and `secondary` instead.

The default configuration on WAN is for DHCP, this must be changed to a static IP address configuration, such as the example WAN addresses in *WAN Interface IP Address Assignments*. Be sure to configure appropriate upstream gateways for IPv4 and IPv6.

The default LAN IPv4 address is `192.168.1.1`, but each node must be moved to its own unique and non-conflicting address. The default LAN IPv6 configuration is set to track WAN, which is not valid for HA, so it must be changed to a static configuration The example addresses for IPv4 and IPv6 are shown in *LAN Interface IP Address Assignments*.

Once each node has a unique LAN IPv4 and IPv6 address, then both nodes may be plugged into the same LAN switch.

Setup Sync Interface

Before proceeding, the Sync interfaces on the cluster nodes must be configured. *Sync Interface IP Address Assignments* lists the addresses to use for the Sync interfaces on each node. Once that has been completed on the primary node, perform it again on the secondary node with the appropriate address values.

To complete the Sync interface configuration, add firewall rules on both nodes to allow synchronization.

At a minimum, the firewall rules must pass configuration synchronization traffic (by default, HTTPS on port TCP `443`), pfsync traffic, and Kea DHCP HA traffic on TCP ports `8765` and `8766`. In most cases, a simple "allow all" style rule is sufficient, but using specific rules is a better practice.

When complete, the rules will look like the example in figure *Example Sync Interface Firewall Rules*, which also includes a rule to allow ICMP echo (ping) for diagnostic purposes.

	States	Protocol	Source	Port	Destination	Port	Gateway	Queue	Schedule	Description	Actions
☐	✓ 0/0 B	IPv4 TCP	SYNC subnets	*	SYNC address	443 (HTTPS)	*	none		Allow configuration synchronization	
☐	✓ 0/67 KiB	IPv4 PFSYNC	SYNC subnets	*	*	*	*	none		Allow state synchronization	
☐	✓ 0/0 B	IPv4 ICMP any	SYNC subnets	*	SYNC subnets	*	*	none		Allow ICMP for diagnostics	
☐	✓ 2/32.47 MiB	IPv4+6 TCP	SYNC subnets	*	SYNC address	8765 - 8766	*	none		Allow DHCP Sync	

Fig. 7: Example Sync Interface Firewall Rules

The secondary does not need all of these rules initially, only a rule to allow traffic to the GUI for XMLRPC to function. The full set of rules will synchronize via XMLRPC configuration synchronization later.

35.19.4 Configure State Synchronization (pfsync)

State synchronization using pfsync must be configured on both the primary and secondary nodes to function.

See also:

State Synchronization Settings (pfsync)

First on the primary node and then on the secondary, perform the following:

- Navigate to **System > High Availability**
- Check **Synchronize States**

- Set **Synchronize Interface** to *SYNC*
- Set a custom **Filter Host ID**

  For example, `1` on the primary node, `2` on the secondary node.
- Set **pfsync Synchronize Peer IP** to the Sync interface IPv4 address of the **other** node

  Set this to `172.16.1.3` on the primary node, or `172.16.1.2` on the secondary node
- Click **Save**

35.19.5 Configure Configuration Synchronization (XMLRPC)

Warning: Configuration synchronization **must only be configured on the primary node**. Never activate options in this section on the secondary node of a two-member cluster.

See also:

Configuration Synchronization Settings (XMLPRC Sync)

On the primary node **only**, perform the following:

- Navigate to **System > High Availability**
- Set **Synchronize Config to IP** to the Sync interface IPv4 address on the secondary node, `172.16.1.3`
- Set **Remote System Username** to `admin`

  Note: This must either be the `admin` account or a user on both nodes with the "System - HA node sync" privilege.
- Set **Remote System Password** to the admin user account password, and repeat the value in the confirmation box.
- Check the boxes for each area to synchronize to the secondary node.

  For this guide, as with most configurations, all boxes are checked.

  Tip: Use the **Toggle All** button to select all of the options at once, rather than selecting them individually.
- Click **Save**

As a quick confirmation that the synchronization worked, on the secondary node navigate to **Firewall > Rules**, **SYNC** tab. The rules entered on the primary should now be present on the tab, and the temporary rule has been removed.

The two nodes are now linked for configuration synchronization! Supported areas will synchronize to the secondary node whenever a change is made on the primary node.

Warning: Do not make changes to the secondary in areas set to be synchronized! These changes will be overwritten the next time the primary node performs a synchronization.

35.19.6 Configuring the CARP Virtual IPs

With configuration synchronization in place, the CARP Virtual IP addresses need only be added to the primary node and they will automatically copy to the secondary node.

Each VIP needs a unique VHID on a given broadcast domain/layer 2. See *CARP VIP VHID Assignments* for the VHIDs to use in this example.

Table 4: CARP VIP VHID Assignments

CARP VIP Address	Interface	VHID
`198.51.100.200/24`	WAN	200
`2001:db8::200/64`	WAN	201
`192.168.1.1/24`	LAN	1
`2001:db8:1:df30::1/64`	LAN	2
`fe80::1:1/64`	LAN	3

- Navigate to **Firewall > Virtual IPs** on the primary node to manage CARP VIPs
- Click  **Add** at the top of the list to create a new VIP.

Note: Each interface handling user traffic must have a CARP VIP, in this case WAN and LAN.

- Fill in the VIP options as described below. See *CARP VIP VHID Assignments* for specific settings unique to each VIP in this example. Refer to *VIP Configuration Options* for more information on the options in general.

  Type
  CARP

  Interface
  The interface upon which the VIP resides, e.g. *WAN*

  Address(es)
  The IP address and subnet mask/prefix value for the VIP. Consult *CARP VIP VHID Assignments* for the address values in this example.

  Note: The subnet mask/prefix must match the subnet mask on the interface IP addresses. For example, the first VIP `198.51.100.200` and `24` on WAN (See *WAN Interface IP Address Assignments*).

  Virtual IP Password
  Password for the CARP VIP. Use a random value.

  This need only match between the two nodes, which will be handled by synchronization. The password and confirm password box must both be filled in and they must match.

  VHID Group
  Virtual ID for the CARP VIP. Consult *CARP VIP VHID Assignments* for the VHID to use for each address in this example.

  Tip: A common tactic is to make the VHID match the last octet of the IP address, e.g. `200` for an address ending in `.200`.

Advertising Frequency
How often the node sends CARP heartbeats on its interface.

Base
Whole seconds between Heartbeats, typically *1*.

Skew
Fractions of a second (1/256th increments).

Note: A primary node is typically set to *0* or *1*, secondary nodes will be *100* or higher. This adjustment is handled automatically by XMLRPC synchronization.

Description
Text to identify the VIP, such as `WAN CARP VIP`.

The above description used the WAN VIP as an example. Repeat the procedure for every required CARP VIP (See *CARP VIP VHID Assignments*).

If there are any additional IP addresses in the WAN subnet that will be used for purposes such as 1:1 NAT, port forwards, VPNs, etc, add them now.

Tip: For HA setups designed with multiple CARP VIPs of the same address family on the same interface, instead consider adding the additional CARP VIPs as IP alias VIPs which use a single CARP VIP as their parent interface. This reduces the number of CARP VIP heartbeats on a network segment and also allows the VIPs to fail as a group. For details, see *Using IP Aliases to Reduce Heartbeat Traffic*.

Click **Apply Changes** after completing the VIP configuration.

After adding VIPs, check **Firewall > Virtual IPs** on the secondary node to ensure that the VIPs synchronized as expected.

The Virtual IP addresses on both nodes will look like *CARP Virtual IP Address List* if the process was successful.

Virtual IP Address

Virtual IP address	Interface	Type	Description	Actions
198.51.100.200/24 (vhid: 200)	WAN	CARP	WAN CARP IPv4 VIP	
192.168.1.1/24 (vhid: 1)	LAN	CARP	LAN CARP IPv4 VIP	
2001:db8::200/64 (vhid: 201)	WAN	CARP	WAN CARP IPv6 VIP	
2001:db8:1:df30::1/64 (vhid: 2)	LAN	CARP	LAN CARP IPv6 VIP	
fe80::1:1/64 (vhid: 3)	LAN	CARP	LAN CARP IPv6 Link-Local VIP	

Fig. 8: CARP Virtual IP Address List

35.19.7 Configure Outbound NAT for CARP

The next step is to configure outbound NAT so that the firewall translates IPv4 traffic from clients on the LAN to the shared IPv4 CARP VIP address on WAN as the address as it exits.

- Navigate to **Firewall > NAT**, **Outbound** tab
- Click to select **Hybrid Outbound NAT rule generation**
- Click **Save**

Hybrid mode allows the default NAT rules to stay in place, but also allows the default rules to be overridden by manually created rules. This way it becomes unnecessary to manage entries for the firewall itself (which **should not** use the CARP VIP for NAT) and it can also make the process less disruptive when adding new interfaces later.

Create outbound NAT rules for internal subnet sources to work with the CARP IP address.

- Click  below the **Mappings** section to add a new rule
- Configure the rule as follows:

  Interface
  WAN

  Address Family
  IPv4

  Source
  LAN Subnets

  Translation, Address
  Choose the WAN CARP IPv4 VIP from the **Address** drop-down, *198.51.100.200*

  Description
  `LAN to WAN`

  Leave all other options at the default values.
- Click **Save**
- Click  below the **Mappings** section to add another new rule to the top of the list for IPsec pass-through.

Note: This is optional and may be omitted if there will not be any LAN clients connecting to external IPsec servers which lack NAT-T support.

- Configure the rule as follows:

  Interface
  WAN

  Address Family
  IPv4

  Source
  LAN Subnets

  Destination

  Type
  Any

  Port
  `500`

  Translation

  Address
  Choose the WAN CARP IPv4 VIP from the **Address** drop-down, *198.51.100.200*

  Port or Range
  Check **Static Port**

Description
`ISAKMP - LAN to WAN`

Leave all other options at the default values.

- Click **Save**
- Click **Apply Changes**

Warning: If an additional local interface is added later, such as a second LAN, DMZ, etc, and that interface uses private IP addresses, then additional outbound NAT rules must be added to translate those sources. Similarly, if additional WANs are added later, they will also need a set of outbound NAT rules.

Danger: Do not use an overly permissive source on outbound NAT rules! If an outbound NAT rule matches traffic from the firewall using a VIP, it can break several protocols and cause instability. Use only local/internal networks as the source on NAT rules, or an alias containing those local private networks.

Any rules using **Localhost** as a source must use an interface address for translation and **not** a CARP VIP.

When complete, the rule changes will look like those found in *Outbound NAT Rules for LAN with CARP VIP*

Mappings

		Interface	Source	Source Port	Destination	Destination Port	NAT Address	NAT Port	Static Port	Description	Actions
☐	✓	WAN	LAN subnets	*	*	500 (ISAKMP)	198.51.100.200 (WAN CARP IPv4 VIP)	*	✓	ISAKMP - LAN to WAN	
☐	✓	WAN	LAN subnets	*	*	*	198.51.100.200 (WAN CARP IPv4 VIP)	*		LAN to WAN	

Fig. 9: Outbound NAT Rules for LAN with CARP VIP

35.19.8 Modifying the DHCP Server

The DHCP server daemons on the cluster nodes need adjustments so that they can work together. The changes will synchronize from the primary to the secondary, so as with the VIPs and Outbound NAT, these changes need only be made on the primary node.

Note: This guide assumes the Kea DHCP Backend is active as it is the only backend which supports HA for both IPv4 and IPv6 (*Server Backend*).

Set the Backend

On **both** nodes, ensure the Kea DHCP backend is active:

- Navigate to **System > Advanced**, **Networking** tab
- Set the **Server Backend** to **Kea DHCP** in the **DHCP Options** section if it is not already selected
- Click **Save** if the value was changed

Configure DHCP for IPv4

On the **primary** node only, enable HA for IPv4 DHCP in the *Kea Settings*:

- Navigate to **Services > DHCP Server**, **Settings** tab
- Check **Enable high availability**
- Set **Node Role** to **Primary**
- Set **Local Name** to a custom value, e.g. `ha-primary`
- Set **Local Address** to the IP address of the sync interface on the primary node, e.g. `172.16.1.2`
- Set **Remote Name** to the name of the secondary node, e.g. `ha-secondary`.
- Set **Remote Address** to the IP address of the Sync interface on the secondary node, e.g. `172.16.1.3`
- Configure TLS support to encrypt the DHCP HA traffic (optional)

  The Sync interface is directly connected in this example so there is no risk of the traffic being intercepted, but using encryption is still a best practice. Consult *TLS Transport* for more information on configuring TLS for DHCP HA. Note that TLS settings do not synchronize and must be configured separately on each node.
- Click **Save**

Note: XMLRPC configuration synchronization will adjust these options appropriately when copying the settings to the secondary node.

Still on the **primary** node only, configure the LAN interface DHCP settings to use the LAN CARP IPv4 VIP:

- Navigate to **Services > DHCP Server**, **LAN** tab
- Set the **DNS Server** to the LAN CARP VIP, here `192.168.1.1`
- Set the **Gateway** to the LAN CARP VIP, here `192.168.1.1`
- Click **Save**

Setting the **DNS Server** and **Gateway** to a CARP VIP ensures that the local clients are talking to the failover address and not directly to either node. This way if the primary fails, the local clients will continue talking to the secondary node.

Configure DHCP for IPv6

Configure DHCPv6 HA

On the **primary** node only, enable HA for IPv6 DHCP in the *Kea Settings*:

- Navigate to **Services > DHCPv6 Server**, **Settings** tab
- Check **Enable high availability**
- Set **Node Role** to **Primary**
- Set **Local Name** to a custom value, e.g. `ha-primary`
- Set **Local Address** to the IP address of the sync interface on the primary node, e.g. `2001:db8:1:df31::2`
- Set **Remote Name** to the name of the secondary node, e.g. `ha-secondary`.
- Set **Remote Address** to the IP address of the Sync interface on the secondary node, e.g. `2001:db8:1:df31::3`

- Configure TLS support to encrypt the DHCP HA traffic (optional)

  The Sync interface is directly connected in this example so there is no risk of the traffic being intercepted, but using encryption is still a best practice. Consult *TLS Transport* for more information on configuring TLS for DHCP HA. Note that TLS settings do not synchronize and must be configured separately on each node.

- Click **Save**

Note: XMLRPC configuration synchronization will adjust these options appropriately when copying the settings to the secondary node.

Configure DHCPv6 Interface Settings

Still on the **primary** node only, configure the LAN interface DHCPv6 settings to use the LAN IPv6 CARP VIP for DNS.

- Navigate to **Services > DHCPv6 Server**, **LAN** tab
- Set the **DNS Server** to the LAN CARP VIP, here `2001:db8:1:df30::1`
- Click **Save**

Configure IPv6 Router Advertisements

Finally, configure IPv6 Router Advertisements (RA) to use the LAN CARP IPv6 Link-Local VIP for the IPv6 gateway:

- Navigate to **Services > Router Advertisement**, **LAN** tab
- Set **Router Mode** to *Managed* so that clients will use DHCPv6 to obtain addresses and other settings.
- Set **RA Interface** to the LAN CARP IPv6 Link-Local VIP, *fe80::1:1*
- Check **Enable DNS**
- Check **Mirror DHCPv6** to have the RA daemon advertise the same DNS settings as the DHCPv6 server
- Click **Save**

35.19.9 Finish Up & Test

At this point the cluster is configured and ready to use. Review the testing procedure in *Verifying Failover Functionality* to confirm it is operating properly.

Once everything tests OK, make configuration backups of both nodes.

35.20 Converting High Availability DHCP from ISC to Kea

This document covers how to convert an existing pfSense® software High Availability (HA) setup from the ISC DHCP backend to the Kea DHCP backend and also explains differences in how each of these backends implements HA failover.

Warning: The ISC DHCP backend is deprecated and will eventually be removed, so converting to the Kea DHCP backend is the best practice once it supports all of the features a deployment needs.

See also:

- *Server Backend*
- *High Availability Configuration Example*

The Kea implementation of HA is fundamentally different from ISC and as a consequence, the HA/failover settings are not compatible between ISC DHCP and Kea DHCP. The conversion process is manual and largely the same as setting up high availability for Kea DHCP from scratch. However, since the Kea HA configuration is much simpler, it is not a lengthy or difficult process.

Converting High Availability DHCP from ISC to Kea

35.20.1 DHCP Backend Differences

There are important differences in high availability operation between the ISC DHCP backend and the Kea DHCP backend, including:

- Kea DHCP operates HA in "hot standby" mode where the primary node serves leases exclusively unless it fails, in which case the standby node serves leases until the primary recovers. Both nodes share lease data as needed. This is similar to the HA behavior of pfSense software in general.

  ISC DHCP behaves closer to an "active/active" load balanced mode which has each node coordinate and serve part of each pool simultaneously and exchange lease data in both directions.

- Kea has a global setting declaring the role of a node as primary or standby.

  ISC attempts to automatically determine the role by inspecting the properties of CARP VIPs which is not always accurate.

- Kea HA serves leases from a secondary node if it boots while the primary node is offline.

  ISC fails to serve leases from a secondary unless it sees the primary node online first.

- Kea DHCP supports HA for IPv6 in DHCPv6.

  ISC has no support for IPv6 HA.

  - As a part of HA support for DHCPv6, XMLRPC configuration synchronization supports copying settings for Kea DHCPv6 between nodes.
  - XMLRPC configuration synchronization for Kea DHCPv6 also synchronizes Router Advertisement settings.

> **Warning:** If an HA cluster had IPv6 configured separately on each node before converting to Kea, the configuration on the secondary node will be overwritten once XMLRPC configuration synchronization is enabled for DHCPv6 on the primary node. If a pool was split between two nodes in this manner, it can be combined into one large pool after converting.

- Kea has one set of global settings for HA per node.

  ISC requires per-interface failover configuration.

  - Despite being configured in different ways, XMLRPC synchronization of HA DHCP settings for Kea and ISC both automatically adjust the values needed for settings on the primary and secondary.

- Kea uses one address per node for HA traffic (lease synchronization, heartbeats, etc.).

  ISC uses manually configured failover addresses on every DHCP interface separately.

  - The best practice with Kea is to use the Sync interface for DHCP HA traffic since it uses a single address. This is safer and more secure as it does not need to flow over every interface separately where it may be exposed to end-user networks.
  - Similarly, firewall rules for Kea only need to be on one interface (e.g. Sync), where ISC DHCP may need firewall rules on every DHCP server interface.

- Kea can use IPv4 or IPv6 for HA traffic in both DHCPv4 and DHCPv6.

  ISC only supports IPv4.

- Kea lease synchronization copies hostnames between nodes.

  ISC lease synchronization does not copy hostnames.

- Kea tracks HA status globally for each node.

  ISC tracks HA status separately for each address pool.

- Kea supports optional encryption of HA traffic using TLS and can also optionally require a client certificate to validate it is speaking to the expected peer.

  ISC does not support encryption or authentication of failover traffic.

  - The TLS settings for HA do not synchronize via XMLRPC configuration synchronization as each node may need to use different certificates.

Backend Difference Summary

The following table summarizes the differences between the backends:

Table 5: High Availability DHCP Backend Comparison

Feature	Kea	ISC
Supported Upstream	Yes	No (Deprecated)
HA Style	Hot Standby	Active/Active
Active/Passive Role	Manual	Automatic
Secondary Only Boot	Yes	No
DHCPv6 HA	Yes	No
DHCPv6+RA XMLRPC Sync	Yes	No
HA Config	Global	Per-Interface
IP Addresses for HA	One per Node	One per Interface per Node
HA Interfaces	Sync	All Enabled for DHCP
HA Transports	IPv4 or IPv6	IPv4 Only
HA Copies Hostnames	Yes	No
HA Status	Per Node	Per Pool
TLS Encryption	Yes (Optional)	No
TLS Authentication	Yes (Optional)	No

35.20.2 Status Differences

The DHCP Lease status for failover information changed significantly between ISC DHCP and Kea DHCP.

The ISC DHCP Lease status page shows a list of **Failover Groups** at the top of the page, as described in *Pool Status (HA/Failover) – ISC DHCP Only*. Each pool has a state for both nodes in the group and the last time the state changed. The information is fairly plain, with only the text of the state fields changing to indicate status.

In contrast, the Kea DHCP HA status is much more user-friendly. It has moved to the bottom of the DHCP Lease status page, as shown in *High Availability Status – Kea DHCP Only*. The Kea DHCP HA status section includes an easy to interpret icon indicating the current state along with information about each node and its status, and a timer indicating the last received heartbeat.

35.20.3 Conversion Process

Converting DHCPv4 from ISC to Kea

- Switch the backend to Kea (*Server Backend*)
- Add firewall rules on the primary node Sync interface which pass IPv4 Kea HA traffic (*Setup Sync Interface*)
- Enable and configure Kea DHCP HA on the primary node (*Configure DHCP for IPv4*)
- Check the DHCP status and ensure the two nodes are communicating properly (*High Availability Status – Kea DHCP Only*)
- Remove any old firewall rules which explicitly passed ISC DHCP failover traffic (TCP ports `519` and `520`). These could be on interface tabs, interface group tabs, floating rules, etc.

Adding DHCPv6 Support after switching to Kea

- Add firewall rules on the primary node Sync interface which pass IPv6 Kea HA traffic (*Setup Sync Interface*)
- Add an IPv6 Link-Local CARP VIP for LAN if one does not already exist, such as `fe80::1:1/64` (*LAN IP Addresses*)
- Enable and configure Kea DHCPv6 HA on the primary node (*Configure DHCPv6 HA*)
- Configure DHCPv6 interfaces to use a CARP VIP for DNS (*Configure DHCPv6 Interface Settings*)
- Configure Router Advertisements for HA using the link-local CARP VIP as the **RA Interface** (*Configure IPv6 Router Advertisements*)
- Enable XMLRPC Synchronization for DHCPv6 (*Configure Configuration Synchronization (XMLRPC)*)
- Adjust the DHCPv6 configuration to account for changes in the pool addresses if the HA cluster had DHCPv6 configured manually without synchronization.
- Check the DHCP status and ensure the two nodes are communicating properly (*High Availability Status – Kea DHCP Only*)

35.21 High Availability Configuration Example with Multi-WAN

High availability (HA) can be deployed for firewall redundancy in a multi-WAN configuration. This section details the VIP and NAT configuration needed for a dual WAN HA deployment.

Note: This recipe is a supplement to *High Availability Configuration Example*. Read through that recipe before proceeding. This document only covers topics specific to high availability and multi-WAN and is not a complete HA configuration guide.

See also:

- *Multiple WAN Connections*

35.21.1 Determine IP Address Assignments

This example uses four IPv4 addresses on each WAN. Each firewall needs an IP address, plus one CARP VIP for Outbound NAT, plus an additional CARP VIP for a 1:1 NAT entry that will be used for an internal mail server in the DMZ segment.

WAN and WAN2 IP Addresses

Table *WAN IP Addresses* shows the IP addresses for both WANs. In most environments these will be public IP addresses.

Table 6: WAN IP Addresses

IP Address	Usage
`198.51.100.200`	Shared CARP VIP for Outbound NAT
`198.51.100.201`	Primary firewall WAN
`198.51.100.202`	Secondary firewall WAN
`198.51.100.203`	Shared CARP VIP for 1:1 NAT

Table 7: WAN2 IP Addresses

IP Address	Usage
203.0.113.10	Shared CARP VIP for Outbound NAT
203.0.113.11	Primary firewall WAN2
203.0.113.12	Secondary firewall WAN2
203.0.113.13	Shared CARP VIP for 1:1 NAT

LAN Addresses

The LAN subnet is 192.168.1.0/24. For this example, the LAN IP addresses are assigned as described in Table *LAN IP Address Assignments*:

Table 8: LAN IP Address Assignments

IP Address	Usage
192.168.1.1	CARP shared LAN VIP
192.168.1.2	Primary firewall LAN
192.168.1.3	Secondary firewall LAN

DMZ Addresses

The DMZ subnet is 192.168.2.0/24. For this example, the DMZ IP addresses are assigned as described in Table *DMZ IP Address Assignments*:

Table 9: DMZ IP Address Assignments

IP Address	Usage
192.168.2.1	CARP shared DMZ VIP
192.168.2.2	Primary firewall DMZ
192.168.2.3	Secondary firewall DMZ

Sync Interface Addressing

There will be no shared CARP VIP on the Sync interface because there is no need for one. These IP addresses are used only for communication between the HA nodes. For this example, 172.16.1.0/24 is the Sync subnet. The two nodes only require one IP address each (two total), but the example uses a /24 size subnet to be consistent with the other internal interfaces. For the last octet of the IP addresses, use the same last octet as the LAN IP address on that node for consistency.

Table 10: Sync IP Address Assignments

IP Address	Usage
172.16.1.2	Primary firewall Sync
172.16.1.3	Secondary firewall Sync

35.21.2 NAT Configuration

The NAT configuration when using HA with Multi-WAN is the same as HA with a single WAN, except the rules are repeated so there is a set for each WAN. Ensure that only CARP VIPs are used for inbound traffic or routing.

See also:

See *Network Address Translation* for more information on NAT configuration.

35.21.3 Firewall Configuration

With Multi-WAN a firewall rule must be in place to pass traffic to local networks using the default gateway. Otherwise, when traffic attempts to reach the CARP address or from LAN to DMZ it will instead go out a WAN connection.

Add a rule at the top of the firewall rules for all internal interfaces which will direct traffic for all local networks to the default gateway. The important part is the gateway **must** be *default* for this rule and not one of the failover or load balance gateway groups. The destination for this rule would be the local LAN network, or an alias containing any locally reachable networks.

See also:

- *Policy Routing Configuration*

35.21.4 Multi-WAN HA with DMZ Diagram

Due to the additional WAN and DMZ elements, a diagram of this layout is much more complex as can be seen in Figure *Diagram of Multi-WAN HA with DMZ*.

35.22 High Availability Configuration Example without NAT

High Availability (HA) can provide redundancy for routed public subnets. This section describes this type of configuration, which is common in large networks, ISP, wireless ISP networks, and data center environments.

Note: This recipe is a supplement to *High Availability Configuration Example*. Read through that recipe before proceeding. This document only covers topics specific to high availability without NAT and is not a complete configuration guide.

As mentioned in *High Availability Configuration Example*, CARP VIPs are the only type of VIPs which provide redundancy for addresses directly handled by the firewall, and CARP VIPs can only be used in conjunction with NAT or services on the firewall itself. However, sources can send traffic to the CARP VIPs, such as delivering traffic from routed subnets, and it will reach the active node for processing even if it isn't involved in NAT or local services.

Note: This recipe only covers IPv4 without NAT as the IPv6 configuration in *High Availability Configuration Example* does not involve NAT, so there are no differences to address.

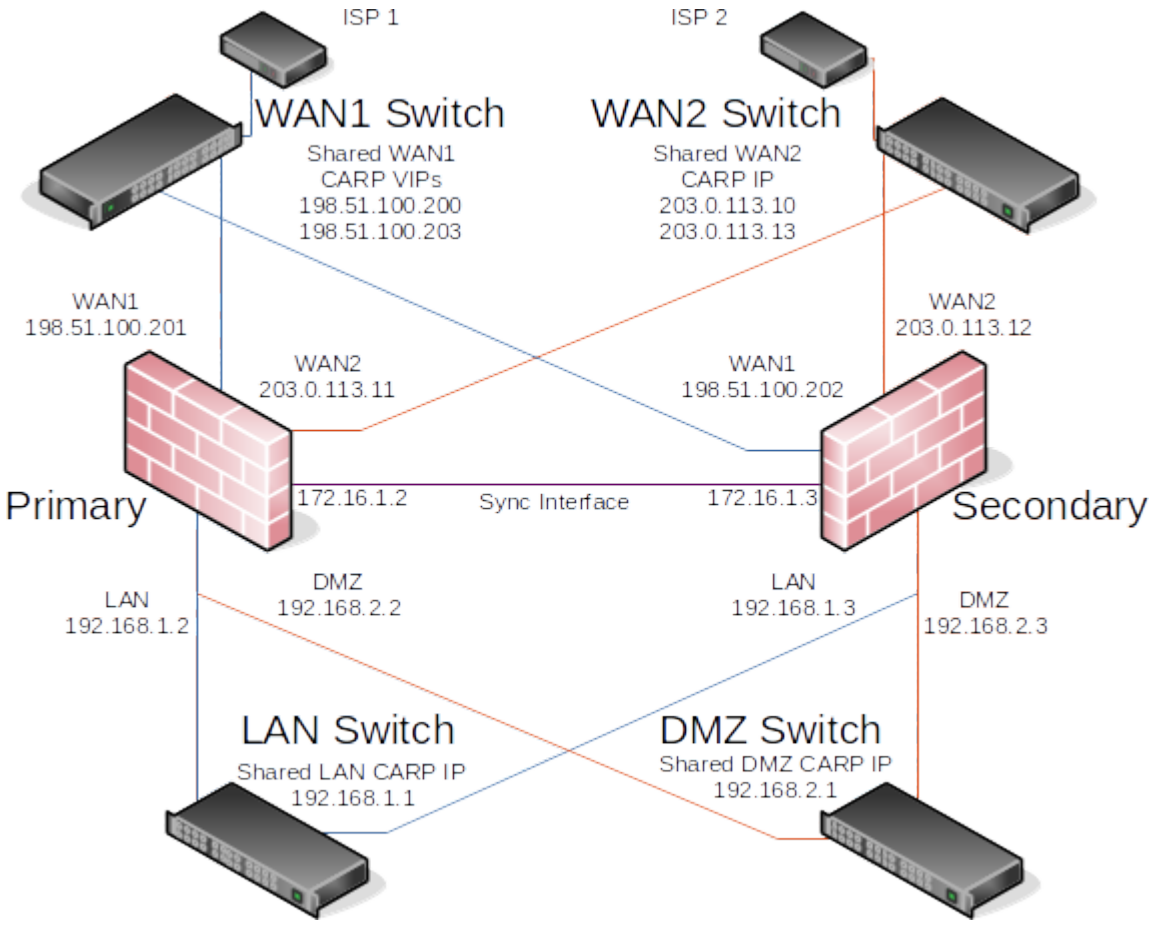

Fig. 10: Diagram of Multi-WAN HA with DMZ

35.22.1 Public IPv4 Address Assignments

HA requires at least a /29 block of public IPv4 addresses for the WAN side of the firewall, which provides six usable IPv4 addresses. Each firewall requires one IPv4 address, and at least one CARP VIP on the WAN side. A two node deployment only requires three addresses, but this is the smallest subnet that will accommodate three usable IPv4 addresses since the upstream router consumes one, and two are lost to the network and broadcast addresses.

Additional public IPv4 address subnets for internal use must be routed to one of the WAN CARP VIPs by the ISP, data center, or upstream router. When the upstream source routes additional subnets to a CARP VIP, the routing will not be dependent upon a single node. The example configuration depicted in this section uses a /24 public IPv4 subnet and splits it into two /25 subnets.

35.22.2 Network Overview

The example network depicted here is a data center environment consisting of two HA nodes with four interfaces each: WAN, WEB (LAN), DBDMZ, and Sync. This network contains a number of web and database servers. It is not based on any real network, but there are countless similar production deployments.

WAN

The WAN side connects to the upstream network, which may be an ISP, a data center, upstream router, or other means of external connectivity.

WEB Network

The WEB segment in this network uses the "LAN" interface but renamed. It contains web servers, so it has been named WEB but it could be called DMZ, SERVERS, or anything desired.

DBDMZ Network

This segment is an OPT interface and contains database servers. It is common to segregate web and database servers into separate networks in hosting environments. The database servers typically do not require direct access from the Internet, and hence are better protected against remote compromise than web servers.

Sync Network

The HA nodes use the Sync network in this diagram to replicate configuration changes via XMLRPC and for state synchronization to replicate state table changes between the two firewalls. As described in other HA documentation sections, the best practice is to use a dedicated interface for this purpose.

Network Layout

Figure *Diagram of HA with Routed IPv4 Subnets* illustrates this network layout, including all routable IP addresses, the WEB network, and the Database DMZ.

Note: Segments containing database servers typically do not need to be publicly accessible, and hence would more commonly use private IP subnets, but the example illustrated here can be used regardless of the function of the two internal subnets.

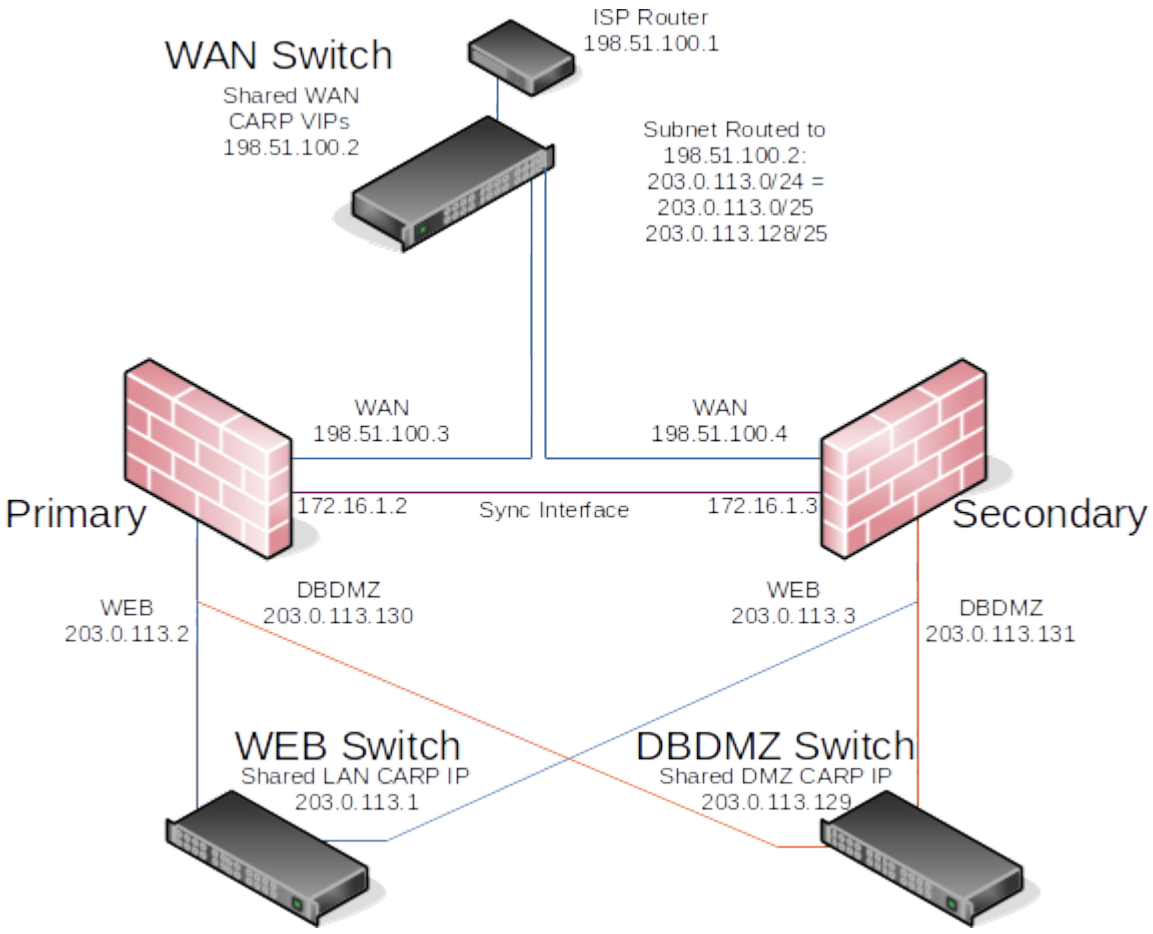

Fig. 11: Diagram of HA with Routed IPv4 Subnets

Outbound NAT

The **Outbound NAT Mode** in **Firewall > NAT** on the **Outbound NAT** tab must be set to **Manual** to properly accommodate this scenario. When the mode is set to **Manual**, saving the settings creates a set of outbound NAT rules equivalent to the rules which were utilized in **Automatic** or **Hybrid** modes.

In the list of rules created by switching to **Manual Outbound NAT**, delete any rules which translate sources using the routed subnets (e.g. WEB Networks, DBDMZ Networks). This effectively disables NAT for the routed subnets.

Warning: **Do not delete** outbound NAT rules that translate from a source of Localhost (`127.0.0.1`) using the WAN interface address(es) as these are necessary to ensure traffic from the firewall itself can egress properly.

See also:

- *Outbound NAT*

Firewall Rules

Firewall rules in this scenario are much simpler as there is no need to consider NAT translation. Allow traffic directly to the necessary destinations as needed.

Warning: As there is no NAT involved, carefully crafting WAN rules becomes more critical as being overly permissive with WAN rules not only can allow remote attackers access to the firewall itself, but all local networks.

Ensure the rules properly segment the DBDMZ from the WEB network; Block or reject any traffic between the segments except what is absolutely required for necessary functionality. For example, only allow connections from web servers to the database port(s) and nothing else.

Note: Best practices and requirements vary wildly in this regard depending on the operating systems and other software involved. Consult documentation for the servers to determine requirements.

35.23 IPsec Remote Access VPN Example Using IKEv1 with Pre-Shared Keys

This article describes how to set up mobile IPsec in pfSense® software with a Pre-Shared Key.

Note: The current best practice is to use IKEv2 with EAP authentication for IPsec Remote Access on modern clients. See *IPsec Remote Access VPN Example Using IKEv2 with EAP-MSCHAPv2* for details.

Warning: There are very few remaining clients which support this type of configuration because it is considered weak compared to other options such as IKEv2 with EAP.

35.23.1 IPsec Server Setup

This is the setup for the pfSense® software side of the connection.

Mobile Clients

- Navigate to **VPN > IPsec**, **Mobile Clients** tab
- Set the options as follows:

  Enable IPsec Mobile Client Support
  Checked

  User Authentication
  Local Database

  Provide a virtual IP address to clients
  Checked

  Enter an unused subnet in the box (e.g. `10.11.200.0`), pick a subnet mask (e.g. `24`)
- Set other options if desired
- Click **Save**
- Click **Apply Changes**
- Click  **Create Phase 1** at the top of the screen if it appears

Phase 1 settings

- Navigate to **VPN > IPsec**
- Locate the Mobile Phase 1 in the list
- Click  to edit the Mobile Phase 1
- Enter the following settings:

  Description
  `Mobile IPsec PSK`

  Key Exchange Version
  Auto to allow both IKEv1 and IKEv2 connections. If all clients support IKEv2, use that instead.

  Note: Some clients, such as the native Android client, require options which only work with IKEv2.

  Authentication method
  Mutual PSK

  Negotiation mode
  Aggressive or *Main* depending on client requirements.

  My identifier
  My IP address

Encryption Algorithm
Create several entries which match values for common clients. Add them in order of preference with the most secure options listed first. For example:

- **Algorithm** *AES128-GCM*, **Hash** *SHA256*, **DH Group** *16* (if using IKEv2 only, required for Android)
- **Algorithm** *AES 256*, **Hash** *SHA512*, **DH Group** *14*
- **Algorithm** *AES 256*, **Hash** *SHA256*, **DH Group** *14*
- **Algorithm** *AES 256*, **Hash** *SHA1*, **DH Group** *14*
- **Algorithm** *AES 128*, **Hash** *SHA256*, **DH Group** *2*
- **Algorithm** *AES 128*, **Hash** *SHA1*, **DH Group** *2*

Life Time
`86400`

NAT Traversal
Force

- Click **Save**

Phase 2 settings

- Click **Show Phase 2 Entries** inside the Mobile phase 1 to expand its phase 2 list
- Click **Add P2** to create a new phase 2 entry
- Enter the following settings:

Description
`Mobile IPsec`

Mode
Tunnel IPv4

Local Network
The network on the firewall site which the clients must reach, e.g. *LAN Subnet*, or *Network* `0.0.0.0/0` to send all traffic over the VPN.

Protocol
ESP

Encryption Algorithms
AES 128

Hash Algorithms
SHA256

PFS key group
off

Lifetime
`28800`

- Add additional phase 2 entries for local networks if necessary
- Click **Save**

- Click **Apply Changes**

User Settings

Create pre-shared keys to identify users for the VPN

- Navigate to **VPN > IPsec**, **Pre-shared keys** tab.
- Click  **Add** to create a new entry
- Enter the settings as follows:

  Identifier
  Any identifier may be used so long as it is unique to the person using the account.

  Tip: E-mail addresses are commonly used as they are more unique than first or last names.

  Secret Type
  PSK

  Pre-Shared Key
  Generate a long/random Pre-Shared Key. The longer and more complex the key, the more secure it is.

  Note: Some clients, such as Linux network manager, require a minimum key length of 20 characters.

- Click **Save**
- Click **Apply Changes**

Firewall Rules

Add firewall rules to pass traffic from clients

- Navigate to **Firewall > Rules**, **IPsec** tab
- Add rules that match traffic to allow from mobile clients or add a rule to pass any protocol/any source/any destination to allow everything.

See also:

IPsec and firewall rules

The firewall configuration is complete.

35.23.2 Client Configuration

Android

Android 11.x and later contain a client compatible with a pre-shared key configuration provided that it uses IKEv2 only. See the inline notes above for additional requirements.

Note: The settings below are from pure Android 11.x. These exact settings may not present on all Android devices, depending on the Android version and changes made by the OEM.

See *Remote Access Mobile VPN Client Compatibility* for additional details.

- Swipe down twice from the top of the screen
- Tap the **Settings** cog
- Tap **Networks & Internet**, **Advanced**, **VPN**
- Tap +
- Enter the connection settings as follows:

  Name
  `pfSense Mobile VPN` or another suitable description

  Type
  IKEv2/IPsec PSK

  Server Address
  The address of the server.

  IPsec Identifier
  The identifier on the pre-shared key for this user (e.g. a username or e-mail address)

  Pre-Shared Key
  The PSK value associated with the identifier for this user.

- Tap **Save**

Windows (Deprecated)

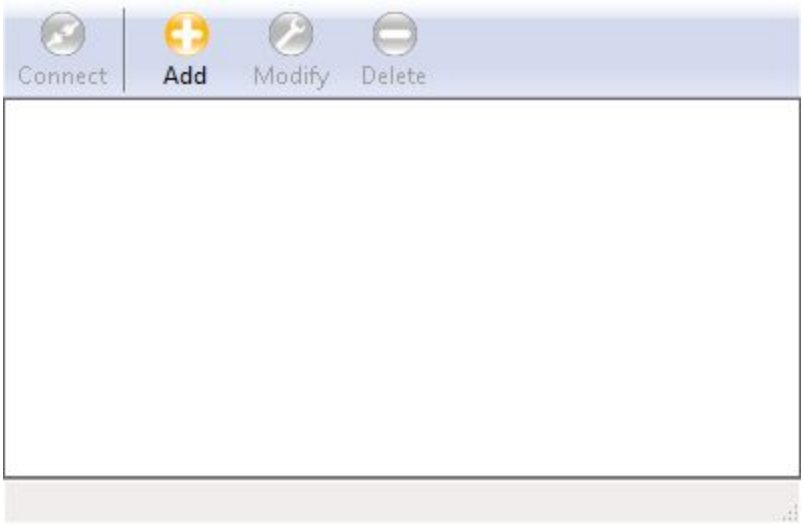
Warning: The Shrew Soft client is deprecated and does not work on current supported versions of Windows. The instructions below remain for reference, but should not be followed exactly.

Some settings below may not match the configuration above due to no longer being supported or because they are weak. If more secure options exist in the client, use them.

This part is done on the end user computer.

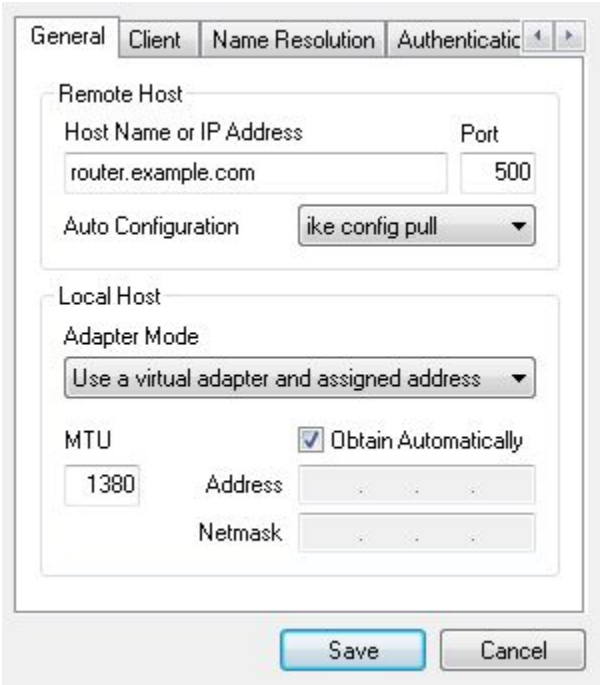
Download and install Shrew Soft VPN.

Once finished, open `ipseca.exe`. The VPN Access Manager window is presented.

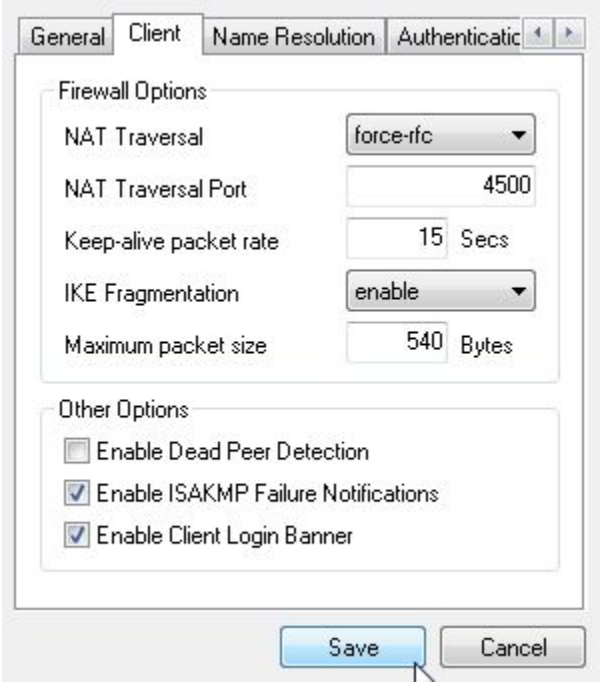


Press the big round **Add** button to set up a tunnel configuration.

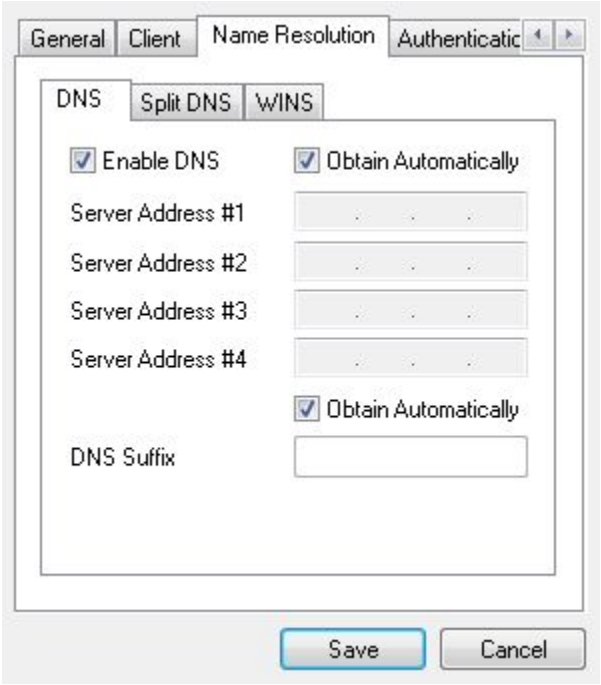
On the **General** tab, enter the IP address or host name of the firewall. Leave the rest as it is. The default values in new versions of the Shrew Soft VPN client may change so in case of doubt, stick to the screenshots.

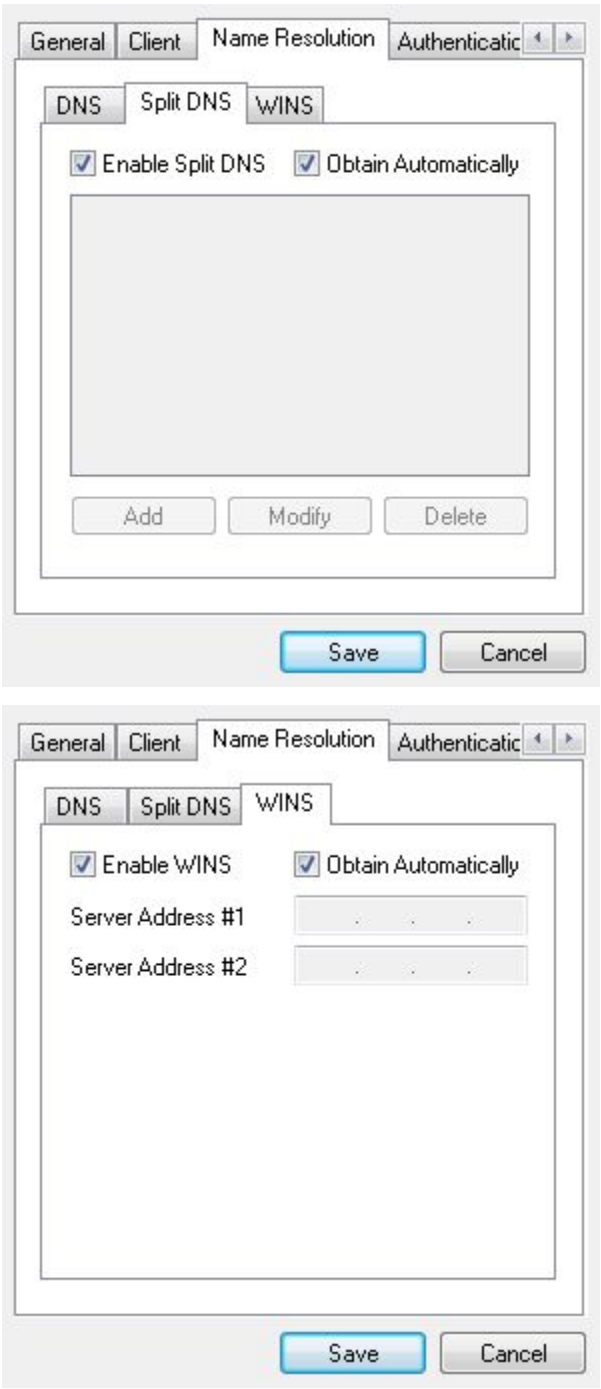


On the **Client** tab, set **NAT Traversal** to **force-rfc** and uncheck **Enable Dead Peer Detection**. If these settings are wrong, an established tunnel may not let any traffic through.

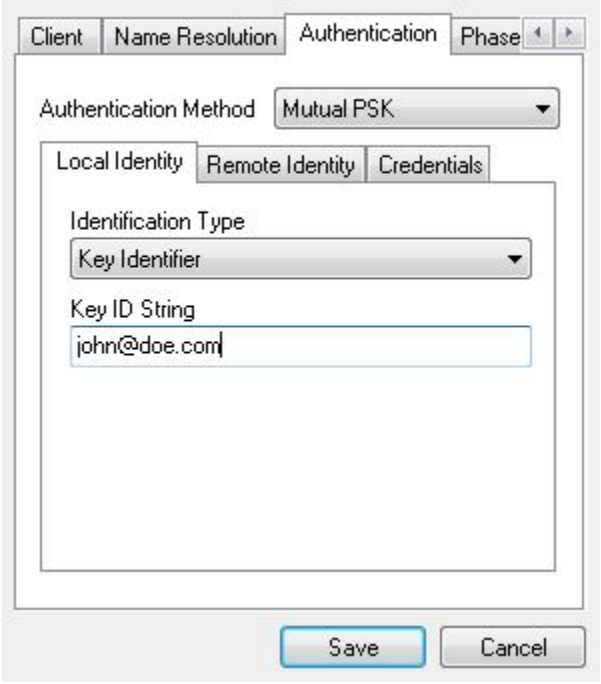


Don't change anything on the **Name Resolution** tab; these settings are all automatically set by the pfSense software. Relevant information could be entered here but if the settings were configured on the firewall, they need not be set here.

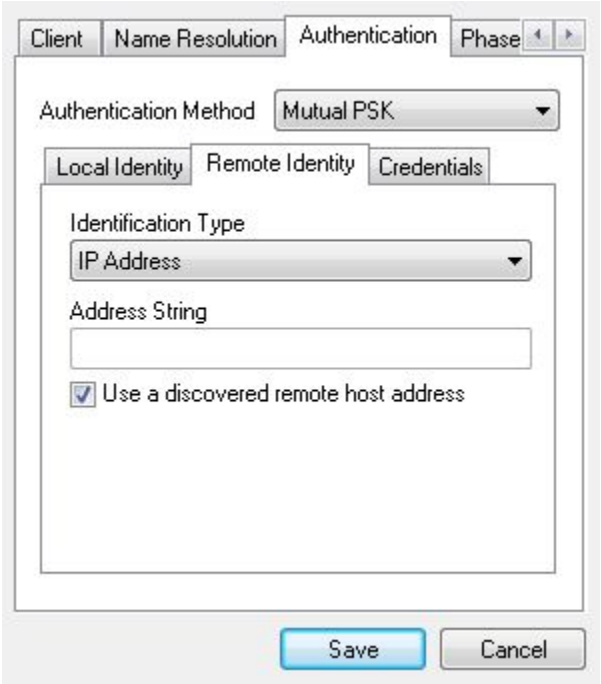




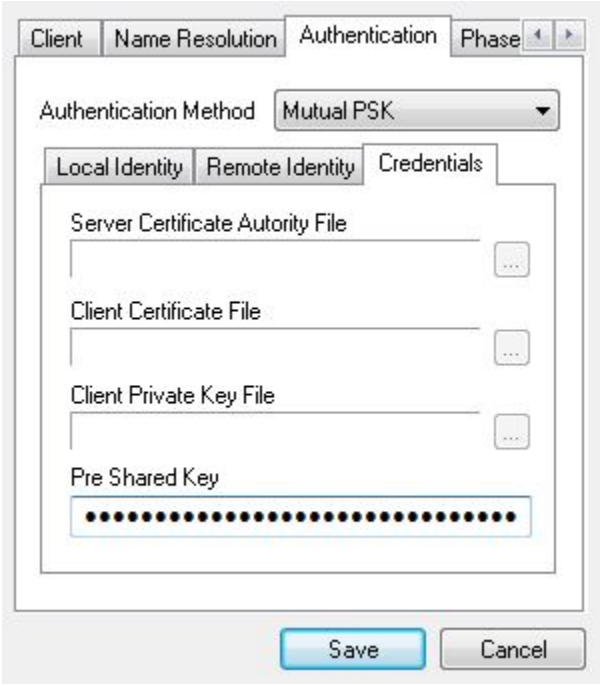
Go to the **Authentication tab**. Set **Authentication Method** to **Mutual PSK**. Under **Local Identity**, choose **Key Identifier** as the **Identification Type** and enter the user's e-mail address (or whatever was used as an identifier) in the **Key ID String** field.



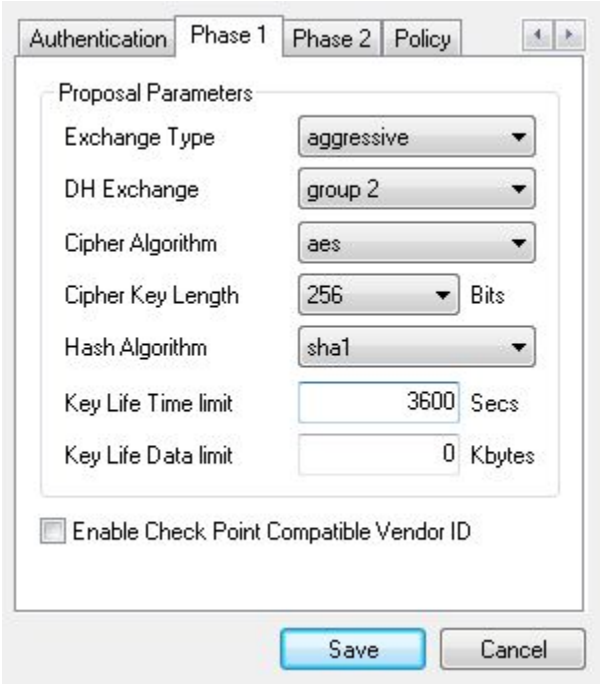
Under **Remote Identity**, set **Identification Type** to **IP Address** and check **Use a discovered remote host address**.



Finally, under **Credentials**, enter the Pre Shared Key associated with the e-mail address.

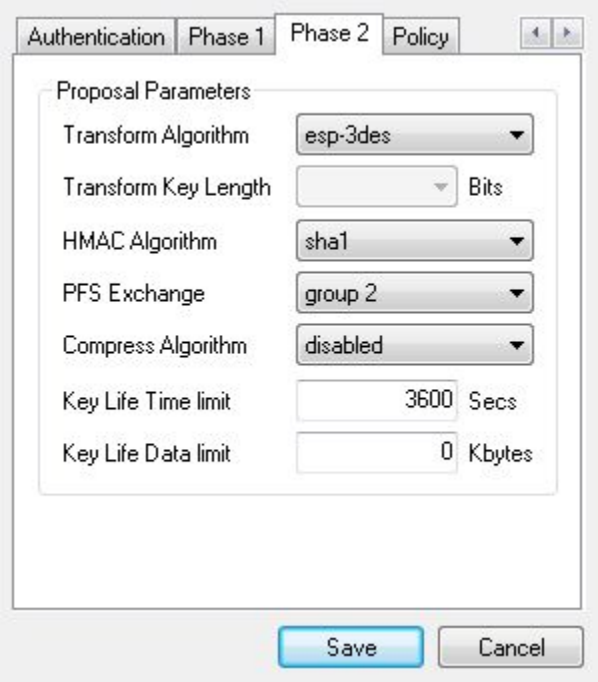


Now scroll over to the **Phase 1** tab. Set the **Cipher Algorithm** to *aes* or whatever was entered on the Phase 1 page in the pfSense software. **Cipher Key Length** to *256* (or whatever etc.) and **Hash Algorithm** to *sha2-256*. Set the **Key Life Time limit** to *3600*.



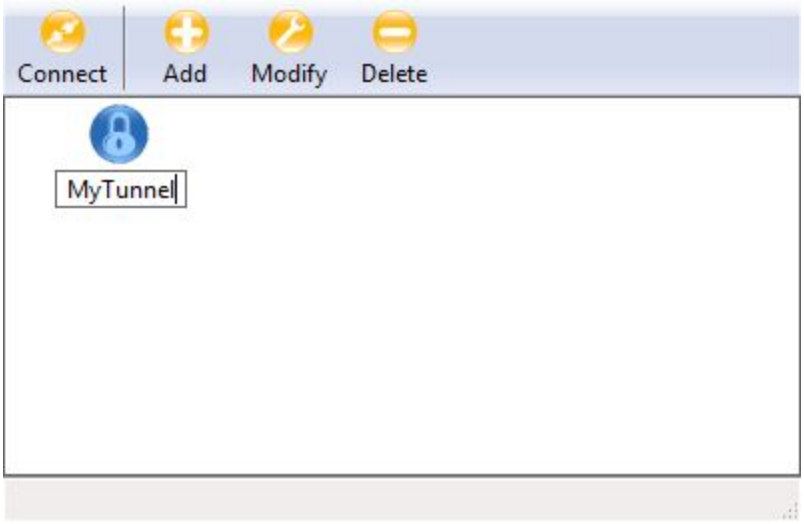
Phase 2 tab: set **Transform Algorithm** to *esp-aes*, **Transform Key Length** to **128**, **HMAC Algorithm** to *sha2-256* and **PFS Exchange** to *group 2*.

Warning: This matches the configuration for the server configured above, but may not match the screenshots since they are from an older OS that isn't available currently to update.

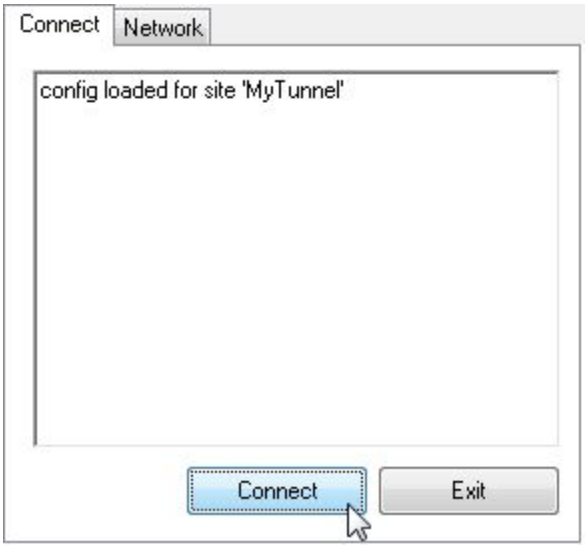


Nearly there! Go to the **Policy** tab and set **Policy Generation Level** to **unique**.

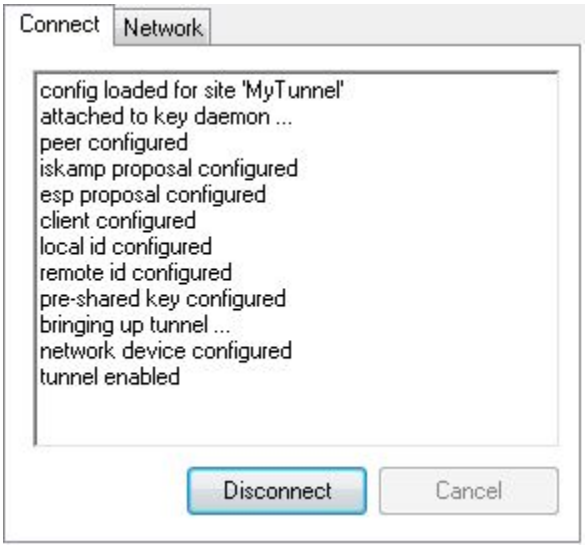
Click **Save** and give the newly created configuration an appropriate name.



Double-click the configuration and the tunnel window will pop up. Click **Connect** to start the tunnel.



Click **Disconnect** to… disconnect the tunnel.



That's it! A working IPsec tunneling system is now in place.

35.24 IPsec Remote Access VPN Example Using IKEv1 with Xauth

This document covers IPsec using Xauth and a mutual Pre-Shared Key.

Note: The current best practice is to use IKEv2 for IPsec Remote Access on modern clients. See *IPsec Remote Access VPN Example Using IKEv2 with EAP-MSCHAPv2* for details.

This setup has been tested and working on various *Android* and *iOS* devices. Other clients may work as well.

35.24.1 IPsec Server Setup

This is the setup for the pfSense® software side of the connection

Mobile Clients

- Navigate to **VPN > IPsec**, **Mobile Clients** tab
- Set the options as follows:

  Enable IPsec Mobile Client Support
  Checked

  User Authentication
  Local Database

  Provide a virtual IP address to clients
  Checked

  Enter an unused subnet in the box (e.g. `10.11.200.0`), pick a subnet mask (e.g. `24`)
- Set other options if desired
- Click **Save**

- Click **Apply Changes**
- Click  **Create Phase 1** at the top of the screen if it appears

Phase 1 settings

- Navigate to **VPN > IPsec**
- Locate the Mobile Phase 1 in the list
- Click  to edit the Mobile Phase 1
- Enter the following settings:

  Description
  `Mobile IPsec PSK + Xauth`

  Key Exchange Version
  IKEv1

  Authentication method
  Mutual PSK + Xauth

  Negotiation mode
  Aggressive or *Main* depending on client requirements.

  My identifier
  My IP address

  Peer identfier
  User fully qualified domain name / E-mail, `vpnusers@example.com`

  Pre-Shared Key
  A long/random pre-shared key suitable for giving to users.

  Encryption Algorithm
  Create several entries which match values for common clients. Add them in order of preference with the most secure options listed first. For example:

  - **Algorithm** *AES 256*, **Hash** *SHA512*, **DH Group** *14*
  - **Algorithm** *AES 256*, **Hash** *SHA256*, **DH Group** *14*
  - **Algorithm** *AES 256*, **Hash** *SHA1*, **DH Group** *14*
  - **Algorithm** *AES 128*, **Hash** *SHA1*, **DH Group** *2*

  Life Time
  `86400`

  NAT Traversal
  Force

- Click **Save**

Phase 2 settings

- Click  **Show Phase 2 Entries** inside the Mobile phase 1 to expand its phase 2 list
- Click  **Add P2** to create a new phase 2 entry
- Enter the following settings:

  Description
  `Mobile IPsec`

  Mode
  Tunnel IPv4

  Local Network
  The network on the firewall site which the clients must reach, e.g. *LAN Subnet*, or *Network* `0.0.0.0/0` to send all traffic over the VPN.

  Protocol
  ESP

  Encryption Algorithms
  AES 128

  Hash Algorithms
  SHA1

  PFS key group
  off

  Lifetime
  `28800`

- Add additional phase 2 entries for local networks if necessary
- Click **Save**
- Click **Apply Changes**

User Settings

- Navigate to **System > User Manager**
- *Add a user*
- Edit the user and grant them the *User - VPN - IPsec xauth Dialin* privilege or add them to a group with this privilege.

Note: Xauth uses both this per-user password and the value of the pre-shared key for different types of authentication. The pre-shared key is used to authenticate the tunnel itself and the per-user password ensures that a particular user is authorized to access the tunnel.

Firewall Rules

Add firewall rules to pass traffic from clients

- Navigate to **Firewall > Rules**, **IPsec** tab
- Add rules that match traffic to allow from mobile clients or add a rule to pass any protocol/any source/any destination to allow everything.

See also:

IPsec and firewall rules

35.24.2 Device Setup (Android)

Note: The settings below are from pure Android 11.x. These exact settings may not present on all Android devices, depending on the Android version and changes made by the OEM.

See *Remote Access Mobile VPN Client Compatibility* for additional details.

- Swipe down twice from the top of the screen
- Tap the **Settings** cog
- Tap **Networks & Internet**, **Advanced**, **VPN**
- Tap +
- Enter the connection settings as follows:

  Name
  `pfSense Mobile VPN` or another suitable description

  Type
  IPsec Xauth PSK

  Server Address
  The address of the server.

  IPsec Identifier
  If the mobile IPsec phase 1 is set for *Aggressive* fill in the identifier set in phase 1 (e.g. `vpnusers@example.com`).

  If the mobile IPsec phase 1 is set for *Main*, leave this at the default empty value of *(not used)*.

  Pre-Shared Key
  The value of the pre-shared key from the mobile phase 1 entry.

  Username
  The username for this xauth user

  Password
  The password for this xauth user

- Tap **Save**

35.24.3 Device Setup (iOS)

- Tap **Settings** > **VPN** or **Settings** > **General** > **VPN**
- Tap **Add VPN Configuration**
- Set **Type** to **IPsec**
- Enter the settings as follows:

  Description
  `pfSense Mobile VPN` or another suitable description

  Server
  The address of the server.

  Account
  The username for this xauth user

  Password
  The password for this xauth user (or leave blank to be prompted every time)

  Group Name
  The identifier set in phase 1 (e.g. `vpnusers@example.com`).

  Secret
  The value of the pre-shared key from the mobile phase 1 entry.

35.24.4 Troubleshooting

By default iOS will tunnel all traffic over the VPN including traffic going to the Internet. If Internet sites are inaccessible once connected, a DNS server may need to be pushed to the client for it to use. This could be the LAN IP address of the firewall if the DNS resolver is enabled or a public DNS server such as `8.8.8.8` and/or `8.8.4.4`.

The reason for the above is that the cellular provider is likely giving mobile devices DNS servers that are only accessible from their network. Once connected to the VPN the DNS servers are now being accessed via the VPN instead of the provider network, thus the queries are likely to be dropped. Supplying a local or public DNS server will work around this problem.

35.25 Configuring IPsec IKEv2 Remote Access VPN Clients

Most operating systems include native client support for IPsec IKEv2 VPN connections, and others typically have an app or add-on package which adds the capability.

This section covers IPsec IKEv2 client configuration for several popular operating systems.

Tip: The *ipsec-profile-wizard* package on pfSense Plus software generates a set of files which can automatically import VPN settings into Apple macOS and iOS (**VPN > IPsec Export: Apple Profile**) as well as Windows clients (**VPN > IPsec Export: Windows**).

This feature allows much greater flexibility in settings as it will configure clients to match what is set on the server specifically rather than making the server accommodate the default settings on various operating systems.

This package is exclusive to pfSense Plus software and is not available on the community edition.

If the package is not already installed, add it using the *Package Manager*.

See also:

Hangouts Archive to watch the September and October 2015 Hangouts on Remote Access VPNs which covers client installations for most operating systems.

35.25.1 Configuring IPsec IKEv2 Remote Access VPN Clients on Windows

Tip: The *ipsec-profile-wizard* package on pfSense Plus software generates a set of files which can automatically import VPN settings into Apple macOS and iOS (**VPN > IPsec Export: Apple Profile**) as well as Windows clients (**VPN > IPsec Export: Windows**).

This feature allows much greater flexibility in settings as it will configure clients to match what is set on the server specifically rather than making the server accommodate the default settings on various operating systems.

This package is exclusive to pfSense Plus software and is not available on the community edition.

If the package is not already installed, add it using the *Package Manager*.

Windows 8 and newer easily support IKEv2 VPNs. Windows 7 supports them as well though the processes are slightly different. The procedure in this section was performed on Windows 10 20H2 but earlier versions are similar.

See also:

The procedure to import certificates to Windows 7 can be found on the strongSwan Wiki

Import the CA to the Client (All EAP types)

This step is necessary for all EAP types (EAP-MSCHAPv2, EAP-RADIUS, EAP-TLS).

- Export the CA Certificate from the pfSense® software GUI and download or copy it to the client PC:
  - Navigate to **System > Certificates**, **Certificate Authorities** tab on the firewall
  - Click  by the CA to download only the certificate
- Locate the downloaded file on the client PC (e.g. VPNCA.crt) as seen in Figure *Downloaded CA Certificate*

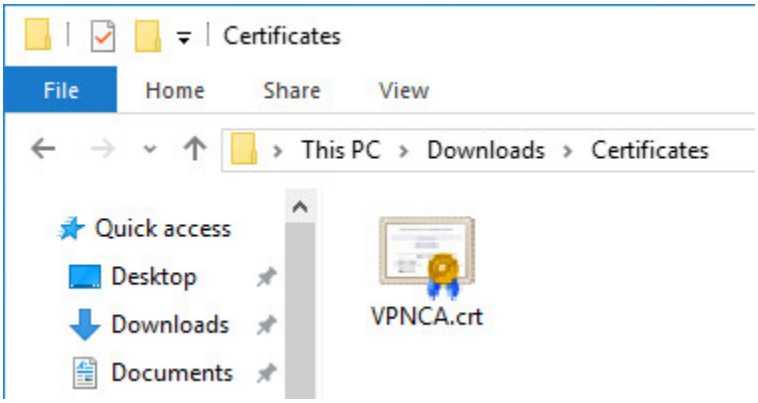


Fig. 12: Downloaded CA Certificate

- Double click the CA file
- Click **Install Certificate…** as shown in *Certificate Properties*

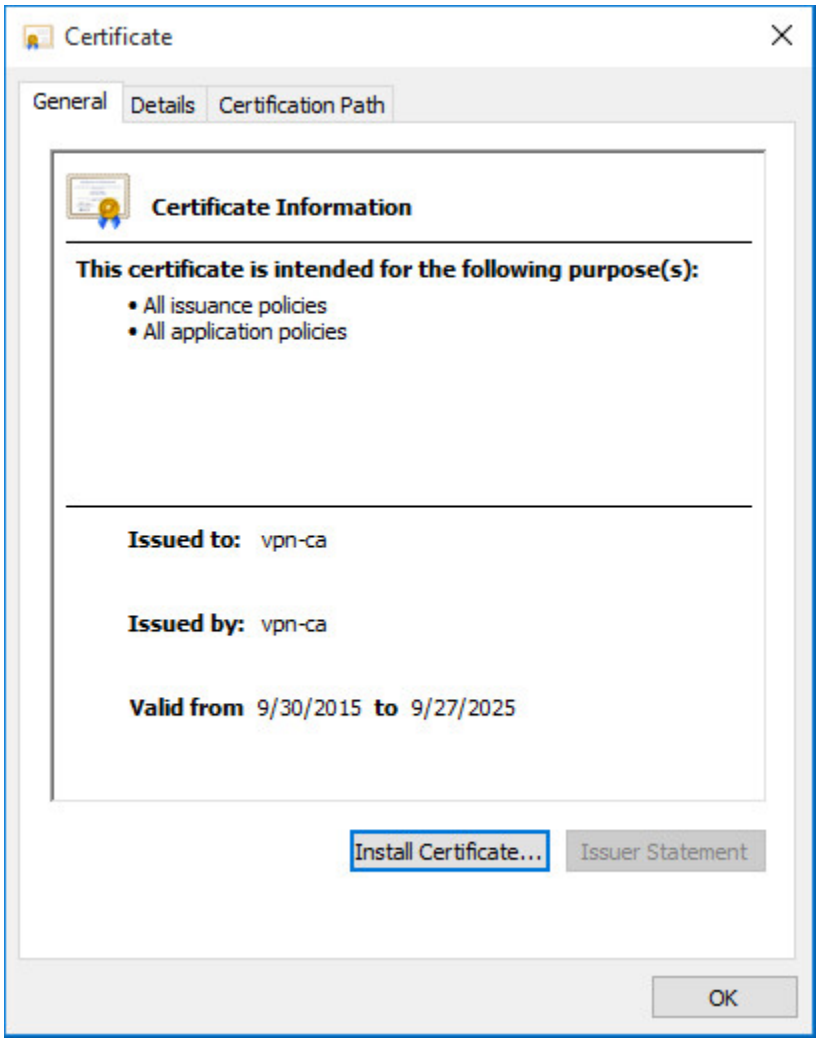

Fig. 13: Certificate Properties

- Select **Local Machine** as shown in *Certificate Import Wizard - Store Location*

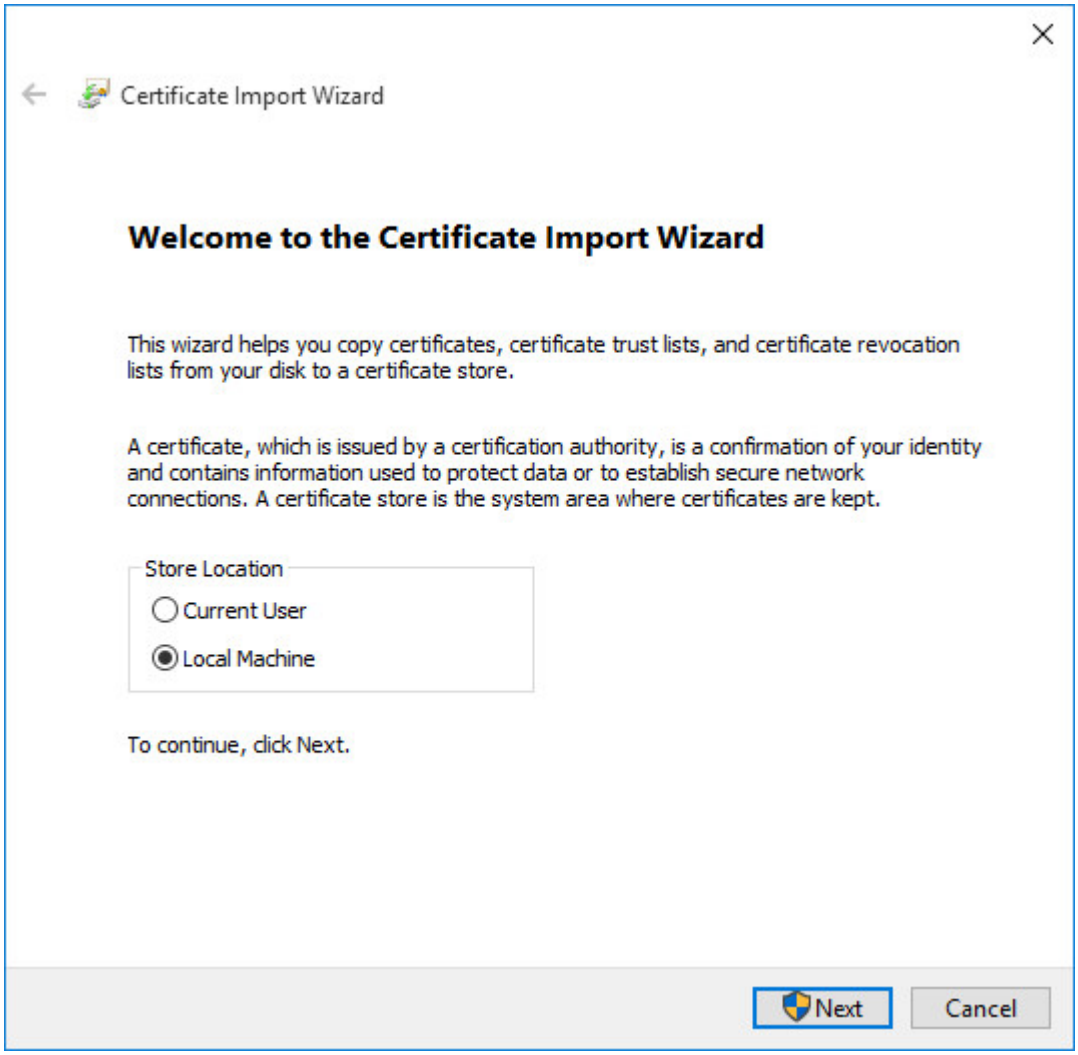

Fig. 14: Certificate Import Wizard - Store Location

- Click **Next**
- Click **Yes** at the UAC prompt if it appears
- Select **Place all Certificates in the following store** as shown in Figure *Certificate Import Wizard - Browse for the Store*
- Click **Browse**
- Click **Trusted Root Certification Authorities** as shown in Figure *Select Certificate Store*
- Click **Next**
- Review the details, they should match those in Figure *Completing the Certificate Import Wizard*
- Click **Finish**
- Click **OK**
- Click **OK**

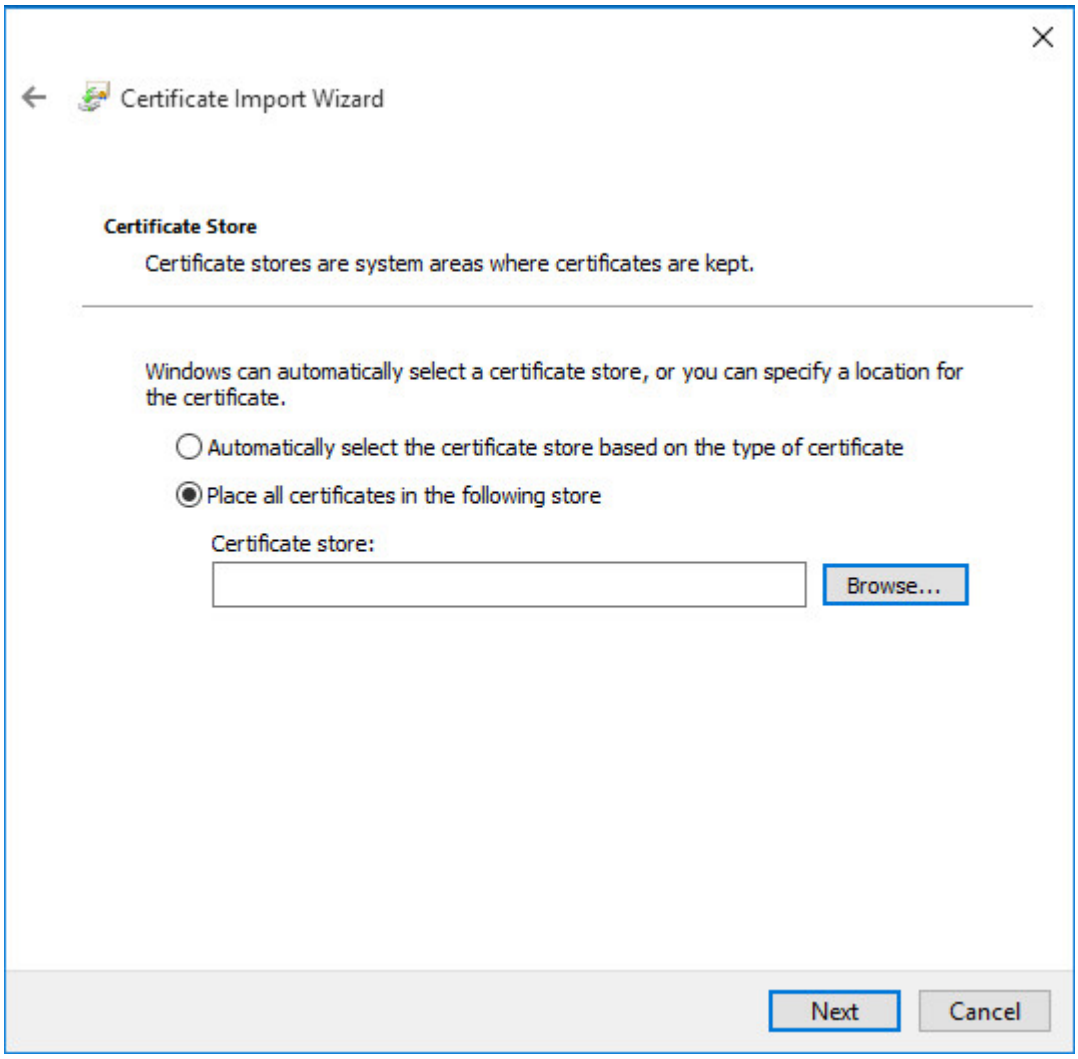

Fig. 15: Certificate Import Wizard - Browse for the Store

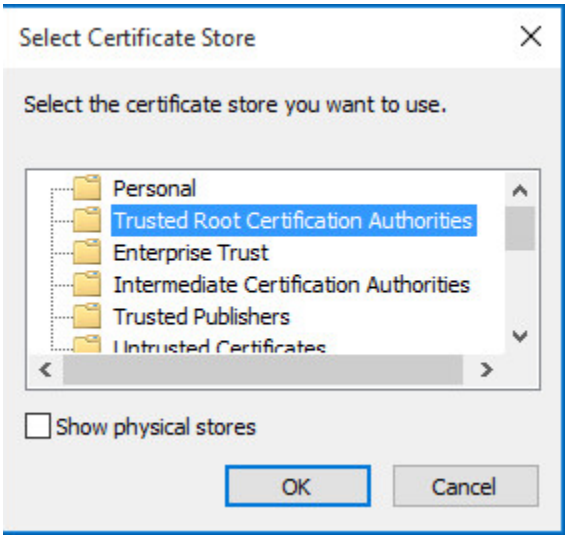

Fig. 16: Select Certificate Store

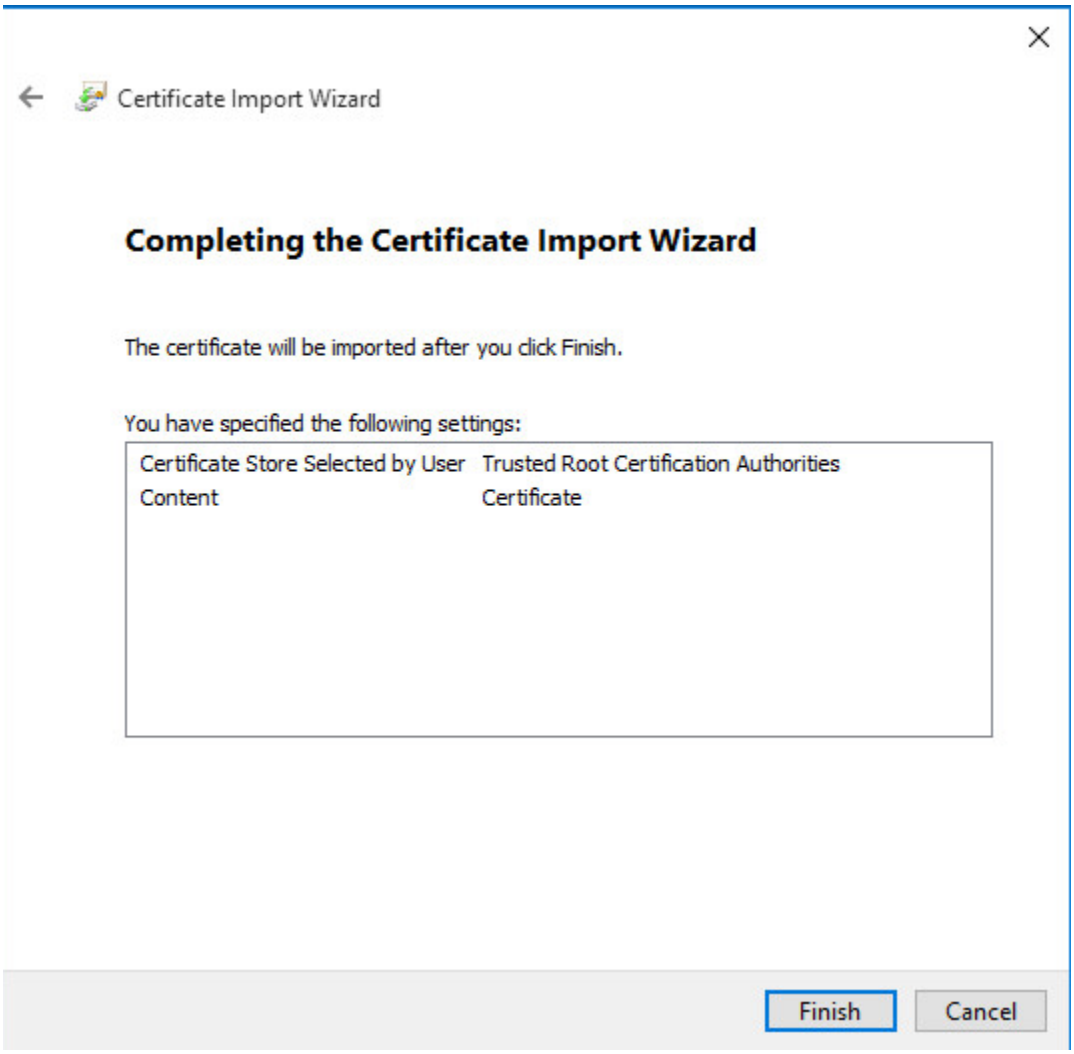

Fig. 17: Completing the Certificate Import Wizard

Import the CA and Client Certificate to the Client (EAP-TLS Only)

This process is only required for EAP-TLS which uses per-user client certificates. For EAP-MSCHAPv2 or EAP-RADIUS, skip to the next section.

- Export client certificate from the firewall and download it to the client PC
  - Navigate to **System > Certificates**, **Certificates** tab
  -  to edit the user certificate
  - Enter an **Export Password** known to the end user which will encrypt the sensitive contents of the archive file
  - Click  **Export PKCS#12** to download a `.p12` file containing the client certificate and key
- Locate the downloaded file on the client PC (e.g. `client1.p12`)
- Double click client certificate `.p12` file
- Select *Current User*
- Click **Next**
- Click **Yes** at the UAC prompt if it appears
- Confirm the proper file is selected
- Click **Next**
- Enter the same **Password** used when exporting the `.p12` file
- Click **Next**
- Click **Next**
- Click **Finish**
- Click **Yes** to confirm adding the certificate data
- Click **OK**

Setup the VPN Connection

Once the certificate has been properly imported it is time to create the client VPN connection. The exact steps will vary depending on the version of Windows being used by the client, but will be close to the following procedure which was perfo

- Open **Network & Internet Settings** on the client PC
- Click **VPN** on the left side
- Click **+ Add a VPN connection**
- Set the fields as follows:

  Example values are shown in Figure *Windows IKEv2 VPN Connection Setup Screen*:

  VPN Provider
  Windows (built-in)

  Connection Name
  `ExampleCo Mobile VPN`

Server Name or Address
`vpn.example.com`

> **Warning:** This value **must** match the contents of the server certificate!

VPN type
IKEv2

Type of sign-in info
User name and password for EAP-MSCHAPv2 or EAP-RADIUS

Certificate for EAP-TLS

Username, Password
Fill in values for this client when using EAP-MSCHAPv2 or EAP-RADIUS. Leave blank to be prompted by Windows.

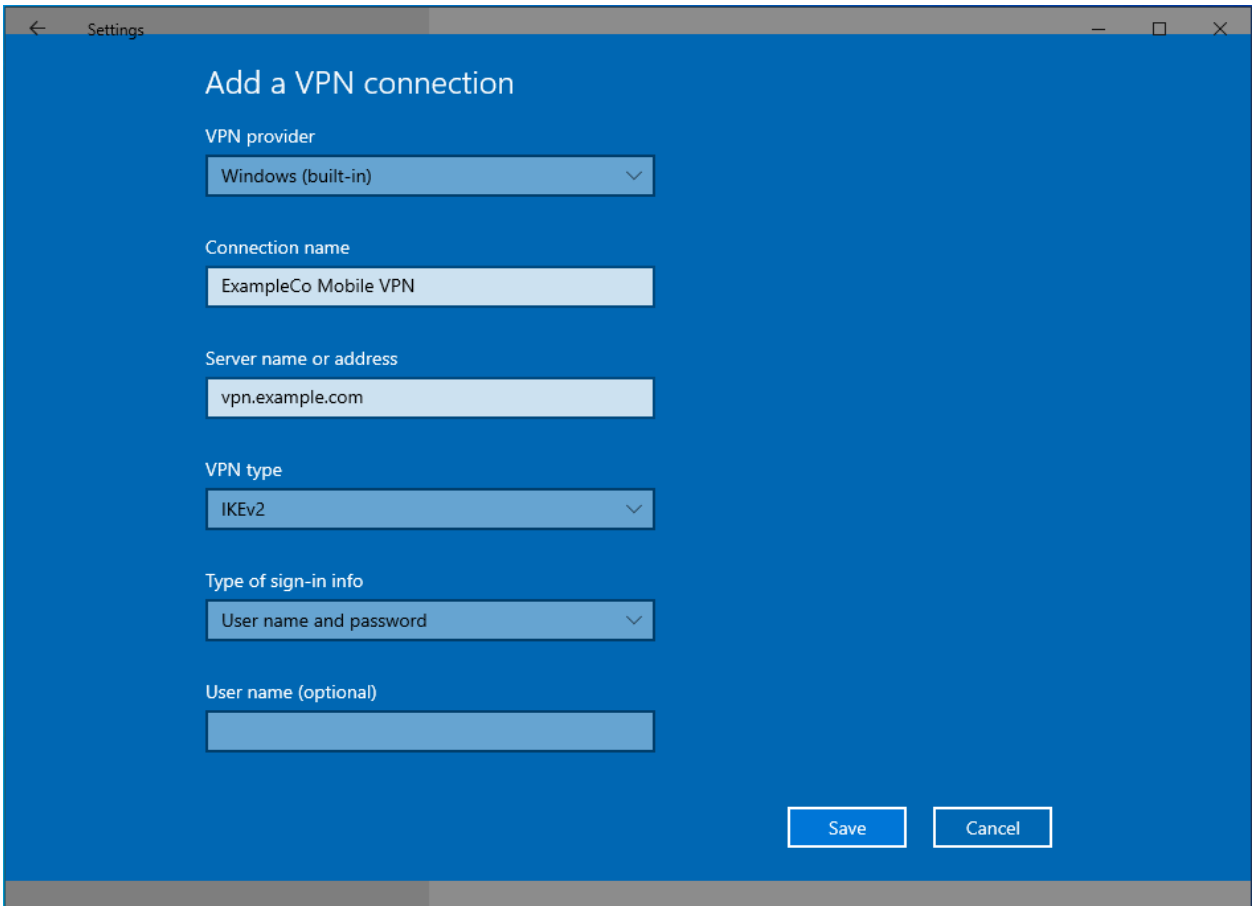

Fig. 18: Windows IKEv2 VPN Connection Setup Screen

- Click **Save**

The connection is now ready to use.

Note: When making the first connection Windows may prompt to approve the server certificate. Check the certificate

and then choose to proceed when prompted.

Disable EKU Check

Windows expects IKEv2 server certificates to contain the IKE intermediate extended key usage attribute (`1.3.6.1.5.5.8.2.2`), among others. Creating a CA and a server certificate in the Certificate Manager will add the correct set of attributes for this usage (*Certificate Settings*).

If the server certificate is created with the wrong settings, or the certificate is generated elsewhere (e.g. via ACME), the certificate may lack these attributes and clients will fail to connect.

To accommodate such certificates, the Extended Key Usage check can be disabled on Windows.

Warning: Disabling this check also disables validation of the certificate common name and SAN fields, so it is potentially dangerous. Any certificate from the same CA could be used for the server when this is disabled, so proceed with caution.

To disable the extended key usage checks:

- Open up **Registry Editor** on the Windows client
- Navigate to the following location in the client registry:

```
HKEY_LOCAL_MACHINE\SYSTEM\CurrentControlSet\services\RasMan\Parameters\
```

- Add a new **DWORD** entry with the following attributes:

  Name
  `DisableIKENameEkuCheck`

  Value
  1

- Reboot the client PC to ensure the new setting is activated

Advanced Windows IPsec settings

With Windows 10 PowerShell cmdlets it is possible to change various advanced settings. The available commands are explained on the Microsoft PowerShell VpnClient module reference.

Routes

Enable split tunneling so that the client does not send all of its traffic across the VPN:

```
PS> Set-VPNconnection -name "ExampleCo Mobile VPN" -SplitTunneling $true
```

Add a VPN connection route to send a specific subnet through the VPN, use:

```
PS> Add-VpnConnectionRoute -ConnectionName "ExampleCo Mobile VPN" -DestinationPrefix 10.
↪4.0.0/24
```

Replace `ExampleCo Mobile VPN` with the actual connection name, and replace `10.4.0.0/24` with the desired destination network. Repeat the add command for each network to route over the VPN.

See also:

For more information, see PowerShell VpnClient module reference

35.25.2 Configuring IPsec IKEv2 Remote Access VPN Clients on Android

---

Note: Android considers using a VPN an action that must be secure. When activating any VPN option the OS will force the user to add a lock method to the device if one is not already present. It does not matter which type of lock is chosen (PIN lock, Pattern lock, Password, etc) but it will not allow a VPN to be configured until a secure lock has been added.

On Android devices with Face lock, that is not available as a secure lock type on its own.

There are two methods to configuring IKEv2 on Android: Natively on Android 11.x and later, or using the strongSwan app from the Play Store.

Native IKEv2 on Android

Android 11.x and later now include several IKEv2 client options compatible with mobile IPsec on pfSense® software. This example covers EAP-MSCHAPv2 which also works with EAP-RADIUS.

Note: The settings below are from pure Android 11.x. These exact settings may not present on all Android devices, depending on the Android version and changes made by the OEM.

Import the Server CA

To validate the server, the client needs to know the server certificate CA. The Android IKEv2 client will only validate against CA entities imported by the user.

Note: Though this validation is optional it is the best practice as otherwise the client cannot verify it is connecting to the correct server.

Warning: Installing a self-signed root CA into Android in this manner carries some danger as the CA could also be used to impersonate other servers. The danger is lower since this is controlled by firewall administrators but the warnings presented when this is done may still confuse and worry end users.

If this is unacceptable, use the strongSwan application instead. It can validate against an existing root CA as well as validating a CA without installing it into the operating system trust store.

- Copy the CA certificate to the device
- Swipe down twice from the top of the screen
- Tap the **Settings** cog
- Tap **Security**, **Encryption & Credentials**

- Tap **Install a certificate**
- Tap **CA certificate**
- Read the warning text
- Tap **Install anyway** to continue
- Locate and tap the CA certificate which was copied to the device

Setup the VPN Connection

- Swipe down twice from the top of the screen
- Tap the **Settings** cog
- Tap **Networks & Internet**, **Advanced**, **VPN**
- Tap +
- Enter the connection settings as follows:

  Name
  `ExampleCo Mobile VPN` or another suitable description

  Type
  IKEv2/IPsec MSCHAPv2

  Server Address
  The address of the server.

  Note: This must match a value in the server certificate. For example, a hostname or IP address in a certificate SAN entry.

  IPsec Identifier
  The identifier on the EAP pre-shared key for this user (e.g. a username or e-mail address)

  IPsec CA Certificate
  Select the imported CA (optional, but the best practice)

  Username
  The identifier for this user again.

  Password
  The EAP key value associated with the identifier for this user.

- Tap **Save**

Connecting and Disconnecting

To Connect:

- Swipe down twice from the top of the screen
- Tap the **Settings** cog
- Tap **Networks & Internet**, **Advanced**, **VPN**
- Tap the name of the VPN
- Tap **Connect**

Android displays a key icon in the notification bar near the network status icons and clocks while a VPN is connected.

To Disconnect:

- Swipe down twice from the top of the screen
- Tap the **Settings** cog
- Tap **Networks & Internet**, **Advanced**, **VPN**
- Tap the name of the VPN
- Tap **Disconnect**

strongSwan App on Android

Before starting, install the strongSwan app from the Play Store:

Setup the VPN Connection

- Copy the CA Certificate to the device
- Open the strongSwan app
- Import the CA:
  - Tap the settings icon (Three vertical dots in the upper right)
  - Tap **CA Certificates**
  - Tap the settings icon (Three vertical dots in the upper right)
  - Tap **Import Certificate**
  - Locate the CA Certificate copied earlier and tap it.
- Tap **Add VPN Profile**
- Enter the address of the firewall as the **Gateway** (e.g. `vpn.example.com`)
- Select *IKEv2 EAP (Username/Password)* for the **Type**
- Enter the **Username**
- Enter the **Password** to have it be remembered or leave it blank to prompt for the password on each connection.
- Check Select automatically under CA Certificate
- Enter a **Profile Name** (optional, if left blank, the gateway address will be used)
- Compare the settings to Figure *Android strongSwan Client Settings*

Connecting and Disconnecting

To Connect:

- Open the strongSwan app
- Tap the desired VPN
- Check **I trust this application** at the security prompt as shown in *Android strongSwan Client Settings*
- Tap OK

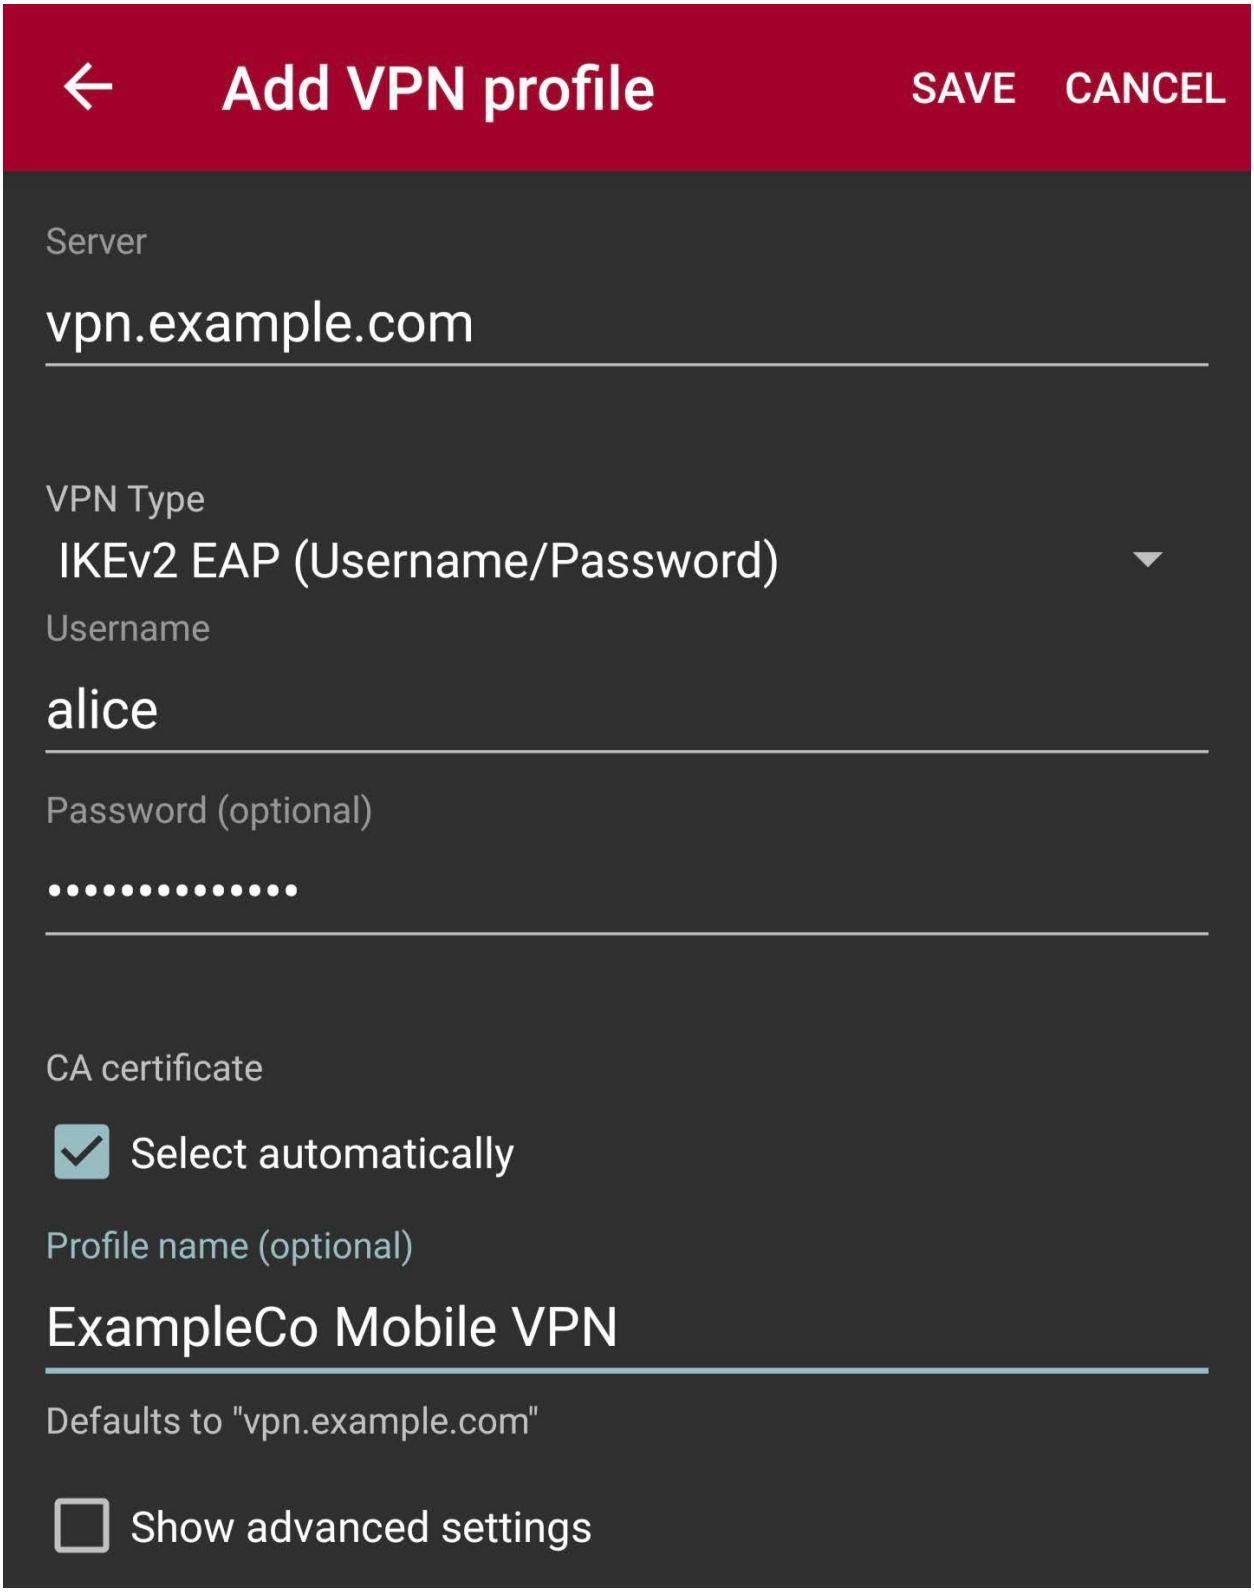

Fig. 19: Android strongSwan Client Settings

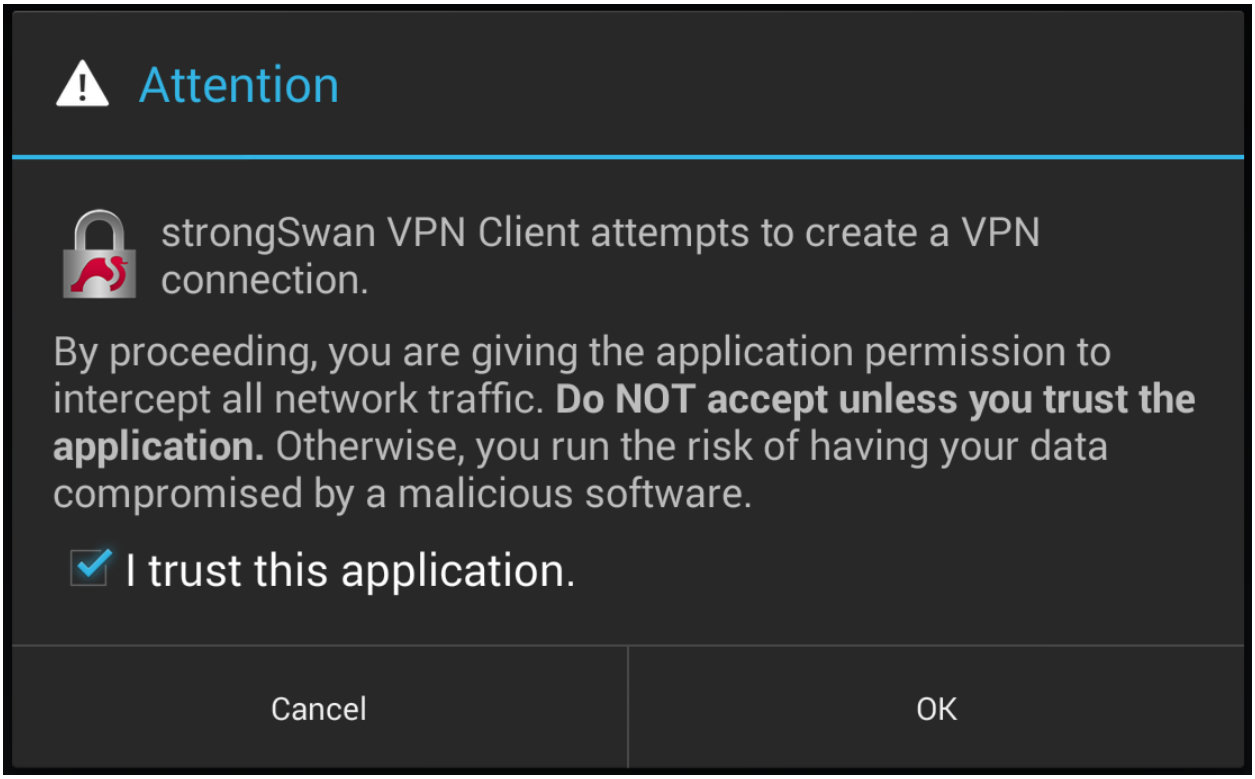

Fig. 20: Android strongSwan Client Settings

To Disconnect:

- Swipe down from the top notification bar
- Tap the strongSwan entry in the notification list
- Tap **Disconnect**

Alternately:

- Open the strongSwan app
- Tap **Disconnect** on the desired VPN

35.25.3 Configuring IPsec IKEv2 Remote Access VPN Clients on macOS

It is possible to configure an IKEv2 type VPN manually in the macOS GUI without needing a VPN Profile configuration file. Basic configuration for IKEv2 is integrated into the network management settings the same as other connections but it is quite limited.

Tip: The *ipsec-profile-wizard* package on pfSense Plus software generates a set of files which can automatically import VPN settings into Apple macOS and iOS (**VPN > IPsec Export: Apple Profile**) as well as Windows clients (**VPN > IPsec Export: Windows**).

This feature allows much greater flexibility in settings as it will configure clients to match what is set on the server specifically rather than making the server accommodate the default settings on various operating systems.

This package is exclusive to pfSense Plus software and is not available on the community edition.

If the package is not already installed, add it using the *Package Manager*.

Warning: The best practice is to use a VPN profile, such as from the Apple Configurator or *IPsec Export Package*. A profile requires less configuration on the client and can use more secure and faster performing options than the client will attempt by default. Additionally, without using a profile it may not be possible to create a mobile IPsec configuration which can natively support different client types.

Import the CA Certificate into macOS

The VPN Server CA Certificate must be imported before a client can connect.

- Copy the CA Certificate to the macOS system
- Double click the CA Certificate File in Finder (Figure *macOS Certificate File in Finder*), which opens Keychain Access

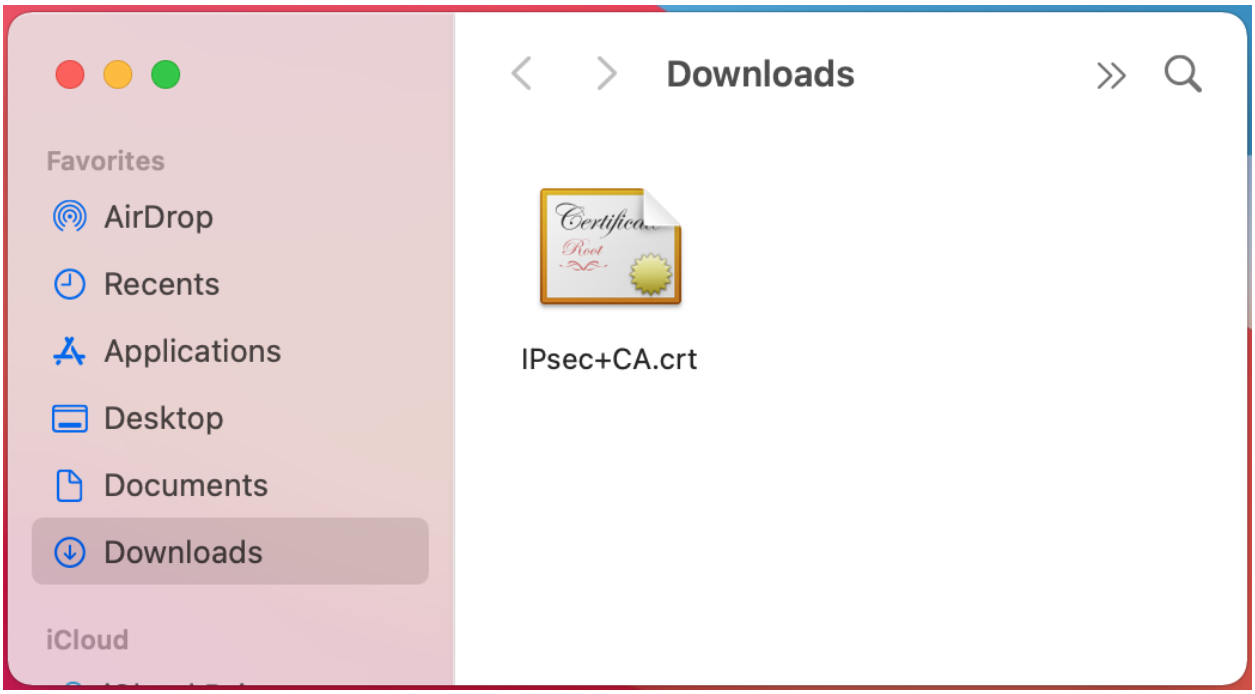

Fig. 21: macOS Certificate File in Finder

- Set **Keychain** to *System* on the **Add Certificates** dialog
- Click **Add**

Note: If this dialog does not appear and the CA is added into another keychain, locate it in Keychain Access and drag it into the **System** keychain.

- Locate the imported certificate under **System**, **Certificates** as shown in Figure *macOS Keychain Access System Certificate List*
- Click the Certificate

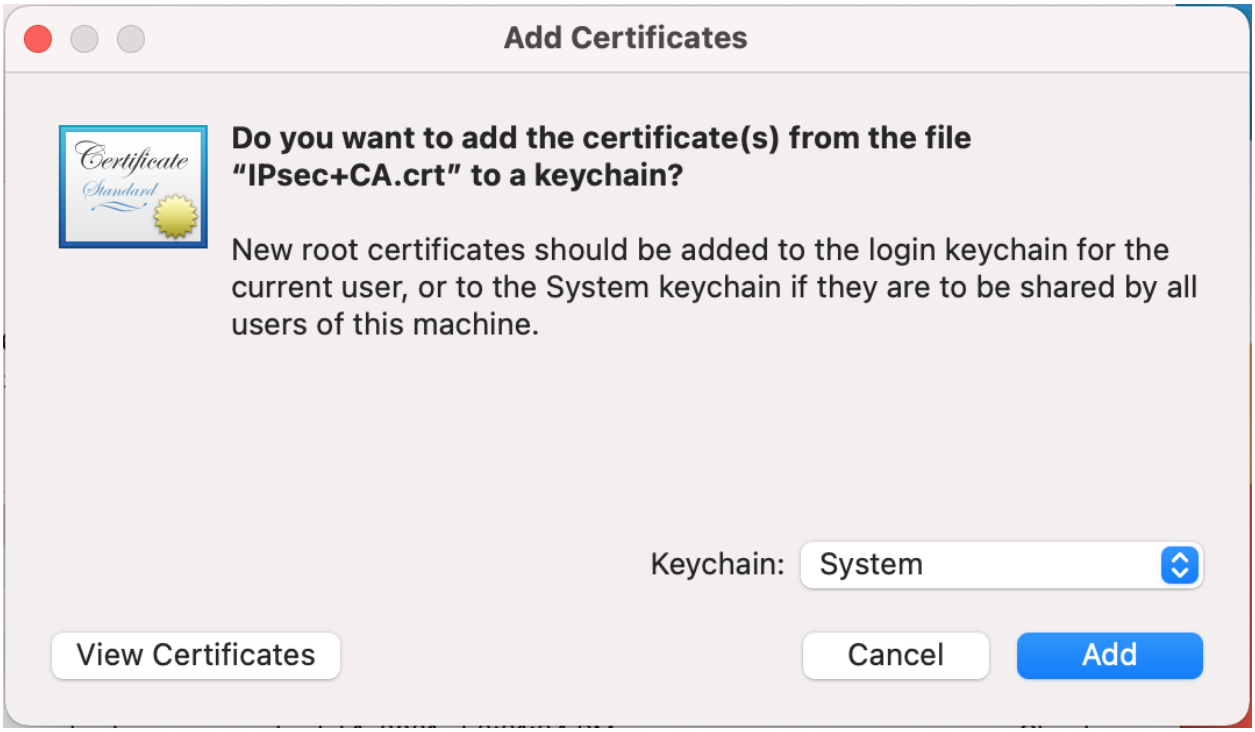

Fig. 22: macOS Keychain Access Add Certificate

- Click **File > Get Info**
- Expand **Trust**
- Set **When using this certificate** to *Always Trust* as shown in Figure *macOS Certificate Trust Settings*
- Click the red close button to close the certificate info window

  This triggers an authentication prompt to allow the change.
- Enter the login credentials and click **Update Settings**
- Quit Keychain Access

The certificate is now located in System Certificates and has been marked as trusted so it can be used for the VPN.

Setup the VPN Connection

- Open System Preferences
- Click **Network**
- Click the lock icon and enter credentials to make changes if the settings have not already been unlocked
- Click + to add a new VPN entry as shown in Figure *macOS Add Network Button*
- Select *VPN* for the **Interface**
- Select *IKEv2* for the **VPN Type** (default)
- Set **Service Name** to a description for the VPN (e.g. `ExampleCo Mobile VPN`) to complete the form, which will look similar to Figure *macOS Create VPN Prompt*
- Click **Create**

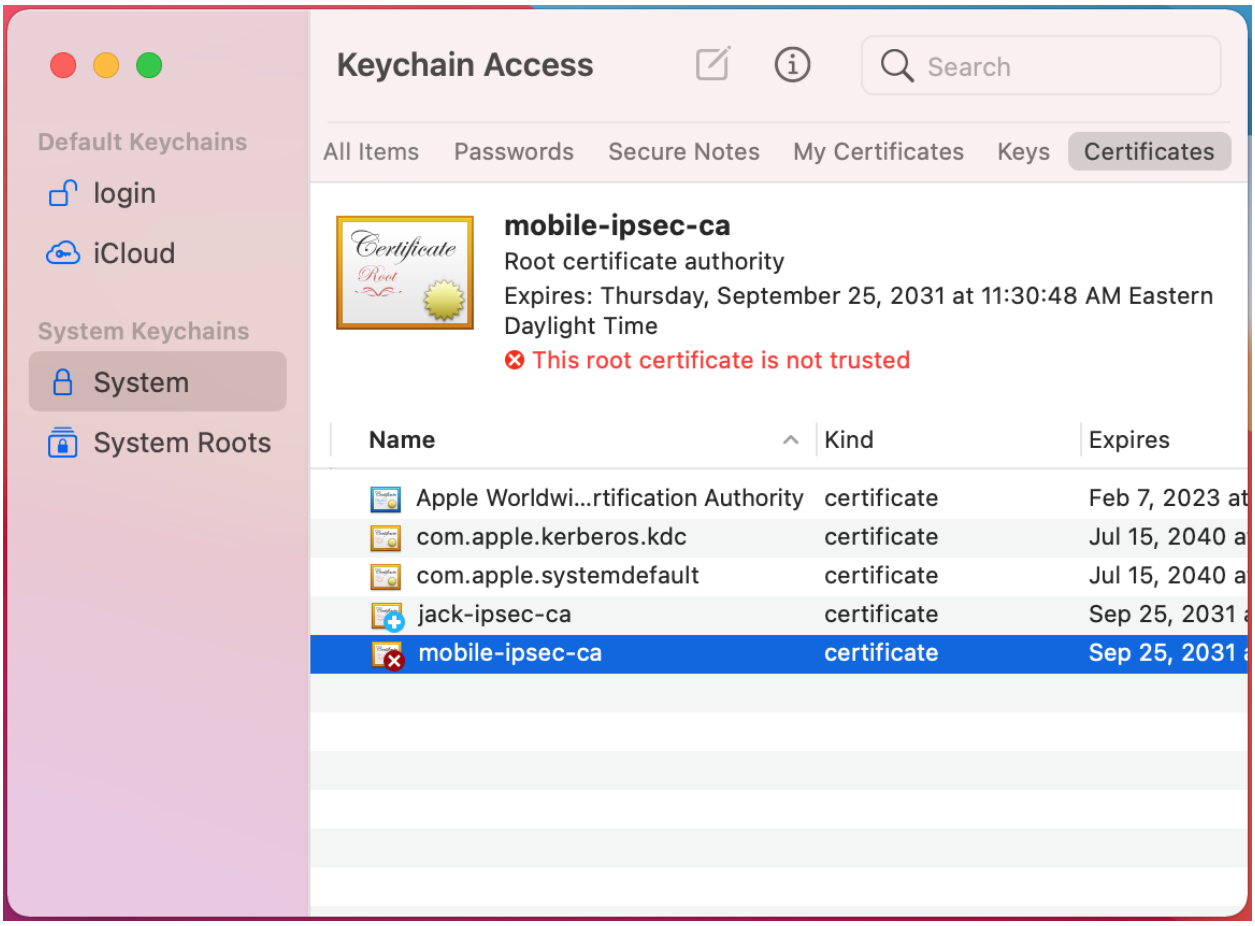

Fig. 23: macOS Keychain Access System Certificate List

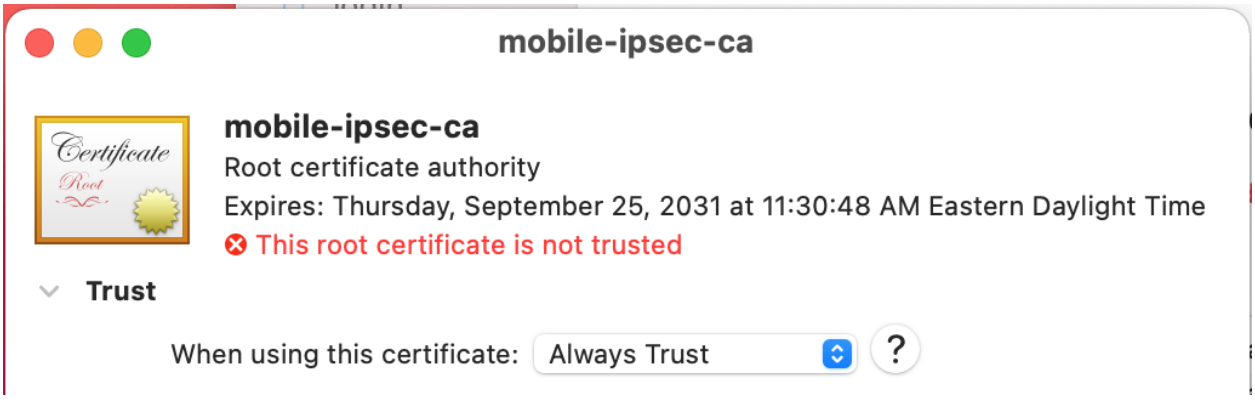

Fig. 24: macOS Certificate Trust Settings

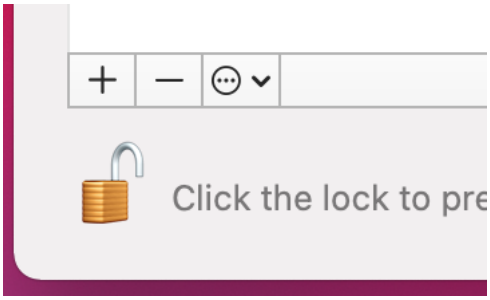

Fig. 25: macOS Add Network Button

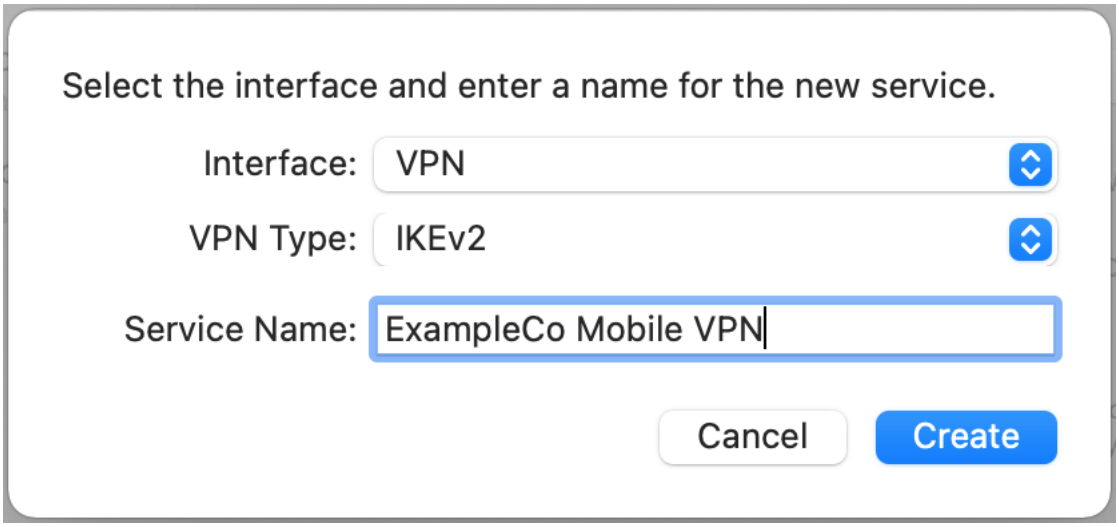

Fig. 26: macOS Create VPN Prompt

- Enter the hostname of the firewall in DNS as the **Server Address**
- Enter the hostname of the firewall again in **Remote ID**

Note: This must match the server certificate's Common Name and SAN entry.

- Leave **Local ID** blank, the settings will now look like Figure *macOS IKEv2 VPN Settings*

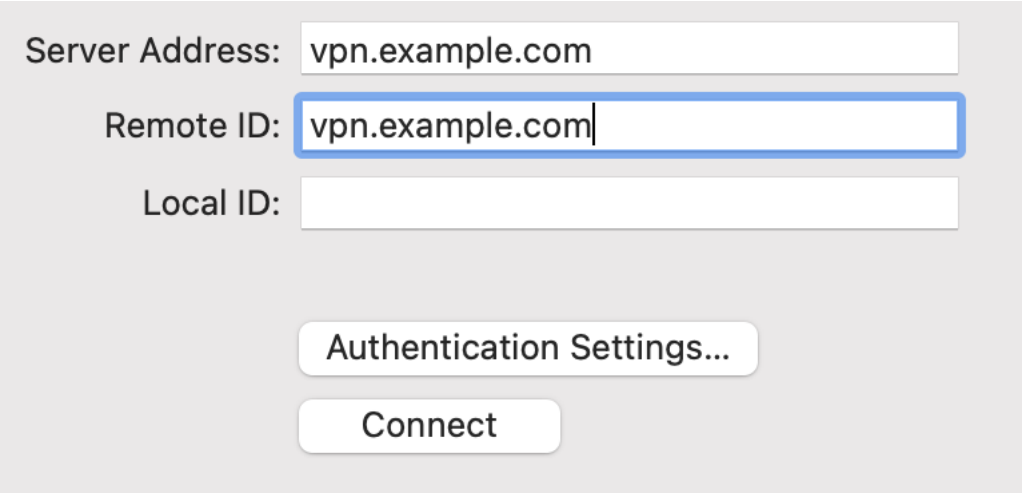

Fig. 27: macOS IKEv2 VPN Settings

- Click **Authentication Settings**
- Select **Username**
- Enter the **Username** and **Password** as shown in Figure *macOS IKEv2 VPN Authentication Settings*

Note: With EAP-MSCHAPv2 the **Username** is the **Identifier** configured for the user's entry on the **Pre-Shared Keys** tab under **VPN > IPsec**. With EAP-RADIUS this would be the username set on the RADIUS server.

- Check **Show VPN status in the menu bar** (if desired)
- Click **Apply**

Connecting and Disconnecting

Managing the connection can be done multiple ways. The first method is to click **Connect** or **Disconnect** on the VPN entry in Network settings. The second, easier method is to check **Show VPN Status in the menu bar** in the VPN settings and then manage the connection from that icon, as shown in Figure *macOS VPN Status Menu*.

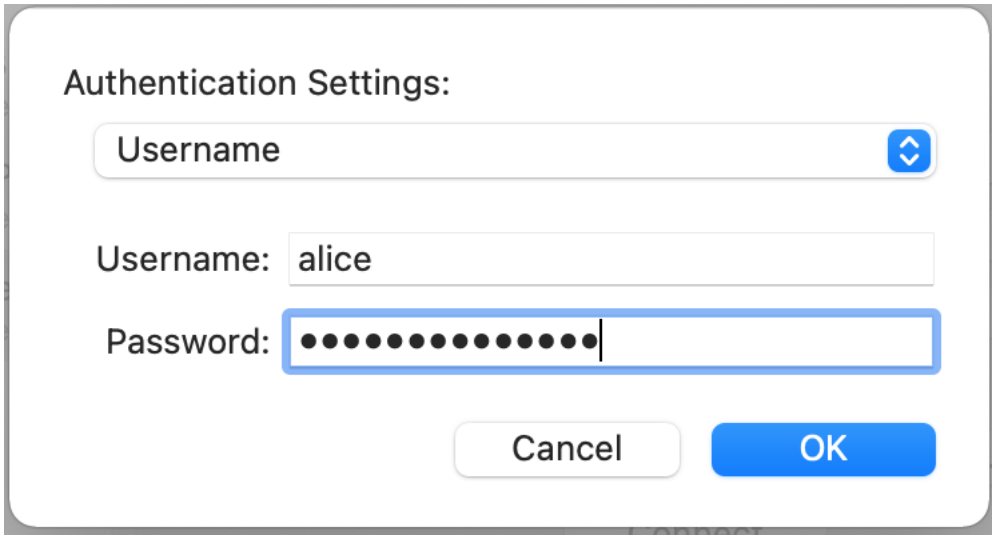

Fig. 28: macOS IKEv2 VPN Authentication Settings

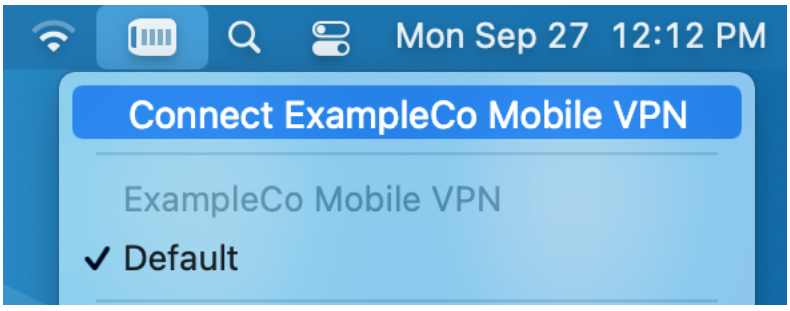

Fig. 29: macOS VPN Status Menu

35.25.4 Configuring IPsec IKEv2 Remote Access VPN Clients on iOS

As of version 9, iOS has built-in support for configuring a basic IKEv2 connection without a VPN Profile.

Tip: The *ipsec-profile-wizard* package on pfSense Plus software generates a set of files which can automatically import VPN settings into Apple macOS and iOS (**VPN > IPsec Export: Apple Profile**) as well as Windows clients (**VPN > IPsec Export: Windows**).

This feature allows much greater flexibility in settings as it will configure clients to match what is set on the server specifically rather than making the server accommodate the default settings on various operating systems.

This package is exclusive to pfSense Plus software and is not available on the community edition.

If the package is not already installed, add it using the *Package Manager*.

Warning: The best practice is to use a VPN profile, such as from the Apple Configurator or *IPsec Export Package*. A profile requires less configuration on the client and can use more secure and faster performing options than the client will attempt by default. Additionally, without using a profile it may not be possible to create a mobile IPsec configuration which can natively support different client types.

Import the CA to the iOS Device

As with other clients, the CA certificate must be installed on the client. Importing the CA Certificate to the client device is a relatively easy process. The first step is to get the CA Certificate to the client device. The easiest way to accomplish this is via e-mail as shown in Figure *iOS Mail Client Receiving CA Certificate*

To install the certificate from e-mail:

- Send the CA Certificate only (not the key) to an e-mail address reachable from the client device
- Open the Mail app on the client device
- Open the message containing the CA Certificate
- Tap the attachment to install the CA Certificate and the **Install Profile** prompt will show as seen in *iOS CA Certificate Install Profile Prompt*

  Note: Newer versions of iOS may copy the CA to an entry under the Settings app for review before it can be installed. The device will instruct the user how to proceed when this happens. Typically this involves opening the Settings app and tapping **Profile Downloaded**.

- Tap **Install** in the upper right, and a warning screen is presented as shown in *iOS CA Certificate Install Warning*
- Tap **Install** in the upper right once more to confirm and then one final prompt is presented as seen in *iOS CA Certificate Confirmation Prompt*
- Tap **Install** at the confirmation prompt and the CA Certificate is now stored as a trusted entry.

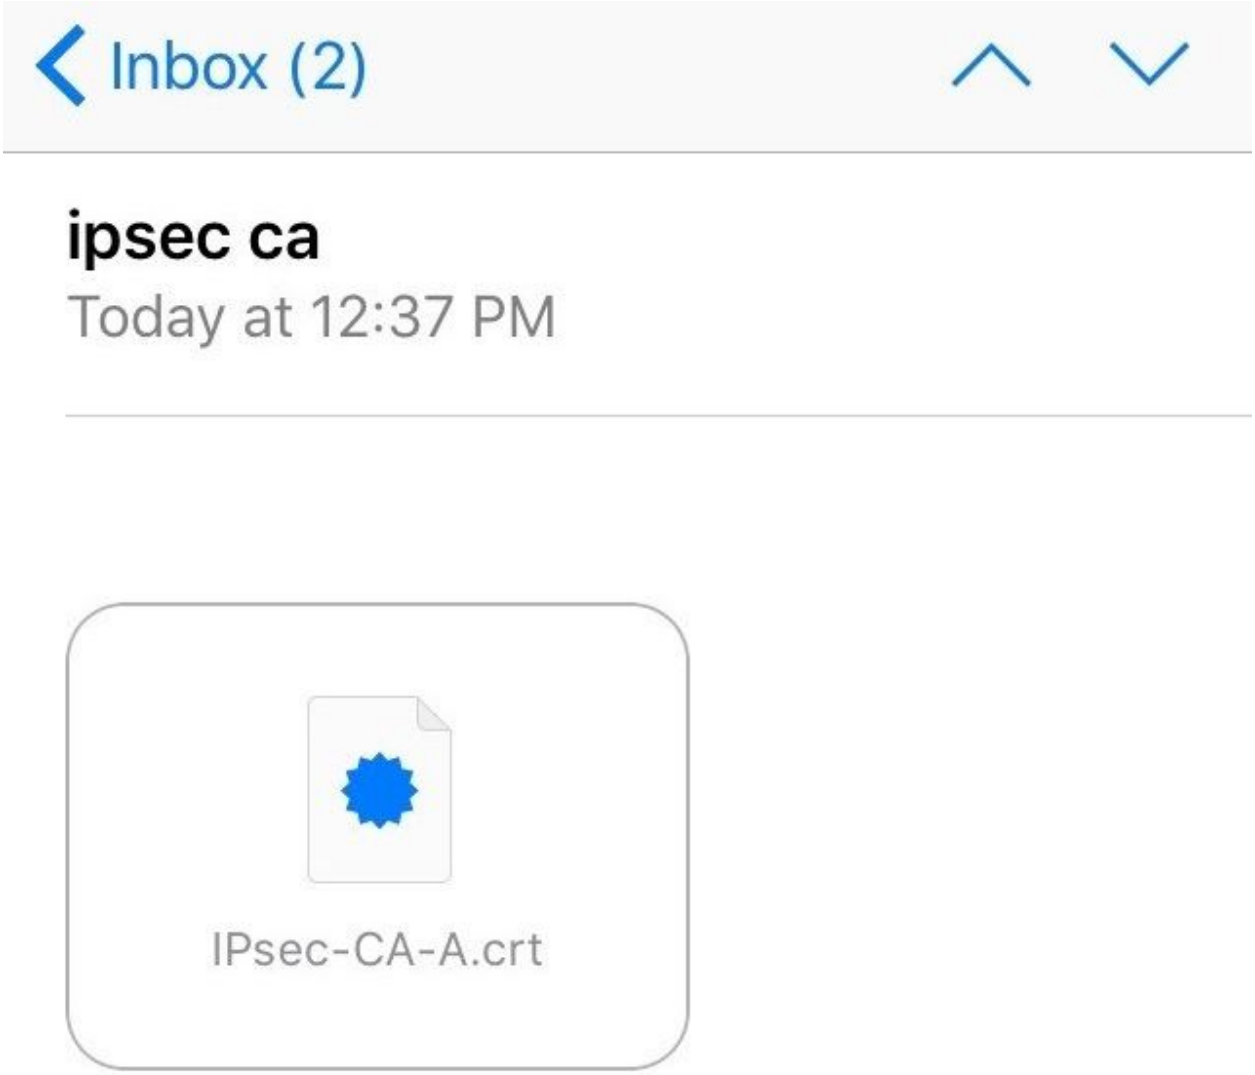

Fig. 30: iOS Mail Client Receiving CA Certificate

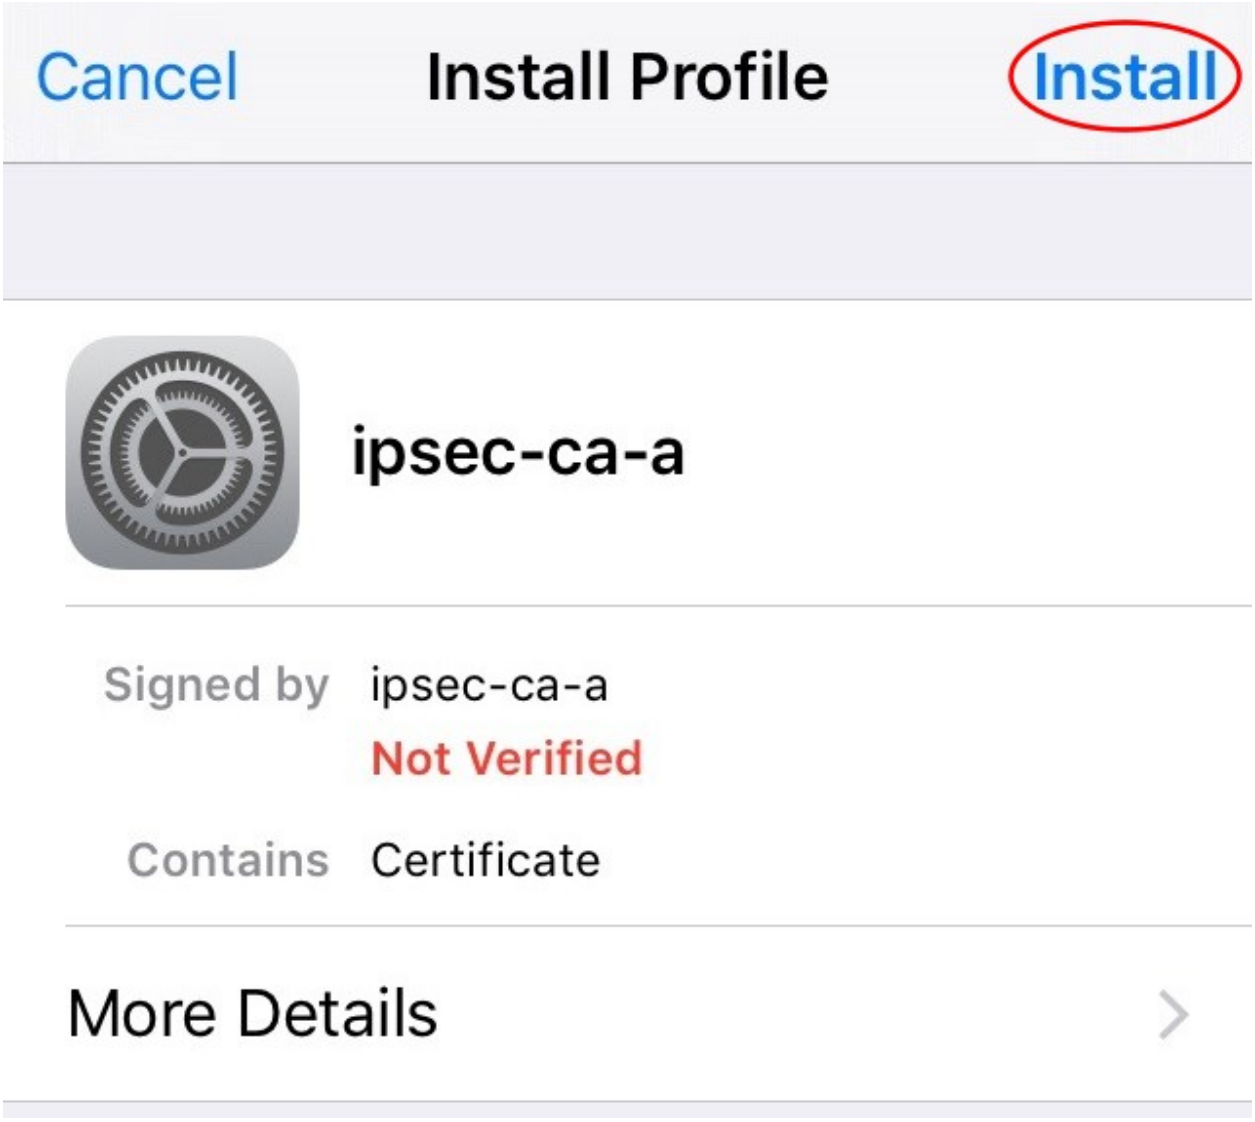

Fig. 31: iOS CA Certificate Install Profile Prompt

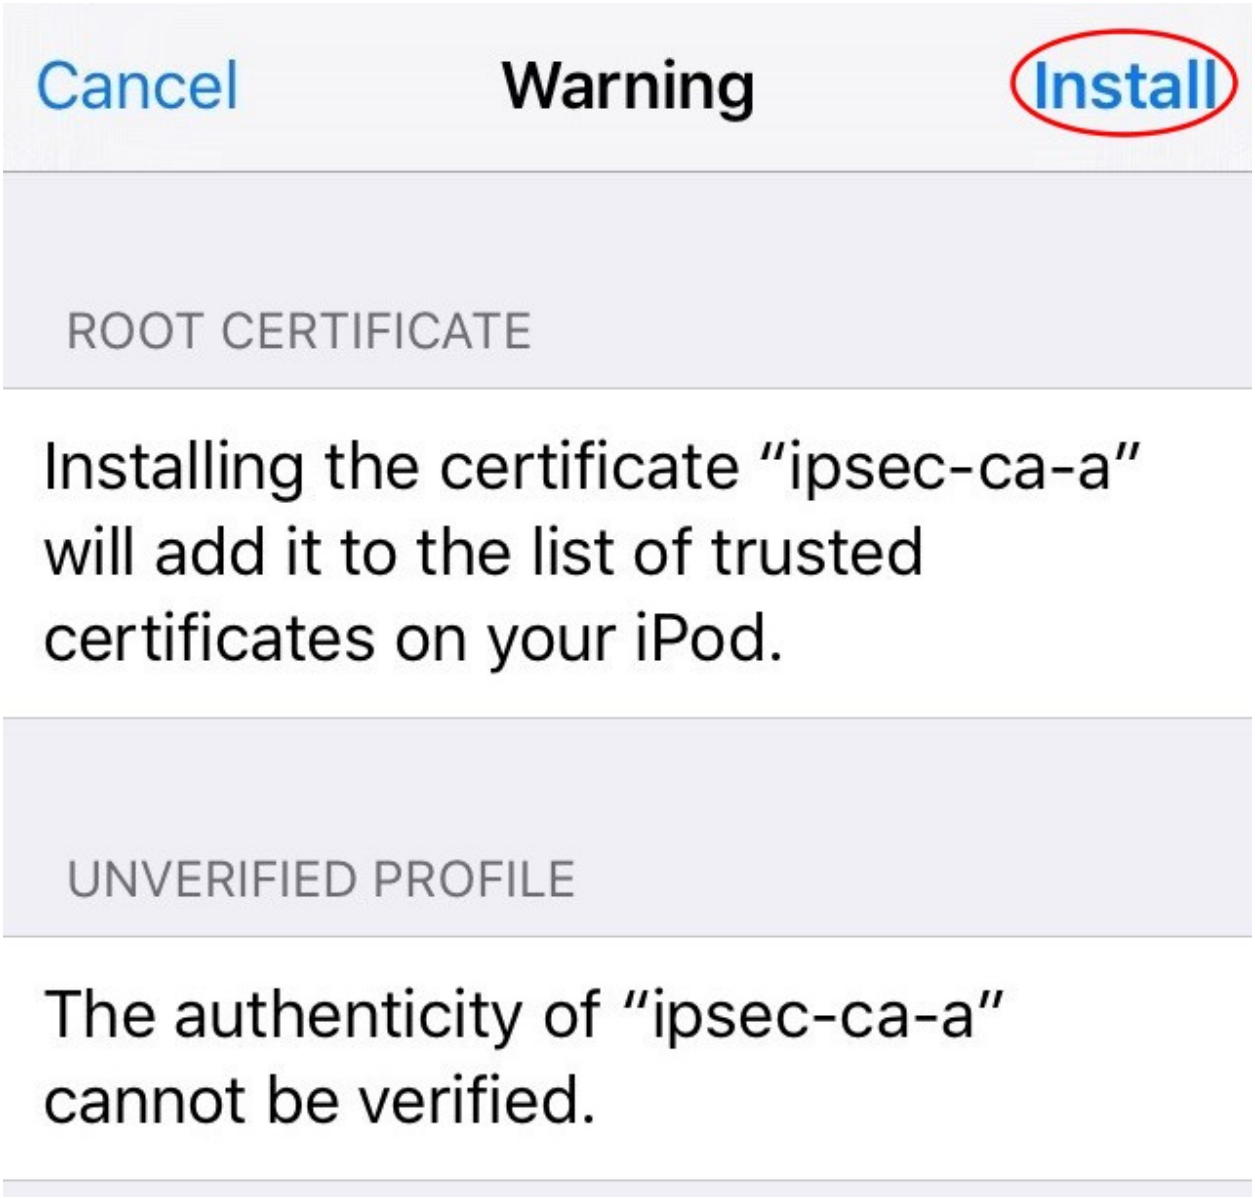

Fig. 32: iOS CA Certificate Install Warning

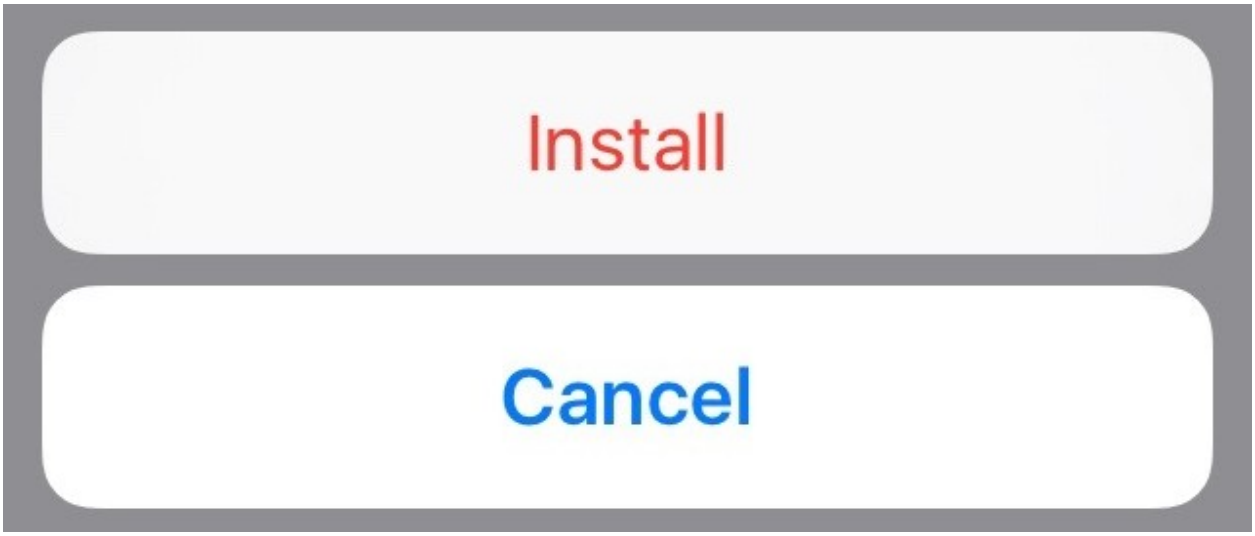

Fig. 33: iOS CA Certificate Confirmation Prompt

Setup the VPN Connection

Once the CA Certificate has been installed, a VPN entry must be configured:

- Open **Settings**
- Tap **VPN**
- Tap **Add VPN Configuration**
- Set **Type** to *IKEv2* (default)
- Fill in the settings as follows:

  Description
  A name for the VPN connection, `ExampleCo VPN`

  Server
  The hostname of the firewall in DNS

  Note: This must match a SAN value in the server certificate.

  Remote ID
  The hostname of the firewall again

  Note: This must match a SAN value in the server certificate.

  Local ID
  Leave blank

  User Authentication
  Username

  Username
  The username for this user.

Note: With EAP-MSCHAPv2 the **Username** is the **Identifier** configured for the user entry on the **Pre-Shared Keys** tab under **VPN > IPsec**. With EAP-RADIUS this would be the username set on the RADIUS server.

Password
The password for this user.

- Tap **Done** to complete the VPN entry. When complete, it looks similar to *iOS IKEv2 Client Settings*

Connecting and Disconnecting

The VPN may be connected or disconnected by visiting the VPN entries under **Settings**. This varies a bit but typically shows in at least two places:

- Settings > VPN
- Settings > General > VPN

The entry directly under **Settings** appears near the top of the list with the other Network entries (Airplane mode, Wi-Fi, and Bluetooth) once there is at least one VPN connection present.

Once in the VPN list, the VPN entry must be selected (shows a checkmark next to its entry) and then the slider may be moved to the "On" position to connect.

35.25.5 Configuring IPsec IKEv2 Remote Access VPN Clients on Ubuntu

This document demonstrates how to configure an IKEv2 EAP-MSCHAPv2 or EAP-RADIUS connection on Ubuntu. This procedure was performed on Linux Mint 20.2 but the procedure is identical on most recent similar distributions.

Before starting, install `network-manager-strongswan` and `strongswan-plugin-eap-mschapv2` using `apt-get` or a similar mechanism.

Setup the VPN Connection

- Copy the CA Certificate for the VPN from the firewall to the workstation
- Click the **Network Manager** icon in the notification tray by the clock

Note: The icon varies depending on the type of network in use.

- Click **Network Connections**
- Click **Add**
- Select *IPsec/IKEv2 (strongswan)* under **VPN** as shown in *Adding an IKEv2 VPN on Ubuntu*

Note: If the option is not present, double check that `network-manager-strongswan` is installed.

- Click **Create**
- Select the **VPN** Tab
- Set the fields as follows:

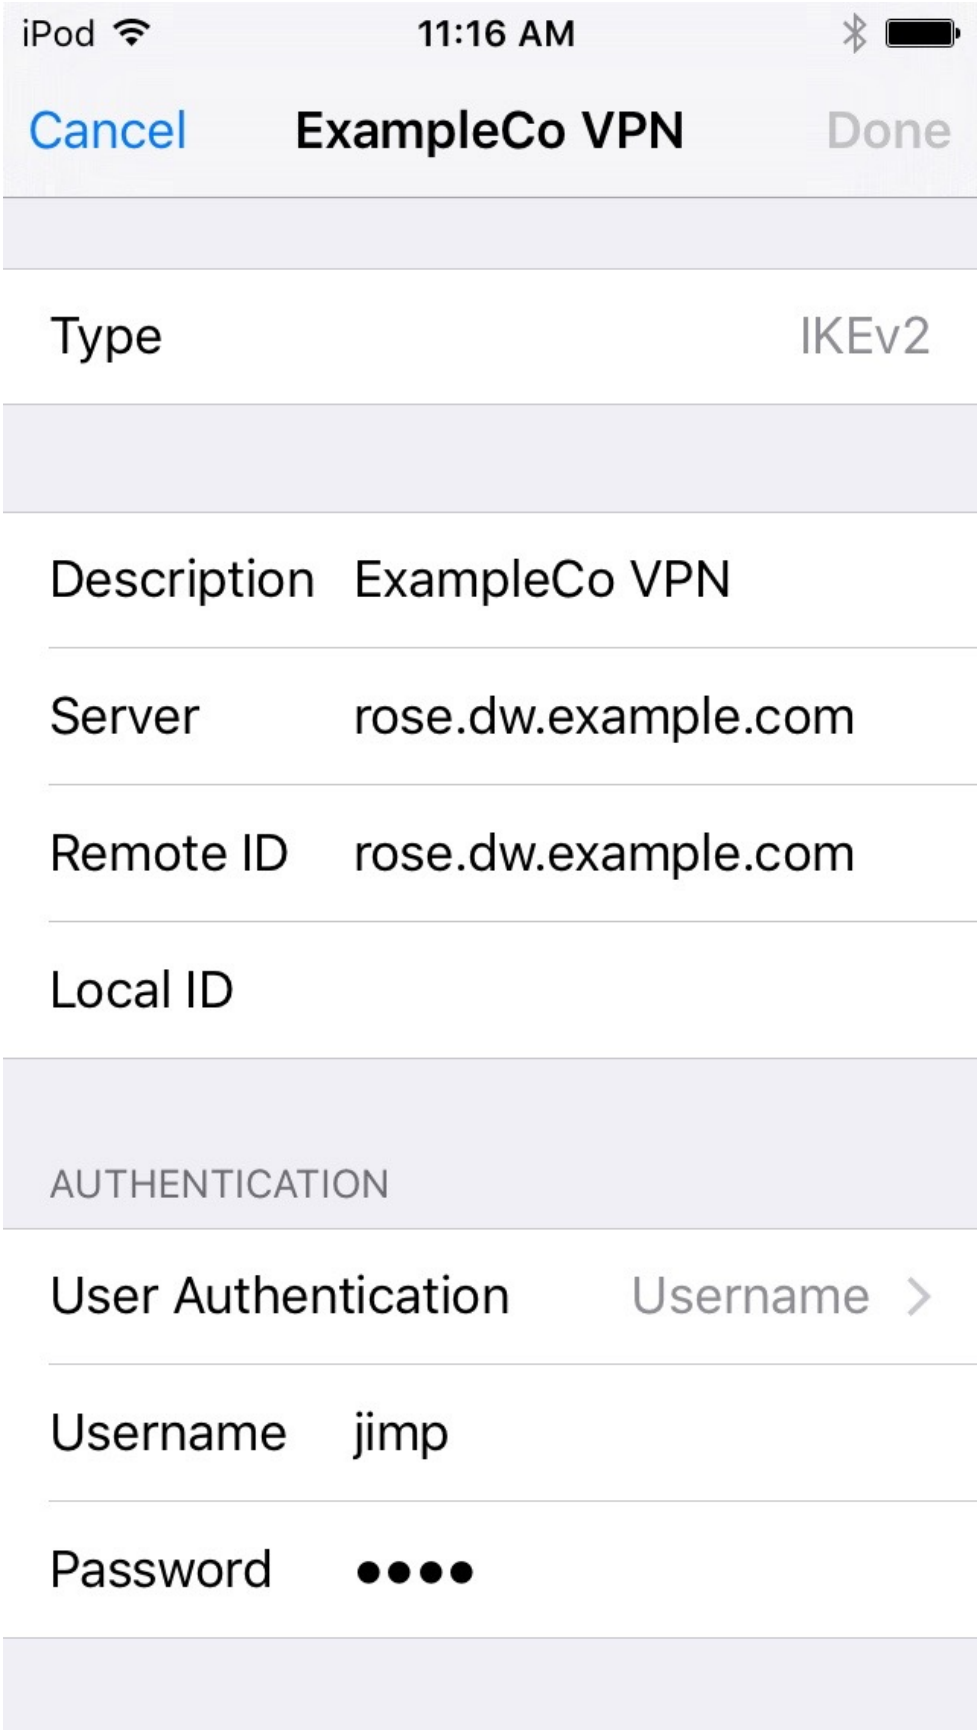

Fig. 34: iOS IKEv2 Client Settings

Fig. 35: iOS VPN List

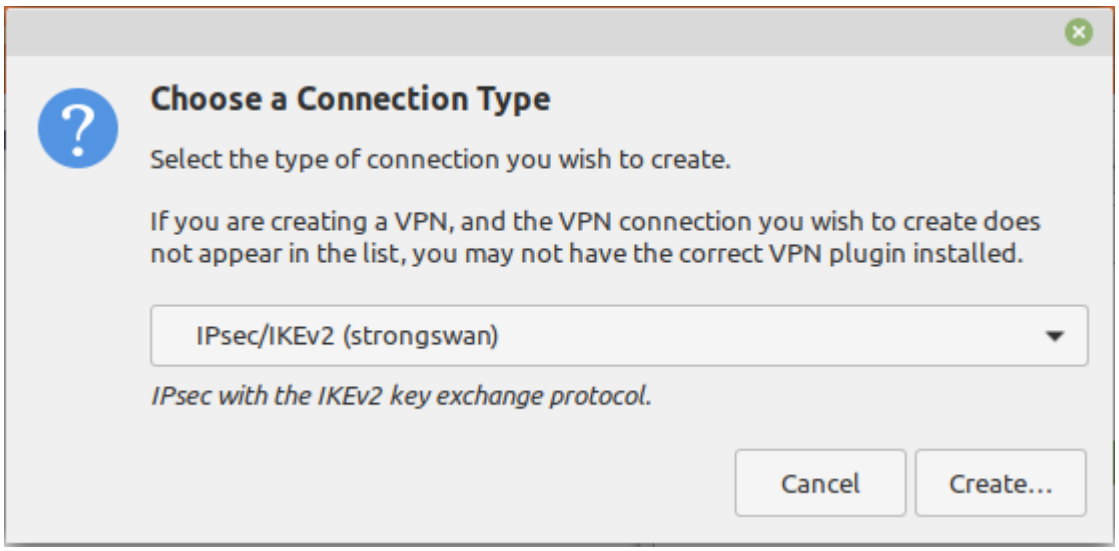

Fig. 36: Adding an IKEv2 VPN on Ubuntu

Connection Name
A name for this connection, `ExampleCo Mobile VPN`.

Address
The **Address** of the firewall, `vpn.example.com`.

Certificate
Click the field and browse to find the downloaded CA Certificate file.

Authentication
EAP

Username
The username to be used for this connection, `alice`.

Password
Click the icon in the **Password** field and select the desired action. The default behavior is to ask for the password on every connection.

To store the password, pick one of the options which allow storing the value then set it in this field.

Request an inner IP address
Checked

- Compare the settings to those shown in figure *Ubuntu VPN Client Settings*
- Click **Save**
- Click **Close**

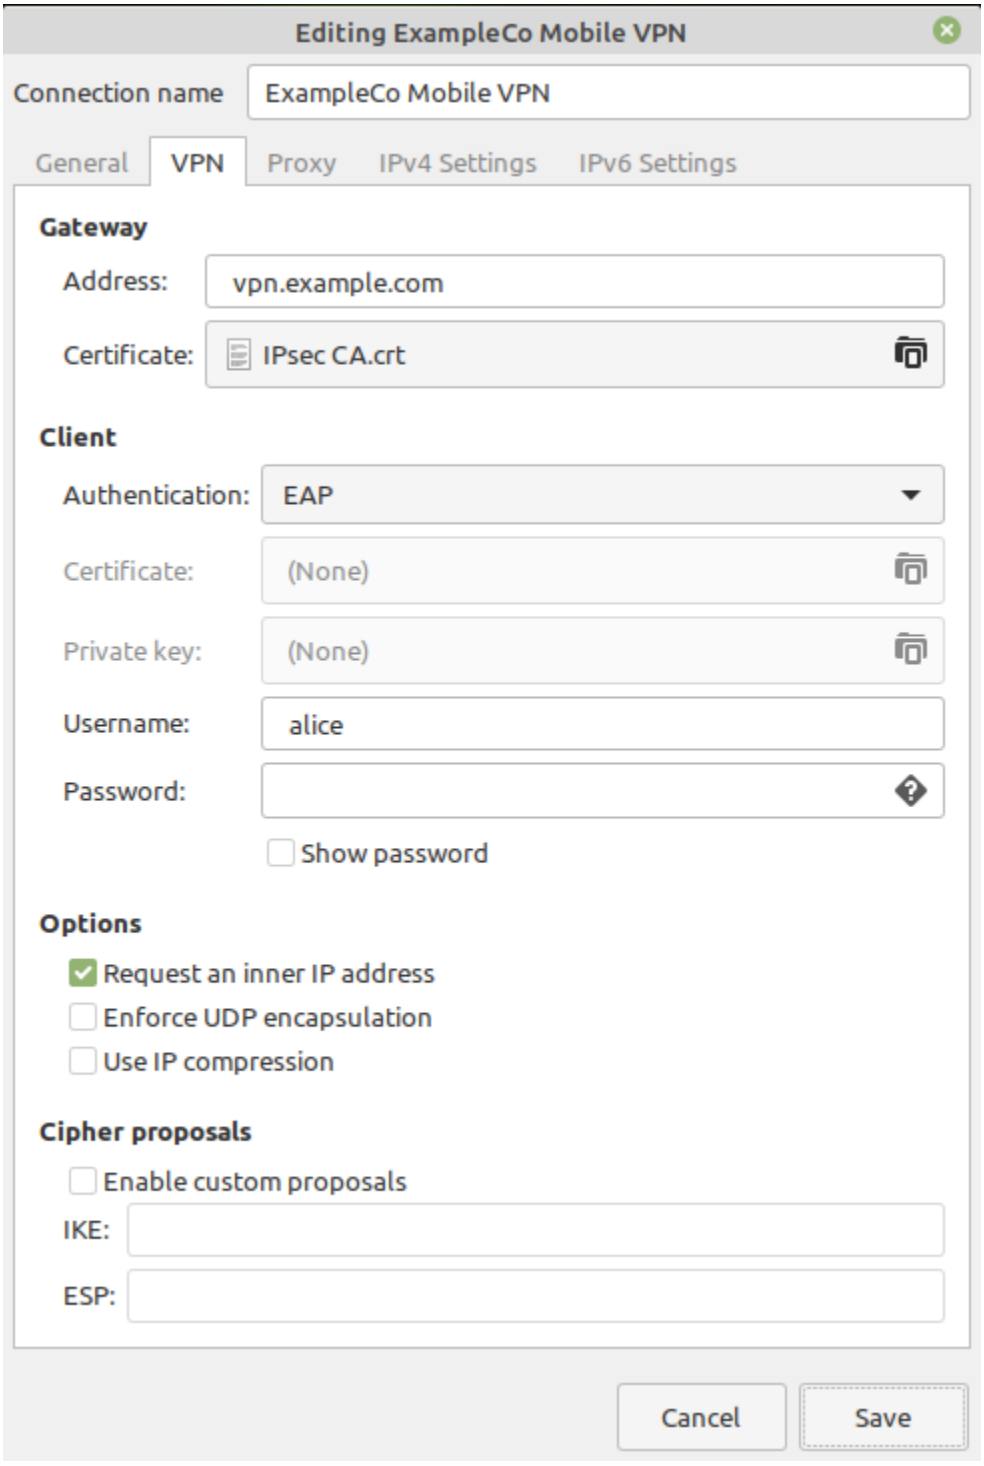

Fig. 37: Ubuntu VPN Client Settings

Connecting and Disconnecting

To Connect:

- Click the **Network Manager** icon
- Click the VPN Name or click **VPN Connections** to move the slider to the *On (1)* position

---

Note: If a password prompt does not appear, the network manager service may need restarted or a reboot of the workstation may be necessary.

To Disconnect:

- Click the **Network Manager** icon
- Click **VPN Connections** to move the slider to the *Off (0)* position

35.26 IPsec Remote Access VPN Example Using IKEv2 with EAP-MSCHAPv2

35.26.1 IKEv2 Server Configuration

There are several components to the server configuration for mobile clients:

- Creating a certificate structure for the VPN
- Configuring the IPsec **Mobile Client** settings
- Creating the phase 1 and phase 2 for the client connection
- Adding IPsec firewall rules.
- Create user credentials for the VPN

IKEv2 Certificate Structure

Tip: A certificate created by the ACME package (*ACME package*) will be natively trusted by many clients and can be used in place of a manually created private CA and server certificate.

Windows clients may not accept an ACME certificate as it may lack a property for IKE in the extended key usage attributes. This check can be disabled, however. See *Disable EKU Check*.

Create a Certificate Authority

If a suitable Certificate Authority (CA) is not present in the certificate manager, creating one is the first task:

- Navigate to **System > Certificates**
- Click  **Add** to create a new certificate authority
- Set the options as follows:

  Descriptive Name
  `Mobile IPsec CA`

  Method
  Create an internal Certificate Authority

  Randomize Serial
  Checked

  Common Name
  `mobile-ipsec-ca`

- Leave the rest of the fields at their default values or adjust to suit local preferences
- Click **Save**

Create a Server Certificate

Warning: Follow these directions exactly, paying close attention to how the server certificate is created at each step. If any one part is incorrect, some or all clients may fail to connect.

- Navigate to **System > Certificates**, **Certificates** tab
- Click  **Add** to create a new certificate
- Set the options as follows:

  Method
  Create an internal Certificate

  Descriptive Name
  `IKEv2 Server`

  Certificate Authority
  Mobile IPsec CA

Common Name
The hostname of the firewall as it exists in DNS, e.g. `vpn.example.com`.

If clients will connect by IP address, place the IP address here instead.

Certificate Type
Server Certificate

Alternative Names

Type
IP Address

Value
The WAN IP address of the firewall , e.g. `198.51.100.3`

Add more **Alternative Names** as needed for additional hostnames or IP addresses on the firewall that clients may use to connect.

- Click **Save**

Mobile Client Settings

The next step is to choose an IP address range to use for mobile clients. Ensure that IP addresses do not overlap any existing network.

> **Warning:** The IP addresses used by mobile clients must differ from those in use at the site hosting the mobile tunnel as well as the LAN from which the client will be connecting.

This example uses `10.3.200.0/24`, but it can be any unused subnet.

- Navigate to **VPN > IPsec**, **Mobile Clients** tab
- Enable IPsec:

Enable IPsec Mobile Client Support
Checked

Fig. 38: Enable Mobile IPsec Clients

- Set the authentication options as follows:

User Authentication
Local Database as seen in Figure *Mobile Clients Authentication*.

This setting is not needed for EAP-MSCHAPv2, but it must have something selected.

> **Tip:** RADIUS servers defined in the User Manager (*User Management and Authentication*) can be selected here for authenticating users when using EAP-RADIUS.

- Set the **Client Configuration** options

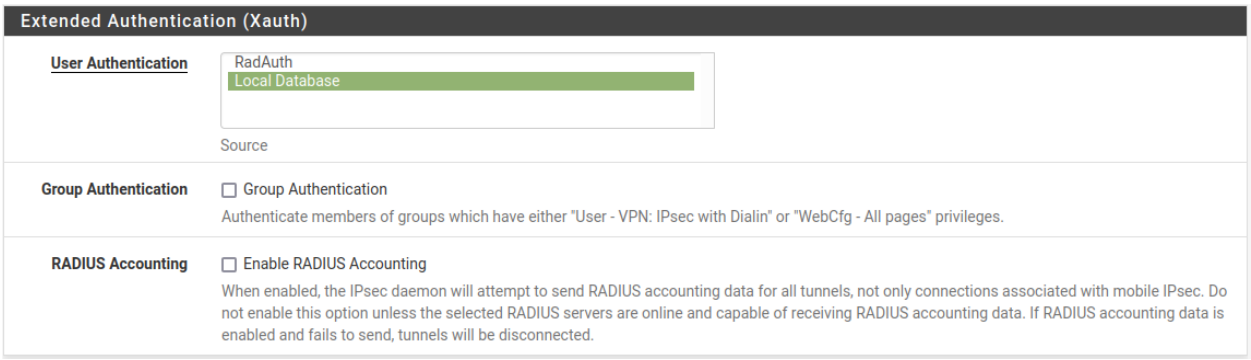

Fig. 39: Mobile Clients Authentication

These settings may be pushed to the client, such as the client IP address and DNS servers. These options are shown in Figure *Mobile Clients Pushed Settings*. Support for these options varies between clients, but is common and well-supported in most current operating systems.

Virtual Address Pool
Checked, `10.3.200.0/24`

Virtual IPv6 Address Pool
Checked, `2001:db8:1:df01::/64`

Network List
Checked

DNS Default Domain
Checked, `example.com`

Split DNS
Checked, `example.com example.org`

DNS Servers
Checked, `10.3.0.1`

See also:

For additional information these options work, see *Client Configuration*.

- Click **Save**
- Click  **Create Phase 1** at the top of the screen if it appears

Phase 1

The phase 1 configuration for mobile clients must be configured as follows:

Description
`Mobile IPsec` or another suitable description

Key Exchange Version
IKEv2

Internet Protocol
IPv4 for this example as it only uses an IPv4 WAN

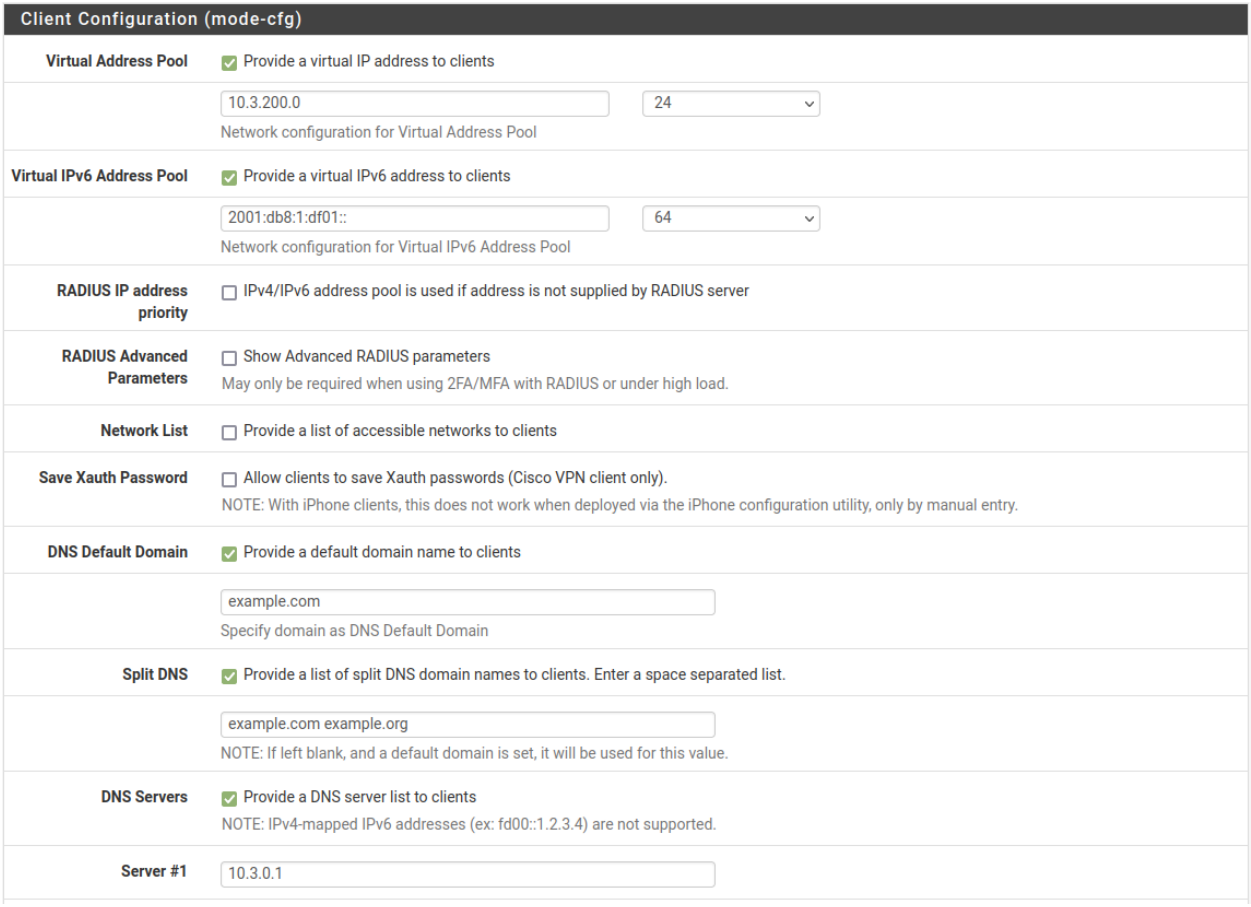

Fig. 40: Mobile Clients Pushed Settings

Fig. 41: Mobile Clients Phase 1 Creation Prompt

Interface
WAN

Authentication Method
EAP-MSCHAPv2

My identifier

Choose *Fully Qualified Domain Name* from the drop-down list and then
enter the hostname of the firewall, `vpn.example.com`.

> **Warning:** This must match the value in the server certificate.

Peer Identifier
Any

My Certificate
Choose the IPsec server certificate created earlier

Encryption Algorithm
Add multiple combinations of encryption, hash, and DH options to accommodate various clients with different requirements. Click  **Add Algorithm** to add more entries. They should be added with the most secure and preferred options first.

A good starting set of options is:

- **Algorithm** *AES256-GCM*, **Hash** *SHA256*, **DH Group** *16*
- **Algorithm** *AES256-GCM*, **Hash** *SHA256*, **DH Group** *2*
- **Algorithm** *AES 256*, **Hash** *SHA256*, **DH Group** *14*
- **Algorithm** *AES 256*, **Hash** *SHA1*, **DH Group** *14*

Life Time
`28800`

MOBIKE
Set to *Enable* to allow clients to roam between IP addresses, otherwise set to *Disable*.

- Click **Save**

Phase 2

- Click  **Show Phase 2 Entries** to expand the list of mobile phase 2 entries
- Click  **Add P2** to add a new mobile phase 2.

Description
`Mobile IPv4`

Mode
Tunnel IPv4

Local Network
Set to *LAN subnet* or another local network.

> **Tip:** To tunnel all traffic over the VPN, use *Network* and enter `0.0.0.0` with a mask of *0*

Protocol
ESP

Encryption algorithms
Set to combinations of options which will be accepted by all possible clients. A good starting set is:

- *AES*, *128*
- *AES128-GCM*, *128*
- *AES256-GCM*, *128*

Hash algorithms
Similar to the algorithm, select all options required by clients:

SHA256, *SHA384*, *SHA512*

PFS
14 (2048 bit)

> **Warning:** Apple iOS does not support PFS in phase 2 when configuring a VPN manually as demonstrated in *Configuring IPsec IKEv2 Remote Access VPN Clients on iOS*. Most other clients require PFS to be enabled. The best practice is to use a VPN profile from the Apple Configurator or *IPsec Export Package* which can support the use of PFS rather than creating a VPN connection manually.

Lifetime
`3600`

- Add another phase 2 entry but this time for IPv6. The settings are identical to the previous entry with the following changes:

  Description
  `Mobile IPv6`

  Mode
  Tunnel IPv6

  Local Network
  LAN subnet as before or use the network value `::` with a mask of *0* to tunnel all traffic.

- Click **Save**
- Click Apply changes

The tunnel setup for mobile clients is complete.

Mobile IPsec User Creation

The next step is to add users for use by EAP-MSCHAPv2.

- Navigate to **VPN > IPsec**, **Pre-Shared Keys** tab
- Click  **Add** to add a new key
- Configure the options as follows:

  Identifier
  The username for the client.

  This can be expressed in multiple ways, such as an e-mail address like `jimp@example.com`

  Secret Type
  EAP

  Pre-Shared Key
  The password for the client, for example `abc123`

- Click **Save**
- Repeat as many times as needed for additional VPN users.

A complete user is shown in Figure *Mobile IPsec User*.

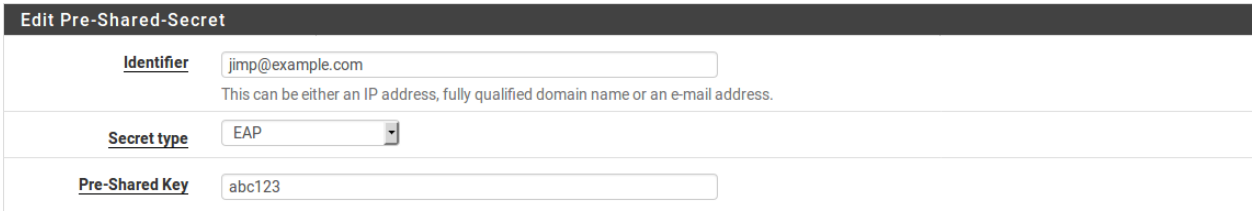

Fig. 42: Mobile IPsec User

Firewall Rules

As with the static site-to-site tunnels, mobile tunnels also require firewall rules at **Firewall > Rules** on the **IPsec** tab. In this instance the source of the traffic would be the subnet chosen for the mobile clients and the destination will be the LAN network, or *any* if tunneling all traffic.

See also:

For more details, *IPsec and firewall rules*.

35.26.2 Client Configuration

Each mobile client device needs a VPN instance or client configured. In some cases a third-party IPsec client may be required. There are many different IPsec clients available for use, some free, and some commercial applications. With IKEv2, as used in this example, many operating systems have native VPN clients and do not need extra software.

Common clients are covered at *Configuring IPsec IKEv2 Remote Access VPN Clients*.

35.27 IPsec Remote Access VPN Example Using IKEv2 with EAP-RADIUS

To setup IKEv2 with EAP-RADIUS, follow the directions for *IKEv2 with EAP-MSCHAPv2* with a slight variation:

- Define a RADIUS server under **System > User Manager**, **Servers** tab before starting
- Select the RADIUS server on **VPN > IPsec**, **Mobile Clients** tab
- Check **Group Authentication** and select **Authentication Groups** list entries to optionally filter access based on *RADIUS group* membership
- Select *EAP-RADIUS* for the **Authentication method** on the Mobile IPsec phase 1 entry

35.27.1 EAP-RADIUS with FreeRADIUS

The default settings are OK for this use case. If the defaults do not work, see *Using EAP and PEAP with FreeRADIUS*

35.27.2 EAP-RADIUS with Windows Network Policy Server (NPS)

To allow strongSwan to authenticate against NPS using EAP-MSCHAPv2, alter the NPS policy as follows:

- Open **Network Policy Server (NPS)**
- Expand **Policies**
- Click **Network Policies**
- Edit the policy currently in use
- Click on the **Constraints** tab
- Click **Authentication Methods**
- Click **Add**
- Select **Microsoft: Secured Password (EAP-MSCHAP v2)**
- Click **OK**
- Click **Apply** (To restart NPS)
- Click **OK**

35.28 IPsec Remote Access VPN Example Using IKEv2 with EAP-TLS

Mobile IPsec using IKEv2 with EAP-TLS enables per-user certificate authentication. To authenticate against the VPN, a user must have a valid certificate signed by a specific certificate authority (CA).

The basic setup is similar to *IPsec Remote Access VPN Example Using IKEv2 with EAP-MSCHAPv2*, this document will focus on the differences.

35.28.1 Setup Certificates

Per-user certificate authentication requires a certificate for the server and a set of certificates the clients.

Note: While these do not have to share the same SA, it makes the process easier.

Create a Certificate Authority

If one is not already available, then the first task is to create a new Certificate Authority as described in *Create a Certificate Authority*.

Create a Server Certificate

Create a server certificate as described in *Create a Server Certificate*.

Create Client Certificates

- Navigate to **System > Certificates**, **Certificates** tab
- Click  to create a new certificate
- Set the options as follows:

  Method
  Create an internal Certificate

  Descriptive Name
  A name associated with the client, for example `client1`.

  This is cosmetic only, so it does not affect values placed in the certificate data.

  Certificate Authority
  Mobile IPsec CA

  Common Name
  The username associated with this user, for example `client1`.

  Note: The best practice is to use identifiers in username, hostname, or FQDN formats for this field.

  Certificate Type
  User Certificate
- Change the other fields if desired to make the information more specific to the user.
- Click **Save**

Repeat as needed for additional clients.

35.28.2 Set up Mobile IPsec for IKEv2+EAP-TLS

With the certificate structure prepared, the next task is to configure the necessary IPsec settings.

Most of this configuration is identical to *IPsec Remote Access VPN Example Using IKEv2 with EAP-MSCHAPv2* and only the differences will be called out.

Mobile Clients

Configure as described in *Mobile Client Settings*.

Phase 1

Configure as described in *Phase 1* but with the following changes:

Authentication method
EAP-TLS

Peer Identifier
Any

Peer Certificate Authority
Select the CA created previously for this purpose.

Phase 2

Configure as described in *Phase 2*.

35.28.3 Add Firewall Rules for IPsec

Add firewall rules to pass traffic from clients as described in *Firewall Rules*.

35.28.4 Configure the Client

The server setup is complete, but the certificates must be imported to the client.

Client configuration for a variety of operating systems is covered in *Configuring IPsec IKEv2 Remote Access VPN Clients*. (e.g. *Configuring IPsec IKEv2 Remote Access VPN Clients on Windows*).

35.29 IPsec Site-to-Site VPN Example with Pre-Shared Keys

A site-to-site IPsec tunnel interconnects two networks as if they were directly connected by a router. Systems at Site A can reach servers or other systems at Site B, and vice versa. This traffic may also be regulated via firewall rules, as with any other network interface. If more than one client will be connecting to another site from the same controlled location, a site-to-site tunnel will likely be more efficient, not to mention more convenient and easier to support.

With a site-to-site tunnel the devices on either local network need not have any knowledge that a VPN exists. No client software is required and all of the work is handled by the tunnel endpoints. This is also a good solution for devices that have network support but do not handle VPN connections such as printers, cameras, HVAC systems, and other embedded hardware.

See also:

- *IPsec*
- *IPsec Configuration*
- *Troubleshooting Duplicate IPsec SA Entries*
- *Client Routing and Gateway Considerations*
- *Accessing Firewall Services over IPsec*

35.29.1 Site-to-site example configuration

The key to making a working IPsec tunnel is to ensure that both sides have matching settings for authentication, encryption, and so on. Before starting make a note of the local and remote WAN IP addresses as well as the local and remote internal subnets that will be carried across the tunnel. Aside from the cosmetic tunnel **Description** and these pieces of information the other connection settings will be identical.

The following settings are assumed by this example and some of the subsequent examples in the IPsec recipes:

Table 11: IPsec Endpoint Settings

Site A		Site B	
Name	Austin Office	Name	London Office
WAN IP	198.51.100.3	WAN IP	203.0.113.5
LAN Subnet	10.3.0.0/24	LAN Subnet	10.5.0.0/24
LAN IP	10.3.0.1	LAN IP	10.5.0.1

Note: To avoid issues with security association duplication, this example uses settings described in *Troubleshooting Duplicate IPsec SA Entries*.

Figure *Site-to-Site IPsec* shows the general layout of this VPN.

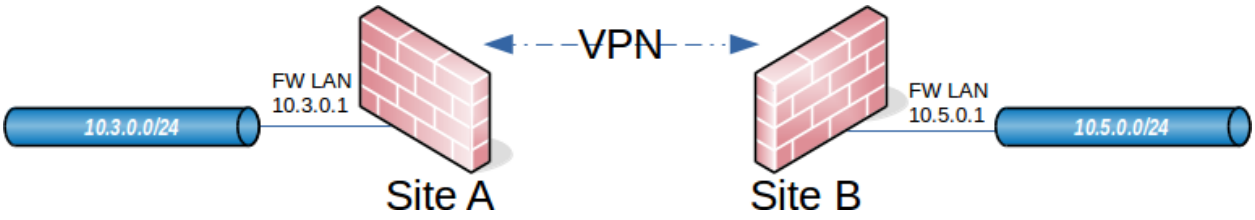

Fig. 43: Site-to-Site IPsec

35.29.2 Site A

Start with configuring the tunnel and related settings on the firewall at Site A.

Phase 1

To add a new IPsec phase 1:

- Navigate to **VPN > IPsec**
- Click  **Add P1**
- Fill in the settings as described below
- Click **Save** when complete

Use the following settings for the phase 1 configuration. Many of these settings may be left at their default values unless otherwise noted.

See also:

For comprehensive coverage of all IPsec phase 1 settings, see *Phase 1 Settings*.

First fill in the top section that holds the general phase 1 information and IKE endpoint configuration, as shown in Figure *figure-vpn-tunnel-settings*. Items in bold are required. Fill in the settings as described:

Description
Text describing the purpose or identity of the tunnel. The best practice is to put the name of Site B in this box, and brief detail about the purpose of the tunnel to help with future administration.

For this example `ExampleCo London Office` is used for the **Description** to identify where this example tunnel terminates.

Disabled
Uncheck this box so that the tunnel will be operational.

Key Exchange version
Specifies whether to use IKEv2 or IKEv1. IKEv2 is the best practice when supported by both endpoints. If one side does not support IKEv2, use IKEv1 instead.

Internet Protocol
IPv4 in most cases unless both WANs have IPv6, in which case either type may be used.

Interface
Most likely set to *WAN* , but see the note at *Interface Selection* on selecting the proper interface when unsure.

Remote Gateway
The WAN address at Site B, `203.0.113.5` in this example.

The next section controls IPsec phase 1 proposals for authentication. The defaults are desirable for most of these settings which simplifies the process.

Authentication Method
The default, *Mutual PSK*, is used for this example.

My Identifier
The default, *My IP Address*, is kept for this example.

Peer Identifier
The default, *Peer IP Address*, is kept for this example.

Pre-Shared Key
Use a strong key, at least 10 characters in length containing a mix of upper and lowercase letters,

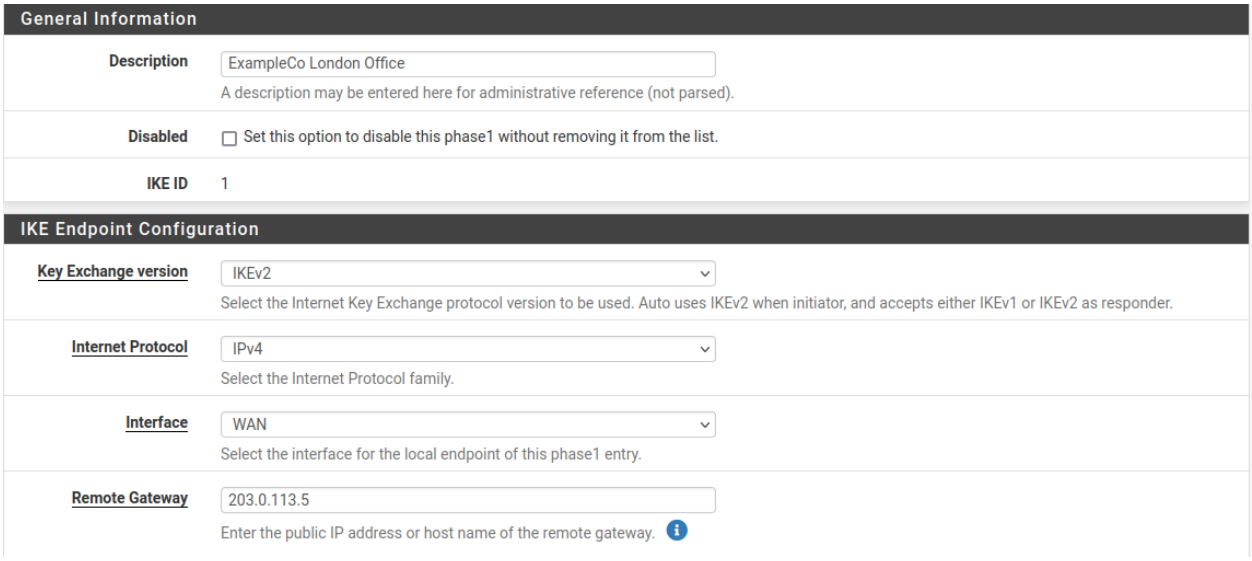

Fig. 44: Site A IPsec Phase 1 General Information and IKE Endpoint Configuration

numbers and symbols. Enter a custom key or click **Generate new Pre-Shared Key** to automatically populate the field with a random long string suitable for use as a Pre-Shared Key.

> **Warning:** This is the most important setting to get correct. As mentioned in the VPN overview, IPsec using pre-shared keys can be broken if the tunnel uses a weak key.

The **exact** same key must be entered into the tunnel configuration for Site B later, so note it down or copy and paste it elsewhere. Copy and paste may come in handy, especially with a complex key.

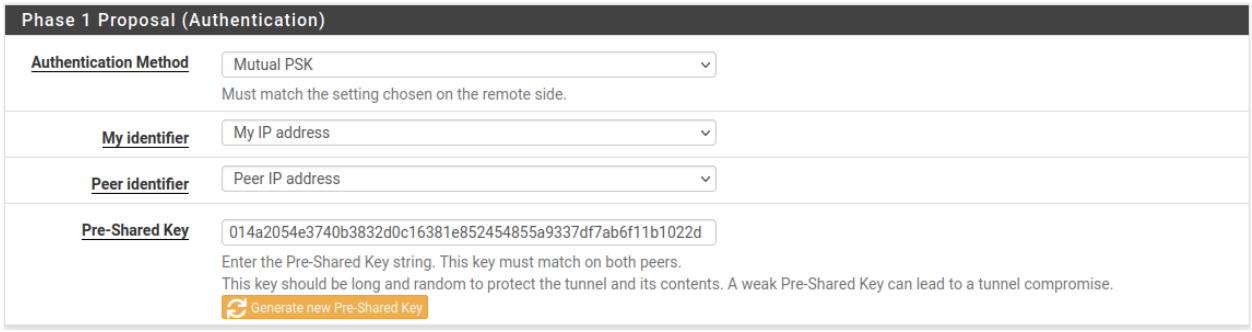

Fig. 45: Site A Phase 1 Authentication Settings

The next section controls IPsec phase 1 proposals for encryption.

Encryption Algorithm
Use *AES* with a **Key Length** of *256 bits*.

Hash Algorithm
Use *SHA256* if both sides support it, otherwise use the strongest hash supported by both endpoints.

DH Group
The default of *14 (2048 bit)* is OK, higher values are more secure but may use more CPU.

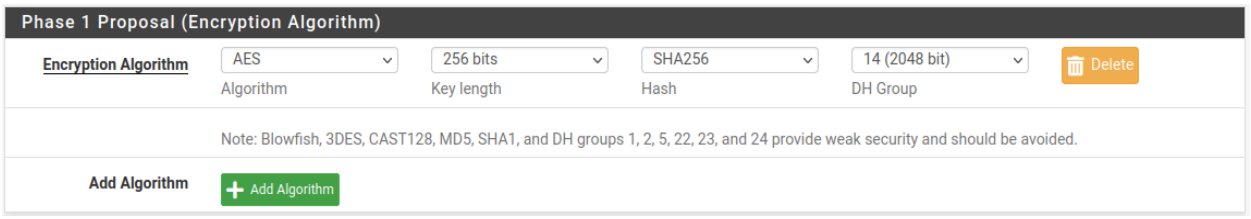

Fig. 46: Site A Phase 1 Encryption Settings

The **Expiration and Replacement** section controls the timing and method by which the phase 1 will be renegotiated.

Life Time
The default `28800` is OK for this endpoint.

See also:

See *Troubleshooting Duplicate IPsec SA Entries* for best practices in choosing life time values.

The other lifetime-related values (**Rekey Time**, **Reauth Time**, **Rand Time**) should be left at their defaults on this endpoint as they are automatically calculated as the correct values.

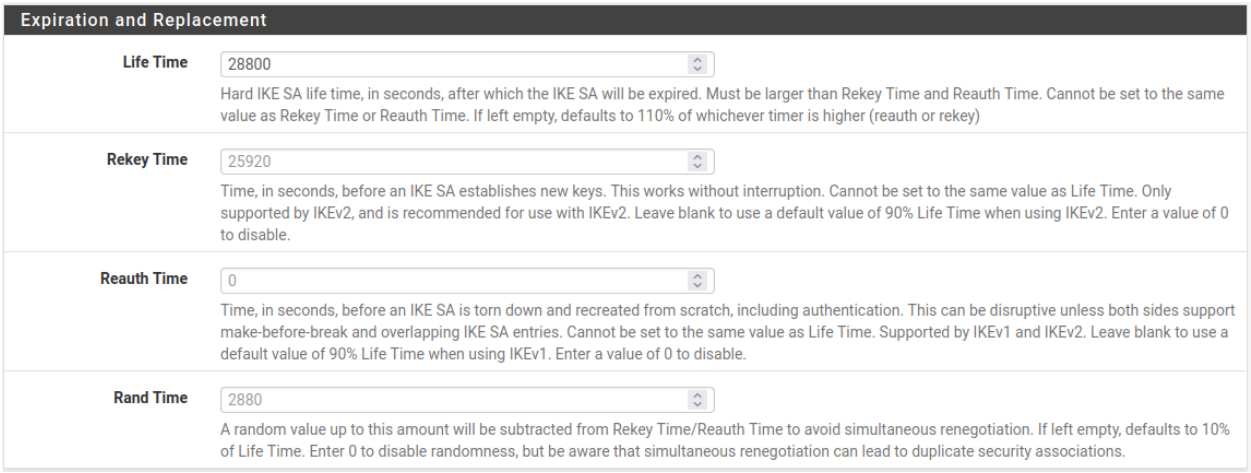

Fig. 47: Site A Phase 1 Lifetime Settings

Finally, the **Advanced** section contains a couple settings to check as well:

Child SA Close Action
Set this endpoint to **Restart/Reconnect** so that the phase 2 entries will be reconnected if they get disconnected.

Dead Peer Detection
Leave checked and at the default values.

Click **Save** to complete the phase 1 setup.

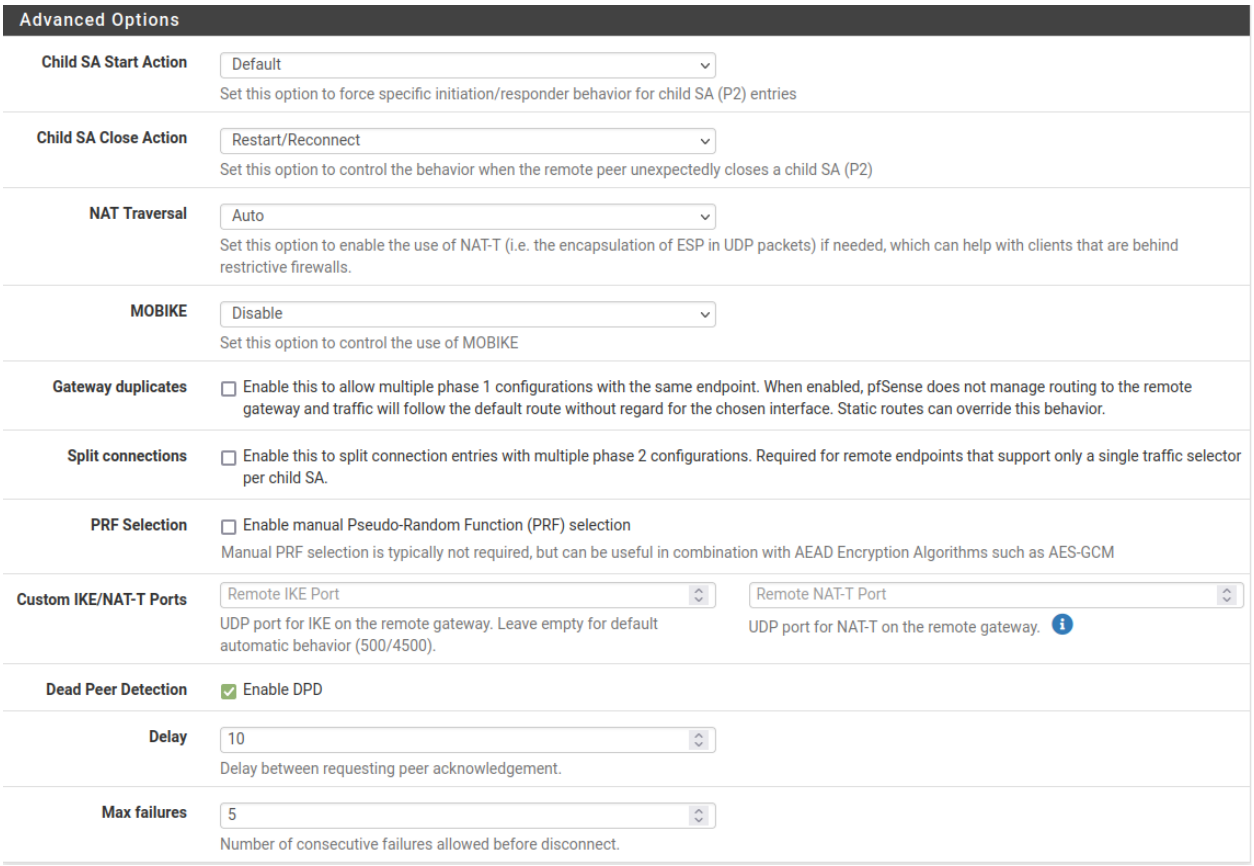

Fig. 48: Site A Phase 1 Advanced Settings

Phase 2

With the phase 1 entry complete, now a new phase 2 definition to the VPN:

- Click  **Show Phase 2 Entries** as seen in Figure *Site A Phase 2 List (Empty)* to expand the phase 2 list for this VPN.
- Click  **Add P2** to add a new phase 2 entry, as seen in Figure *Adding a Phase 2 entry to Site A*.

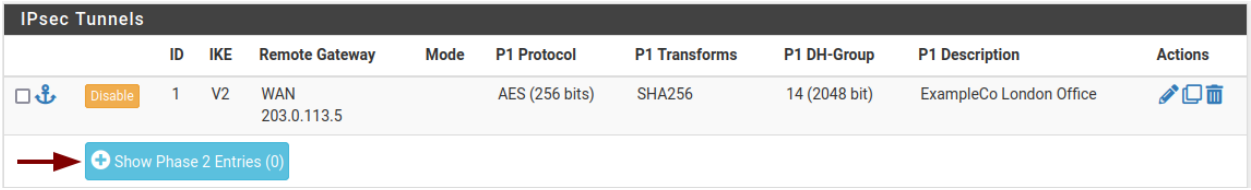

Fig. 49: Site A Phase 2 List (Empty)

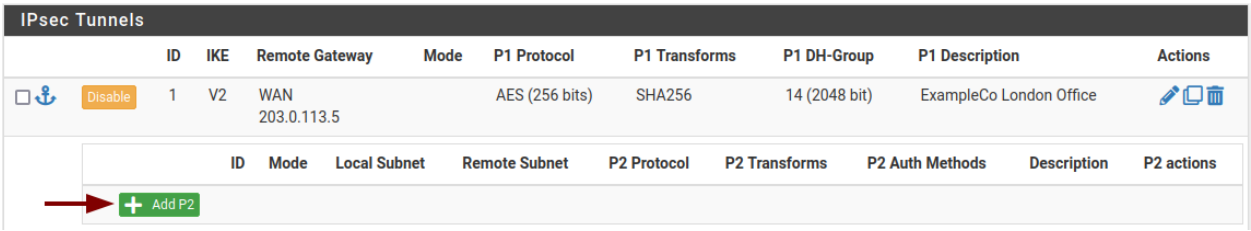

Fig. 50: Adding a Phase 2 entry to Site A

Now add settings for phase 2 on this VPN. The settings for phase 2 (Figure *Site A Phase 2 General Information and Networks*) can vary more than phase 1.

See also:

For comprehensive coverage of all IPsec phase 2 settings, see *Phase 2 Settings*.

Description
A brief description of the network(s) involved in this phase 2 entry.

Mode
Since this example is for a policy-based tunnel, select *Tunnel IPv4*

Local Network
In most cases the best practice is to leave this as *LAN Subnet*, but it can be changed to *Network* with the proper subnet value filled in. In this case that would be `10.3.0.0/24`. Leaving it as *LAN Subnet* will ensure that if the network is renumbered in the future, this end of the tunnel will follow. If that does happen, the other end must be changed manually.

NAT/BINAT
Set to *None*.

Remote Network
Set to the network at Site B, in this case `10.5.0.0/24`.

The next section of the phase 2 settings covers traffic encryption. **Encryption algorithms** and **Hash algorithms** can both be set to allow multiple options in phase 2, and both sides will negotiate and agree upon the settings so long as

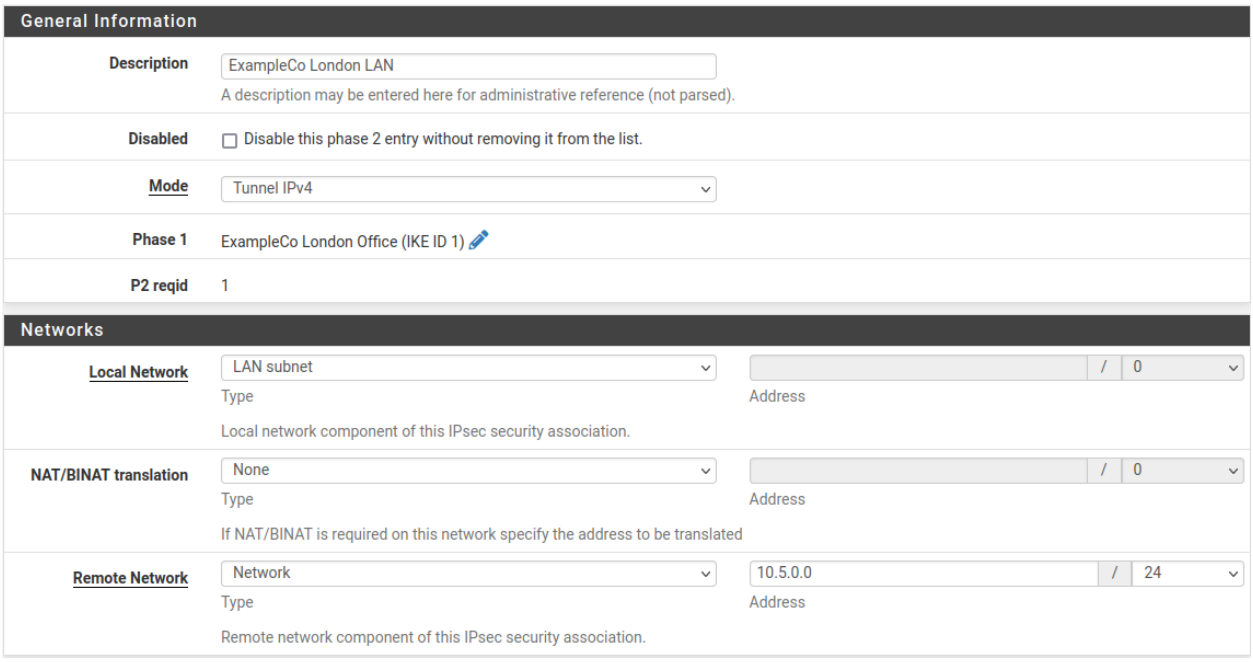

Fig. 51: Site A Phase 2 General Information and Networks

each side has at least one of each in common. In some cases that may be a good thing, but it is usually better to restrict this to the single specific options desired on both sides.

Protocol
Set to *ESP* for encryption.

Encryption algorithm
The best practice is to use an AEAD cipher such as AES-GCM if it is supported by both endpoints.

Select *AES256-GCM* with a *128 bit* key length. Otherwise, use *AES 256*, or the highest strength cipher supported by both endpoints.

Hash algorithm
If AES-GCM is selected for **Encryption Algorithm** do not select any hashes.

Otherwise, use *SHA256* or whichever hash supported by both sides is strongest.

PFS
Perfect Forward Secrecy (PFS) is optional but can help protect against certain key attacks. This example uses *14 (2048 bit)*.

Next are the settings which govern timing and methods for renewing phase 2 keys.

Life Time
Use `3600` for this example, and leave **Rekey Time** and **Rand Time** at their default calculated placeholder values.

To finalize the settings and put them into action:

- Click *Save*
- Click *Apply Changes* on the IPsec Tunnels screen, as seen in Figure *Apply IPsec Settings*.

The tunnel configuration for Site A is now complete.

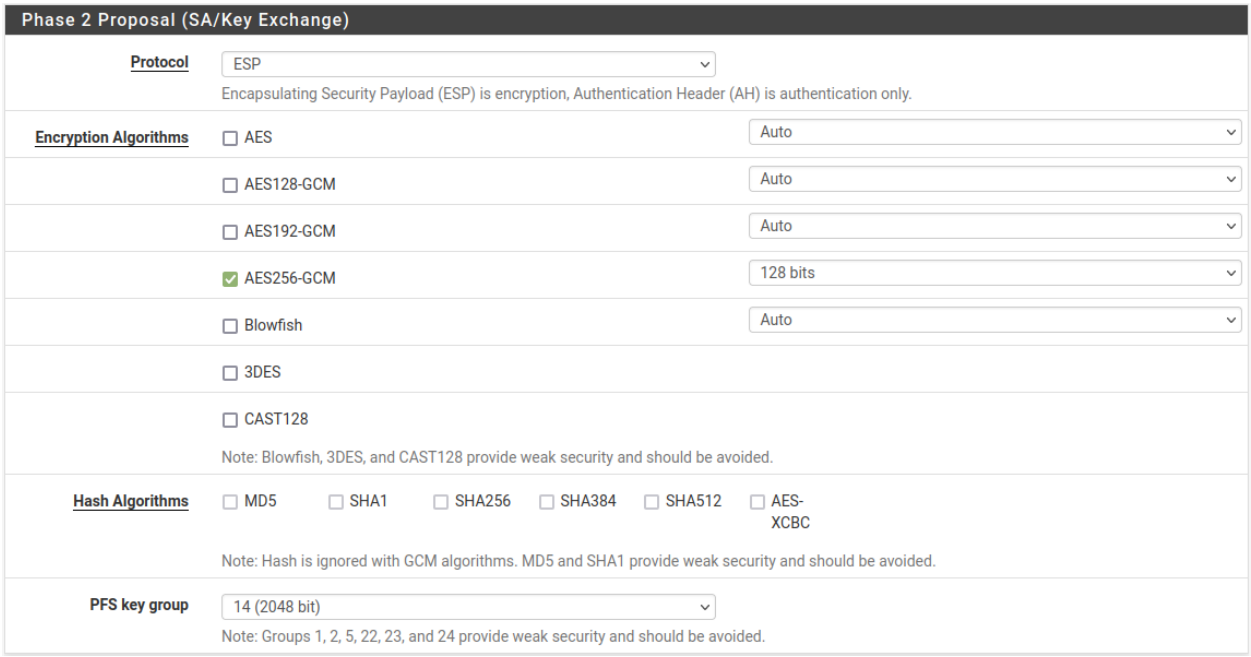

Fig. 52: Site A Phase 2 Proposal Settings

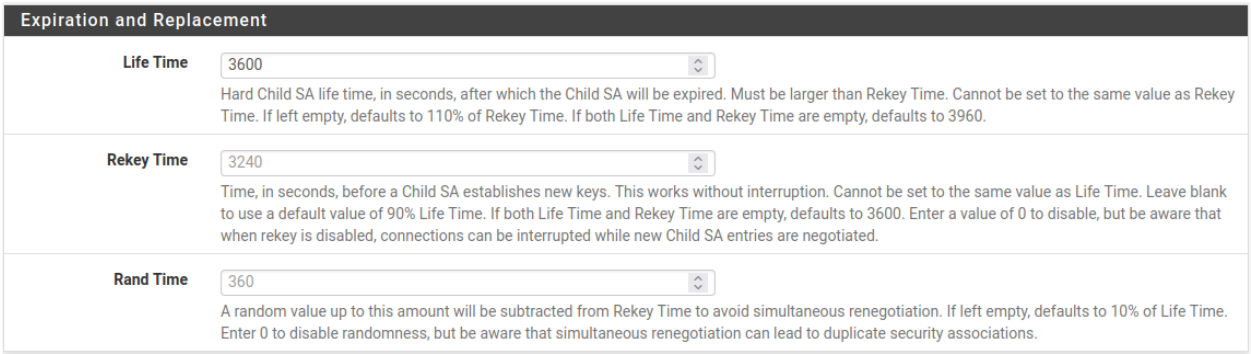

Fig. 53: Site A Phase 2 Expiration and Replacement Settings

Fig. 54: Apply IPsec Settings

Firewall Rules

Firewall rules are necessary to allow traffic from the network at Site B to enter through the IPsec tunnel.

Navigate to **Firewall > Rules** on the **IPsec** tab and add rules there to pass traffic from the remote side of the VPN.

See also:

See *Firewall* for specifics on adding rules, and *IPsec and firewall rules* for firewall rule advice specific to IPsec.

Rules may be as permissive or restrictive as desired. For example, they can allow any protocol from anywhere to anywhere or only allow TCP from a certain host on Site B to a certain host at Site A on a certain port.

As with other firewall rules the connections are checked on the way *into* the firewall; the source of all traffic on the IPsec tab rules will be remote VPN networks, such as those at Site B.

Make sure the source addresses on the firewall rules match Site B addresses, such as `10.5.0.0/24`. The destination addresses will be on Site A, such as `10.3.0.0/24`.

35.29.3 Site B

Now that Site A is configured, it is time to tackle Site B. Repeat the process on the Site B endpoint to add a tunnel.

Only a few parts of this setup will differ from Site A as shown in Figure *Site B Phase 1 General Settings* and Figure *Site B Phase 2 General Settings*:

- The phase 1 settings for Description, WAN address, Life Time, Child SA Start Action, and Child SA Close Action
- The phase 2 tunnel networks and Life Time

Add a phase 1 entry to the Site B firewall using identical settings used on Site A but with the following differences:

Description
`ExampleCo Austin Office`.

Remote Gateway
The WAN address at Site A, `198.51.100.3`.

Life Time
At least 10% higher than Site A, `31680`

Child SA Start Action
Set to **None (Responder Only)** so that this endpoint will not initiate on its own, but will wait for Site A to initiate.

Child SA Close Action
Set this endpoint to **Close Connection and clear SA** so that the phase 2 will not automatically reconnect, since Site A will be managing that.

- Click **Save**

Add a phase 2 entry to the Site B firewall using identical settings used on Site A but with the following differences.

Description
`ExampleCo Austin LAN`.

Remote Subnet
The network at Site A, in this case `10.3.0.0/24`.

Life Time
At least 10% higher than Site A, `5400`

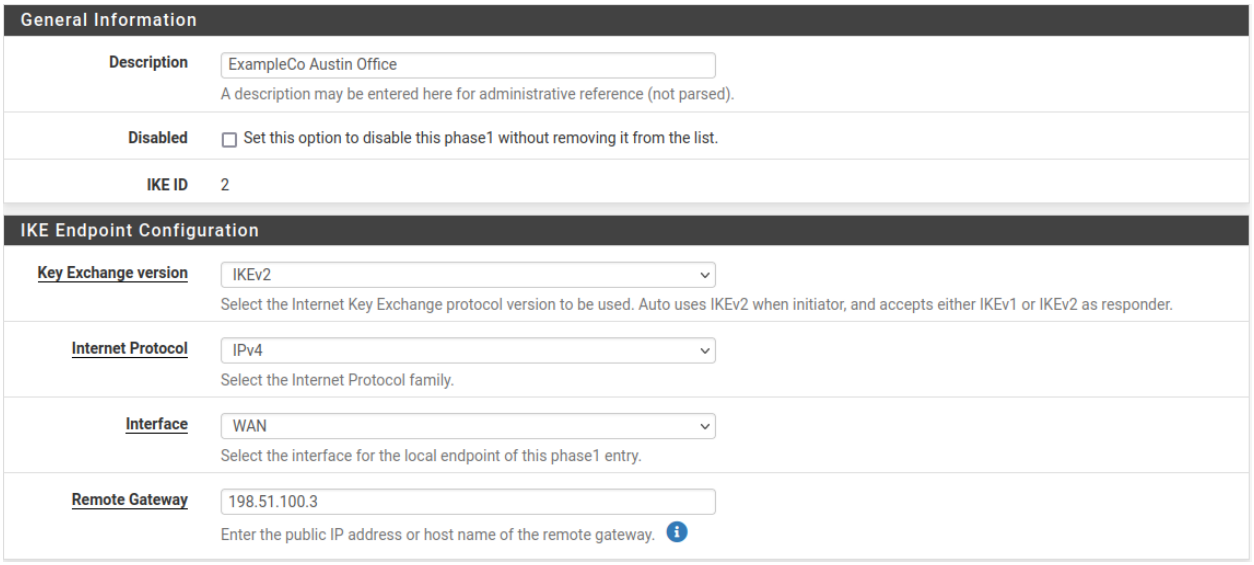

Fig. 55: Site B Phase 1 General Settings

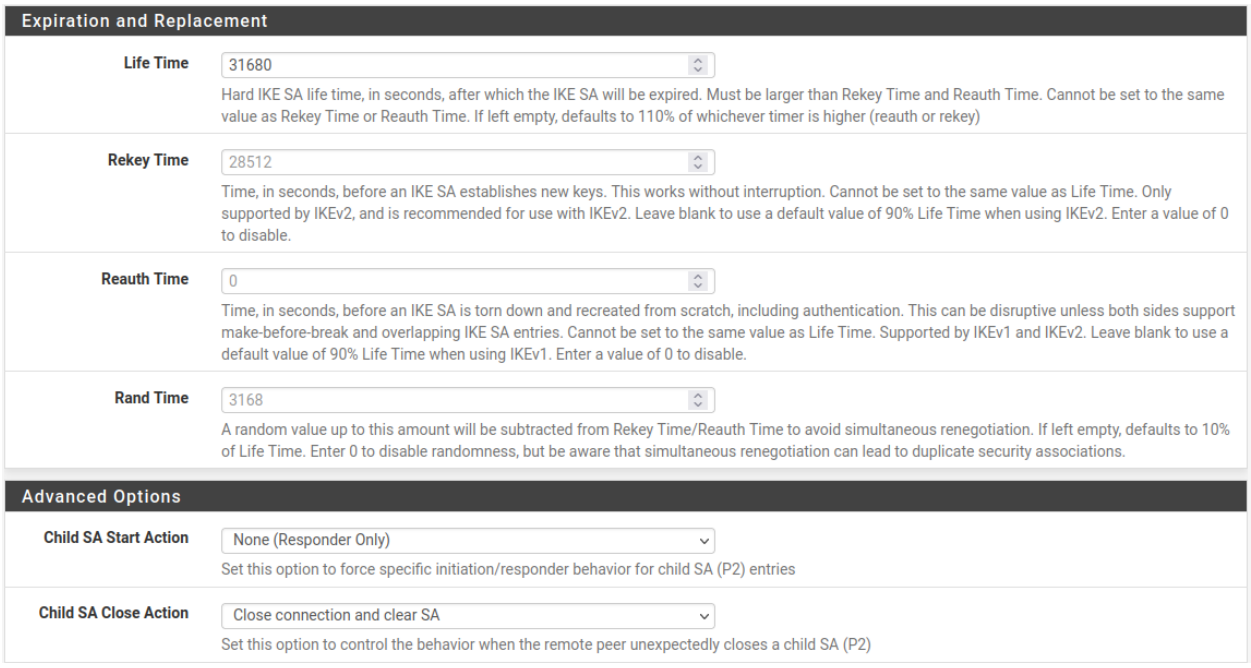

Fig. 56: Site B Phase 1 Other Settings

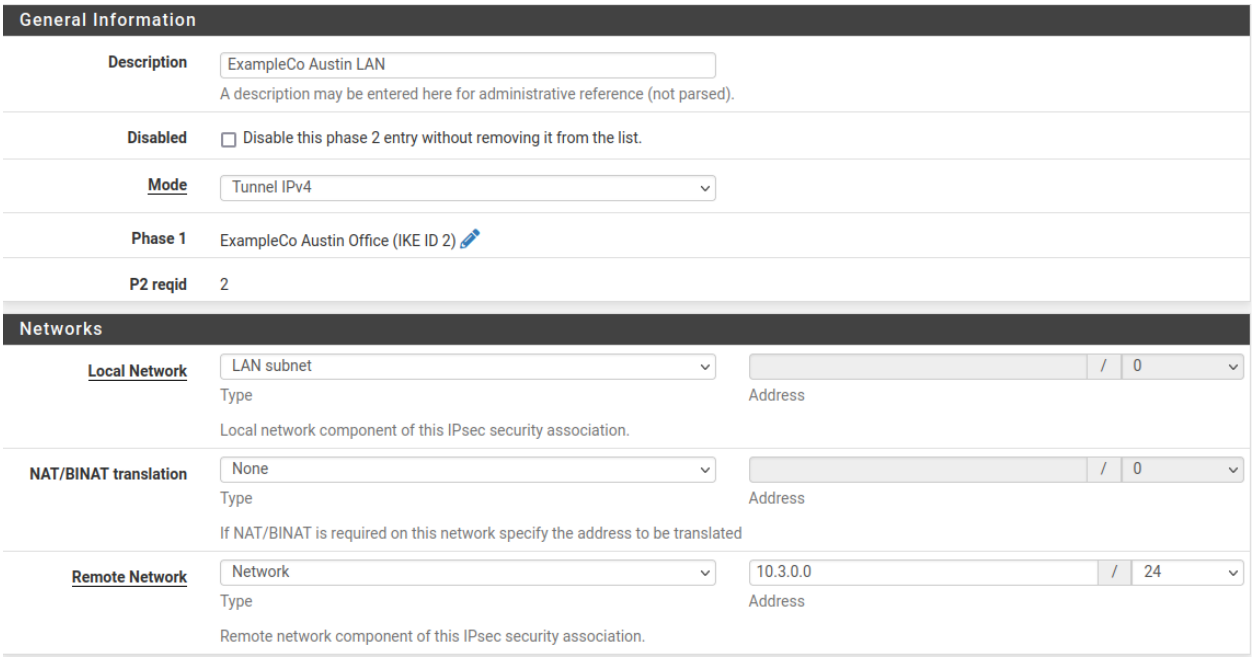

Fig. 57: Site B Phase 2 General Settings

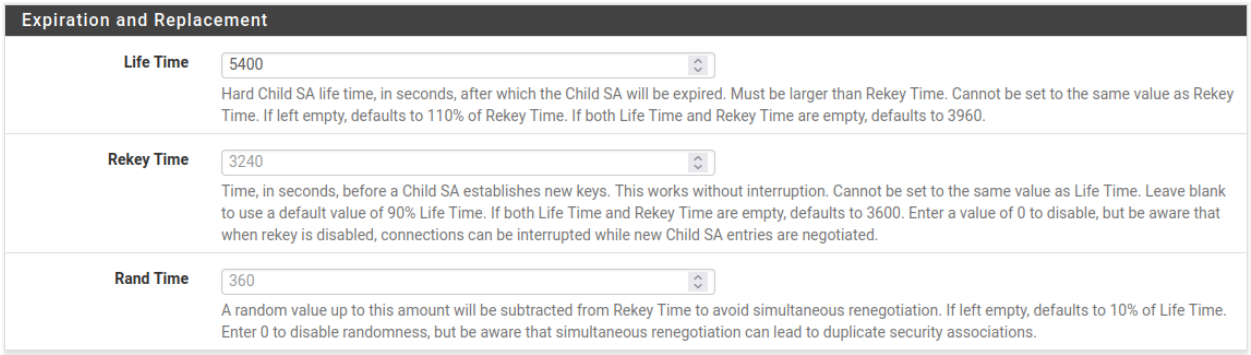

Fig. 58: Site B Phase 2 Lifetime Settings

- Click **Save**
- Click **Apply changes** on the IPsec Tunnels screen.

As with Site A, firewall rules must also be added to allow traffic on the tunnel to cross from Site A to Site B. Add these rules to the **IPsec** tab under **Firewall > Rules**. For more details, see *IPsec and firewall rules*. This time, the source of the traffic would be Site A, destination Site B.

35.29.4 Check Status

Both tunnels are now configured and active. Check the IPsec status by visiting **Status > IPsec**. A description of the tunnel is shown along with its status.

If the tunnel is not listed as **Established**, there may be a problem establishing the tunnel. This soon, the most likely reason is that no traffic has attempted to cross the tunnel.

A connect button is offered on this screen that will attempt to initiate the tunnel. Click the  **Connect VPN** button to attempt to bring up the tunnel as seen in Figure *Site A IPsec Status*.

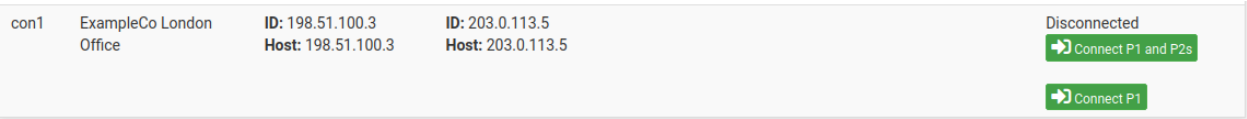

Fig. 59: Site A IPsec Status

If the connect button does not appear try to ping a system in the remote subnet at Site B from a device inside of the phase 2 local network at Site A (or vice versa) and see if the tunnel establishes. Look at *Testing IPsec Connectivity* for other means of testing a tunnel.

Failing that, the IPsec logs will typically offer an explanation. They are located under **Status > System Logs** on the **IPsec** tab. Be sure to check the status and logs at both sites. For more troubleshooting information, check the *Troubleshooting IPsec VPNs* section later in this chapter.

When the tunnel is connected the status will look like Figure *Site A IPsec Status while Connected*.

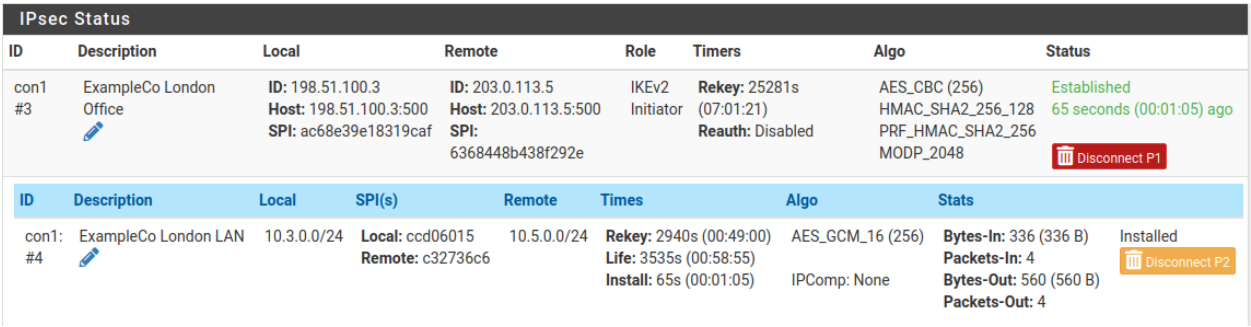

Fig. 60: Site A IPsec Status while Connected

35.30 Routing Internet Traffic Through a Site-to-Site IPsec Tunnel

It is possible to use IPsec on a firewall running pfSense® software to send Internet traffic from a remote site such that it appears to be coming from another location. This may be needed if a vendor requires that connections originate from a specific address.

The basis of this tunnel is a working site-to-site IPsec VPN as described in *IPsec Site-to-Site VPN Example with Pre-Shared Keys*. Refer to that recipe for detailed instructions. Only the differences from that recipe will be mentioned here.

As a reminder, this example uses two sites:

- **Site A** is the main site. The Internet traffic will *exit* this location.
- **Site B** is a remote office with LAN subnet `10.5.0.0/24`. This is the source of local traffic which will traverse the tunnel and reach the Internet through site A.

The only differences from tunnel in *IPsec Site-to-Site VPN Example with Pre-Shared Keys* are:

Site A, phase 2

Local Network
`0.0.0.0/0`

Site B, phase 2

Remote Network
`0.0.0.0/0`

This will cause the firewall to send **all** traffic from the LAN through the IPsec tunnel to the remote end of the tunnel.

35.30.1 Allow IPsec traffic through the firewall

Since this tunnel must pass traffic from the Internet, the firewall rules must be fairly lenient. The rules on site A will need to pass traffic from a source of the site B LAN (`10.5.0.0/24`) to a destination of *any*.

Tip: To prevent site B from reaching sensitive local resources at site A or sites connected to additional VPNs, place block rules above the rule passing the Internet traffic.

The rules at site B do not necessarily have to allow much traffic back through unless there are public resources at site B which will be reached across the tunnel (e.g. 1:1 NAT, port forwards).

35.30.2 Configure outbound NAT

For site B to reach the Internet, site A must perform outbound NAT on the traffic from the site B LAN (`10.5.0.0/24`) as it leaves the WAN.

To do this, first change the outbound NAT mode on the site A firewall:

- Navigate to **Firewall > NAT**, **Outbound** tab
- Set the **Outbound NAT Mode** to **Hybrid Outbound NAT**

Note: If site A is already on this mode or set to **Manual**, then do not change the mode.

- Click **Save**

Using this mode will allow the default automatic NAT rules to continue working without needing a full manual ruleset. Now add a custom rule to the top of the list which will match site B:

- Click  **Add**
- Set the following values:

  Source
  Network, `10.5.0.0/24`

  Destination
  Any

  Translation Address
  Interface Address

  Description
  `NAT for IPsec tunnel Site B`

- Click **Save**
- Click **Apply changes**.

The new entry is now in the outbound NAT rule list.

At this point site B will have a working Internet connection through the IPsec tunnel and the Internet provider at site A. Any Internet traffic from site B will look as if it were coming from site A.

35.31 IPsec Site-to-Site VPN Example with Certificate Authentication

Using certificate-based authentication for identification of VPN tunnel peers is much stronger than using a simple Pre-Shared Key but it is more difficult to configure and manage.

Certificate authentication requires a PKI structure. Depending on the setup, each side may utilize its own certificate authority (CA) or they may share a common CA. This example utilizes a different CA on each node to more closely resemble connecting to third parties.

See also:

CA and certificate entries can be created and imported in the GUI by the *Certificate Manager*.

35.31.1 Required Information

Endpoint A:

Item	Value
Hostname	office.vpn.example.com
WAN IP Address	`198.51.100.16`

Endpoint B:

Item	Value
Hostname	home.vpn.example.com
WAN IP Address	`198.51.100.17`

35.31.2 Create CA

First, create a Certificate Authority (CA) on each side:

On Endpoint A:

- Navigate to **System > Certificates**, **CAs** tab
- Click  **Add**
- Set the options as follows:

  Descriptive Name
  `Office VPN CA`

  Method
  Create an internal Certificate Authority

  Randomize Serial
  Checked

  Common Name
  `office-vpn-ca`
- Leave the rest of the fields at their default values or adjust to suit local preferences
- Click **Save**
- Click  to export this CA as a file in the browser

On Endpoint B:

- Navigate to **System > Certificates**, **CAs** tab
- Click  **Add**
- Set the options as follows:

  Descriptive Name
  `Home VPN CA`

  Method
  Create an internal Certificate Authority

  Randomize Serial
  Checked

  Common Name
  `home-vpn-ca`
- Leave the rest of the fields at their default values or adjust to suit local preferences
- Click **Save**

- Click  to export this CA as a file in the browser

35.31.3 Import Peer CAs

Next, import the new CA entries into the peer. For example, import the Home CA to the Office side, and vice versa.

Note: This step only requires the certificate data, **not** the key. The key belonging to the CA should not be copied off the firewall where it was created.

On Endpoint A:

- Navigate to **System > Certificates**, **CAs** tab
- Click  **Add**
- Set the options as follows:

  Descriptive Name
  `Home VPN CA`

  Method
  Import an existing Certificate Authority

  Certificate Data
  Paste the contents of the exported `Home VPN CA.crt` file.

- Click **Save**

On Endpoint B:

- Navigate to **System > Certificates**, **CAs** tab
- Click  **Add**
- Set the options as follows:

  Descriptive Name
  `Office VPN CA`

  Method
  Import an existing Certificate Authority

  Certificate Data
  Paste the contents of the exported `Office VPN CA.crt` file.

- Click **Save**

35.31.4 Create Endpoint Certificates

On Endpoint A:

- Navigate to **System > Certificates**, **Certificates** tab
- Click  **Add**
- Set the options as follows:

  Method
  Create an internal Certificate

  Descriptive Name
  `Office VPN Certificate`

  Certificate Authority
  Office VPN CA

  Common Name
  `office-vpn-cert`

  Certificate Type
  User Certificate

  Alternative Names

  Type
  FQDN or Hostname

  Value
  `office.vpn.example.com`

- Click  **Add**
- Set the new row options to:

  Alternative Names

  Type
  IP Address

  Value
  `198.51.100.16`

  Note: If the IP address is dynamic, skip this step or use the LAN IP address.

- Leave the rest of the fields at their default values or adjust to suit local preferences
- Click **Save**

On Endpoint B:

- Navigate to **System > Certificates**, **Certificates** tab
- Click  **Add**
- Set the options as follows:

Method
Create an internal Certificate

Descriptive Name
`Home VPN Certificate`

Certificate Authority
Home VPN CA

Common Name
`home-vpn-cert`

Certificate Type
User Certificate

Alternative Names

Type
FQDN or Hostname

Value
`home.vpn.example.com`

- Click  **Add**
- Set the new row options to:

Alternative Names

Type
IP Address

Value
`198.51.100.17`

Note: If the IP address is dynamic, skip this step or use the LAN IP address.

- Leave the rest of the fields at their default values or adjust to suit local preferences
- Click **Save**

35.31.5 Setup IPsec VPN

On both firewalls, configure the IPsec tunnel as described in *IPsec Site-to-Site VPN Example with Pre-Shared Keys*, with the following exceptions:

Endpoint A:

Authentication method
Mutual Certificate

My Identifier
Set appropriately to *match the certificate* for **this** endpoint

Peer Identifier
Set appropriately to *match the certificate* of the **peer**

My Certificate
Office VPN Certificate

Peer Certificate Authority
Home VPN CA

Endpoint B:

Authentication method
Mutual Certificate

My Identifier
Set appropriately to *match the certificate* for **this** endpoint

Peer Identifier
Set appropriately to *match the certificate* of the **peer**

My Certificate
Home VPN Certificate

Peer Certificate Authority
Office VPN CA

35.31.6 Matching Certificate and Identifiers

In order for the IPsec daemon to properly match a certificate and its keys to a peer, the local and peer identifier must match data in the certificate **exactly**.

> **Warning:** Do not place quotes (single or double) around the identifier values.

There are several ways to accomplish this matching. The key factors are:

- The IPsec daemon must be able to confirm that an endpoint matches the expected identifier, which matches a peer to a specific tunnel.
- The IPsec daemon must be able to match that identifier to a certificate and validate its trust, which confirms the identity and authenticates the tunnel peer.

The following identifier types are the best practices to use with certificate authentication:

Fully Qualified Domain Name
This choice can work with fully qualified domain names or short hostnames. If the certificates were created as specified in *Create Endpoint Certificates*, use the full hostname such as `office.vpn.example.com` or `home.vpn.example.com`. This is the easiest choice and most likely to succeed, assuming the SAN value is present in the certificate.

Modern certificates typically include the certificate CN as a SAN entry, so the CN may also be used if it resembles a hostname (e.g. `office-vpn-cert`). Check the certificate properties to ensure it is present as an FQDN SAN entry.

> **Warning:** This mode will not work if the CN contains spaces or other characters not compatible with hostnames.

ASN.1 Distinguished Name
The full ASN.1 Distinguished Name of the certificate. This is similar to the certificate subject but has stricter rules about its order.

This can be formatted in several ways so long as it matches the data in the certificate exactly, for example:

- `/CN=host.example.com/C=US/ST=Texas/L=Austin/O=Example Co`
- `CN=host.example.com, C=US, ST=Texas, L=Austin, O=Example Co`
- `CN = host.example.com, C = US, ST = Texas, L = Austin, O = Example Co`

Note: The type, number, and order of fields will vary depending on how the certificate was made.

To find this string, inspect the certificate in one of the following ways:

- From the **Certificate Manager**, **Certificates** tab, find the entry and click the  icon to expand the certificate details. In the details, copy the contents of the **DN:** field exactly.

```
DN: /CN=host.example.com/C=US/ST=Texas/L=Austin/O=Example Co
```

- Use OpenSSL on a copy of the certificate contents and look for the **Subject** contents:

```
$ openssl x509 -text -noout -in mycert.crt | grep Subject:
        Subject: CN = host.example.com, C = US, ST = Texas, L = Austin,␣
↪O = Example Co
```

- If the certificate is configured in IPsec already, look at how `strongSwan` reports the certificate subject:

```
$ swanctl --list-certs | grep subject
  subject:  "CN=host.example.com, C=US, ST=Texas, L=Austin, O=Example Co
↪"
```

Warning: When copying these values remember that they must be entered **exactly** as shown but **without** any single or double quotes around the string. Only include the DN contents and not any headers or labels such as `DN:` or `Subject:`.

My IP Address / Peer IP Address

These choices are viable if all of the following items are true:

- Both endpoints have static IP addresses
- These static IP addresses are used as the **Remote Gateway** address on each side of the IPsec tunnel
- The static IP address of an endpoint is present in its certificate as a SAN

IP Address

Similar to the **My IP Address / Peer IP Address** case above, but instead of using endpoint static IP addresses, uses a pre-determined local addresses instead. This could be the LAN IP address or another agreed upon address which does not change. This value does not need to match the **Remote Gateway** address in this case.

- The value must be present as an IP address type SAN in the certificate

In most cases, this is not ideal, and the hostname is easier to use instead.

35.31.7 Troubleshooting

If the IPsec daemon cannot match an identifier to a known certificate, the following error is logged on one or both of the peers:

```
charon[5319]: 08[IKE] <con100000|1> no trusted RSA public key found for '<identifier>'
```

In that case:

- Check over all of the identifier data again to ensure that the values **exactly** match an appropriate certificate field (DN, SAN, etc.)
- If using an ASN.1 DN, ensure the order of DN/subject components **exactly** matches the order reported by the DN field in the Certificate Manager, `strongSwan`, or `openssl`
- Ensure there are no single or double quotes around the identifier value in the GUI
- Ensure the correct **Peer Certificate Authority** is imported and selected

Attempt to initiate the tunnel in both directions manually and compare output (*Manually connect IPsec from the shell*).

35.32 Configuring IPv6 Through A Tunnel Broker Service

A location that does not have access to native IPv6 connectivity may obtain it using a tunnel broker service such as Hurricane Electric. Similarly, a core site with IPv6 can deliver IPv6 connectivity to a remote site by using a VPN or GIF tunnel.

This section provides the process for connecting pfSense® software with Hurricane Electric (Often abbreviated to HE.net or HE) for IPv6 transit. Using HE.net is simple and easy. It allows for multi-tunnel setup, each with a transport `/64` and a routed `/64`. Also included is a routed `/48` to be used with one the tunnels. It is a great way to get a lot of routed IPv6 space to experiment with and learn, all for free.

35.32.1 Sign Up for Service

ICMP echo requests must be allowed to the WAN from the tunnel broker server or it cannot function. A rule to pass ICMP echo requests from a source of *any* is an acceptable temporary measure. Once the tunnel endpoint for HE.net has been chosen, the rule can be made more specific.

To get started on HE.net, sign up at www.tunnelbroker.net. HE.net will allocate `/64` networks after registering and selecting a regional IPv6 tunnel server.

A summary of the tunnel configuration can be viewed on HE.net's website as seen in Figure *HE.net Tunnel Config Summary*. It contains important information such as:

Tunnel ID
: A number to uniquely identify this tunnel.

Server IPv4 Address
: IP address of the HE.net tunnel server

Client IPv4 Address
: The external IP address of the firewall

Server IPv6 Addresses
: The IPv6 address used inside the tunnel for the remote endpoint.

Client IPv6 Addresses
: The IPv6 address used inside the tunnel for this firewall.

Routed IPv6 Prefixes
The IPv6 prefixes routed to the firewall over this tunnel. By default there is at least a `/64` prefix listed, but HE.net can also allocate a `/48` upon request.

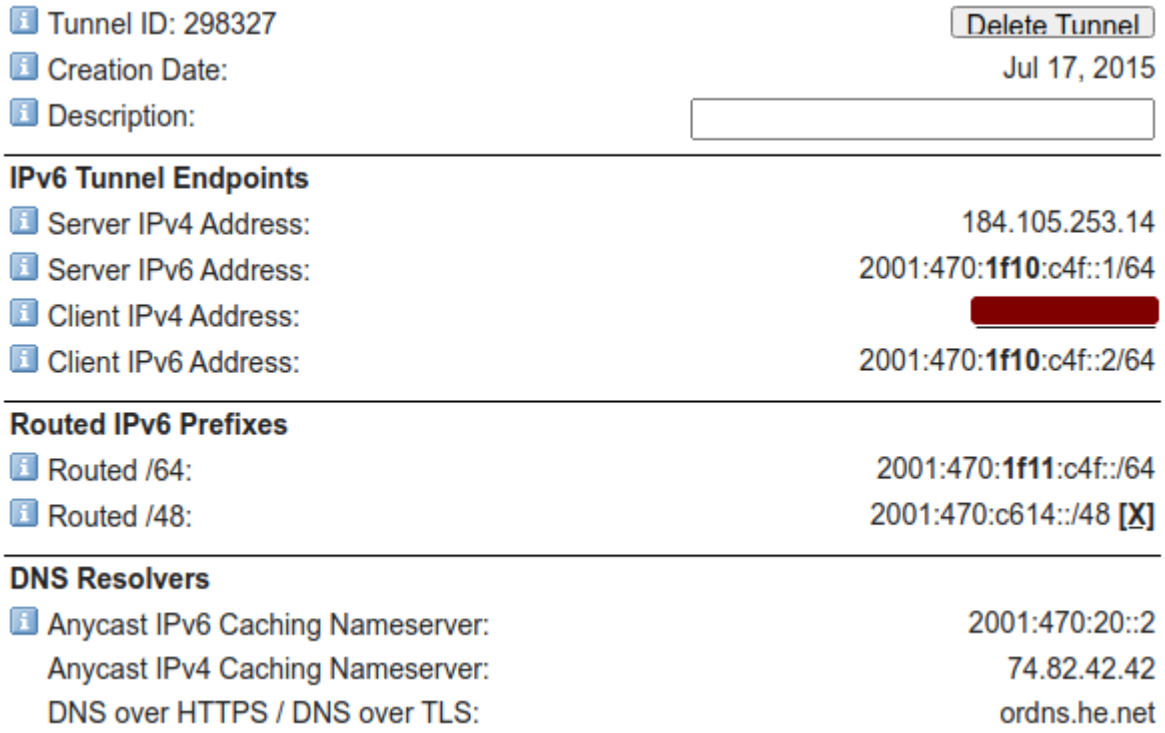

Fig. 61: HE.net Tunnel Config Summary

The **Advanced** tab on the tunnel broker site has two additional notable options:

MTU
The MTU for packets sent by HE.net over the tunnel.

If the WAN used for terminating the GIF tunnel is PPPoE or another WAN type with a low MTU, move the slider down as needed. For example, a common MTU for PPPoE lines with a tunnel broker is `1452`.

Update Key
A key for updating the tunnel address using dynamic DNS mechanisms.

If the WAN has a dynamic IP address (e.g. DHCP, PPPoE), note this key for later use.

Once the initial setup for the tunnel service is complete, configure the firewall to use the tunnel.

35.32.2 Allow IPv6 Traffic

New installations of pfSense software allow IPv6 traffic by default. Configurations upgraded from older versions may still be set to block IPv6.

To enable IPv6 traffic, perform the following:

- Navigate to **System > Advanced** on the **Networking** tab
- Check **Allow IPv6** if not already checked
- Click **Save**

35.32.3 Allow ICMP

The firewall must allow ICMP echo requests on the WAN address that is terminating the tunnel. This allows HE.net to ensure that the firewall is online and reachable. If the firewall blocks ICMP the tunnel broker may refuse to setup the tunnel to the IPv4 address.

Edit the ICMP rule created earlier, or create a new rule to allow ICMP echo requests from a source IP address of the **Server IPv4 Address** in the tunnel configuration as shown in Figure *Example ICMP Rule*.

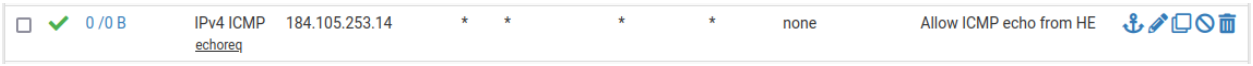

Fig. 62: Example ICMP Rule

35.32.4 Create and Assign the GIF Interface

Next, create the interface for the GIF tunnel. Complete the fields with the corresponding information from the tunnel broker configuration summary.

- Navigate to **Interfaces > Assignments** on the **GIF** tab
- Click  **Add** to add a new entry
- Configure the settings as follows:

  Parent Interface
  The WAN where the tunnel terminates. This would be the WAN which has the **Client IPv4 Address** on the tunnel broker.

  GIF Remote Address
  The **Server IPv4 Address** on the summary.

  GIF Tunnel Local Address
  The **Client IPv6 Address** on the summary.

  GIF Tunnel Remote Address
  The **Server IPv6 Address** on the summary, along the with prefix length (typically `/64`).

  Description
  Text describing the tunnel, such as `HE Tunnel Broker`

- Leave remaining options blank or unchecked
- Click **Save**

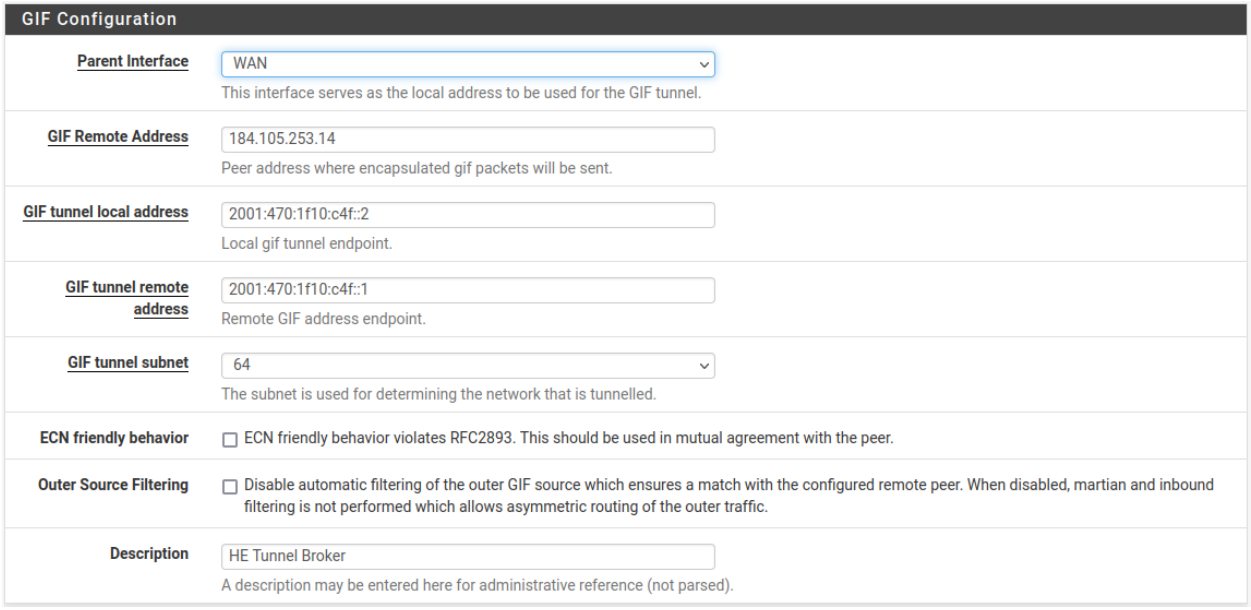

Fig. 63: Example GIF Tunnel

See Figure *Example GIF Tunnel*.

Note: If the WAN containing this tunnel uses a dynamic IP address, see *Updating the Tunnel Endpoint* for information on how to keep the tunnel endpoint IP address updated with HE.net.

Now assign the GIF tunnel as an interface:

- Navigate to **Interfaces > Assignments**, **Interface Assignments** tab
- Select the newly created GIF under **Available Network Ports**
- Click  **Add** to add it as a new interface

35.32.5 Configure the New OPT Interface

The new interface is accessible at **Interfaces > OPTx**, where `x` is a sequential number assigned to the interface.

- Navigate to the new interface configuration page. (**Interfaces > OPTx**)
- Check **Enable Interface**
- Enter a name for the interface in the **Description** field, e.g. `WANv6`
- Click **Save**
- Click **Apply Changes**

Warning: After applying the interface changes the firewall may need to be restarted before the interface configuration will be fully operational. Check **Status > Interfaces** and if the **IPv6 Address** field is missing or empty for the assigned GIF interface, reboot the firewall.

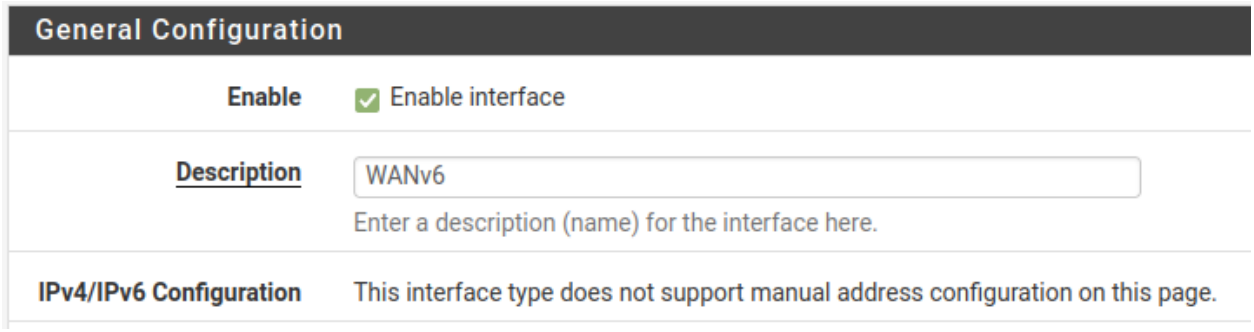

Fig. 64: Example Tunnel Interface

35.32.6 Setup the IPv6 Gateway

The firewall automatically creates a dynamic IPv6 gateway for the assigned GIF interface, but it is not yet marked as default.

- Navigate to **System > Routing**
- Set **Default Gateway IPv6** to the dynamic IPv6 gateway with the same name as the IPv6 WAN created above (e.g. `WANV6_TUNNELV6`)
- Click **Save**
- Click **Apply Changes**

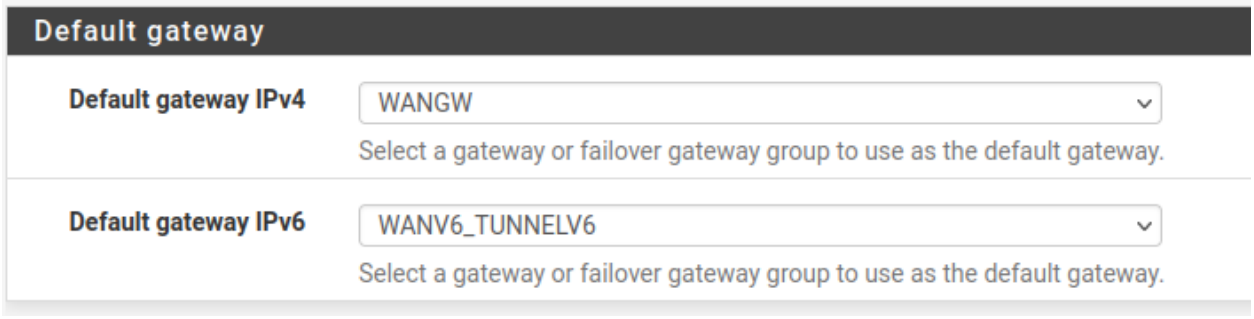

Fig. 65: Example Tunnel Gateway

Navigate to **Status > Gateways** to view the gateway status. The gateway will show as "Online" if the tunnel is operational, as seen in Figure *Example Tunnel Gateway Status*.

Fig. 66: Example Tunnel Gateway Status

35.32.7 Setup IPv6 DNS

The firewall DNS configuration likely already properly handles DNS queries for `AAAA` records already. If the firewall is configured to use the *DNS Resolver* in resolver mode, which is the default, then nothing needs to be done.

If the firewall is configured to use the DNS Resolver in forwarding mode, or it uses the *DNS Forwarder*, then the best practice is to add the tunnel broker *DNS Servers* under **System > General Setup**.

Enter at least one IPv6 DNS server or use a public DNS service such as Google public IPv6 DNS servers (`2001:4860:4860::8888`, `2001:4860:4860::8844`), Quad9, or CloudFlare.

At this point the firewall itself should have full working IPv6 connectivity.

35.32.8 Setup LAN for IPv6

For clients on LAN to access the internet using IPv6, the LAN must also be configured for IPv6.

The most common method is to set LAN as dual stack IPv4 and IPv6.

- Navigate to **Interfaces > LAN**
- Change the configuration as follows:

  IPv6 Configuration Type
  Static IPv6

  Static IPv6 Configuration
  Enter an IPv6 address from the **Routed /64** in the tunnel broker configuration with a prefix length of `64`.

  For example, use `2001:db8:1111:2222::1` for the LAN IPv6 address if the **Routed /64** is `2001:db8:1111:2222::/64`.
- Click **Save**
- Click **Apply Changes**

Alternately, use a `/64` from within the Routed `/48` prefix.

Setup DHCPv6 and/or Router Advertisements

Router Advertisements and/or DHCPv6 can assign IPv6 addresses to clients automatically. This is covered in detail in *IPv6 Router Advertisements*.

A brief overview is as follows:

- Navigate to **Services > DHCPv6 Server**
- Change to the local interface where IPv6 clients are located
- Check **Enable**
- Enter a range of IPv6 IP addresses inside the new LAN IPv6 prefix
- Click **Save**
- Navigate to **Services > **Router Advertisement**
- Change to the local interface where IPv6 clients are located
- Set the **Mode** to *Managed* (DHCPv6 only) or *Assisted* (DHCPv6+SLAAC)
- Click **Save**

Modes are described in greater detail at *Router Advertisements (Or: "Where is the DHCPv6 gateway option?")*.

To assign IPv6 addresses to LAN clients manually, use the firewall LAN IPv6 address as the gateway with a proper matching prefix length, and pick addresses from within the LAN prefix.

35.32.9 Add Firewall Rules

Now add firewall rules which allow IPv6 traffic from hosts on LAN.

Note: The default LAN ruleset on current installations already contains a rule to pass IPv6, but the best practice is to check and confirm it is present and configured appropriately.

- Navigate to **Firewall > Rules**, **LAN** tab.
- Check the list for an existing IPv6 rule

  If a rule to pass appropriate IPv6 traffic already exists, then no additional action is necessary.

- Click  **Add** to add a new rule to the bottom of the list
- Configure the rule as follows:

  Address Family
  IPv6

  Source
  LAN Net

  Destination
  Any

- Click **Save**
- Click **Apply Changes**

If a local interface contains servers which need to handle public IPv6 requests, add firewall rules on the tab for the IPv6 WAN (the assigned GIF interface) to allow IPv6 traffic to reach the servers on required ports.

35.32.10 Reboot

The best practice is to restart the firewall and then the clients before testing connectivity.

Reboot the firewall first using **Diagnostics > Reboot**. Monitor the boot process for errors and check the interface and gateway status once it is back online. This not only ensures that the firewall is configured properly but will also be configured correctly on subsequent reboots.

Next, reboot a client to test. Some clients may automatically obtain an IPv6 address while they are up and running, some may need their networking services restarted, and others will only check at boot time. Thus, the best practice is to reboot the client to ensure it obtains IPv6 configuration parameters from the firewall.

Note: If a client does not obtain an IPv6 address, check its network settings to see if IPv6 support is enabled and active. Additionally, some clients do not support certain types of IPv6 configuration. For example, Android clients do not support DHCPv6 but they do support SLAAC.

35.32.11 Try It!

Finally, check for IPv6 connectivity using a site such as test-ipv6.com. An example of the output results of a successful configuration from a client on LAN is in Figure *IPv6 Test Results*.

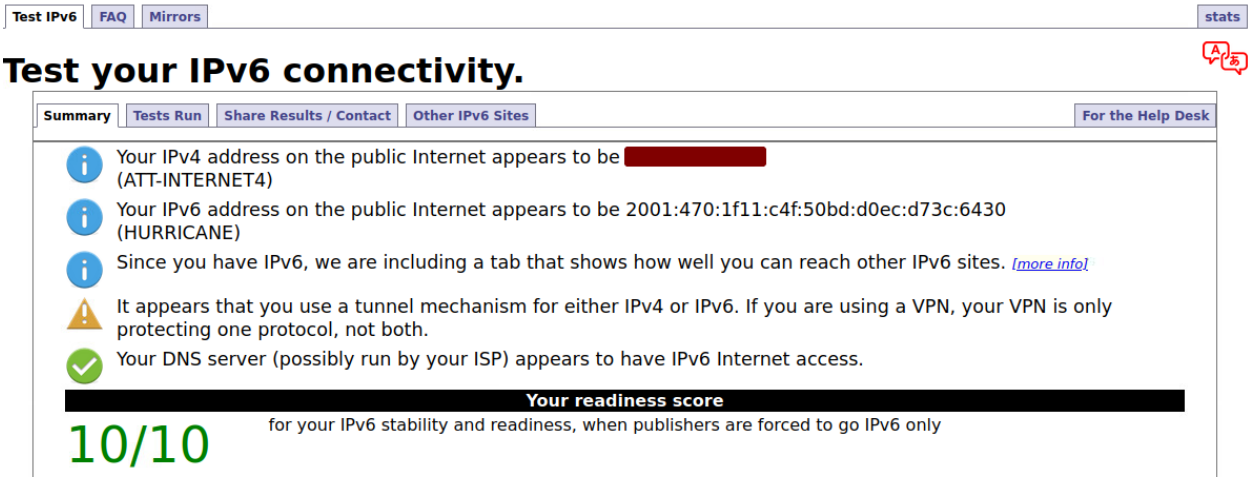

Fig. 67: IPv6 Test Results

35.32.12 Updating the Tunnel Endpoint

The firewall can still use HE.net as a tunnel broker on dynamic WAN types such as DHCP or PPPoE. pfSense software includes a Dynamic DNS type which updates the tunnel endpoint IP address whenever the WAN interface IP changes.

If necessary, configure Dynamic DNS as follows:

- Navigate to **Services > Dynamic DNS**
- Click **Add** to add a new entry
- Configure the entry as follows:

  Service Type
  HE.net Tunnelbroker

  Interface to Monitor
  WAN

  Hostname
  Enter the **Tunnel ID** from the tunnel broker configuration.

  Username
  The **Username** for the tunnel broker site.

  Password
  Enter either the **Password** or **Update Key** for the tunnel broker site.

  Description
  Text describing the entry, e.g. `HE Tunnel`

- Click **Save and Force Update**

If and when the WAN IP address changes, the firewall will automatically update the tunnel broker configuration.

35.33 L2TP/IPsec Remote Access VPN Configuration Example

On current versions of pfSense® software, L2TP/IPsec may be configured for mobile clients, though it is not a desirable configuration.

> **Warning:** Users have reported issues with Windows L2TP/IPsec clients behind NAT. If the clients will be behind NAT, Windows clients will most likely not function.
>
> Consider an IKEv2 implementation instead.

As warned at the start of the chapter, the Windows client, among others, and the strongSwan IPsec daemon are not always compatible, leading to failure in many cases. The best practice is to use another solution such as IKEv2 instead of L2TP/IPsec.

See also:

IPsec Remote Access VPN Example Using IKEv2 with EAP-MSCHAPv2 contains a walkthrough for configuring IKEv2.

Before configuring the IPsec portion, setup the L2TP server as described in *L2TP Server Configuration* and add users, firewall rules, etc, as covered there.

35.33.1 Setup IPsec

These settings have been tested and found to work with some clients, but other similar settings may function as well. Feel free to try other encryption algorithms, hashes, etc.

Mobile Clients Tab

- Navigate to **VPN > IPsec**, **Mobile Clients** tab in the pfSense software GUI
- Configure the settings as follows:

  Enable IPsec Mobile Client Support
  Checked

  User Authentication
  Local Database (Not used, but the option must have something selected)

  Provide a virtual IP address to clients
  Unchecked

  Provide a list of accessible networks to clients
  Unchecked

- Click **Save**

Phase 1

- Click the **Create Phase1** button at the top if it appears, or edit the existing Mobile IPsec Phase 1
  - If there is no Phase 1, and the **Create Phase1** button does not appear, navigate back to the **Mobile Clients** tab and click it there.
- Configure the settings as follows:

  Key Exchange version
  v1 or *Auto*

  Description
  Text describing the tunnel

  Authentication method
  Mutual PSK

  Negotiation Mode
  Main

  My Identifier
  My IP address

  Encryption algorithm
  AES 256

  Hash algorithm
  SHA1

  DH key group
  14 (2048 bit)

  Note: iOS and other platforms may work with a **DH key group** of *2* instead.

  Lifetime
  `28800`

  Disable Rekey
  Unchecked

  NAT Traversal
  Auto

  Enable DPD
  Checked, set for `10` seconds and `5` retries
- Click **Save**

Phase 2

- Click  **Show Phase 2 Entries** to show the Mobile IPsec Phase 2 list
- Click  **Add P2** to add a new Phase 2 entry if one does not exist, or click  to edit an existing entry
- Configure the settings as follows:

Mode
Transport

Description
Text describing the tunnel

Protocol
ESP

Encryption algorithms
ONLY *AES 128*

Hash algorithms
ONLY *SHA1*

PFS Key Group
off

Lifetime
`3600`

- Click **Save**

Pre-Shared Key

The Pre-Shared Key for the connection, which is common for all clients, must be configured in a special way.

- Navigate to **VPN > IPsec**, **Pre-Shared Keys** tab on pfSense software
- Click  **Add** to add a new PSK
- Configure the settings as follows:

Identifier
`allusers`

Note: The `allusers` name is a special keyword used by pfSense software to configure a wildcard PSK, which is necessary for L2TP/IPsec to function. Do not use any other **Identifier** for this PSK!

Secret Type
PSK

Pre-Shared Key
A password for the user, such as `aaabbbccc` – ideally one a lot longer, more random, and secure!

- Click **Save**
- Click **Apply Changes**

35.33.2 IPsec Firewall Rules

Firewall rules are necessary to pass traffic from the client host over IPsec to establish the L2TP tunnel, and inside L2TP to pass the actual tunneled VPN traffic to systems across the VPN. Adding the L2TP rules was covered in the previous section. To add IPsec rules:

- Navigate to **Firewall > Rules**, **IPsec** tab
- Review the current rules. If there is an "allow all" style rule, then there is no need to add another. Continue to the next task.
- Click  **Add** to add a new rule to the top of the list
- Configure the options as follows:

  Protocol
  any

  Source
  any

  Destination
  any

Note: This does not have to pass all traffic, but must at least pass L2TP (UDP port `1701`) to the WAN IP address of the firewall.

- Click **Save**
- Click **Apply Changes**

35.33.3 DNS Configuration

If DNS servers are supplied to the clients and the Unbound **DNS Resolver** is used, then the subnet chosen for the L2TP clients must be added to its access list.

- Navigate to **Services > DNS Resolver**, **Access Lists** tab
- Click  **Add** to add a new access list
- Enter an **Access List Name**, such as *VPN Users*
- Set **Action** to *Allow*
- Click  **Add Network** under **Networks** to add a new network
- Enter the VPN client subnet into the **Network** box, e.g. `10.3.177.128`
- Choose the proper **CIDR**, e.g. `25`
- Click **Save**
- Click **Apply Changes**

35.33.4 Client Setup

When configuring clients, there are a few points to look for:

- Ensure that the client operating system configuration is set to connect to the proper external address for the VPN.
- It may be necessary to force the VPN type to **L2TP/IPsec** on the client if it has an automatic mode.
- The client authentication type must match what is configured on the L2TP server (e.g. *CHAP*)

35.34 Connecting to L2TP/IPsec from Android

The L2TP/IPsec client on Android has the ability to set a custom identifier, which allows L2TP/IPsec to function with the server on pfSense® software using Pre-Shared Keys. Clients on other operating systems do not allow for this, which makes them incompatible with current versions of pfSense software.

35.34.1 IPsec Setup

The setup is similar to a standard *IPsec Remote Access VPN Example Using IKEv1 with Xauth* setup except that xauth is not used, but rather "**Mutual PSK**", and Phase 2 uses **Transport** mode rather than Tunnel.

Pre-Shared Keys

After the tunnel has been configured, click to the "Pre-Shared Keys" tab in the IPsec settings, and add IPsec keys. A single group key may be used if desired, or make many keys for different users.

That's it for IPsec!

35.34.2 L2TP Setup

To setup L2TP:

- Navigate to VPN > L2TP
- Configure the settings as follows:

  Enable L2TP Server
  Checked

  Interface
  WAN (or the same chosen for IPsec)

  Server Address
  An **unused IP address** in a new subnet, e.g `x.x.x.2`.

  > **Warning:** This **MUST NOT** overlap any IP address in use on the firewall.

  Remote Address Range
  The starting IP of the clients, e.g. `x.x.x.128`

  Subnet netmask
  The netmask for the client connection, the server IP address should be included in this subnet, e.g. `/24`

Secret
blank

This does not appear to work, at least with the Android version tested.

Encryption Type
CHAP is recommended

L2TP DNS Servers
The LAN IP address of the firewall or another internal DNS server

RADIUS settings
Configure if needed, otherwise leave them at defaults

- Save
- Navigate to the Users tab
- Add L2TP user accounts and passwords
- Navigate to **Firewall > Rules** on the **L2TP VPN** tab
- Add afirewall rule to pass traffic, e.g from any to any or much more restrictive if preferred.

35.34.3 Android Client Setup

On the phone/tablet/device:

- Navigate to the system settings and VPN settings (varies by device and specific Android version
- Tap **Add VPN Profile**
- Configure the settings as follows:

Name
Enter a name

Type
Tap *L2TP/IPsec PSK*

Server Address
The WAN IP of the firewall (or the IP address of the interface chosen for IPsec and L2TP)

L2TP Secret
blank

IPsec Identifier
Enter the identifier for the PSK entered previously, either a per-user or common identifier

IPsec Pre-Shared Key
The PSK that goes with the identifier for this user/group

Advanced Options
May be used to control which networks will attempt to use the VPN, or specify custom DNS server and domains for this client.

- Tap **Save**
- Tap the newly created VPN entry in the VPN list
- Enter the **username** and **password** from the **L2TP Users**
- Check **Save account information** to save the VPN credentials (not recommended!),
- Tap **Connect**

The connection should then connect and function. If it does not work, check the IPsec logs and the **Status > System Logs**, **VPN**, **L2TP Raw log** to see more specific errors.

35.34.4 Other Thoughts

In theory, Mutual RSA should also work, but so far it has not succeeded in testing. In RSA mode, Phase 1 requires main mode, but otherwise should be OK.

35.35 Migrating an Assigned LAN to LAGG

Only unassigned physical ports can be added to a LAGG, so to move an assigned LAN interface to a LAGG requires some shuffling around.

In this example, the LAN of a device (`igc0`) will be moved into a LAGG with another port on the same device (`igc1`).

35.35.1 Warnings/Precautions

It is best to perform this change from an interface that is not involved, such as a secondary LAN, DMZ, OPT port, perhaps WAN or VPN. Though if the switch is properly configured there should be no loss of connectivity, at least with LACP. Other modes may vary.

35.35.2 Prerequisites/Assumptions

The switch must be properly configured to accommodate the LAGG. This typically means configuring an LACP group and setting ports to use that group. The NICs involved, in this example `igc1` and `igc0`, should be connected to properly configured ports on the switch before starting.

35.35.3 Migrate LAN to a LAGG

- Ensure the second NIC for the LAGG is not assigned (e.g. `igc1` mapped to *LAN2*, *OPTx*, etc.)
  - Check **Interfaces > Assignments** and remove its entry if present.
- Create a new LAGG including only the second NIC
  - Navigate to **Interfaces > Assignments** on the **LAGG** tab
  - Click  to create a new LAGG
  - Click to select the NIC to use with this LAGG (`igc1`)
  - Select the proper LAGG protocol, such as *LACP*
  - Enter a description
  - Click **Save**
- Navigate to **Interfaces > Assignments**, change the assignment of LAN to the newly created LAGG interface (`lagg0`)
- Click **Save**
- Navigate back to the **LAGG** tab

- Click  to edit the LAGG
- Ctrl-click to add in the port that was formerly assigned to LAN (`igc0`) so that both NICs are selected
- Click **Save**

Now both `igc1` and `igc0` are members of a LAGG and that LAGG is the LAN interface with all of the existing configuration in place.

35.35.4 VLANS

If any VLANs were in use directly on the interfaces involved, migrate them as follows:

- Add new VLAN tags using the LAGG interface as the parent (**Interfaces > Assignments**, **VLAN** tab)
- Fix the assignments to use the LAGG versions of the tags (**Interfaces > Assignments**)
- Remove the old tags from the physical interface(s) (**Interfaces > Assignments**, **VLAN** tab)

> **Warning: Do not edit the existing tags and change the parent interface**
>
> Changing the parent in place will cause problems with the interface assignments. Always create new tags, switch the assignments, then remove the old tags.

35.36 Accessing a CPE/Modem from Inside the Firewall

Most end-user Customer Premise Equipment (CPE) devices like cable or DSL modems have a web interfaces on a private IP address. Since these sit outside the firewall and do not typically have a public IP address, accessing them isn't as straight forward as it might seem. The firewall is typically assigned a public IP, and sends all outbound traffic upstream to the ISP. The ISP won't route the private subnet back to the modem, leaving it unreachable. This page describes the work around needed to access the management interface on the modem from the inside of the network.

Note: The CPE management IP address **must** be on a different IP subnet than the internal network. If it is not, attempts to connect to it will never go to the firewall to be routed out to the modem, as hosts on the internal network would try to connect to it on the local network and fail.

35.36.1 Configure a new Interface

A PPPoE WAN is actually assigned to a virtual PPPoE adapter, not the physical port.

- Navigate to **Interfaces > Assignments**
- Set **Available network ports:** to the physical network card for the PPPoE WAN

  For example, if the WAN is *PPPOE0(ix3)*, choose *ix3*.

- Click  **Add** to assign this port as a new OPT interface
- Navigate to **Interfaces > (new OPT interface)**
- Configure the settings as follows:

Enable
Checked

Description
`ModemAccess` or a similar useful name.

IPv4 Configuration Type
Static

IPv4 Address
Configure an IP address in the same subnet as the modem, such as `192.168.1.5/24`.

IPv4 Upstream Gateway
None

Do not set a gateway.

- Click **Save**
- Click **Apply Changes**

35.36.2 Configure NAT

Now NAT needs to be configured to translate traffic destined to the modem to the new interface. This is necessary so the modem sees the traffic sourced from an IP on its local subnet. Without this NAT, it would be necessary to configure a route on the modem so it knows how to reach the internal subnet. With some modems this isn't possible, and in most cases it's easier to NAT the traffic so routing isn't a concern.

To add the NAT:

- Navigate to **Firewall > NAT**, **Outbound** tab.
- Switch to **Hybrid Outbound NAT** and click **Save**
- Click  to add a new Outbound NAT rule
- Configure the settings as follows:

  Interface
  ModemAccess

  Source
  Network, enter the LAN subnet

  Destination
  The IP subnet of the modem

  Translation
  Interface Address

- Click **Save**
- Click **Apply changes**

It should now be possible to access the modem from LAN.

35.37 Configuring Multi-WAN for IPv6

Multi-WAN can be utilized with IPv6 provided that the firewall is connected to multiple ISPs or tunnels with static addresses.

See also:

See *Configuring IPv6 Through A Tunnel Broker Service* for help setting up a tunnel.

Gateway Groups work the same for IPv6 as they do for IPv4, but address families cannot be mixed within a group. A group must contain either *only* IPv4 gateways, or *only* IPv6 gateways.

Throughout this section "Second WAN" refers to the second or additional interface with IPv6 connectivity. It can be an actual interface that has native connectivity, or a tunnel interface when using a tunnel broker.

35.37.1 Caveats

In most cases, NAT is not used with IPv6 in any capacity as everything is routed. That is great for connectivity and for businesses or locations that can afford Provider Independent (PI) address space and a BGP peering, but it doesn't work in practice for small business and home users.

Network Prefix Translation (NPt) allows one subnet to be used for LAN which has full connectivity via its native WAN, but also has translated connectivity on the additional WANs so it appears to originate there. While not true connectivity for the LAN subnet via the alternate paths, it is better than no connectivity at all if the primary WAN is down.

Warning: This does not work for dynamic IPv6 types where the subnet is not static, such as DHCP6-PD.

35.37.2 Requirements

To setup Multi-WAN for IPv6 the firewall must have:

- IPv6 connectivity with static addresses on two or more WANs
- Gateways added to **System > Routing** for both IPv6 WANs, and confirmed connectivity on both.
- A routed `/64` from each provider/path
- LAN using a static routed `/64` or similar

35.37.3 Setup

The setup for IPv6 Multi-WAN is very close to the setup for IPv4. The main difference is that it uses NPt instead of NAT.

First, under **System > Routing** on the **Gateway Groups** tab, add Gateway Groups for the IPv6 gateways, with the tiers setup as desired. This works identically to IPv4.

Next, navigate to **System > General** and set one IPv6 DNS server set for each IPv6 WAN, also identically to IPv4.

Now add an NPt entry under **Firewall > NAT** on the **NPt** tab, using the following settings:

Interface
: Secondary WAN (or tunnel if using a broker)

Internal IPv6 Prefix
: The *LAN* IPv6 subnet

Destination IPv6 Prefix
The **routed IPv6 subnet** for the *secondary* WAN or tunnel

Note: This is **not** the `/64` of the WAN interface itself – it is the `/64` routed to the firewall on that WAN by the upstream.

What this does is akin to 1:1 NAT for IPv4, but for the entire subnet. As traffic leaves the second WAN, if it is coming from the LAN subnet, it will be translated to the equivalent IP address in the other subnet.

For example if the firewall has `2001:xxx:yyy::/64` on LAN, and `2001:aaa:bbb::/64` on the second WAN, then `2001:xxx:yyy::5` would appear as `2001:aaa:bbb::5` if the traffic goes out the second WAN. For more information on NPt, see *IPv6 Network Prefix Translation (NPt)*.

As with IPv4, the Gateway Groups must be used on LAN firewall rules. Edit the LAN rules for IPv6 traffic and set them use the gateway group, making sure to have rules for directly connected subnets/VPNs without a gateway set so they are not policy routed.

35.37.4 Alternate Tactics

Some users prefer to configure LAN with a "private" IPv6 subnet from the `fc00::/7` space and setup NPt for both WANs.

35.38 Configuring NAT for a VoIP PBX

For VoIP there are typically a few components to get right for proper inbound and outbound audio from a local PBX.

1. Port forward entries with firewall rules (Or 1:1 NAT with Firewall Rules)
2. Manual Outbound NAT with a rule at the top set to perform static port NAT on traffic from the PBX (Or 1:1 NAT)
3. On the PBX, ensure it is set properly for NAT with the correct external IP and local subnets defined.

35.38.1 Aliases to make it easy

It is easiest to start by making a few entries under **Firewall > Aliases** to make the rules easier to accomplish:

- Host alias for the PBX itself, named `PBX`, containing the local IP address of the PBX.
- Network or Host alias called `SIP_Trunks` for the upstream SIP trunk addresses, if known. If the `SIP_Trunk` address/network is not known or changes, do not make an alias and leave these values set to *any*.
- Port alias called `PBX_Ports` containing all of the port numbers needed for SIP, RTP, and other control ports. (usually `5060` and `10000:20000`, but varies from provider to provider and PBX implementation)

35.38.2 Port Forwards

Create a port forward:

- Navigate to **Firewall > NAT**, **Port Forwards** tab
- Create a new entry and configure it as follows:

  Interface
  WAN

  Protocol
  UDP (or *TCP/UDP* if needed)

  Source
  Type *Address or Alias*: *SIP_Trunks* – or a *Any* for the type if the SIP trunk IP addresses are not known.

  Source Port
  any/any

  Destination
  WAN address or external VIP for the PBX

  Destination Port
  PBX_Ports

  Redirect target IP
  PBX

  Redirect target port
  PBX_Ports

- Click **Save**
- Click **Apply Changes**

35.38.3 Outbound NAT

Setup *Hybrid Outbound NAT*.

- Navigate to **Firewall > NAT**, **Outbound** tab
- Select *Hybrid Outbound NAT*
- Click **Save**
- Click  to create a new rule at the top of the list.
- Configure the rule as follows:

  Interface
  WAN

  Protocol
  UDP

  Source
  Network, *PBX*

  Source Port
  blank

Destination
Network, *SIP_Trunks* – Or *Any* for the type if the SIP trunk IP addresses are not known

Destination Port
PBX_Ports (or leave blank)

Translation
Interface address if using the WAN IP address, or the external VIP for the PBX

Port
blank

Static Port
CHECKED

- Click **Save**
- Click **Apply Changes**

35.38.4 Reset States

After making the changes to NAT rules, the states for the PBX must be reset.

- Navigate to **Diagnostics > States**
- Enter the IP address of the PBX and click **Filter**
- Click **Kill**

Once the PBX re-registers it test inbound and outbound calls and confirm inbound and outbound audio works as expected.

35.39 Configuring NAT for VoIP Phones

If VoIP is being used, the default settings may not be correct in certain circumstances. The default settings handle the majority of scenarios, but depending on the specifics of a particular setup, changes may be necessary to obtain a working configuration.

The following sections will help to get local handsets working with a remote PBX.

See also:

If the PBX is local and trying to communicate with a remote SIP trunk, see *Configuring NAT for a VoIP PBX* for more ideas.

35.39.1 Disable source port rewriting

By default pfSense® software rewrites the source port on all outbound traffic. This is necessary for proper NAT in some circumstances such as having multiple SIP phones behind a single public IP registering to a single external PBX. With a minority of providers, rewriting the source port of RTP can cause one way audio. In that case, setup manual outbound NAT and *Static Port* on all UDP traffic potentially with the exclusion of UDP `5060`.

Performing static port NAT on UDP `5060` traffic by default is not desirable because it breaks more scenarios than it helps in current environments. However, in cases where a PBX requires static port on UDP `5060`, configuring outbound NAT to perform static port NAT for `udp/5060` will allow it to function. This can be done using Hybrid outbound NAT and a phone-specific rule or by using manual outbound NAT.

35.39.2 Set Conservative state table optimization

The default UDP timeouts in pf are too low for some VoIP services. If phones mostly work, but randomly disconnect, set **Firewall Optimization Options** to *Conservative* under **System > Advanced**, **Firewall/NAT** tab.

A keep-alive or re-registration on the phone set for 20-30 seconds or so can also help, and is often a better solution.

35.39.3 Use the siproxd package

The *Siproxd package* is used only for deployments with local phones and a remote PBX where rewriting the source port breaks the ability to connect because the service will not work with rewritten source ports. In this very specific circumstance the siproxd package enables multiple phones to connect to a single outside server with a static source port of `5060`.

Do not use this package if the PBX is local. Only use it if the upstream PBX strictly requires all phones to have a source port of `5060`.

35.39.4 Disable scrub

In very rare circumstances, scrubbing needs to be disabled under **System > Advanced**, **Firewall/NAT tab**. In most cases this should be left at the default setting (unchecked). Only change this setting if it has been determined it is necessary to do so. Some phones send malformed packets that will be silently dropped without scrub active (e.g. unfragmented packets that claim to be fragmented).

35.40 Configuring NAT64 for IPv6-only Clients

This recipe covers the configuration of *NAT64* to allow local IPv6-only clients to contact remote resources only reachable over IPv4.

This entire process is transparent to the client software, such as a web browser. It will act as though it is communicating directly to IPv6 hosts even when using hostnames for sites with no IPv6 connectivity.

See also:

- *NAT64*
- *NAT64 Firewall Rule Configuration*
- *PREF64*
- *DNS64*

35.40.1 Base Configuration

This guide assumes the firewall already has working IPv6 and IPv4 connectivity and at least one local interface which is configured for IPv6 clients.

Consult the *NAT64 Requirements* for other prerequisite configuration items.

35.40.2 Configure NAT64 Firewall Rules

The first step is to configure a *NAT64 firewall rule* to perform the IPv6 to IPv4 translation:

- Navigate to **Firewall > Rules**
- Navigate to the tab for the IPv6 only client interface
- Click  to add a new firewall rule
- Configure the rule as follows

  Action
  Pass

  Address Family
  IPv6

  Enable NAT64
  Checked

  Protocol
  Any

  Address Family Translation Source
  Automatic (default)

  Destination
  Leave at the current value which should be the default NAT64 prefix, `69:ff9b::/96`.

  Description
  `Default Allow IPv6 to IPv4 via NAT64`

- Click **Save**
- Drag and move the rule so it is *above* any other default IPv6 allow rule

  If this rule is below another rule which passes IPv6 to any destination, it would never be matched.

- Click **Save**
- Click **Apply Changes**

The rule should look similar to the following:

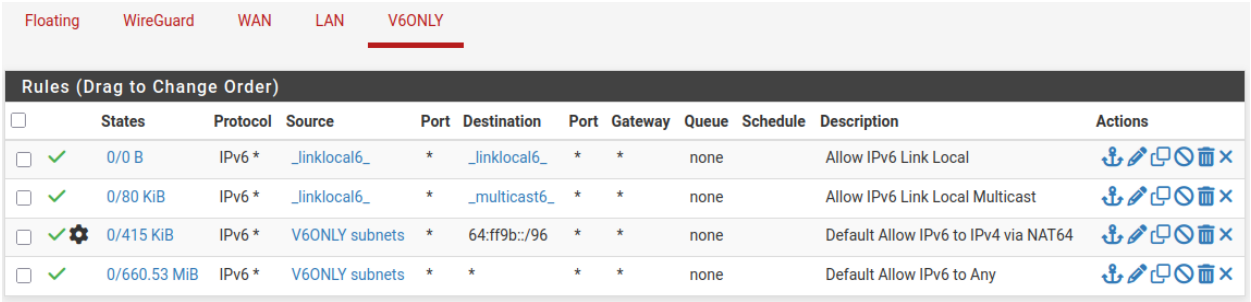

Fig. 68: IPv6 Client Interface Firewall Rules with NAT64

35.40.3 Configure DHCPv6 for DNS

NAT64 requires working DNS so clients must have a way to be informed about DNS server addresses. It is possible to deliver this via router advertisements (RDNSS/DNSSL) but not all clients support those methods, so configuring DHCPv6 for DNS is a safe backup.

- Navigate to **Services > DHCPv6 Server**
- Navigate to the tab for the IPv6 only client interface
- Ensure the service is **Enabled** and has **Enable DNS** checked
- Manually change the **DNS Servers** list if the default entries are not acceptable.
- Click **Save**
- Click **Apply Changes**

35.40.4 Configure PREF64

Router advertisements can use *PREF64* to announce the NAT64 prefix to IPv6 clients for automatic discovery:

- Navigate to **Services > Router Advertisement**
- Navigate to the tab for the IPv6 only client interface
- Ensure the **Router Mode** is set to one of *Managed*, *Assisted*, or *Stateless DHCP*.
- Set **NAT64 Prefix** to `64:ff9b::/96`
- Check **Enable DNS** to enable RDNSS/DNSSL
- Check **Mirror DHCPv6** or manually enter DNS servers
- Click **Save**

35.40.5 Configure DNS64

DNS64 includes IPv6-mapped IPv4 addresses in DNS responses so IPv6-only clients can contact these hosts via NAT64. This behavior is not active by default and must be enabled separately.

- Navigate to **Services > DNS Resolver**
- Navigate to the **Advanced Settings** tab
- Check **Enable DNS64 (RFC 6147)**
- Set **DNS64 Prefix** to `64:ff9b::/96`
- Click **Save**
- Click **Apply Changes**

35.40.6 Configure IPv4 DHCP (Optional)

If the segment does not have IPv4 DHCP enabled, it can remain disabled.

However, if the segment has local/private IPv4 configured, such as for a VPN, but no external IPv4 connectivity, then clients can be sent a DHCP option which informs them to prefer IPv6 for external communication.

Note: This guide assumes Kea is in use for DHCP service

- Navigate to **Services > DHCP Server**
- Navigate to the tab for the IPv6 only client interface
- Locate the **Custom Configuration** section near the bottom of the page
- Set **JSON Configuration** to the following:

```
{
  "option-data": [
    {
      "name": "v6-only-preferred",
      "data": "3600"
    }
  ]
}
```

This enables DHCP option `108` for IPv4 DHCP clients on that segment and clients which respect this option should only contact IPv6 servers when possible.

35.40.7 Finish Up / Testing

IPv6 clients on the configured interface should now be able to contact IPv4 only Internet sites and have their traffic translated automatically.

Connectivity can be tested manually as described in *Contacting Remote IPv4 Hosts*.

A popular testing technique is to attempt loading a well-known Internet site which only has IPv4 connectivity, such as `https://github.com`.

Contacting IPv4 addresses directly using IPv4 notation may be possible depending on the presence of a customer-side translator (CLAT), but this is completely dependent on the client and is not handled at the firewall level.

35.41 Exporting NetFlow with softflowd

softflowd is a NetFlow collector that can be deployed on pfSense® software.

Tip: This recipe requires an add-on package. pfSense Plus software contains a native solution which is easier to configure and more efficient: *Firewall Packet Flow Data*.

35.41.1 Installing softflowd

There is a package available under **System > Packages** on the **Available Packages** tab. Find it in the list, click at the end of its row, and confirm the installation.

35.41.2 Configuring and Launching softflowd

Once the package has been installed, visit **Services > softflowd** to configure the service.

Interface
Ctrl-click to select all of the interfaces upon which the daemon will gather NetFlow data.

Host
The target NetFlow server which will receive flow data.

Port
The port on the **Host** which is listening for NetFlow data.

Max Flows
The number of flows to track before older flows expire.

NetFlow Version
The desired version of the NetFlow protocol.

See also:

See NetFlow Versions on Wikipedia for more information.

35.41.3 Controlling softflowd from the Command Line

To view statistics about the running softflowd process, run the following command, replacing `igc0` with the actual network interface to query:

```
: softflowctl -c /var/run/softflowd.igc0.ctl statistics
```

To expire all flows and force an update to be sent to the netflow server, run the following command, replacing `igc0` with the actual network interface to control:

```
: softflowctl -c /var/run/softflowd.igc0.ctl expire-all
```

35.41.4 Known issues

See also:

The pfSense software issue tracker contains a list of known issues with this package.

35.41.5 Package Support

This package is currently supported by Netgate TAC to those with an active support subscription.

35.42 OpenVPN Site-to-Site Configuration Example with SSL/TLS

A site-to-site connection using **SSL/TLS** in client/server mode works for connecting one or more remote sites and is especially convenient for managing a large number of remote sites connecting back to a central site in a hub-and- spoke fashion.

35.42.1 Example Configuration Overview

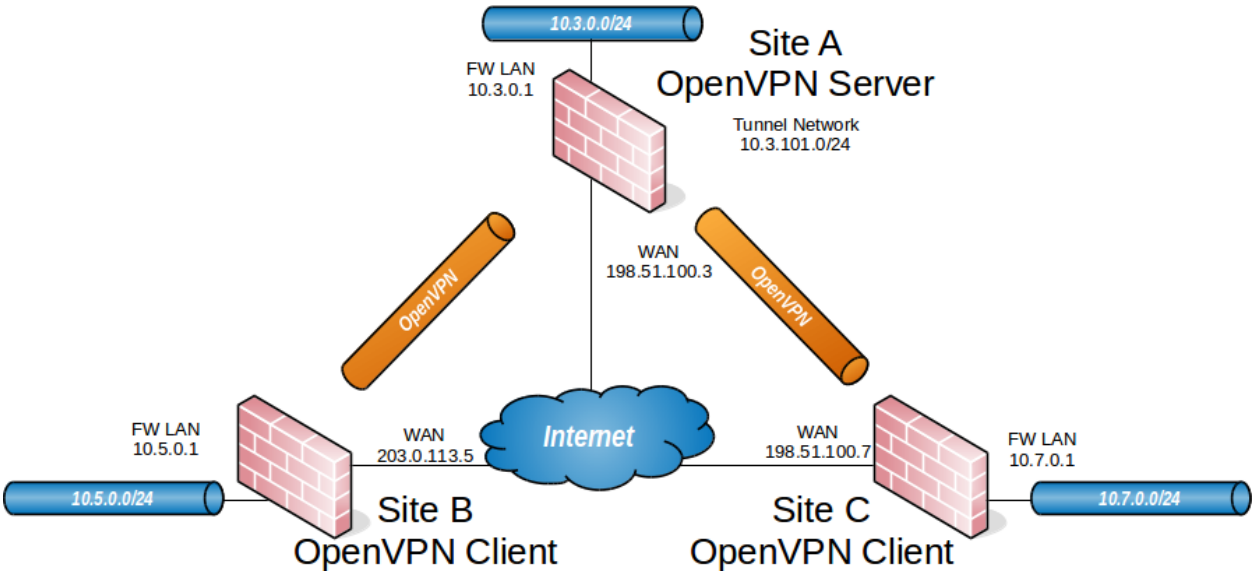

Fig. 69: OpenVPN Example Site-to-Site SSL/TLS Network

When configuring a site-to-site OpenVPN connection using SSL/TLS one firewall will be the server and the others will be clients.

Tip: Usually the main location will be the server and the remote offices will act as clients, though if one location has a static IP address and more bandwidth than the main office that may be a more desirable location for the server.

This style of VPN requires a dedicated subnet for the OpenVPN interconnection between networks in addition to the subnets on both ends. Figure *OpenVPN Example Site-to-Site SSL/TLS Network* shows a depiction of this layout, using `10.3.101.0/24` as the IPv4 Tunnel Network for the VPN. This can be any valid IPv4 subnet so long as it does not overlap another subnet currently in use on any of the connected networks.

OpenVPN allocates IP addresses the same way it does for remote access clients. When using a **Topology** style of *subnet*, each client obtains one IP address in a common subnet. When using a **Topology** style of *net30*, each connecting client gets a /30 subnet to interconnect itself with the server.

See also:

The *subnet* topology style uses address space efficiently and has very few quirks with its behavior compared to the alternatives. See *Topology* for more details.

The following sections describe how to configure the server and client sides of the connection.

35.42.2 Summary of Requirements

This style of VPN requires several items, all of which are covered in this recipe:

On the Server at the main site:

- A certificate structure including a Certificate authority, server certificate, and one or more client certificate(s)
- An OpenVPN Server instance
- OpenVPN Client Specific Override entries for **all** clients

On each remote site:

- Imported CA and client certificate
- OpenVPN Client instance

35.42.3 Example Configuration Settings

Table 12: OpenVPN Endpoint Settings - Site A - Server

Site A - Server	
Name	Austin Office
WAN Address	198.51.100.3
LAN Subnet	10.3.0.0/24
LAN Address	10.3.0.1
CA Name	S2SCA
Cert CN	serverA
Tunnel Net	10.3.101.0/24

Table 13: OpenVPN Endpoint Settings - Site B - Client

Site B - Client	
Name	London Office
Cert CN	clientB
WAN Address	203.0.113.5
LAN Subnet	10.5.0.0/24
LAN Address	10.5.0.1

Table 14: OpenVPN Endpoint Settings - Site C - Client

Site C - Client	
Name	Colorado Office
Cert CN	clientC
WAN Address	198.51.100.7
LAN Subnet	10.7.0.0/24
LAN Address	10.7.0.1

35.42.4 Configuring SSL/TLS Server Side

The server **requires** two items for **each** network reachable through an OpenVPN client:

- An entry in the **IPv4 Remote network(s)** field on the **server instance**.

  This configures a `route` to tell the operating system that OpenVPN knows about a remote network. This makes the OS hand packets for the destination network over to OpenVPN.

- An entry in the **IPv4 Remote network(s)** field of an **OpenVPN Client Specific Override**.

  This configures an internal route (`iroute`) to tell OpenVPN how to route a subnet to a specific client certificate. This allows OpenVPN to deliver packets for the destination network to the appropriate connected client without hardcoding its address anywhere.

More detail on these will follow in the example.

Warning: This setup assumes the server will not be using DCO, as that requires a different routing configuration. For a similar recipe that works with DCO, see *OpenVPN Site-to-Site Configuration Example with SSL/TLS and DCO*.

See also:

- *Client Specific Overrides*
- *Troubleshooting OpenVPN Internal Routing (iroute)*
- *Tunnel Settings*

Create Certificate Structure

The first step is to create a certificate structure for this VPN.

This example uses the names listed in *Example Configuration Settings* – The CA is named `S2SCA`, the Server CN is named `serverA`, and the clients are `clientB` and `clientC`.

See also:

Certificate Management

Create a Certificate Authority

Create a CA unique to this VPN:

- Navigate to **System > Certificates**, **Authorities** tab
- Click  **Add** to create a new a CA
- Enter the settings as follows:

  Descriptive Name
  `S2SCA`

  Method
  Create an internal Certificate Authority

  Randomize Serial
  Checked

Key Type
RSA, *2048* (or higher)

Digest Algorithm
sha256 (or higher)

Lifetime (days)
`3650`

Common Name
`S2SCA`

Subject Component Fields
The remaining fields are optional, but can be set to reflect the location of the CA.

- Click **Save**

Create a Server Certificate

Create a server certificate signed by the VPN CA:

- Navigate to **System > Certificates**, **Certificates** tab
- Click  **Add/Sign** to create a new certificate
- Enter the settings as follows:

Method
Create an internal Certificate

Descriptive Name
`serverA`

Certificate Authority
S2SCA

Key Type
RSA, *2048* (or higher)

Digest Algorithm
sha256 (or higher)

Lifetime (days)
`398`

Note: Some current operating systems and software limit server certificates to a maximum lifetime of `398` days for security reasons. Clients on these platforms may reject a server certificate with a longer lifetime.

Common Name
`serverA`

Subject Component Fields
The fields contain data copied from the CA and are optional, but can be set to reflect the location of the server.

Certificate Type
Server Certificate

> **Warning:** This setting is critical, **do not forget to set this value**!

Alternative Names
Optional extra entries, if needed, which specify alternate ways to identify the server. This can be left blank if the certificate will only be used by OpenVPN. Otherwise, add fields with additional information such as alternate hostnames, static IP addresses, and so on which are relevant to this server.

- Click **Save**

Create User Certificates

Create user certificates for each remote site signed by the VPN CA.

- Navigate to **System > Certificates**, **Certificates** tab
- Click  **Add/Sign** to create a new certificate
- Enter the settings as follows:

Method
Create an internal Certificate

Descriptive Name
`clientB`

Certificate Authority
S2SCA

Key Type
RSA, *2048* (or higher)

Digest Algorithm
sha256 (or higher)

Lifetime (days)
`3650`

Common Name
`clientB`

Subject Component Fields
The fields contain data copied from the CA and are optional, but can be set to reflect the location of the client.

Certificate Type
User Certificate

> **Warning:** This setting is critical, **do not forget to set this value**!

Alternative Names
Optional extra entries which specify alternate ways to identify the client. These can be left blank if the certificate will only be used by OpenVPN. Otherwise, add fields with additional information such as alternate hostnames, static IP addresses, and so on which are relevant to this client.

- Click **Save**

Repeat this process for every client (e.g. `clientC` and any future clients).

Export Certificates

The next task is to export the certificates and keys which the client requires when connecting to the OpenVPN server.

- Navigate to **System > Certificates**, **Authorities** tab
- Click  on the row for the CA to export its certificate
- Navigate to **System > Certificates**, **Certificates** tab
- Click  on the row for each client certificate to export the certificates
- Click  on the row for each client certificate to export the private key for the client certificates.

Warning: **Do not** export the CA key, server certificate, or server key! The client does not need these files and copying them unnecessarily significantly weakens the security of the VPN.

Configure the OpenVPN Server Instance

- Navigate to **VPN > OpenVPN**, **Servers** tab
- Click  **Add** to create a new server
- Fill in the fields as described below, with everything else left at defaults.

  Use values appropriate for this network, or the defaults if unsure.

  See also:

  See *Server Configuration Options* for details on each of these options.

  Description
  Enter text to describe the connection, e.g. `Site-to-Site VPN`.

  Server Mode
  Peer to Peer (SSL/TLS)

  DCO (Plus Only)
  This example uses routing that only functions when DCO is **disabled**. To use DCO on the server, check this box to activate the feature and read the DCO section of the documentation for specifics on how routing differs.

  See also:

  - For additional information on DCO in general, see *OpenVPN Data Channel Offload (DCO)*.
  - For a similar recipe that works with DCO, see *OpenVPN Site-to-Site Configuration Example with SSL/TLS and DCO*.

  Device Mode
  tun

Protocol
UDP on IPv4 only

Interface
WAN

Local Port
`1194`

TLS Configuration
Check the **Use a TLS Key** box to enable TLS authentication which provides protection for the tunnel control channel.

Leave **Automatically generate a TLS Key** checked so the firewall will generate a new key automatically the first time this entry is saved.

Peer Certificate Authority
Select the CA created at the beginning of this process (`S2SCA`)

Peer Certificate Revocation List
Select a CRL for the CA, if one exists.

Server Certificate
Select the server certificate created at the beginning of this process (`serverA`)

IPv4 Tunnel Network
Enter the chosen tunnel network, `10.3.101.0/24`

IPv4 Local Network(s)
Enter the LAN subnets for all sites including the server: `10.3.0.0/24, 10.5.0.0/24, 10.7.0.0/24`

Note: If there are more networks on the server side that clients need to reach, such as networks reachable via static routes, other VPNs, and so on, add them as additional entries in the **IPv4 Local Network** box.

IPv4 Remote Network(s)
Enter **only** the client LAN subnets: `10.5.0.0/24, 10.7.0.0/24`

Inter-client communication
Check if the client sites will communicate between each other. Leave unchecked if the remote clients only communicate with the server network(s).

Inactive
`0` to disable disconnecting idle clients, so that site-to-site connections can stay up indefinitely.

- Click Save.
- Click  to edit the new server instance
- Find the **TLS Key** box
- Select all of the text inside
- Copy the text to the clipboard
- Save this to a file or paste it into a text editor such as Notepad temporarily

Create Client-Specific Overrides

Now add **Client Specific Overrides** for each client site. These tie a client subnet to a particular certificate so that OpenVPN can properly route a subnet to the correct site.

- Navigate to **VPN > OpenVPN**, **Client Specific Overrides** tab
- Click  to add a new override
- Fill in the fields on this screen as follows:

  Description
  A name for the override, such as the common name of the client (e.g. `clientB`).

  Common Name
  Enter the CN of the first client site. In this example, that is `clientB`.

  Server List
  Select the server instance configured previously.

  IPv4 Remote Network/s
  The clientB LAN subnet, `10.5.0.0/24`.

  Note: This field sets up the internal route (`iroute`) for OpenVPN.

- Click **Save**

Add an override for the second site, adjusting the **Description**. **Common Name** and **IPv4 Remote Network** to match. In the example for site C, these values would be `clientC` and `10.7.0.0/24` respectively.

See also:

- *Client Specific Overrides*
- *Troubleshooting OpenVPN Internal Routing (iroute)*
- *Tunnel Settings*

Firewall Rules

External Traffic (WAN)

Next, add a firewall rule for the WAN interface which allows access to the OpenVPN server.

- Navigate to **Firewall > Rules**, **WAN** tab
- Click  **Add** to create a new rule at the top of the list
- Set the options as follows:

  Protocol
  UDP

  Source
  any (since multiple sites must connect)

> **Tip:** For extra security, if the clients have static IP addresses, create an alias containing these addresses, then set it as the source on this rule.

Destination
WAN Address

Destination port
`1194`

Description
`OpenVPN Multi-Site VPN`

- Click **Save**
- Click **Apply Changes**

Tunneled Traffic

Now add a rule to the **OpenVPN** tab to pass traffic over the VPN from the Client-side LAN to the Server-side LAN. This can be an "Allow all" style rule or a set of stricter rules. This example allows all traffic using this rule:

- Navigate to **Firewall > Rules**, **OpenVPN** tab
- Click  **Add** to create a new rule at the top of the list
- Set the options as follows:

Protocol
any

Source
any

> **Tip:** For extra security, create an alias containing only the remote hosts or subnets which must initiate contact with hosts on the sever LAN, then use that alias as the source on this rule.

Destination
any

> **Tip:** For extra security, create an alias containing only the local hosts or subnets on the server LAN which must accept connections from remote hosts across the VPN, then use that alias as the destination on this rule.

Description
`Allow all on OpenVPN`

- Click **Save**
- Click **Apply Changes**

That completes the server setup, next, now move on to configure the clients.

35.42.5 Configuring SSL/TLS Client Side

Import CA and Certificate

On the client, import the CA certificate along with the client certificate and key for that site. This is the same CA and client certificate created earlier in this document.

See also:

Certificate Management

Import these items at **System > Certificates**.

First import the CA:

- Navigate to **System > Certificates**, **Authorities** tab
- Click  **Add** to create a new certificate authority
- Enter the settings as follows:

  Descriptive Name
  `S2SCA`

  Method
  Import an existing Certificate Authority

  Certificate Data
  Open the CA certificate file in a text editor on the client PC, select all of the text, and copy it to the clipboard. Then paste it into this field.

- Click **Save**

Next, import the client certificate:

- Navigate to **System > Certificates**, **Certificates** tab
- Click  **Add** to create a new certificate
- Enter the settings as follows:

  Method
  Import an existing Certificate

  Descriptive Name
  `clientB VPN Certificate`

  Certificate Type
  X.509 (PEM)

  Certificate Data
  Open the client certificate file in a text editor on the client PC, select all of the text, and copy it to the clipboard. Then paste it into this field.

  Private Key Data
  Open the client certificate private key in a text editor on the client PC, select all of the text, and copy it to the clipboard. Then paste it into this field.

- Click **Save**

Repeat these steps on each client firewall.

Configure the OpenVPN Client Instance

After importing the certificates, create the OpenVPN client:

- Navigate to **VPN > OpenVPN**, **Clients** tab
- Click  **Add** to create a new client
- Fill in the fields as follows, with everything else left at defaults:

  See also:

  See *Client Configuration Options* for details on each of these options.

  Description
  Text to describe the connection (e.g. `Site A VPN`)

  Server Mode
  Peer to Peer (SSL/TLS)

  DCO (Plus Only)
  Check this box to activate the *OpenVPN Data Channel Offload (DCO)* feature for the client if desired.

  See also:

  See *OpenVPN Data Channel Offload (DCO)* for additional information.

  Device Mode
  tun

  Protocol
  UDP on IPv4 only

  Interface
  WAN

  Server host or address
  The public IP address or hostname of the OpenVPN server (`198.51.100.3` in this example)

  Server Port
  `1194`

  Use a TLS Key
  Checked

  Automatically generate a TLS key
  Unchecked

  TLS Key
  Paste in the TLS key copied from the server instance

  Peer Certificate Authority
  The CA imported at the beginning of this process

  Client Certificate
  The client certificate imported at the beginning of this process

- Click Save

Note: With SSL/TLS server/client configurations such as this example, routes and other configuration options are automatically pushed from the server and thus not present in the client configuration. If the client side must reach additional networks, configure them in the **server** settings or a client- specific override as **Local Networks**.

Firewall Rules

This next step is optional depending on whether or not hosts on the server network or other client sites need to initiate contact with hosts on the client network. If the other sites do not need to initiate contact with this client, then no action is necessary.

If the other sites needs to initiate contact, then this traffic requires a firewall rule on the **OpenVPN** tab on the *client* firewall to allow traffic from other VPN sites to reach the Client-side LAN. An "Allow all" style rule is OK in some cases, but a set of stricter rules is the best practice.

This example allows all traffic:

- Navigate to **Firewall > Rules**, **OpenVPN** tab
- Click  **Add** to create a new rule at the top of the list
- Set the options as follows:

  Protocol
  any

  Source
  any

  Tip: For extra security, create an alias containing only the remote hosts or subnets which must initiate contact with hosts on the client LAN, then use that alias as the source on this rule.

  Destination
  any

  Tip: For extra security, create an alias containing only the local hosts or subnets on the client LAN which must accept connections from remote hosts across the VPN, then use that alias as the destination on this rule.

  Description
  `Allow all on OpenVPN`
- Click **Save**
- Click **Apply Changes**

35.42.6 Testing the Connection

The configuration is now complete. The OpenVPN client instance automatically starts when created, so it should already be attempting to connect at this point and if the configuration is correct, it will be connected.

Try to ping across to the remote end LAN to verify connectivity.

See also:

Troubleshooting OpenVPN.

35.43 OpenVPN Site-to-Site Configuration Example with SSL/TLS and DCO

A site-to-site server using OpenVPN and Data Channel Offload (DCO) in Peer-to-Peer SSL/TLS mode can connect one remote site and can work with either static or dynamic routing. OpenVPN DCO allows for huge performance gains when processing encrypted OpenVPN data by reducing the amount of context switching that happens for each packet.

Note: DCO is available exclusively in pfSense Plus software.

See also:

- *OpenVPN Site-to-Site Configuration Example with SSL/TLS (without DCO)*, upon which this recipe is based.
- *OpenVPN Data Channel Offload (DCO)*
- *OpenVPN*

35.43.1 Warnings and Limitations

Note: Some OpenVPN features and use cases are not compatible with DCO. See *Limitations* for a list of known DCO limitations.

- This configuration does not require assigning the OpenVPN instance on either side as an interface in pfSense Plus software. While assigning the interface may work, this recipe assumes the interface is **not** assigned on the server or client.
- When DCO is enabled on pfSense Plus software, OpenVPN handles the routing in a much different manner at the operating system level. DCO is not compatible with internal routing in OpenVPN (`iroute`) which limits a server to one client. However, it is compatible with routing traffic on the interface using the operating system routing table, which allows OpenVPN with DCO to utilize dynamic routing protocols such as BGP or OSPF to exchange routes between VPN peers.
- Static routes must be configured through OpenVPN itself and not by using gateways and routing in pfSense Plus software.
- Each server can only have one client connection, however, separate servers can be created for each remote client by changing the port number and tunnel network to unique values for each client/server pair.
- OpenVPN DCO is **not compatible** with a `/30` or smaller tunnel network. There are problems with the code for this mode in OpenVPN which can lead to failed connections and instability. That style of connection is being phased out of OpenVPN itself, so the best practice is to avoid that type of configuration.

35.43.2 Example Configuration Overview

When configuring a site-to-site OpenVPN connection using SSL/TLS one node will be the server and the other will be a client.

Tip: Usually a primary site or data center will be the server and a smaller or remote site will act as a client. However, if a remote site has a static IP address and more bandwidth than the primary site that may be a more desirable location for the server.

This style of VPN requires a dedicated subnet for the OpenVPN interconnection between networks in addition to the subnets on both ends. This can be any valid IPv4 subnet so long as it is **larger** than a `/30` (e.g. `/29` or `/24`) and it does not overlap another subnet currently in use on any of the connected networks.

OpenVPN allocates IP addresses for this type of configuration the same way it does for remote access clients. Using a **Topology** style of *subnet*, the client obtains an IP address in a common subnet with the server.

35.43.3 Summary of Requirements

This style of VPN requires several items, all of which are covered in this recipe:

On the server:

- A certificate structure including a certificate authority, server certificate, and a client certificate
- An OpenVPN server instance
- An IPv4 subnet for the OpenVPN tunnel network, larger than a `/30`, such as `10.18.104.0/29`.
- Firewall rules on the WAN to allow a connection from the client node

On the client:

- Imported CA and client certificate
- OpenVPN client instance

On both nodes:

- pfSense Plus software version 22.05 or later for DCO support

  The best practice is to use the current supported version, pfSense Plus software version 25.07-RELEASE
- Firewall rules to pass traffic inside the tunnel
- An appropriate routing configuration (static or dynamic) – specifics vary by method, see *Configuring Routing for SSL/TLS with DCO*.

35.43.4 Example Configuration Settings

Table 15: OpenVPN Endpoint Settings - Site A - Server

Site A - Server	
Name	Austin
CA Name	S2SCA
Cert CN	serverA
WAN Address	198.51.100.18
LAN Subnet	10.18.0.0/24
LAN Address	10.18.0.1
Tunnel Net	10.18.104.0/29

Table 16: OpenVPN Endpoint Settings - Site B - Client

Site B - Client	
Name	Colorado
Cert CN	clientB
WAN Address	203.0.113.19
LAN Subnet	10.19.0.0/24
LAN Address	10.19.0.1

35.43.5 Configuring SSL/TLS with DCO Server Instance

The server configuration consists of a certificate structure, OpenVPN server instance, firewall rules, and a routing configuration.

Note: Parts of this configuration will vary depending on the routing style the tunnel will use. See *Configuring Routing for SSL/TLS with DCO* for details.

Create Certificate Structure

The first step is to create a certificate structure for this VPN.

This example uses the names listed in *Example Configuration Settings* – The CA is named `S2SCA`, the server certificate CN is `serverA`, and the client certificate CN is `clientB`.

See also:

Certificate Management

Create a Certificate Authority

Create a CA unique to this VPN:

- Navigate to **System > Certificates**, **Authorities** tab
- Click  **Add** to create a new a CA
- Enter the settings as follows:

  Descriptive Name
  `S2SCA`

  Method
  Create an internal Certificate Authority

  Randomize Serial
  Checked

  Key Type
  RSA, *2048* (or higher)

  Digest Algorithm
  sha256 (or higher)

  Lifetime (days)
  `3650`

  Common Name
  `S2SCA`

  Subject Component Fields
  The remaining fields are optional, but can be set to reflect the location of the CA.

- Click **Save**

Create a Server Certificate

Create a server certificate signed by the VPN CA:

- Navigate to **System > Certificates**, **Certificates** tab
- Click  **Add/Sign** to create a new certificate
- Enter the settings as follows:

  Method
  Create an internal Certificate

  Descriptive Name
  `serverA`

  Certificate Authority
  S2SCA

  Key Type
  RSA, *2048* (or higher)

  Digest Algorithm
  sha256 (or higher)

Lifetime (days)
`398`

> **Note:** Some operating systems and software limit server certificates to a maximum lifetime of `398` days for security reasons. Clients on these platforms may reject a server certificate with a longer lifetime.

Common Name
`serverA`

Subject Component Fields
The fields contain data copied from the CA and are optional, but can be set to reflect the location of the server.

Certificate Type
Server Certificate

> **Warning:** This setting is critical, **do not forget to set this value**!

Alternative Names
Optional extra entries, if needed, which specify alternate ways to identify the server. This can be left blank if the certificate will only be used by OpenVPN. Otherwise, add fields with additional information such as alternate hostnames, static IP addresses, and so on which are relevant to this server.

- Click **Save**

Create User Certificate

Create a user certificate for the remote site signed by the VPN CA.

- Navigate to **System > Certificates**, **Certificates** tab
- Click  **Add/Sign** to create a new certificate
- Enter the settings as follows:

Method
Create an internal Certificate

Descriptive Name
`clientB`

Certificate Authority
S2SCA

Key Type
RSA, *2048* (or higher)

Digest Algorithm
sha256 (or higher)

Lifetime (days)
`3650`

Common Name
`clientB`

Subject Component Fields
The fields contain data copied from the CA and are optional, but can be set to reflect the location of the client.

Certificate Type
User Certificate

> **Warning:** This setting is critical, **do not forget to set this value**!

Alternative Names
Optional extra entries which specify alternate ways to identify the client. These can be left blank if the certificate will only be used by OpenVPN. Otherwise, add fields with additional information such as alternate hostnames, static IP addresses, and so on which are relevant to this client.

- Click **Save**

Export Certificates

The next task is to export the certificates and keys which the client requires when connecting to the OpenVPN server.

- Navigate to **System > Certificates**, **Authorities** tab
- Click  on the row for the CA to export its certificate
- Navigate to **System > Certificates**, **Certificates** tab
- Click  on the row for the client certificate to export the certificate
- Click  on the row for the client certificate to export the private key for the client certificate

> **Warning:** **Do not** export the CA key, server certificate, or server key! The client does not need these files and copying them unnecessarily significantly weakens the security of the VPN.

Configure the OpenVPN Server Instance

- Navigate to **VPN > OpenVPN**, **Servers** tab
- Click  **Add** to create a new server
- Fill in the fields as described below, with everything else left at defaults.

  Use values appropriate for this network, or the defaults if unsure.

  See also:

  - See *Server Configuration Options* for details on each of these options.
  - See *OpenVPN Data Channel Offload (DCO)* for details on options which are incompatible with DCO.

Description
Enter text to describe the connection, e.g. `Site-to-Site VPN`.

Server Mode
Peer to Peer (SSL/TLS)

> **Warning:** DCO requires SSL/TLS, shared key is not compatible.

DCO (Plus Only)
Checked

Protocol
UDP on IPv4 only

> **Note:** DCO is not compatible with TCP.

Interface
WAN

Local Port
`1194`

TLS Configuration
Check the **Use a TLS Key** box to enable TLS authentication which provides protection for the tunnel control channel.

Leave **Automatically generate a TLS Key** checked so the firewall will generate a new key automatically the first time this entry is saved.

Peer Certificate Authority
Select the CA created at the beginning of this process (`S2SCA`)

Peer Certificate Revocation List
Select a CRL for the CA, if one exists.

Server Certificate
Select the server certificate created at the beginning of this process (`serverA`)

Data Encryption Algorithms
DCO is limited to the AES-256-GCM, AES-128-GCM, and ChaCha20-Poly1305 encryption algorithms. Any of these options will work, provided the same algorithms are selected on the server and client side.

The best algorithm for an environment depends on the hardware and what it may be capable of accelerating. See *Cryptographic & Thermal Hardware* for details.

IPv4 Tunnel Network
Enter the chosen tunnel network, `10.18.104.0/29`

> **Warning:** This cannot be set to a `/30` or `/31` subnet, it must be a larger subnet, such as a `/29` or `/24`.

IPv4 Local Network(s)
If this setup uses static routing, enter the LAN subnet(s) for the **server** site: `10.18.0.0/24`.

This will push a route for these networks to the client.

Tip: If there are more networks on the server side that clients need to reach, such as networks reachable via static routes, other VPNs, and so on, add them as additional entries in the **IPv4 Local Network** box separated by a comma. For example, `10.18.0.0/24, 10.18.5.0/24`.

See also:

See *Configuring Routing for SSL/TLS with DCO* for details on alternative routing configurations.

IPv4 Remote Network(s)
If this setup uses static routing, enter the LAN subnet(s) for the **client** site: `10.19.0.0/24`.

This will direct the operating system to deliver traffic for these networks to this OpenVPN instance.

Tip: If there are more networks on the client side that the server side needs to reach, such as networks reachable via static routes, other VPNs, and so on, add them as additional entries in the **IPv4 Remote Network** box separated by a comma. For example, `10.18.0.0/24, 10.18.5.0/24`.

See also:

See *Configuring Routing for SSL/TLS with DCO* for details on alternative routing configurations.

Other options can remain at their default values.

- Click Save.
- Click  to edit the new server instance
- Find the **TLS Key** box
- Select all of the text inside
- Copy the text to the clipboard
- Save this to a file or paste it into a text editor such as Notepad temporarily

Firewall Rules

External Traffic (WAN)

Next, add a firewall rule for the WAN interface which allows access to the OpenVPN server.

- Navigate to **Firewall > Rules**, **WAN** tab
- Click  **Add** to create a new rule at the top of the list
- Set the options as follows:

Protocol
UDP

Source
Any

If the client has a static IP address, set it as the source on this rule instead, either directly or by using an alias.

Destination
WAN Address

Destination port
`1194`

Description
`OpenVPN Site-to-Site DCO VPN`

- Click **Save**
- Click **Apply Changes**

Tunneled Traffic

Now add a rule to the **OpenVPN** tab to pass traffic over the VPN from the Client-side LAN to the Server-side LAN. This can be an "allow all" style rule or a set of stricter rules. This example allows all traffic using this rule:

- Navigate to **Firewall > Rules**, **OpenVPN** tab
- Click  **Add** to create a new rule at the top of the list
- Set the options as follows:

Protocol
Any

Source
Any

Tip: For extra security, create an alias containing only the remote hosts or subnets which must initiate contact with hosts on the sever LAN, then use that alias as the source on this rule.

Destination
Any

Tip: For extra security, create an alias containing only the local hosts or subnets on the server LAN which must accept connections from remote hosts across the VPN, then use that alias as the destination on this rule.

Description
`Allow all tunneled OpenVPN traffic from clientB`

- Click **Save**
- Click **Apply Changes**

That completes the server setup, now move on to configure the client.

35.43.6 Configuring SSL/TLS with DCO Client Instance

The client configuration consists of an imported certificate structure, OpenVPN client instance, firewall rules, and a routing configuration.

Note: Parts of this configuration will vary depending on the routing style the tunnel will use. See *Configuring Routing for SSL/TLS with DCO* for details.

Import CA and Certificate

On the client, import the CA certificate along with the client certificate and key. This is the same CA and client certificate created earlier in this document.

See also:

Certificate Management

Import these items at **System > Certificates**.

First import the CA:

- Navigate to **System > Certificates**, **Authorities** tab
- Click  **Add** to create a new certificate authority
- Enter the settings as follows:

  Descriptive Name
  `S2SCA`

  Method
  Import an existing Certificate Authority

  Certificate Data
  Open the CA certificate file in a text editor on the client PC, select all of the text, and copy it to the clipboard. Then paste it into this field.

- Click **Save**

Next, import the client certificate:

- Navigate to **System > Certificates**, **Certificates** tab
- Click  **Add** to create a new certificate
- Enter the settings as follows:

  Method
  Import an existing Certificate

  Descriptive Name
  `clientB VPN Certificate`

  Certificate Type
  X.509 (PEM)

Certificate Data
Open the client certificate file in a text editor on the client PC, select all of the text, and copy it to the clipboard. Then paste it into this field.

Private Key Data
Open the client certificate private key in a text editor on the client PC, select all of the text, and copy it to the clipboard. Then paste it into this field.

- Click **Save**

Configure the OpenVPN Client Instance

After importing the certificates, create the OpenVPN client:

- Navigate to **VPN > OpenVPN**, **Clients** tab
- Click  **Add** to create a new client
- Fill in the fields as follows, with everything else left at defaults:

  See also:

  See *Client Configuration Options* for details on each of these options.

  Description
  Text to describe the connection (e.g. `Site A VPN`)

  Server Mode
  Peer to Peer (SSL/TLS)

  DCO (Plus Only)
  Checked

  Protocol
  UDP on IPv4 only

  Interface
  WAN

  Server host or address
  The public IP address or hostname of the OpenVPN server (`198.51.100.18` in this example)

  Server Port
  `1194`

  Use a TLS Key
  Checked

  Automatically generate a TLS key
  Unchecked

  TLS Key
  Paste in the TLS key copied from the server instance

  Peer Certificate Authority
  The CA imported at the beginning of this process

  Client Certificate
  The client certificate imported at the beginning of this process

  Data Encryption Algorithms
  Match the algorithm(s) selected in the server configuration

IPv4 Tunnel Network
Leave blank

- Click Save

Note: With SSL/TLS server/client configurations such as this example, the server automatically pushes address configuration, routes, and certain other options to the client. These options do not need to be present in the client configuration.

If the client side must reach additional networks, configure them in the **server** settings.

Firewall Rules

This next step is optional depending on whether or not hosts on the server network need to initiate contact with hosts on the client network. If the other site does not need to initiate contact with hosts behind this client, then no action is necessary.

Incoming connections from the server side to the client side require a firewall rule on the **OpenVPN** tab on the *client* firewall. An "allow all" style rule is OK in some cases, but a set of stricter rules is the best practice.

This example allows all traffic:

- Navigate to **Firewall > Rules**, **OpenVPN** tab
- Click  **Add** to create a new rule at the top of the list
- Set the options as follows:

  Protocol
  Any

  Source
  Any

  Tip: For extra security, create an alias containing only the remote hosts or subnets which must initiate contact with hosts on the client side, then use that alias as the source on this rule.

  Destination
  Any

  Tip: For extra security, create an alias containing only the local hosts or subnets on the client side which must accept connections from remote hosts across the VPN, then use that alias as the destination on this rule.

  Description
  `Allow all tunneled OpenVPN traffic from serverA`

- Click **Save**
- Click **Apply Changes**

35.43.7 Configuring Routing for SSL/TLS with DCO

Since OpenVPN with DCO enabled cannot handle routing internally in OpenVPN, it requires extra steps to manage routes in certain cases.

Static Routing

The example in this recipe already configures static routing by using the **IPv4 Local Network(s)** and **IPv4 Remote Network(s)** configuration options.

This is the most basic method as it only requires configuring these two values on the server side, and the client side automatically picks up routes the server pushes.

Dynamic Routing with BGP

With DCO enabled the operating system can support routing over the OpenVPN interface using BGP. However, BGP requires a static neighbor address so there is one pre-requisite step before configuring BGP itself.

Create Client-Specific Override

On the server side, add a **Client Specific Override** for the client certificate to set a static IP address in the tunnel network. With this override entry present, the client instance will obtain the same static IP address each time the VPN connects. This is necessary so the BGP configuration on the server side can locate the client as a neighbor.

- Navigate to **VPN > OpenVPN**, **Client Specific Overrides** tab
- Click  to add a new override
- Fill in the fields on this screen as follows:

  Description
  A name for the override, such as the common name of the client (e.g. `clientB`).

  Common Name
  Enter the CN of the client node. In this example, that is `clientB`.

  Server List
  Select the server instance description.

  IPv4 Tunnel Network
  A static address inside the server **IPv4 Tunnel Network**, e.g. `10.18.104.2/29`.

  > **Warning:** The CIDR mask on this entry **must match** the CIDR mask on the server **IPv4 Tunnel Network**.

- Click **Save**

See also:

- *Client Specific Overrides*

Install and configure FRR and BGP

The FRR add-on package available for pfSense Plus software provides BGP routing functionality. BGP must be configured on **both** the server and client nodes with appropriate settings for each.

BGP configurations can be quite complex and vary significantly for each environment. As such, examples are unlikely to match the needs of most environments. There is a BGP example in *BGP Example Configuration* which works for a basic configuration between two peers, as in this recipe.

When following the *BGP Example Configuration* note the following items of interest:

- BGP peering happens on the **OpenVPN tunnel interface and addresses**. The neighbor address for each peer is the VPN interface IP address on the peer. The server side is always the first address in the subnet (e.g. `10.18.104.1`), the client side will be the IP address set in the client-specific override (e.g. `10.18.104.2`).
- Ensure firewall rules on the OpenVPN tab pass BGP traffic on TCP port 179.

Dynamic Routing with OSPF

With DCO enabled the operating system can support routing over the OpenVPN interface using OSPF.

The FRR add-on package available for pfSense Plus software provides OSPF routing functionality. OSPF must be configured on **both** the server and client nodes with appropriate settings for each.

OSPF configurations can be quite complex and vary significantly for each environment. As such, examples are unlikely to match the needs of most environments. There is an OSPF example in *OSPF Example Configuration* which works for a basic configuration between two peers, as in this recipe.

When following the *OSPF Example Configuration* note the following items of interest:

- OSPF peering happens on the **OpenVPN tunnel interface and addresses**.
- Use the OpenVPN server/client interfaces as the backbone area (`0.0.0.0`) interfaces in the example.
- Firewall rules on the OpenVPN tab must pass the OSPF **Protocol**. It is not TCP or UDP. An "allow all" style rule which passes *Any* **Protocol** is also a viable choice, though less secure.
- Firewall rules on the OpenVPN tab must pass multicast traffic destinations for OSPF protocol traffic, it cannot be restricted to specific sources and destinations.

35.43.8 Testing the Connection

The configuration is now complete. OpenVPN client instances automatically start when created, so it will attempt to connect at this point and if the configuration is correct, it will successfully connect to the server.

Try initiating a ping from one LAN to the other LAN in each direction to verify connectivity.

See also:

Troubleshooting OpenVPN.

35.44 OpenVPN Site-to-Site Configuration Example with Shared Key

This section describes the configuration process for a site-to-site connection using a **shared key** style point-to-point mode OpenVPN tunnel. Other names for this style of configuration are static key or pre-shared key (PSK).

> **Danger:** Shared key mode has been deprecated by OpenVPN as it is no longer considered sufficiently secure for modern requirements.
>
> **Shared key mode will be removed from future versions of OpenVPN**. Users **should not** create any new shared key tunnels and should **immediately** convert any existing shared key tunnels to SSL/TLS mode.
>
> When an SSL/TLS instance is configured with a `/30` tunnel network it behaves in a similar manner to shared key mode. The primary difference is the need to create and distribute the certificate structure to peers. See *OpenVPN Site-to-Site Configuration Example with SSL/TLS* for information on configuring OpenVPN in SSL/TLS mode.

In this mode each server instance can only accommodate a single client. Additionally, the server cannot push settings to the client, so routes must be added on both peers and other settings must match identically.

See also:

OpenVPN Site-to-Site Configuration Example with SSL/TLS

35.44.1 Example Configuration Overview

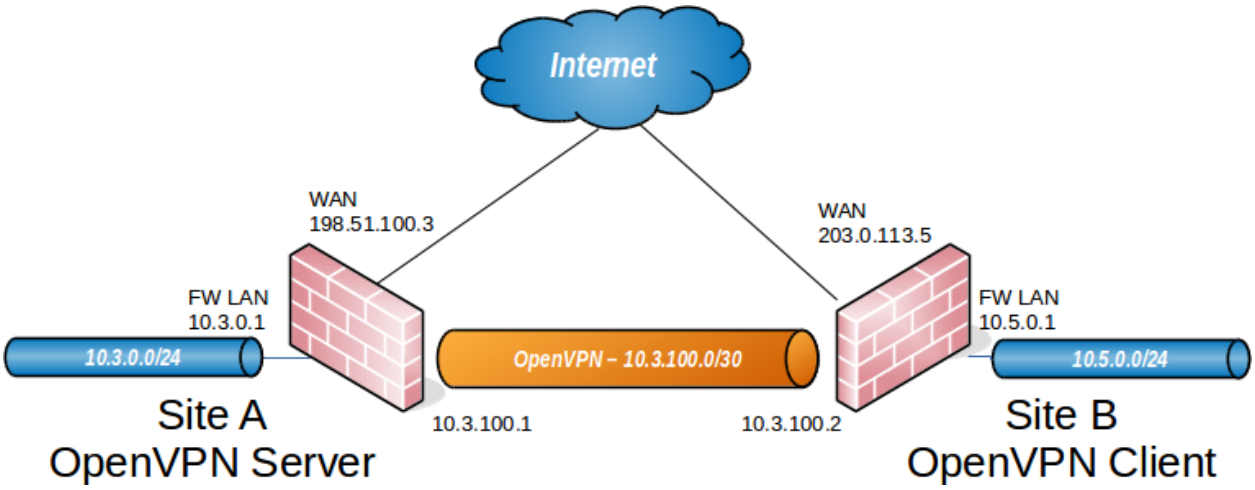

Fig. 70: OpenVPN Example Site-to-Site Network

One firewall will act as the server and the other will act as a client.

> **Tip:** Typically the main location will be the server side and the remote office will act as a client, though the opposite is functionally equivalent.

In addition to the subnets on both ends this setup requires a dedicated subnet for the OpenVPN interconnection between networks. Figure *OpenVPN Example Site-to-Site Network* shows a depiction of this layout, using `10.3.100.0/24` as the IPv4 VPN Tunnel Network. This can be any subnet so long as it does not overlap another subnet currently in use on the network.

35.44.2 Example Configuration Settings

Table 17: OpenVPN Endpoint Settings - Site A - Server

Site A - Server	
Name	Austin Office
WAN Address	198.51.100.3
LAN Subnet	10.3.0.0/24
LAN Address	10.3.0.1
Tunnel Net	10.3.100.0/30

Table 18: OpenVPN Endpoint Settings - Site B - Client

Site B - Client	
Name	London Office
WAN Address	203.0.113.5
LAN Subnet	10.5.0.0/24
LAN Address	10.5.0.1
Tunnel Net | 10.3.100.0/30	

35.44.3 Configuring PSK Server Side

Configure the OpenVPN Server Instance

- Navigate to **VPN > OpenVPN**, **Server** tab
- Click  **Add** to create a new server entry
- Fill in the fields as follows, with everything else left at defaults:

  See also:

  See *Server Configuration Options* for details on each of these options.

  Description
  Text to describe the connection (e.g. `ExampleCo Site B VPN`)

  Server Mode
  Peer to Peer (Shared Key)

  Device Mode
  tun

  Protocol
  UDP on IPv4 only

  Interface
  WAN

  Local Port
  `1194`

  Shared key
  Check **Automatically generate a shared key**

Tunnel Network
`10.3.100.0/30`

Remote network
The LAN on the Site B side, `10.5.0.0/24`

Note: If there are more networks at Site B, such as networks reachable via static routes, other VPNs, and so on, add them as additional entries separated by a comma (`,`).

- Click **Save**
- Click  to edit this server instance again
- Find the **Shared Key** box
- Select all text inside the **Shared Key** box
- Copy the text to the clipboard
- Save the contents to a file or paste into a text editor such as Notepad temporarily

Firewall Rules

External Traffic (WAN)

Next, add a firewall rule on WAN allowing access to the OpenVPN server.

- Navigate to **Firewall > Rules**, **WAN** tab
- Click  **Add** to create a new rule at the top of the list
- Set the options as follows:

  Protocol
  UDP

  Source
  Address or Alias, `203.0.113.5`

  Set the source address to match the client WAN IP address. If the client has a dynamic IP address, set the source to *Any*.

  Destination
  WAN Address

  Destination port
  `1194`

  Description
  `OpenVPN from Site B`

- Click **Save**
- Click **Apply Changes**

When finished, the rule will look like Figure *OpenVPN Example Site-to-Site WAN Firewall Rule*.

Fig. 71: OpenVPN Example Site-to-Site WAN Firewall Rule

Tunneled Traffic

Now add a rule to the **OpenVPN** tab to pass traffic over the VPN from the Client-side LAN to the Server-side LAN. This can be an "Allow all" style rule or a set of stricter rules. This example allows all traffic using this rule:

- Navigate to **Firewall > Rules**, **OpenVPN** tab
- Click  **Add** to create a new rule at the top of the list
- Set the options as follows:

  Protocol
  any

  Source
  any

  Tip: For extra security, create an alias containing only the remote hosts or subnets which must initiate contact with hosts on the sever LAN, then use that alias as the source on this rule.

  Destination
  any

  Tip: For extra security, create an alias containing only the local hosts or subnets on the server LAN which must accept connections from remote hosts across the VPN, then use that alias as the destination on this rule.

  Description
  `Allow all on OpenVPN`

- Click **Save**
- Click **Apply Changes**

That completes the server setup, next, now move on to configure the client.

35.44.4 Configuring PSK Client Side

Configure the OpenVPN Client Instance

- Navigate to **VPN > OpenVPN**, **Client** tab on the client system
- Click  **Add** to create a new OpenVPN client instance
- Fill in the fields as follows, with everything else left at defaults:

  See also:

  See *Client Configuration Options* for details on each of these options.

Description
Text to describe the connection (e.g. `ExampleCo Site A VPN`)

Server Mode
Peer to Peer (Shared Key)

Device Mode
tun

Protocol
UDP on IPv4 only

Interface
WAN

Server host or address
The public IP address or hostname of the OpenVPN server (`198.51.100.3` in this example)

Server Port
`1194`

Shared key
Uncheck **Automatically generate a shared key**, then paste in the shared key for the connection using the key copied from the server instance created previously.

Tunnel Network
`10.3.100.0/30`

> **Warning:** This must match the server side exactly. The firewall will use the correct address for each end of the tunnel.

Remote network
The LAN on the Site A side, `10.3.0.0/24`

> **Note:** If there are more networks at Site A, such as networks reachable via static routes, other VPNs, and so on, add them as additional entries separated by a comma (`,`).

- Click **Save**

Firewall Rules

This setup does not require firewall rules on the client side WAN interface because the client only initiates outbound connections. The server never initiates connections to the client.

This next step is optional depending on whether or not hosts on the server network need to initiate contact with hosts on the client network. If server network hosts do not need to initiate contact with this client, then no action is necessary.

If hosts on the server side need to initiate contact, then this traffic requires a firewall rule on the **OpenVPN** tab on the *client* firewall to allow traffic from the Server-side LAN to reach the Client-side LAN. An "Allow all" style rule is OK in some cases, but a set of stricter rules is the best practice.

This example allows all traffic:

- Navigate to **Firewall > Rules**, **OpenVPN** tab
- Click  **Add** to create a new rule at the top of the list

- Set the options as follows:

  Protocol
  any

  Source
  any

  Tip: For extra security, create an alias containing only the remote hosts or subnets which must initiate contact with hosts on the client LAN, then use that alias as the source on this rule.

  Destination
  any

  Tip: For extra security, create an alias containing only the local hosts or subnets on the client LAN which must accept connections from remote hosts across the VPN, then use that alias as the destination on this rule.

  Description
  `Allow all on OpenVPN`

- Click **Save**
- Click **Apply Changes**

The configuration of the client is complete.

35.44.5 Testing the connection

The configuration is now complete. The OpenVPN client instance automatically starts when created, so it should already be attempting to connect at this point and if the configuration is correct, it will be connected.

Try to ping across to the remote end LAN to verify connectivity.

See also:

Troubleshooting OpenVPN.

35.45 OpenVPN Remote Access Configuration Example

The OpenVPN wizard on pfSense® software is a convenient way to setup a remote access VPN for mobile clients. The wizard configures all of the necessary prerequisites for an OpenVPN remote access server:

- An authentication source (Local, RADIUS server, or LDAP server)
- A certificate authority (CA)
- A server certificate
- An OpenVPN server instance

At the end of the wizard the firewall will have a fully functioning sever, ready to accept connections from users. This server configuration can then be altered as needed.

This document uses an example setup to aide in explaining the options available in the wizard.

See also:

Server Configuration Options

35.45.1 Before Starting The Wizard

Before starting the wizard, plan the design of the VPN.

Determine an IP addressing scheme

The OpenVPN server requires a dedicated subnet for communication between the server and the OpenVPN clients. This is the **Tunnel Network** in the server configuration. The server uses the first address in this subnet for itself to act as a gateway and it allocates IP addresses within this subnet to clients.

When selecting internal subnets for a single location, ideally choose subnets which can be CIDR summarized with other internal subnets. This example uses `10.3.0.0/24` for LAN and `10.3.201.0/24` for the remote access OpenVPN server. These two networks can be summarized with `10.3.0.0/16`, which makes routing easier to manage.

See also:

CIDR Summarization

Example Network

Figure *OpenVPN Example Remote Access Network* shows a depiction of this example deployment.

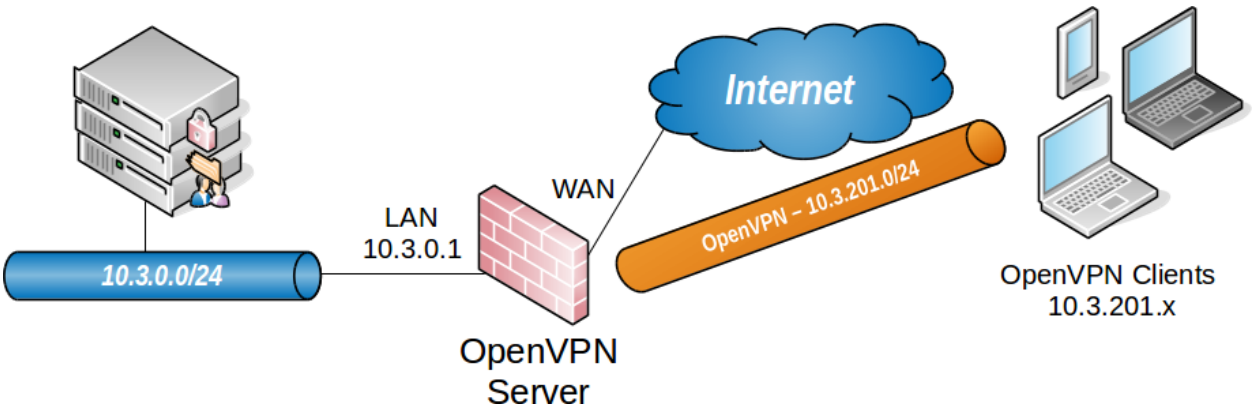

Fig. 72: OpenVPN Example Remote Access Network

Table 19: OpenVPN Remote Access Server Settings

Remote Access Server	
WAN Address	198.51.100.3
LAN Subnet	10.3.0.0/24
LAN Address	10.3.0.1
Tunnel Net	10.3.201.0/24

35.45.2 OpenVPN Wizard Walkthrough

To start the OpenVPN Remote Access Server Setup wizard:

- Navigate to **VPN > OpenVPN**
- Click the **Wizards** tab

The GUI presents the first step of the wizard automatically

Note: The option for *OpenVPN Data Channel Offload (DCO)* is not included in this wizard. To use DCO on this server, run the wizard first then after completing the wizard, edit the server instance and enable the DCO option.

Choose Authentication Type

On the first screen of the wizard, select the authentication backend server type. The choices available for **Type of Server** are *Local User Access*, *LDAP*, and *RADIUS*.

See also:

Authentication Servers

Local User Access
Manage the users, passwords, and certificates using the *User Manager* on this firewall.

Sets the server mode to *Remote Access (SSL/TLS + User Auth)* which requires user authentication as well as per-user certificates.

Local User Access easily handles per-user certificates, managed completely in the GUI. This is much more secure, but depending on the number of users which will access the service, may be less convenient than using a central authentication system.

LDAP / RADIUS
If the network has an existing authentication system already in place, such as Active Directory, pick *LDAP* or *RADIUS* depending on which method that system accepts.

LDAP and *RADIUS* both set the server mode to *Remote Access (User Auth)*, which does not require per-user certificates.

Note: The server mode can be adjusted later to require certificates, but administrators must manually create per-user certificates for *LDAP* or *RADIUS* users.

Click  **Next** to continue.

For *Local User Access*, the wizard skips the LDAP and RADIUS configuration steps.

For *LDAP* or *RADIUS* the wizard will present appropriate authentication server configuration options next. This example uses *Local User Access*, but this document discusses the other options for completeness.

Choosing an LDAP Server

If the user manager configuration on this firewall contains one or more LDAP servers, the wizard offers these LDAP servers as options it can use for this VPN.

Click  **Add new LDAP server** to create a different LDAP server entry.

Click  **Next** to continue using the server selected in the **LDAP Servers** list.

If the firewall configuration does not contain any LDAP servers, the wizard skips this step.

See also:

Authentication Servers

Adding an LDAP Server

If the user manager configuration on this firewall does not contain an LDAP server, or if the user chose to create a new LDAP server, the wizard presents a screen to define a new server.

The values for the options on this screen depend on the specific LDAP directory configuration and structure. For guidance, consult the LDAP server administrator, software vendor, or documentation.

Note: The details of LDAP servers are covered in *LDAP Authentication Servers*.

This document omits some detail since the options are discussed in-depth by that other section.

The wizard offers the following LDAP authentication server parameters:

Name
Descriptive name for this LDAP server, for reference.

Hostname or IP address
The hostname or IP address of the LDAP server.

If the firewall will contact this server using an encrypted method, this value must match the contents of the LDAP server certificate.

Port
The port on which the LDAP server is listening for requests.

The default port is `389` for standard TCP connections and `636` for SSL.

Transport
Sets the method the firewall will use when performing LDAP queries to the server.

Standard TCP
Unencrypted connections using plain TCP.

STARTTLS Encrypted
Connects to the standard TCP port and then attempts to negotiate TLS encryption.

SSL/TLS Encrypted
Secure connections using TLS encryption.

A standard TCP connection is typically sufficient for initial testing, and potentially for local servers or those only accessible over secure connections. If the server is remote or crosses any untrusted network

links, an encrypted method is essential. Using an encrypted method is always the best practice, but may not always be viable.

> **Warning:** When the firewall uses an encrypted method to contact the LDAP server, the **Hostname or IP address** above must match a value in the LDAP server certificate.

Peer Certificate Authority
To use SSL/TLS or STARTTLS transports, the firewall must trust the CA of the LDAP server. This can be accomplished by any of the following methods:

- Import the CA into the certificate manager and select it from the list in this option.
- Import the CA into the certificate manager with the **Trust Store** option set, which adds the imported CA into the list of CAs which the firewall trusts globally. Then select *global* from this list.
- If the LDAP server certificate is signed by a globally trusted CA, such as Let's Encrypt, then select *global*.

Search Scope Level
Selects how deep the firewall will search in the LDAP directory, *One Level* or *Entire Subtree*.

In almost all cases, *Entire Subtree* is the correct choice.

Search Scope Base DN
The distinguished name (DN) upon which the firewall bases its search. For example `DC=example, DC=com`.

Authentication Containers
These values specify where the directory stores user data. For example, `CN=Users;DC=example`.

LDAP Bind User DN
If the LDAP server requires authenticated binds when performing queries, this field sets the distinguished name the firewall uses for this bind action.

If this is blank the firewall performs an anonymous bind without credentials.

LDAP Bind Password
The password for authenticated binds. The firewall only uses this value if **LDAP Bind User DN** has a value.

User Naming Attribute
Varies depending on the LDAP directory software and structure.

Typically `cn` for OpenLDAP and Novell eDirectory, and `samAccountName` for Microsoft Active Directory.

Group Naming Attribute
Varies depending on the LDAP directory software and structure, but is most typically `cn`.

Member Naming Attribute
Varies depending on the LDAP directory software and structure.

Typically `member` on OpenLDAP, `memberOf` on Microsoft Active Directory, and `uniqueMember` on Novell eDirectory.

See also:

LDAP Authentication Servers explains the remaining options in detail, and when a server may require them.

Click  **Add new server** to continue.

Choosing a RADIUS Server

If the user manager configuration on this firewall contains one or more RADIUS servers, the wizard offers these RADIUS servers as options it can use for this VPN.

Click  **Add new RADIUS server** to create a different RADIUS server entry.

Click  **Next** to continue using the server selected in the **RADIUS Servers** list.

If the firewall configuration does not contain any RADIUS servers, the wizard skips this step.

See also:

Authentication Servers

Adding a RADIUS Server

If the user manager configuration on this firewall does not contain a RADIUS server, or if the user chose to create a new RADIUS server, the wizard presents a screen to define a new server.

The values for the options on this screen depend on the specific RADIUS configuration and structure. For guidance, consult the RADIUS server administrator, software vendor, or documentation.

Note: The details of RADIUS servers are covered in *RADIUS Authentication Servers*.

This document omits some detail since the options are discussed in-depth by that other section.

The wizard offers the following RADIUS authentication server parameters:

Name
: Descriptive name for this RADIUS server, for reference.

Hostname or IP address
: The hostname or IP address of the RADIUS server.

Authentication Port
: Port used by the RADIUS server for accepting authentication requests, typically `1812`.

Shared Secret
: The password the RADIUS server expects from this firewall when it submits authentication requests (e.g. password on the NAS entry.)

Click  **Add new server** to continue.

Choosing a Certificate Authority

If the certificate manager configuration on this firewall contains one or more certificate authorities, the wizard offers these CA entries as options it can use for this VPN.

Click  **Add new CA** to create a different certificate authority.

Click  **Next** to continue using the certificate authority selected in the **Certificate authority** list.

If the firewall configuration does not contain any CA entries, the wizard skips this step.

See also:

Certificate Management

Creating a Certificate Authority

If the certificate manager configuration on this firewall does not contain a CA, or if the user chose to create a new CA, the wizard presents a screen to define a new CA.

See also:

For more information on creating and managing CAs, see *Certificate Authority Management*.

This document omits some detail since the options are discussed in-depth by that other section.

The firewall uses this entry as a root CA which can sign server and user certificates. Clients can use this CA to validate the server, and the server can use this CA to validate clients. Because this CA is self-signed, only clients which are supplied with a copy of this CA certificate will trust other certificates signed by this CA.

The wizard offers the following CA parameters:

Descriptive Name
`ExampleCoCA`

A name for reference to identify this certificate. This is the same as **Common Name** field for other certificates.

Note: Although this field can technically contain spaces, the best practice is to conform the contents of this field to the format allowed for fully qualified domain names.

Some clients have issues handling entries with spaces properly.

Key Length
`2048`

Size of the CA private key which the wizard will generate.

Larger keys offer increased security but larger keys are generally slower to use.

Lifetime
`3650`

The time, in days, for which this CA will remain valid.

For a self-signed CA such as this, the default of `3650` is acceptable, which is approximately 10 years.

The remaining fields are optional but define additional identifying data for the CA "subject"/distinguished name. For small deployments this may not matter much, but for larger organizations with CA entries at multiple sites, this can help ensure each CA is easily identifiable.

Country Code
`US`

(Optional) Two-letter ISO country code (e.g. US, AU, CA).

ExampleCo is located in the United States which has an ISO country code of `US`.

To locate an appropriate ISO code for other countries, use the ISO Online Browsing Platform site.

State or Province
`Texas`

(Optional) Full unabbreviated State or Province name (e.g. Texas, Indiana, California).

ExampleCo is located in `Texas`.

City
`Austin`

(Optional) City or other Locality name (e.g. Austin, Indianapolis, Toronto).

ExampleCo headquarters is in `Austin`.

Organization
`ExampleCo`

(Optional) Organization name, often the Company or Group name.

> **Warning:** Do not use any special characters in this field, not even punctuation such as a period or comma.

Click  **Add new CA** finish the CA creation process.

Choosing a Server Certificate

If the certificate manager configuration on this firewall contains one or more certificates, the wizard offers these certificate entries as options it can use for this VPN.

Click  **Add new Certificate** to create a different certificate.

Click  **Next** to continue using the certificate selected in the **Certificate** list.

If the firewall configuration does not contain any certificate entries, the wizard skips this step.

See also:

Certificate Management

Adding a Server Certificate

If the certificate manager configuration on this firewall does not contain a certificate, or if the user chose to create a new certificate, the wizard presents a screen to define a new server certificate.

See also:

For more information on creating and managing certificates, see *Certificate Management*.

This document omits some detail since the options are discussed in-depth by that other section.

This server certificate verifies the identity of the server to the clients. The CA set in the previous wizard steps will sign this certificate. In most cases, as with this example, the server certificate uses the same information from the previous step and the wizard pre-fills the form automatically.

Descriptive Name
`vpn.example.com`

This is the common name (CN) field of the server certificate and the firewall also uses this name to reference the certificate.

The best practice is to set this to the fully qualified hostname of the firewall.

Note: Although this field can technically contain spaces, the best practice is to conform the contents of this field to the format allowed for fully qualified domain names.

Some clients have issues handling entries with spaces properly.

Key Length
`2048`

Size of the CA private key which the wizard will generate.

Larger keys offer increased security but larger keys are generally slower to use.

Lifetime
`398`

The time in days that this certificate will be valid. The best practice is to set this to `398` days or less.

Note: Some current operating systems and software limit server certificates to a maximum lifetime of `398` days for security reasons. Clients on these platforms may reject a server certificate with a longer lifetime.

The remaining fields are optional but define additional identifying data for the server certificate "subject"/distinguished name. For small deployments this may not matter much, but for larger organizations with many server certificates, this can help ensure each certificate is easily identifiable.

Country Code
`US`

(Optional) Two-letter ISO country code (e.g. US, AU, CA).

ExampleCo is located in the United States which has an ISO country code of `US`.

To locate an appropriate ISO code for other countries, use the ISO Online Browsing Platform site.

State or Province
`Texas`

(Optional) Full unabbreviated State or Province name (e.g. Texas, Indiana, California).

ExampleCo is located in `Texas`.

City
`Austin`

(Optional) City or other Locality name (e.g. Austin, Indianapolis, Toronto).

ExampleCo headquarters is in `Austin`.

Organization
`ExampleCo`

(Optional) Organization name, often the Company or Group name.

> **Warning:** Do not use any special characters in this field, not even punctuation such as a period or comma.

Click  **Create New Certificate** to continue.

Configuring OpenVPN Server Settings

The options on this step of the wizard configure each aspect of how the OpenVPN server itself behave as well as options the server will pass on to clients.

See also:

The options presented here are the same as those in *Server Configuration Options*. Refer to that section for details.

Because the options are covered in detail in that section, this document only mentions the settings used by this example.

General OpenVPN Server Information

These options control how the OpenVPN instance operates.

Interface
WAN

Protocol
UDP on IPv4 Only

Local Port
`1194`

The wizard suggests the first unused port number starting with port `1194`. If there is an existing OpenVPN server on that port, use a different port number.

Description
`ExampleCo Mobile VPN Clients`

Cryptographic Settings

These options control how the server encrypts and authenticates traffic in the tunnel.

TLS Authentication
Check **Enable authentication of TLS packets**

Using TLS authentication is the best practice.

Generate TLS Key
Check **Automatically generate a shared TLS authentication key**

TLS Shared Key
Blank

The wizard disables this field when **Automatically generate a shared TLS authentication key** is checked.

DH Parameters Length
2048

This value is a good balance of speed and strength.

Data Encryption Negotiation
Checked

This allows the server to automatically negotiate encryption settings with clients.

Note: Disabling this option is deprecated, but still present on this version for compatibility.

Data Encryption Algorithms
AES-256-GCM, *AES-128-GCM*, and *CHACHA20-POLY1305*

The best practice is to use the default suggested values as noted above.

Fallback Data Encryption Algorithm
AES-256-CBC

This algorithm is used when negotiation fails, for example with a client that is too old to support negotiation.

Auth Digest Algorithm
SHA256 (256-bit)

Tunnel Settings

These options control how the server routes traffic from remote clients.

Tunnel Network
`10.3.201.0/24`

This is the tunnel network from the table at the start of this example (*OpenVPN Remote Access Server Settings*).

Redirect Gateway
Unchecked

For this example, The VPN will only carry traffic destined for subnets at the main office.

Local Network
`10.3.0.0/24`

This is the server-side LAN subnet from the table at the start of this example (*OpenVPN Remote Access Server Settings*).

Concurrent Connections
Blank

This example does not limit the number of clients which can connect at the same time.

Allow Compression
Refuse any non-stub compression (Most secure)

The best practice is to disable compression for security reasons.

Compression
Disable Compression [Omit Preference]

The best practice is to disable compression for security reasons.

Type-of-Service
Unchecked

There is no traffic on this example VPN which requires prioritization/QoS.

Inter-Client Communication
Unchecked

The clients on this VPN have no need to connect to other VPN client hosts.

Duplicate Connections
Unchecked

This example uses unique certificates for every client and does not allow multiple connections per client.

Client Settings

These options control specific settings the server pushes to clients when they establish a connection.

Dynamic IP
Checked

The clients connect from all over the country and unknown mobile networks and their IP addresses are likely to change without notice.

Topology
Subnet

The method the server uses to assign IP addresses to clients.

DNS Default Domain
`example.com`

The domain name used by ExampleCo.

DNS Servers
`10.3.0.5`

A list of internal DNS servers. ExampleCo has a Windows Active Directory Domain Controller which is configured to act as a DNS server at `10.3.0.5`.

NTP Servers
`10.3.0.6`

A dedicated local NTP server exists at `10.3.0.6`.

Advanced
Blank

At this time no additional tweaks are necessary.

Click  **Next** to continue.

Firewall Rule Configuration

By default the firewall blocks all traffic from connecting to VPNs or passing over VPN tunnels. This step of the wizard adds firewall rules automatically to allow traffic to connect to the VPN and also so connected clients can pass traffic over the VPN.

Traffic from clients to server
Checked

When checked, the wizard adds a firewall rule on the chosen interface outside of the tunnel where the server is listening (e.g. *WAN*) which allows VPN clients to connect. The rule created by this option allows all clients from any source IP address to connect by default.

Since clients in this example are connecting from all over the country, the rule created by the wizard for this option is ideal.

Tip: To allow connections from a limited set of IP addresses or subnets, either make a custom rule or check this box and alter the rule it creates.

Traffic from clients through VPN tunnel
Checked

This setting allows all traffic to cross inside the OpenVPN tunnel. This is desirable for this example.

Click  **Next** to continue.

Finishing the Wizard

Click  **Finish** to complete the wizard.

At this point, the firewall now contains a full OpenVPN remote access server configuration which is ready for client connections.

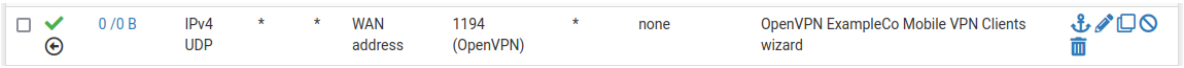
From here, the next steps are to add users and configure client devices.

If this setup requires adjustments to the automatically generated firewall rules, make them now.

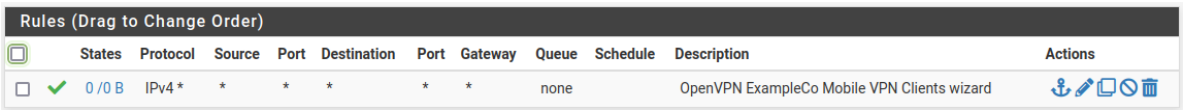
35.45.3 Verifying the Setup

Look at firewall rules (**WAN** and **OpenVPN** tabs)

- **WAN** tab rule should pass from any to the *OpenVPN* port on the *WAN address*



- **OpenVPN** tab rule should allow all traffic from any/to any



35.45.4 Adjustments

Numerous settings are not present in the wizard but might be a better fit for certain deployments than the defaults chosen by the wizard.

Server Mode

The OpenVPN **Server Mode** allows selecting a choice between requiring Certificates, User Authentication, or both. The wizard defaults to *Remote Access (SSL/TLS + User Auth)* when using local users and *Remote Access (User Auth)* for RADIUS and LDAP. The possible values for this choice and their advantages are:

Remote Access (SSL/TLS + User Auth)

- Requires both certificates **and** username/password
- Each user has a unique client configuration which includes their personal certificate and key
- Most secure as there are multiple factors of authentication (TLS Key and Certificate that the user has, and the username/password they know)

Remote Access (SSL/TLS)

- Certificates only, no authentication
- Each user has a unique client configuration which includes their personal certificate and key
- Useful if clients should not be prompted to enter a username and password
- Less secure as it relies only on something the user has (TLS key and certificate)

Remote Access (User Auth)

- Authentication only, no certificates
- Useful if the clients cannot have individual certificates
- Commonly used for external authentication (RADIUS, LDAP)
- All clients can use the same exported client configuration and/or software package
- Less secure as it relies on a shared TLS key plus only something the user knows (User-name/password)

OpenVPN Data Channel Offload (DCO)

OpenVPN Data Channel Offload (DCO), a pfSense Plus exclusive feature, can potentially increase performance of OpenVPN well beyond the capabilities of traditional OpenVPN connections.

Note: Some OpenVPN features and use cases are not compatible with DCO. See *Limitations* for a list of known DCO limitations.

Certificate Revocation

Compromised certificates can be revoked by a Certificate Revocation List (CRL). CRL entries are managed at **System > Certificates**, on the **Certificate Revocation** tab. Create a new CRL, add the certificate to it, and then select that CRL on the OpenVPN server settings.

See also:

Certificate Revocation List Management

35.45.5 Adding a User with a Certificate

If the server mode includes local user authentication, a user must be exist in the user manager for each client which will connect to the VPN.

See also:

This is a simplified version of the process. For more detail, see:

- *Adding OpenVPN Remote Access Users*
- *Manage Local Users*
- *User Certificates*
- Navigate to **System > User Manager**
- Click  To add a user
- Fill in the settings as follows:

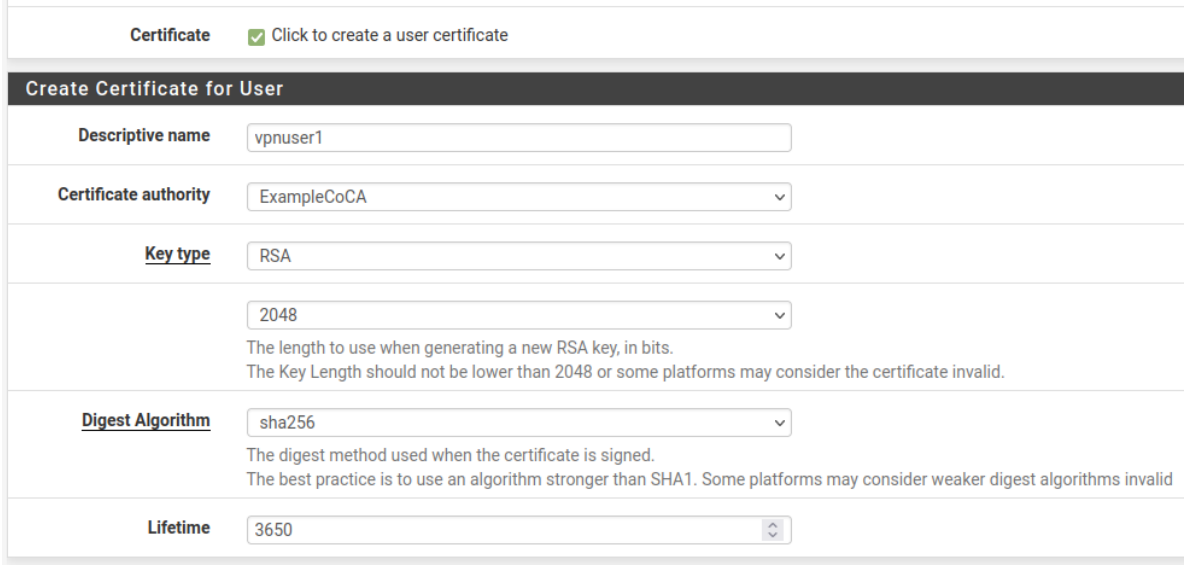
  Username
  The username for this client.

  Password/Confirm password
  The password for this client.

  Click to create a user certificate
  Checked

  Descriptive Name
  Same value as the **Username**

  Certificate Authority
  The CA used by the OpenVPN server.



- Click **Save**

35.45.6 OpenVPN Client Export Package

The OpenVPN Client Export Package can export client configurations formatted for a wide variety of platforms. It can also export a pre-packaged Windows installer executable which includes the configuration bundled inside for a painless client installation.

See also:

OpenVPN Client Export Package

35.46 Adding OpenVPN Remote Access Users

The method for adding users to the VPN depends upon the OpenVPN server authentication method and backend (e.g. Local Database, RADIUS, LDAP).

See also:

- *OpenVPN Remote Access Configuration Example*
- *Server Configuration Options*
- *User Management and Authentication*
- *User Certificates*

35.46.1 Local Database

OpenVPN authenticates local database users based on their entries in the user manager.

To create a new user with a certificate, follow these steps:

- Navigate to **System > User Manager**
- Click  To add a user
- Fill in the settings as follows:

  Username
  The username for this client.

  Password/Confirm password
  The password for this client.

  Full Name
  An optional longer name for this user.

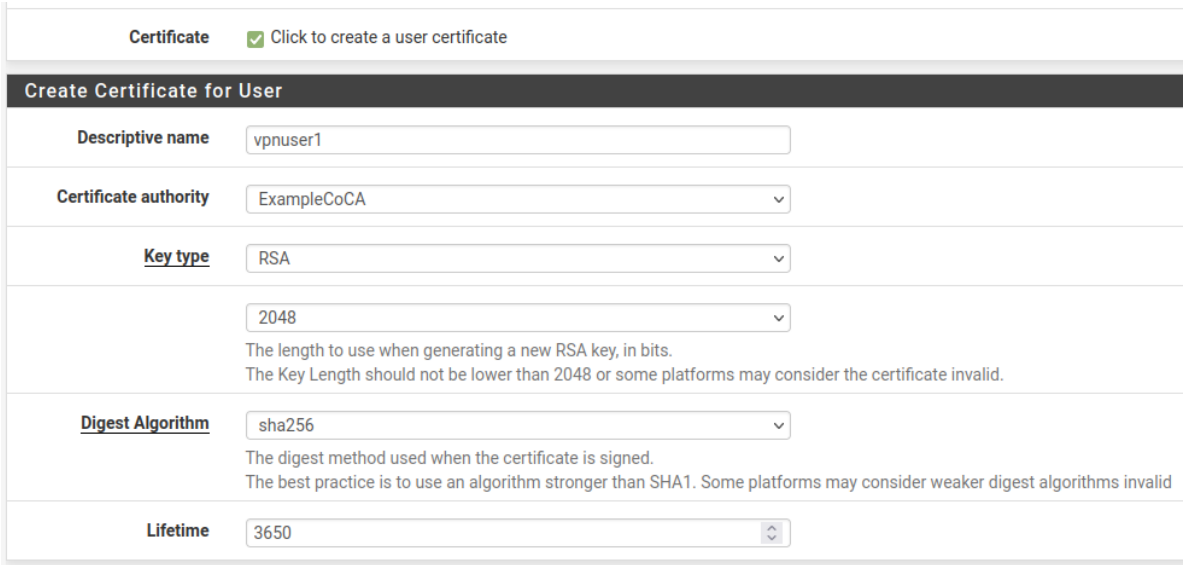
  Click to create a user certificate
  Checked

  Descriptive Name
  Same value as the **Username**

  Certificate Authority
  The CA used by the OpenVPN server.

  Key Type
  The type of private key to use for this certificate, either *RSA* or *ECDSA* and its accompanying **Key Length** (RSA) or **Curve** (ECDSA). The default is an acceptable choice.

  Lifetime
  The number of days for which the certificate is valid. The default of `3650` (approximately 10 years) is acceptable for a user certificate.



- Click **Save**

To view or change the user:

- Navigate to **System > User Manager**
- Click  next to the row containing the user to see/edit

To export a user certificate and key:

Note: The OpenVPN Client Export Package (*OpenVPN Client Export Package*) can package up the certificates and other data automatically. The client export package is a much easier way to download client configurations and installation files than exporting these items manually.

- Navigate to **System > Certificates**, **Certificates** tab
- Locate the user certificate in the list
- Click  to download the user certificates
- Click  to download the key for the certificate

  ---

  Tip: To password protect the private key, edit the certificate, enter an **Export Password**, and click **Export Private Key** on that page.

- Click  to download a PKCS#12 bundle which includes the user certificate and key, and the CA Certificate (optional).

  Tip: To password protect the PKCS#12 bundle, edit the certificate, enter an **Export Password**, and click **Export PKCS#12** on that page.

Most use cases which utilize a user certificate will also require the CA Certificate which signed the user certificate. Export the CA certificate from its entry on **System > Certificates**, **CAs** tab or use one of the PKCS#12 bundle options.

35.46.2 LDAP or RADIUS Users

Adding LDAP and RADIUS users fully depends on the server implementation and management tools, which are beyond the scope of this documentation. Contact the server administrator or software vendor for assistance.

Certificates for LDAP or RADIUS users cannot be created from within the firewall GUI in a way that reflects a user-certificate relationship but they can be created independently as user certificates in the certificate manager. Create user certificates with the certificate manager as described in *User Certificates*

35.47 Installing OpenVPN Remote Access Clients

Most end-user devices require installation of an OpenVPN client as the client functionality is not yet built into most operating systems. This section provides an overview of OpenVPN client installation on several common operating systems.

The *OpenVPN Client Export Package* automatically generates client configuration files and installation bundles for use by client devices.

See also:

Visit the Hangouts Archive to watch the September and October 2015 Hangouts on Remote Access VPNs which covers client installations for most operating systems.

35.47.1 Installing the OpenVPN Client on Windows

The OpenVPN project provides 64-bit and 32-bit installers for Windows 7 through Windows 11 on The OpenVPN Community Downloads Page. Alternately, use *OpenVPN Client Export Package* to create a self-executable client installer bundled with an appropriate configuration file.

The client installation is straightforward, the user can accept all the default values and actions.

Current stable versions of the OpenVPN client for Windows utilize a system service so the GUI can run without elevated privileges. Once installed, a user does not need administrative access to run the client.

While running, the OpenVPN client appears as an icon in the system tray. This icon can connect/disconnect VPNs or display additional information, such as connection logs.

The installation creates a new **Local Area Connection** adapter on the client system for OpenVPN. This interface indicates it is connected when the client has established a VPN connection and will otherwise show as disconnected. OpenVPN manages the configuration of this adapter and it does not require any manual adjustments.

35.47.2 Installing the OpenVPN Client on macOS

There are three client options for macOS:

- The OpenVPN command line client. Most users prefer a graphical client, so this document does not cover that option.
- Tunnelblick, a free option available for download at the Tunnelblick Website.
- The commercial Viscosity client. At the time of this writing, it costs $14 USD for a single seat. Viscosity is a much nicer client and well worth the cost for frequent OpenVPN users.

Both Tunnelblick and Viscosity are easy to install, with no configuration options during installation. Both clients can accept configurations generated by the *OpenVPN Client Export Package*.

Configuring Viscosity

The Viscosity client can be configured manually or it can import configurations from the OpenVPN Client Export package.

Viscosity provides a GUI configuration tool that can generate the underlying OpenVPN client configuration based on a manual configuration. This section covers the must simpler process of importing a Viscosity bundle generated by the OpenVPN Client Export package.

- Download a copy of the **Viscosity bundle** for the client from the OpenVPN Client Export package
- Locate the bundle file

  The bundle filename ends in `.visc.zip` indicating that it is a compressed archive.
- Copy this bundle file to a folder on the client Mac
- Double click this file and macOS expands it to `Viscosity.visc`
- Double click `Viscosity.visc` and Viscosity will open and import the connection as shown in Figure *Viscosity Import*

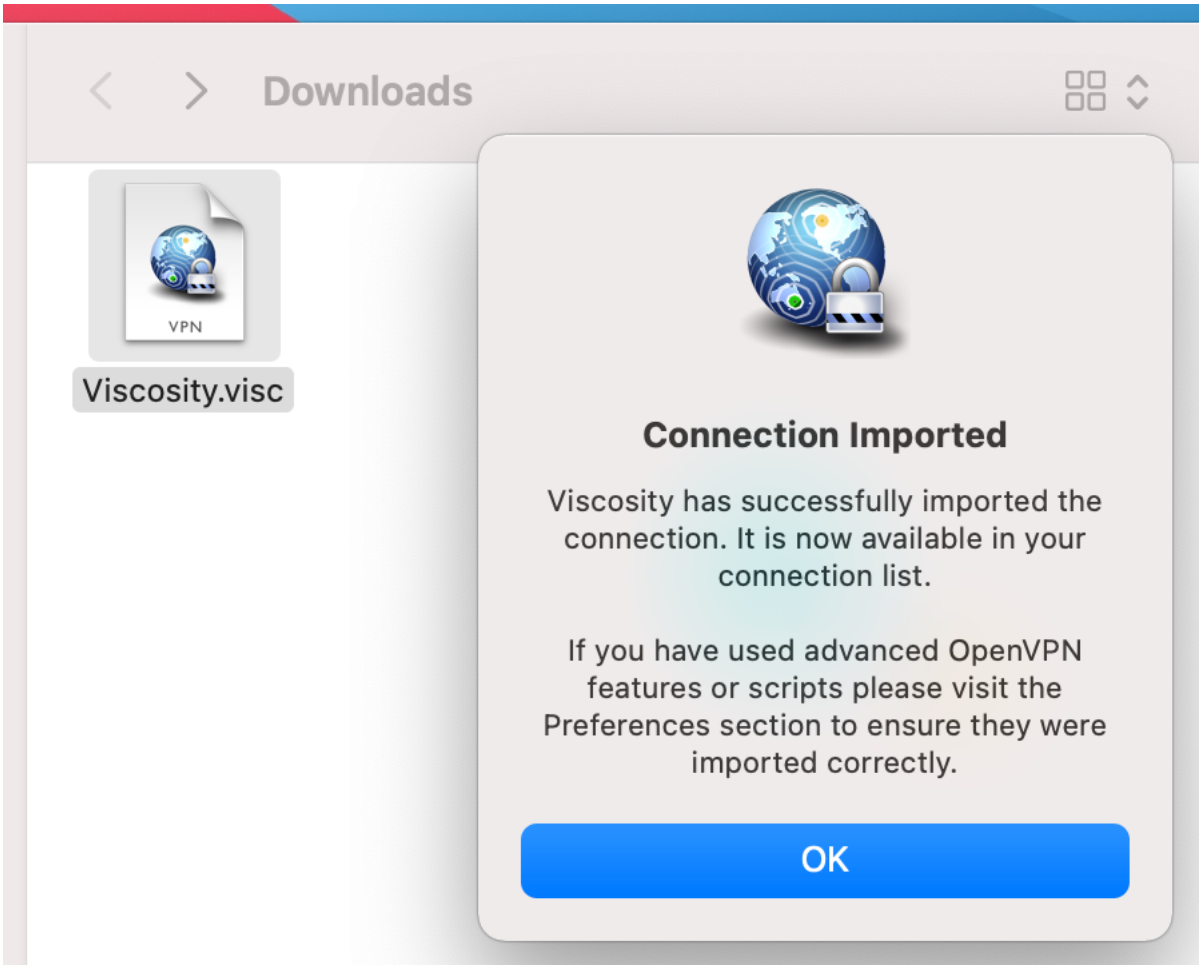


Fig. 73: Viscosity Import

- Delete the `Viscosity.visc` directory and the `.zip` archive
- Viscosity will be running after import and has an icon in the menu bar which looks like a circle with a lock

- Click the Viscosity icon in the menu bar at the top of the screen
- Click **Preferences** to check if Viscosity imported the configuration as shown in Figure *Viscosity Preferences*

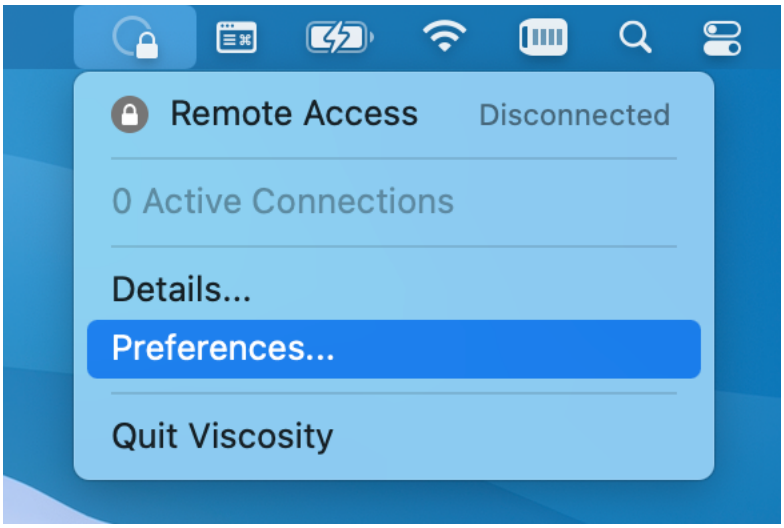

Fig. 74: Viscosity Preferences

- Check the **Connections** area to see if Viscosity imported the connection successfully as shown in Figure *Viscosity View Connections*.
- Close the Preferences screen

Connecting a VPN with Viscosity

- Click the Viscosity icon in the menu bar
- Click the name of the VPN connection to connect as shown in Figure *Viscosity Connect*

  After a few seconds the lock icon for this connection in the Viscosity menu will turn green if the connection attempt succeeds, and Viscosity displays some basic connection information.

Note: When at least one VPN is connected the appearance of the Viscosity icon also changes from a faint circle with a lock to a dark circle with a lock, but this can be easy to miss.

View Connection Status in Viscosity

To view status information about a VPN connection:

- Click the Viscosity icon
- Click **Details** as shown in Figure *Viscosity Menu*

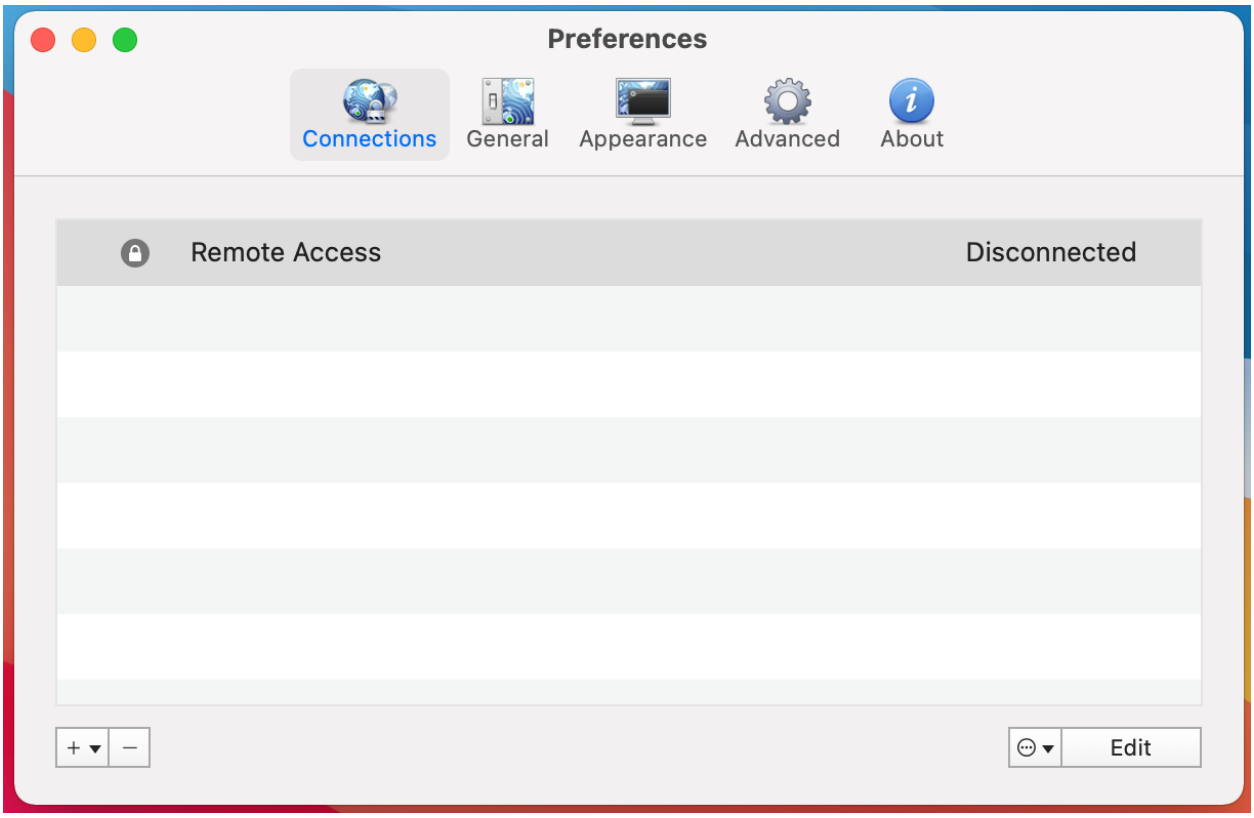

Fig. 75: Viscosity View Connections

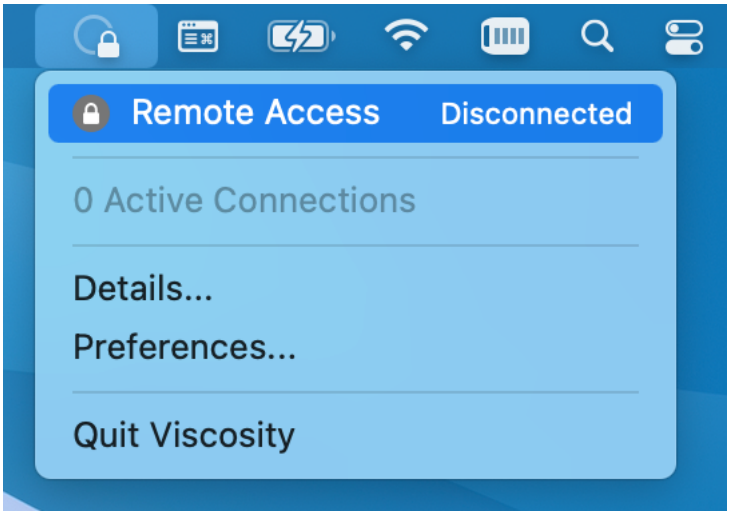

Fig. 76: Viscosity Connect

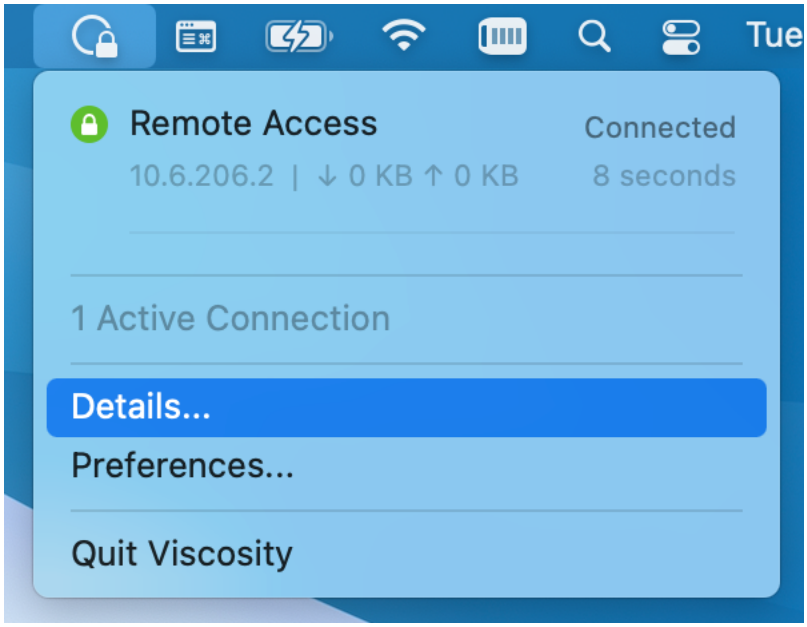

Fig. 77: Viscosity Menu

Basic Status, Bandwidth Graph

The top of the details screen (Figure *Viscosity Details: Bandwidth Graph*) shows the connection status, connected time, the client IP address, and the IP address of the server.

The bottom of the details screen contains a real-time bandwidth graph which shows the current throughput in and out of this OpenVPN connection.

Traffic Counters, Connection Details

The up/down arrow button in the middle of the details screen displays additional network traffic statistics. This function shows the total amount of traffic sent and received by the VPN client.

This screen also contains additional connection information such as DNS Servers assigned to this VPN by the server or local configuration, and the encryption algorithms used by the client to secure communications with the server.

Viscosity Client Logs

The third icon in the middle of the **Details** screen shows the OpenVPN log file (Figure *Viscosity Details: Logs*). If there is any trouble connecting, review the logs here to help determine the problem.

See also:

Troubleshooting OpenVPN.

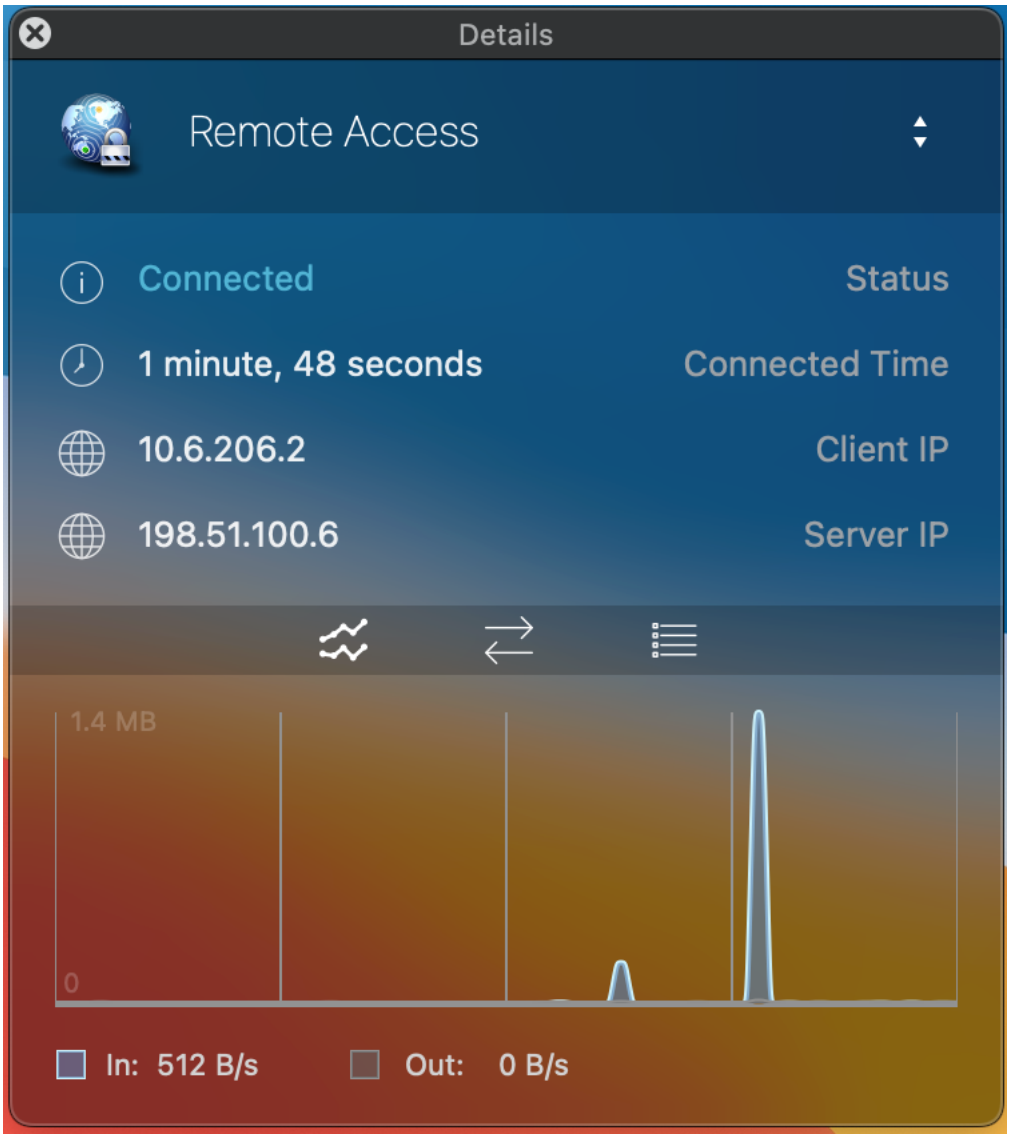

Fig. 78: Viscosity Details: Bandwidth Graph

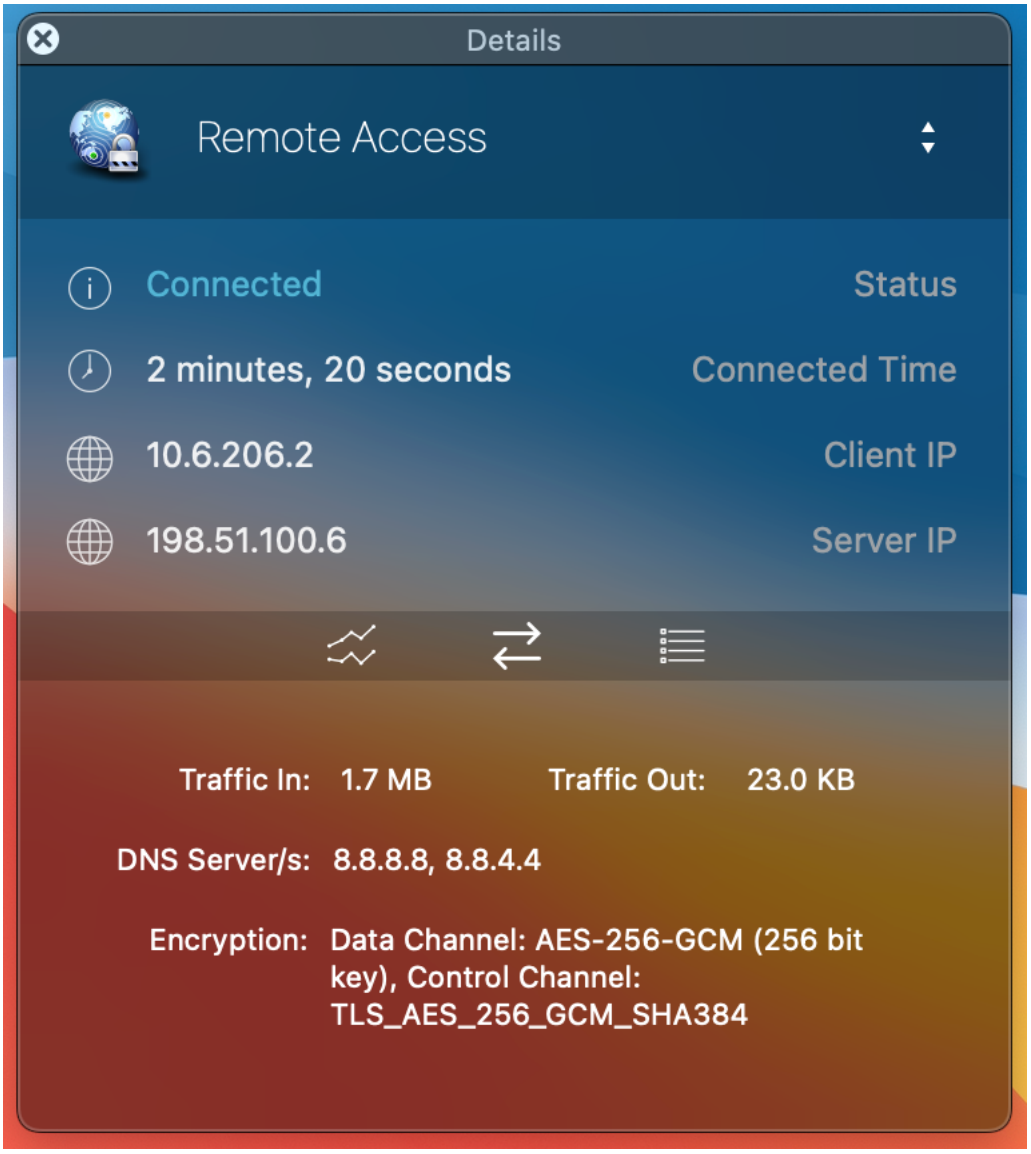

Fig. 79: Viscosity Details: Traffic Statistics

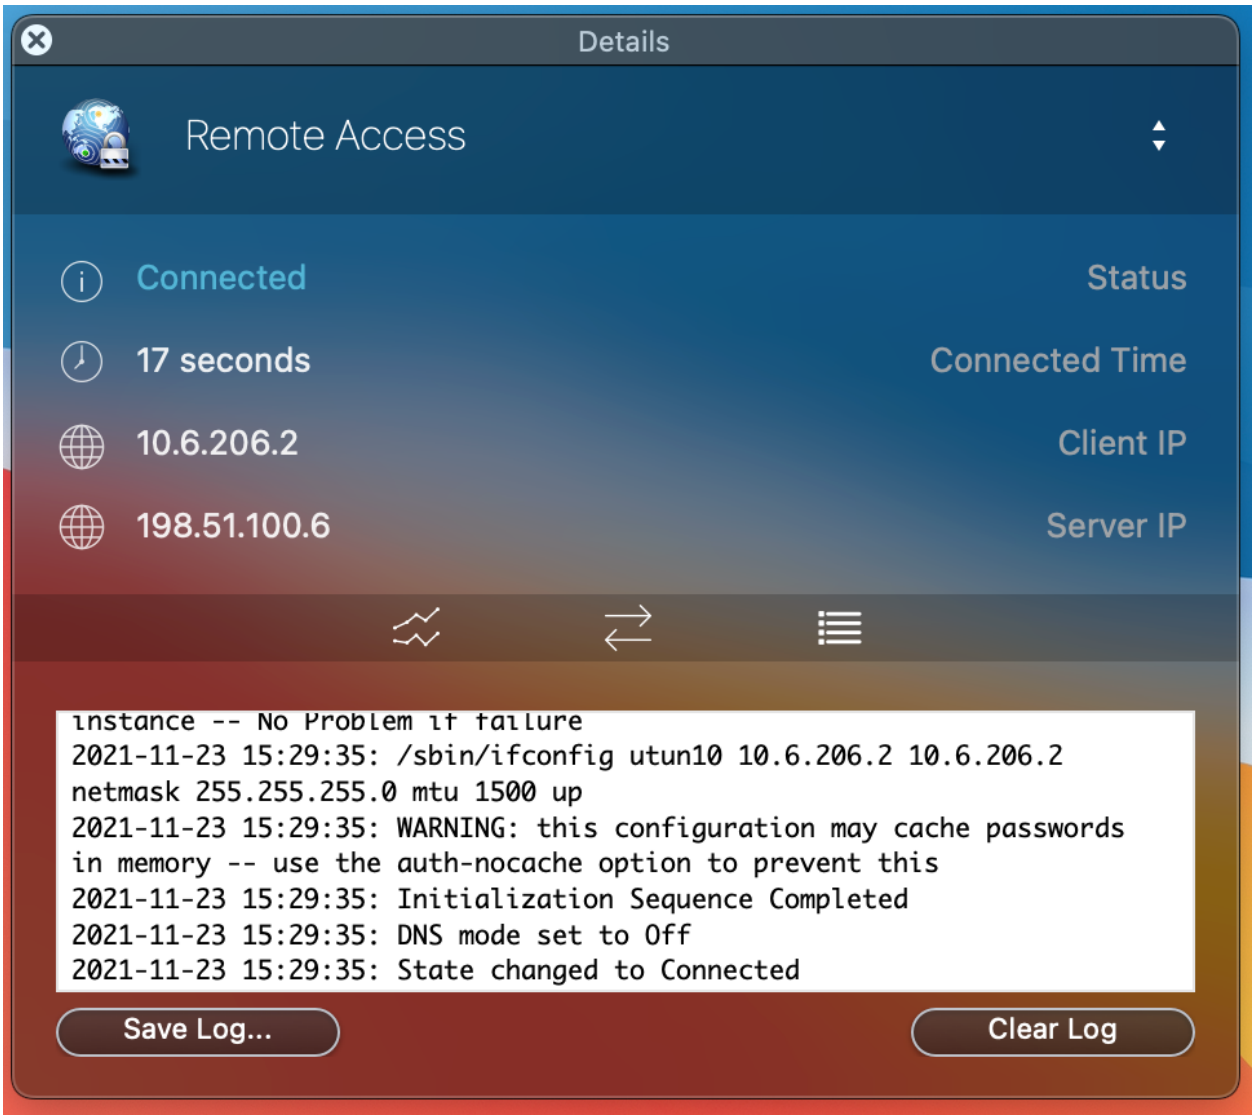

Fig. 80: Viscosity Details: Logs

35.47.3 Installing the OpenVPN Client on iOS

iOS is also capable of running OpenVPN natively using the iOS OpenVPN Connect client available in the App Store. The OpenVPN configuration and certificates must be generated outside of the iOS device and then imported to the app.

The *OpenVPN Client Export Package* can export an **OpenVPN Connect** type **Inline Configuration** compatible with this app. Export a configuration file then transfer the resulting `.ovpn` file to the target device using iTunes to transfer the files into the app or e-mail it to the device.

Using other methods to get files onto the device remotely, such as Dropbox, Google Drive, or Box will work similarly to the e-mail method are generally more secure as the contents will remain private and possibly encrypted depending on the method and storage.

If using the e-mail method, use the following procedure:

- Export the **OpenVPN Connect** type **Inline Configuration** file for the VPN.
- Send the exported file in an e-mail to an account configured on the iOS device
- Install the OpenVPN Connect app on the device
- Open the Mail app on the device
- Open the e-mail message containing the attachment
- Tap the attachment. When it is tapped one of the choices will be to open it with the OpenVPN Connect app
- Tap to select the OpenVPN connect app and it will offer to import the configuration
- Tap the + button and the profile will be imported

Using iTunes to transfer the configuration to the iOS device is simple and more secure than e-mail.

- Export the **OpenVPN Connect** type **Inline Configuration** file for the VPN.
- Connect the iOS device to the computer and open iTunes
- Find and install the OpenVPN Connect app
- Click the device icon inside of iTunes in the toolbar
- Select **Apps** on the left side of the window
- Locate the **File Sharing** section At the bottom of this screen (scroll down)
- Click the icon for OpenVPN under **File Sharing** and a list of files will show on the right under the heading **OpenVPN Documents**
- Copy the file to the device by using ONE of the following methods. The file will be immediately available on the iOS device.
  - Use Finder to drag and drop the `.ovpn` file into this area **OR**
  - Click **Add** and locate the file to import
- Open the OpenVPN Connect app and it will offer to import the profile
- Tap the + button, and the profile will be imported

If the OpenVPN server requires user authentication the app will prompt for the credentials, which may optionally be saved. Underneath the credential prompt is a connection status which will change between **Disconnected** and **Connected** and also indicates when a connection is being attempted. Clicking this will open the OpenVPN client log which is very useful if connection problems are encountered.

To connect the VPN, move the slider at the bottom of the profile from **Off** to **On** and the app will attempt to connect. To manually disconnect, move the slider back to **Off**.

35.47.4 Installing the OpenVPN Client on Android

For devices running Android there is a free OpenVPN app in the Google Play store that works excellently without needing root access. It is called OpenVPN for Android by Arne Schwabe.

The *OpenVPN Client Export Package* can export an **Android** type **Inline Configuration** compatible with the app.

- Export an **Android** type inline configuration from the OpenVPN Client Export package
- Transfer this `.ovpn` file to the target device

  It can be copied directly, e-mailed to the device, or by other similar methods of copying files to the device.
- Open the **OpenVPN for Android** app
- Tap Import (File folder icon at upper right)
- Find the `.ovpn` file saved above and tap it
- Tap Import (Disk icon at upper right)

The app shows the imported VPN in the connection list. Edit the entry to change the name and other details.

Tap the VPN to connect. If the OpenVPN server requires user authentication, the app will prompt for credentials when connecting.

Note: The Android OpenVPN Connect client also works on Android and does not require root. It works identically to the iOS client by the same name. It lacks the ability to fully configure the VPN in the GUI, so it is not as convenient to use. Use the **OpenVPN Connect** type **Inline Configuration** export for use with that client on both Android and iOS.

35.47.5 Installing the OpenVPN Client on FreeBSD

If the client has a stock FreeBSD installation, OpenVPN is in the pre-compiled packages repository as well as in the ports collection.

To install OpenVPN, run the following as the `root` user or via `sudo`:

```
# pkg install openvpn
```

Alternately, compile the client from ports:

```
# cd /usr/ports/security/openvpn && make install clean
```

35.47.6 Installing the OpenVPN Client on Linux

Installing OpenVPN on Linux varies depending on the distribution, method of managing software installations, and network management software on the client device.

OpenVPN is included in the package repositories of most major Linux distributions. With all the various possibilities between countless distributions, and adequate information already available in other sources online, this documentation will not cover specifics. Search the Internet for the distribution of choice and "installing OpenVPN" to find information.

Ubuntu-based distributions have OpenVPN management integrated with Network Manager, but it requires installing an extra module.

35.47.7 Installing the OpenVPN Client Configuration Manually

Performing a manual client installation instead of using the *OpenVPN Client Export Package* requires additional steps to install the software and settings onto the client devices. Installing the client on other operating systems is left up to the reader.

After installing OpenVPN, copy the certificates to the client and create the client configuration file.

Copy certificates

Three files from the firewall are needed for each client: the CA certificate, the client certificate, and the client key. The configuration may require a fourth file, the TLS key, if the server is configured for TLS authentication.

- Export the CA certificate from **System Cert > Manager** on the **CAs** tab, save this as `ca.crt`
- Export the client certificate and key as described in *Local Database*, save these as `username.crt` and `username.key`
- Copy these files to the OpenVPN `config` directory on the client
- Copy the TLS key from the server configuration screen If TLS authentication is used on this OpenVPN server. Save this into a new text file called `tls.key` and include it in the `config` folder as well.

Create Configuration

After copying the certificates to the client, the OpenVPN client configuration file must be created. This can be done with any plain text file editor such as Notepad on Windows. The following shows the options most frequently used:

```
client
dev tun
proto udp
remote vpn.example.com 1194
ping 10
resolv-retry infinite
nobind
persist-key
persist-tun
ca ca.crt
cert username.crt
key username.key
verb 3
comp-lzo
tls-auth tls.key 1
auth-user-pass
```

remote
: The host and port of the remote OpenVPN server. Can be an IP address or FQDN.

proto
: The protocol used by the OpenVPN connection. Change this line to `proto tcp` if the OpenVPN server uses TCP.

ca, cert, key
: Must be modified accordingly for each client to reflect the filenames saved previously.

tls-auth
: If TLS authentication is not used, the tls-auth line may be omitted.

auth-user-pass
If the remote access VPN does not include username and password authentication, omit this line.

See also:

For a more complete reference on the OpenVPN directives, refer to the OpenVPN manual.

Distributing configuration and keys to clients

The easiest way to distribute the keys and OpenVPN configuration to clients is via the *OpenVPN Client Export Package*. If that package is not a viable choice, place the needed files in a ZIP archive or self-extracting archive automatically extracting to `C:\Program Files\OpenVPN\config` or the appropriate path for the client in question.

Warning: Transmit this configuration securely to the end user, never allow it to pass over untrusted networks unencrypted.

35.48 Authenticating OpenVPN Users with FreeRADIUS

Using OpenVPN with the *FreeRADIUS package*.

35.48.1 Purpose

This document demonstrates how to setup OpenVPN with RADIUS user authentication provided by the FreeRADIUS package.

The firewall can centrally manage usernames and passwords and this method also supports additional RADIUS-specific options. This is a plus because login times, access limits, and other options are possible.

See also:

FreeRADIUS package Controlling Client Parameters via RADIUS

35.48.2 Requirements

- A working OpenVPN remote access server (*OpenVPN Remote Access Configuration Example*)
- The FreeRADIUS Package (*FreeRADIUS package*)

35.48.3 Add an interface to FreeRADIUS

- Navigate to **Services > FreeRADIUS**, **Interfaces** tab
- Click  **Add** to create a new entry
- Enter the following settings, which may already be the default values:

  Interface IP Address
  * or `127.0.0.1` to bind only to Localhost

  Port
  `1812`

Interface Type
Authentication

IP Version
IPv4

- Click **Save**

35.48.4 Add a NAS client to FreeRADIUS

- Navigate to **Services > FreeRADIUS**, **NAS / Clients** tab
- Click  **Add** to create a new entry
- Enter the following settings:

Client IP Address
`127.0.0.1`

Client Shortname
Enter the firewall hostname (without the domain)

Client Shared Secret
Enter a secure password

Description
`Local firewall authentication` or similar text to identify this entry

- Click **Save**

35.48.5 Add Users

- Navigate to **Services > FreeRADIUS**, **Users** tab.

Note: Manage *every* user which will authenticate with FreeRADIUS/OpenVPN on this tab.

- Click  **Add** to create a new entry
- Enter the following settings:

Username / Password
The credentials for this user.

Number of simultaneous connections
(Optional) The number of active connections this user may have at the same time. Leave empty for no limit.

Session Timeout
(Optional) The amount of time, in seconds, before the user is disconnected and must login again.

Set any other options as needed to configure or restrict the user in various ways.

See also:

Controlling Client Parameters via RADIUS

- Click **Save**

- Repeat as needed for additional users

35.48.6 Add an Authentication Server

- Navigate to **System > User Manager**, **Authentication Servers** tab
- Click  **Add** to create a new entry
- Enter the following settings:

  Descriptive name
  `Local FreeRADIUS`

  Type
  RADIUS

  Hostname or IP address
  `127.0.0.1`

  Shared Secret
  The password added to the NAS entry in a previous step

  Services offered
  Authentication

  Authentication port
  `1812`

- Click **Save**

35.48.7 Test RADIUS Authentication

- Navigate to **Diagnostics > Authentication**
- Select the newly created authentication server (e.g. *Local FreeRADIUS*)
- Fill in a **Username** and **Password** for a user entry in FreeRADIUS
- Click **Test**

If the test succeeded, continue. Otherwise, see the *Troubleshooting section*.

35.48.8 Configure OpenVPN to use RADIUS

- Navigate to **VPN > OpenVPN**, **Servers** tab
- Edit the existing remote access OpenVPN server
- Set the **Mode** to either **Remote Access (User Auth)** or **Remote Access (SSL/TLS + User Auth)** if it is not already set to one or the other.
- Set **Backend for authentication** to the FreeRADIUS authentication server (e.g. *Local FreeRADIUS*)
- Click **Save**
- Attempt to connect and authenticate with an OpenVPN client

  If the test succeeded, the setup is complete. Otherwise, see the *Troubleshooting section*.

35.48.9 Troubleshooting

The following options can be helpful in troubleshooting FreeRADIUS and OpenVPN. Commands must be run at a shell prompt either via the console or via SSH unless otherwise specified.

See also:

FreeRADIUS package contains additional troubleshooting information.

Increase the verbosity of OpenVPN Logs

- Navigate to **VPN > OpenVPN** and select the server
- Change **Verbosity level** to *7*

  This will log everything from OpenVPN
- Attempt to connect and authenticate with an OpenVPN client
- Navigate to **Status > System Logs**, **OpenVPN** tab to *check the OpenVPN log* for relevant messages

  Alternately, watch the log from an SSH or console shell prompt:

```
# tail -F /var/log/openvpn.log
```

Watch FreeRADIUS Logs

FreeRADIUS can also log attempted connections/authorizations to find potential problems.

- Navigate to **Services > FreeRADIUS**, **Settings** tab
- Set the options under **Logging Configuration** to help locate problems.

  At a minimum, set the following:

  RADIUS Logging Destination
  System Logs

  RADIUS Logging
  Enable

  The remaining options can be left at their defaults but can aid further in debugging if necessary.
- Click **Save**
- Attempt to connect and authenticate with an OpenVPN client
- Navigate to **Status > System Logs** to *check the system log* for relevant messages

  Alternately, watch the log from an SSH or console shell prompt:

```
# tail -F /var/log/system.log
```

Seek Additional Help

If the cause of the problem is not obvious from the logs, use the information gathered in the previous steps to search the web and/or post on the Netgate Forum for assistance.

35.49 Authenticating OpenVPN Users with RADIUS via Active Directory

This recipe describes the procedure to setup OpenVPN on pfSense® software with user authentication handled via RADIUS on an Active Directory server.

35.49.1 Setup the Windows Server

- Setup the Windows Server for an Active Directory role
- Add users to the Windows Server (optionally in a common group for VPN users)
- Setup the NPS role as described in *Authenticating from Active Directory using RADIUS/NPS* which allows the Windows Server to handle RADIUS requests

35.49.2 Add Authentication Server

- Navigate to **System > User Manager**, **Authentication Servers** tab
- Click  **Add** to create a new entry
- Enter the following settings:

  Descriptive name
  `Active Directory NPS`

  Type
  RADIUS

  Hostname or IP address
  `198.51.100.30` – Replace this with the IP address of the Windows server

  Shared Secret
  The password added to the NAS entry in NPS

  Services offered
  Authentication

  Authentication port
  `1812`

- Click **Save**

35.49.3 Setup OpenVPN Remote Access Server

The recipe *OpenVPN Remote Access Configuration Example* covers the OpenVPN server setup, so there is no need to duplicate the instructions here.

Choose the Active Directory NPS RADIUS authentication server entry during the wizard or configure it as the backend for authentication after completing the wizard.

35.49.4 Setup Clients

Use the *OpenVPN Client Export Package* to generate configuration files and/or installation packages for clients.

Clients are available for a wide variety of operating systems, see the installation guides at *Installing OpenVPN Remote Access Clients*.

35.50 Connecting OpenVPN Sites with Conflicting IP Subnets

One common use of NAT with OpenVPN is to mask conflicting LAN subnets between two locations. If two networks are using the exact same subnet, or overlapping subnets, as their LAN or other internal network they cannot communicate across a site-to-site VPN without NAT.

Danger: Shared key mode has been deprecated by OpenVPN as it is no longer considered sufficiently secure for modern requirements.

Shared key mode will be removed from future versions of OpenVPN. Users **should not** create any new shared key tunnels and should **immediately** convert any existing shared key tunnels to SSL/TLS mode.

When an SSL/TLS instance is configured with a `/30` tunnel network it behaves in a similar manner to shared key mode. The primary difference is the need to create and distribute the certificate structure to peers. See *OpenVPN Site-to-Site Configuration Example with SSL/TLS* for information on configuring OpenVPN in SSL/TLS mode.

35.50.1 Site-to Site Example

In this example `10.3.0.0/24` is the LAN on both sides of a VPN. Hosts on the `10.3.0.0/24` subnet will never reach the other end of the VPN to communicate with the remote `10.3.0.0/24` subnet. Clients will always treat that network as local, attempting to reach the other systems via ARP. With NAT, however, the remote side can be made to function as if it were using a different subnet.

Note: Utilizing NAT will work for many protocols but some that are commonly desirable across VPN connections, primarily SMB/CIFS file sharing between Windows hosts, may not function in combination with NAT. If hosts use a protocol which is not capable of functioning with NAT, this is not a viable solution.

Figure *Site to Site with Conflicting Subnets* shows an example where both ends are using the same subnet. After assigning the OpenVPN interface to an OPT interface on both sides, as described in *Assigning OpenVPN Interfaces*, 1:1 NAT can be applied.

The firewall at Site A translates its LAN to `172.16.1.0/24` and the firewall at Site B translates to `172.17.1.0/24`. A 1:1 NAT entry on each firewall translates its entire /24 range.

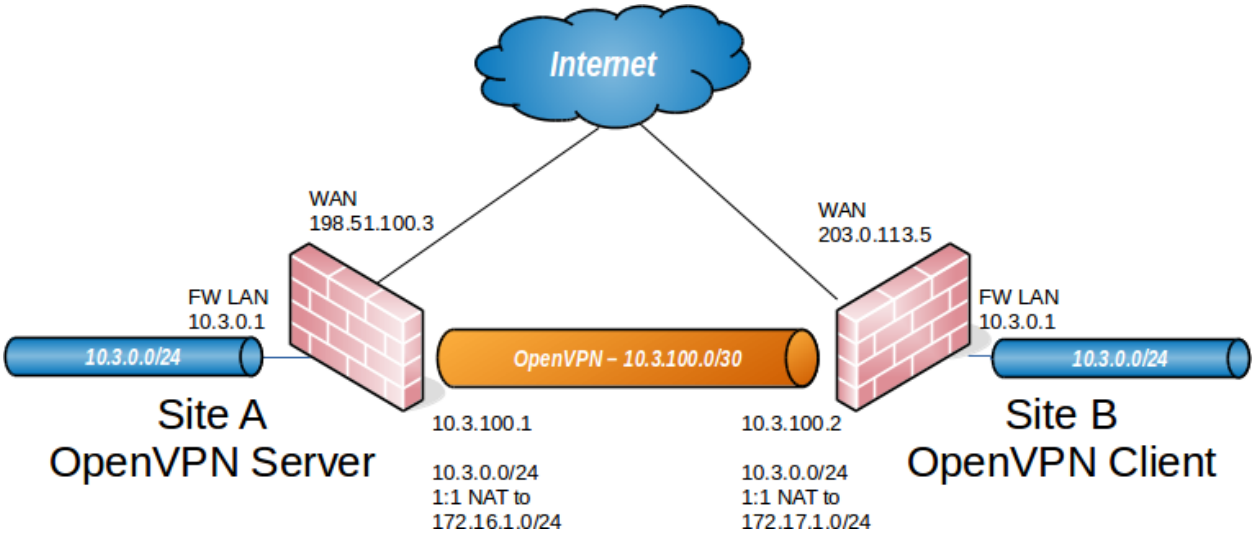

Fig. 81: Site to Site with Conflicting Subnets

To reach Site A from Site B, clients at Site B use `172.16.1.x` IP addresses. The 1:1 NAT rule translates the last octet in the `10.3.0.x` IP address to the last octet in `172.16.1.x`. A client at Site B attempting to reach `10.3.0.10` at Site A would use `172.16.1.10`. To reach `10.3.0.50` at Site B from Site A, a client would use `172.17.1.50`.

Figure *Site B 1:1 NAT Configuration* show the 1:1 NAT configuration for each side, where the *tun* interface is assigned as OPT1.

In the OpenVPN configuration on both sides, the **Remote network** must be the *translated* IP subnet, not `10.3.0.0/24`. In this example, the **Remote Network** at Site A is `172.17.1.0/24`, and Site B is `172.16.1.0/24`.

After applying the NAT configuration changes and configuring the remote networks accordingly on both sides, the networks will be able to communicate using the translated subnets.

35.50.2 Site-to-Multi-Site Example

This section describes how to map multiple subnets that have the same IP address range using OpenVPN so that they can be accessed from a central site. For example `192.168.0/24` is a very common addressing scheme and the main site may need to access all the systems on those networks.

This is the desired outcome, Site 0 is the hub:

```
Site 0 - 10.1.1/24
Site 1 - 192.168.0/24 -> 10.10.1/24
Site 2 - 192.168.0/24 -> 10.10.2/24
Site 3 - 192.168.0/24 -> 10.10.3/24
```

For example, with this type of setup in place, site 0 can access `192.168.0.33` at site 2 as `10.10.2.33`.

Note: This configuration requires 1:1 NAT which means that some things may not work, see notes in the remaining sections for details.

There are multiple alternate ways to reach this goal. This example has the remote sites (Sites 1-3) run the "server" and Site 0 runs the "clients". Either direction works.

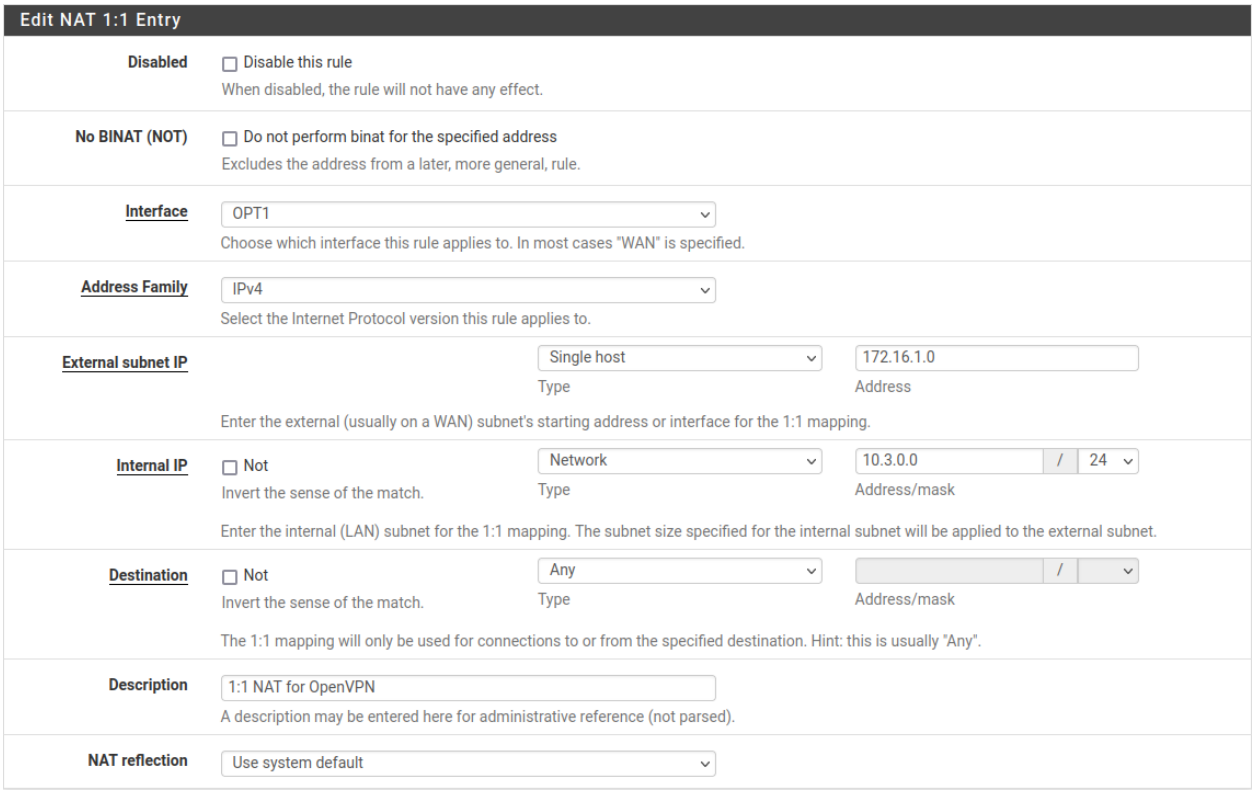

Fig. 82: Site A 1:1 NAT Configuration

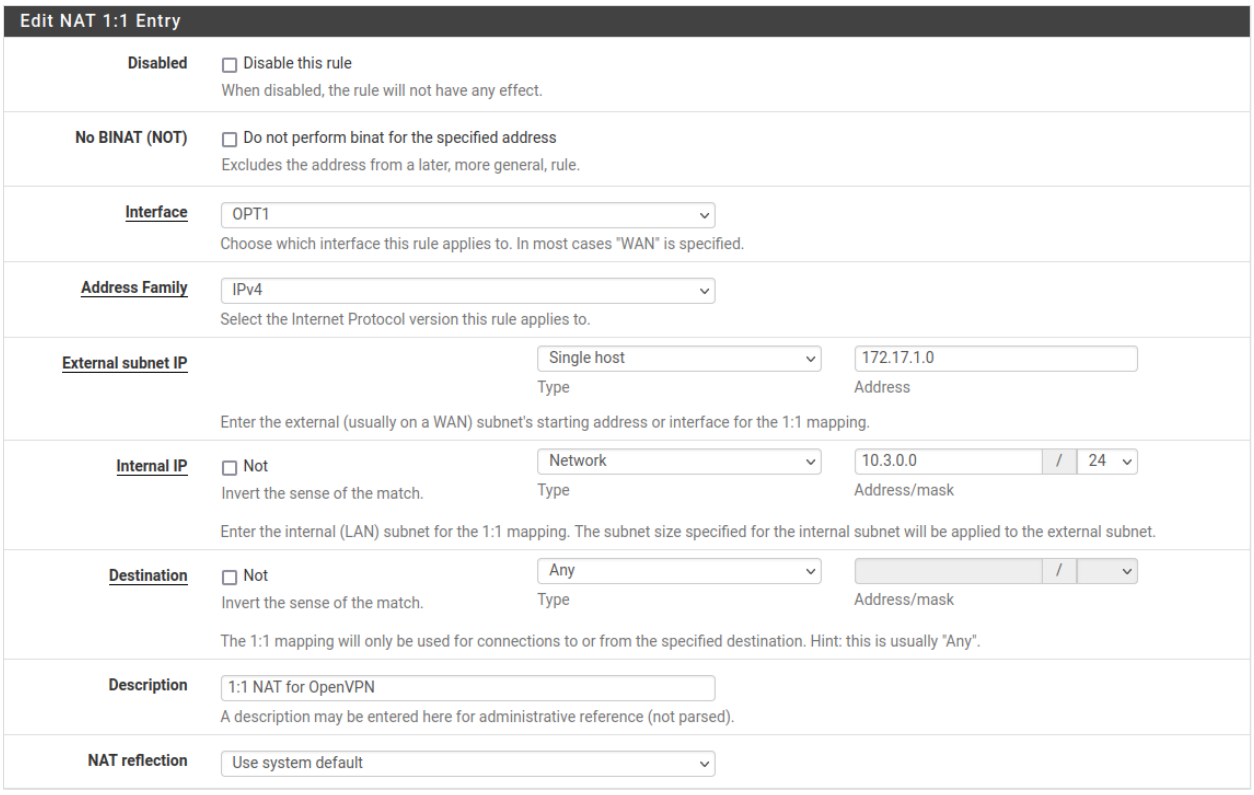

Fig. 83: Site B 1:1 NAT Configuration

Preliminary

Pick **two** ranges for this scheme. The first range is for mapping subnets and the second range is for OpenVPN client to server connections. This example uses `10.10.0.0/16` for the mappings and `10.254.100/24` for the VPN endpoints. The first choice supports up to 253 mappings and the second choice gives 64 `/30` subnets to link it all up.

Examples before NAT:

Site 0 to Site 1:

```
           <--------             (OpenVPN)            ---------->

10.1.1/24 --- 10.254.100.2/30 --- INTERNET --- 10.254.100.1/30 --- 192.168.0/24
```

Site 0 to Site 2:

```
           <--------             (OpenVPN)            ---------->

10.1.1/24 --- 10.254.100.6/30 --- INTERNET --- 10.254.100.5/30 --- 192.168.0/24
```

Note: Notice how the addresses on the right are not unique - they are always `192.168.0.0/24`.

NAT can make each remote site unique:

```
10.1.1/24 --- (OpenVPN) --- INTERNET --- OpenVPN_Interface - NAT - 10.10.1/24 <=> 192.
↪168.0/24
10.1.1/24 --- (OpenVPN) --- INTERNET --- OpenVPN_Interface - NAT - 10.10.2/24 <=> 192.
↪168.0/24
10.1.1/24 --- (OpenVPN) --- INTERNET --- OpenVPN_Interface - NAT - 10.10.3/24 <=> 192.
↪168.0/24
```

Site 0 sends packets to a destination in the mapped subnet down the tunnel which corresponds to the desired Site 1, 2, or 3 and the NAT at the other end translates to and from that mapping and sends the result back to Site 0.

Recipe

In the following examples, only necessary changes from default are given. Pick suitable transports (UDP by default) and ports (1194 by default) Put in a suitable firewall rule on the server WAN interfaces to allow the inbound connection VPN. This should be restricted to the WAN IP address of Site 0. Both ends must have a suitable firewall rule on the OpenVPN interface for traffic to pass.

At Site 1-3

OpenVPN server

At each remote site, create a new OpenVPN server:

Server Mode
: Peer to Peer

Description
: Link to Site 0

TLS authentication
Check "Automatically generate a shared TLS authentication key."

IPv4 Tunnel Network
Link subnet, e.g. `10.254.100.0/30`

IPv4 Remote networks
IP address range(s) at Site 0, e.g. `10.1.1.0/24`

If Site 0 has multiple IP ranges then specify them all in IPv4 Remote networks, comma separated. After saving, edit the VPN instance and copy the shared key to the other end (see below)

1:1 NAT

Add one of these for *each* network range at Site 0:

Interface
OpenVPN

External subnet IP
Mapping subnet, first IP address, e.g. `10.10.1.0`

Internal IP
LAN net

Destination
Network, IP range at Site 0, e.g. `10.1.1.0/24`

Not the default gateway

If this firewall is not the default gateway for the site then use an outbound NAT rule on LAN to ensure that replies from the clients return via the OpenVPN tunnel. Without this, the systems at Sites 1-3 will reply via their default gateway because they will be unaware of the Site 0 network. Another option is to put a suitable route on the site gateway via the LAN address of the OpenVPN system but this will introduce an asymmetric route and which will potentially break things even more than the double NAT.

At Site 0

OpenVPN client

Create a separate OpenVPN client for each remote subnet (Where examples are given they are for Site 1):

Server mode
Peer to Peer (Shared key)

Server host or address
IP address of the remote site

Description
Text to describe the connection, such as the site name, mapping subnet, and link subnet. For example, `Site 1 10.254.100.0/30 10.10.1.0/24`

Shared Key
Copy from the server for the site link

IPv4 Tunnel Network
Link subnet, e.g. `10.254.100.0/30`

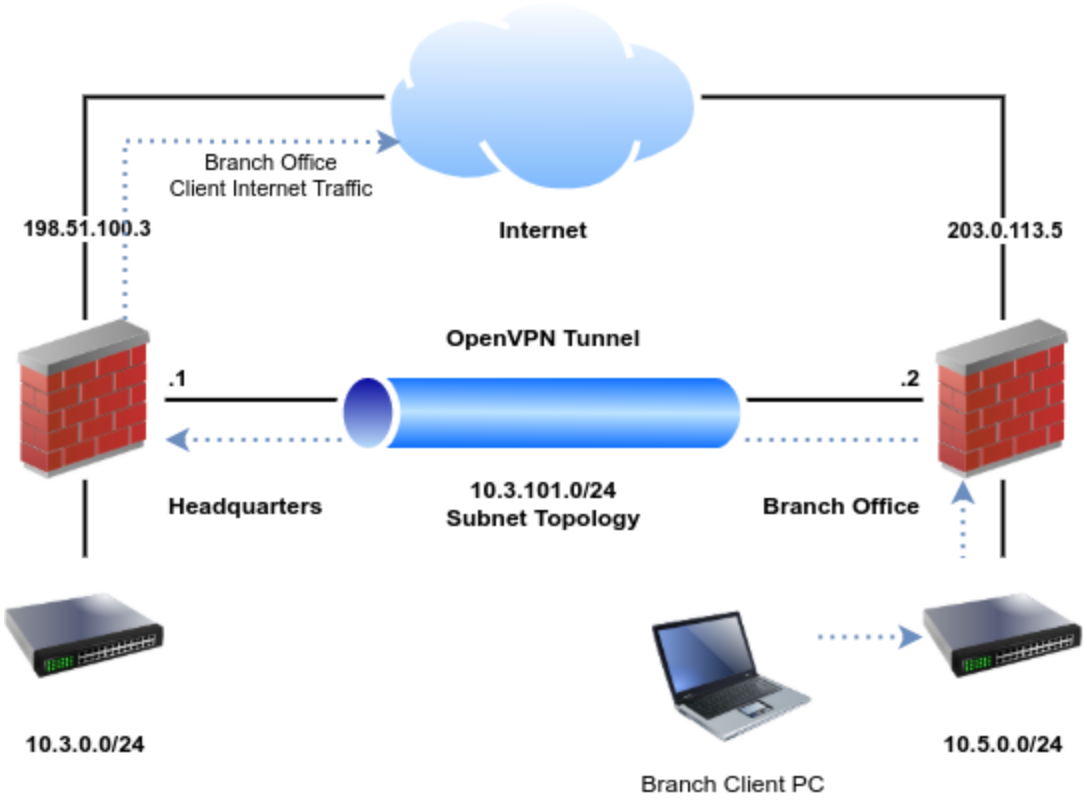
IPv4 Remote networks
Mapping network, e.g. `10.10.1.0/24`

Notes

- SIP and RTP can be tricky with NAT involved
- DNS may not work well under this scheme
- Anything relying on DNS may have issues, such as web links that do not use the passed host name but use the built in name
- Do not forget to put suitable firewall access rules on the various OpenVPN interfaces

35.51 Routing Internet Traffic Through A Site-To-Site OpenVPN Tunnel

This article shows how route Internet traffic from one site through a second site over OpenVPN on pfSense® software.



See also:

This is similar to using IPsec to accomplish the same task, as described in *Routing Internet Traffic Through a Site-to-Site IPsec Tunnel*

The OpenVPN portion is similar to the basic site-to-site setup detailed in *OpenVPN Site-to-Site Configuration Example with SSL/TLS*.

35.51.1 Design

In this scenario, the headquarters site will be the server and branch offices will be clients. The basic settings are identical to the *Example Configuration Settings* from the SSL/TLS recipe:

Table 20: OpenVPN Endpoint Settings - Headquarters

Headquarters - Server	
WAN Address	198.51.100.3
LAN Subnet	10.3.0.0/24
LAN Address	10.3.0.1
CA Name	S2SCA
Cert CN	serverA
Tunnel Net	10.3.101.0/24

Table 21: OpenVPN Endpoint Settings - Branch Office

Branch Office - Client	
Cert CN	clientB
WAN Address	203.0.113.5
LAN Subnet	10.5.0.0/24
LAN Address	10.5.0.1

35.51.2 OpenVPN Configuration

Setup the entire site-to-site VPN as detailed in *OpenVPN Site-to-Site Configuration Example with SSL/TLS* which will result in a usable base from which the remainder of the settings can be built. That example uses two remote offices, so only the first remote office is necessary here. Configure as many as the use case requires.

35.51.3 Configure outbound NAT

For clients at the remote office to reach the Internet through the headquarters, the headquarters site must perform outbound NAT on the traffic from the remote office LAN (`10.5.0.0/24`) as it leaves the WAN.

Note: While it is also possible to perform NAT on the client side firewall OpenVPN interface, that would negatively impact non-Internet VPN traffic and also results in double NAT for Internet traffic which can cause problems with certain protocols.

To setup outbound NAT on the headquarters firewall, first change the outbound NAT mode:

- Navigate to **Firewall > NAT**, **Outbound** tab on the headquarters firewall
- Set the **Outbound NAT Mode** to **Hybrid Outbound NAT**

  Note: If the headquarters firewall is already on this mode or set to **Manual**, then do not change the mode.

- Click **Save**

Using this mode allows the default automatic NAT rules to continue working without needing a full manual ruleset. Now add a custom rule to the top of the list which matches the remote office LAN:

- Click  **Add**
- Set the following values:

  Source
  Network, `10.5.0.0/24`

  Destination
  Any

  Translation Address
  Interface Address

  Description
  `NAT for OpenVPN remote office`

- Click **Save**
- Click **Apply changes**.

The new entry is now in the outbound NAT rule list.

35.51.4 Configure Client OpenVPN Gateway Behavior

The OpenVPN server can optionally instruct the client to send all of its Internet traffic over the VPN, including traffic from the client firewall itself. This can be convenient as it is less to configure, but it does not lend itself well to selective control over the traffic which crosses the VPN.

Note: If the use case only requires redirecting LAN client traffic via policy routing then skip this step.

To configure this:

- Navigate to **VPN > OpenVPN**, **Servers** tab on the headquarters firewall
- Edit the OpenVPN server instance
- Check **Redirect IPv4 Gateway**
- Click **Save**

Next time the client connects, OpenVPN will automatically set the default gateway for the firewall to the VPN server while it is connected.

35.51.5 Assign OpenVPN Interfaces

On the server and every client, assign this OpenVPN instance as an interface, following the procedure in *Assigning OpenVPN Interfaces*.

This will setup the necessary gateways and routing behavior which take care of some parts of the setup automatically. The gateways can be used for policy routing and failover to selectively handle client traffic in different ways.

35.51.6 Setup Gateway Groups

Note: This step is optional if the use case does not call for policy routing or failover.

Assigned OpenVPN interfaces automatically create gateways which can be used for gateway groups and policy routing. These are located under **System > Routing**.

Using one of these gateways a gateway group can enable several different types of scenarios:

- Send client traffic over the VPN, allow it to exit the Internet directly if the VPN is down.
- If there are multiple VPNs, client traffic could fail between them, or even load balance connections between them.
- Failover between the VPN and other types of private circuits or higher cost connections if it fails.

Create a gateway group as described in *Gateway Groups* using whichever parameters best fit the use case.

35.51.7 OpenVPN Firewall Rules

Since this tunnel must pass traffic from the Internet, the firewall rules must be fairly lenient. The rules at the headquarters site will need to pass traffic from a source of the remote office LAN (`10.5.0.0/24`) to a destination of *any*.

These firewall rules should be placed on the assigned OpenVPN interface tab where possible, and not on the OpenVPN tab of the firewall rules. This helps ensure proper routing and return routing.

Tip: To prevent the remote office from reaching sensitive local resources at headquarters or sites connected to additional VPNs, place block rules for those sensitive destinations above the rule passing the Internet traffic.

The rules on the remote office firewall do not necessarily have to allow much traffic back through unless there are public resources at the remote office which must be reached across the tunnel (e.g. 1:1 NAT, port forwards).

35.51.8 Setup Policy Routing

Policy routing (*Policy Routing Configuration*) allows the firewall to selectively match and route client traffic over the VPN that otherwise would follow the default routing table when exiting the firewall. For example, firewall rules could match only HTTP and HTTPS traffic and send them across the VPN. The other traffic would exit the remote office Internet connection directly.

This gives firewall administrators fine-grained control over traffic flow, rather than directly all traffic over the VPN. The downside is that it doesn't control traffic from the firewall itself, only traffic coming from other interfaces on the firewall.

Note: These policy routing rules go on the local interfaces which contain the clients that initiate traffic, such as LAN. They do not go on VPN interfaces.

In this example, the firewall will route all traffic from hosts on the LAN across the VPN:

- Navigate to **Firewall Rules**, **LAN** tab on the remote office firewall
- Edit the default rule which matches LAN traffic (e.g. `Default allow LAN to any rule`)
- Click **Display Advanced**

- Set the **Gateway** to the assigned OpenVPN interface gateway, or a suitable gateway group.
- Click **Save**
- Click **Apply Changes**

Note: If this rule is set to both IPv4 and IPv6, this change may not work. Duplicate the rule and set one to only IPv4 and one to only IPv6, then set appropriate gateways on each as needed.

35.51.9 Test the Configuration

From this point, new connections made from the remote office LAN will be sent over the VPN. Open a site to check the client IP address, such as doing a Google search for `what is my ip address`. The result should be the WAN IP address of the headquarters firewall.

If it is not, then check the LAN firewall rules, the headquarters OpenVPN firewall rules, and the headquarters outbound NAT rules.

35.51.10 Bonus Topics

Adding More Clients

The example in *OpenVPN Site-to-Site Configuration Example with SSL/TLS* already shows how to accommodate multiple clients, but for this type of setup it takes a couple more steps:

- On the headquarters firewall, add more outbound NAT rules to cover the new client LAN subnets.
- On the headquarters firewall, ensure the OpenVPN interface firewall rules allow traffic from the new client LAN subnets.
- On the remote office firewall, assign the OpenVPN interface.

  Since there is only one server, there is no need to do this again on the headquarters firewall.
- On the remote office firewall, setup gateway groups and policy routing.

Note: This assumes the setup was based on SSL/TLS in client/server mode. If the setup used a /30 tunnel network, that will require an additional server and an additional interface assignment at headquarters.

Port Forwarding or 1:1 NAT to hosts at the Remote Office

It is possible to forward traffic initiated by hosts on the Internet to a server at the remote office in a couple different ways. This can be useful, for example, if a server was relocated but there are still outdated DNS records or links pointing to the old location.

This can work in one of two ways:

- If the client gateway is redirected using the OpenVPN server option, there is no need for additional configuration. Add the port forwards or 1:1 NAT and it will work as-is.
- If the OpenVPN interfaces are assigned, this can work by allowing the `reply-to` keyword in `pf` to handle return routing. The remainder of this section covers this process.

For the `reply-to` method to work, a few points must be followed:

- The OpenVPN interface on the remote office must be assigned
- The firewall rules on the **OpenVPN** tab at the remote office **must not** match this traffic
- The firewall rules on the assigned OpenVPN interface tab **must** match this traffic

With the appropriate configuration in place on the remote office firewall, then port forwards or 1:1 NAT on the headquarters site can be set to a destination on the remote office LAN.

35.52 Bridging OpenVPN Connections to Local Networks

The examples in most other OpenVPN recipes are routed using *tun* interfaces which operate at layer 3 and are generally the best practice. OpenVPN also offers the option of using *tap* interfaces, which operate at layer 2 and support bridging clients directly onto the LAN or other internal network. This can make the remote clients appear to be on the local LAN.

See also:

See *Device Mode* for information on differences between *tun* and *tap* interfaces.

35.52.1 OpenVPN Server Settings

Most of the settings for a bridged remote access VPN are the same as for a traditional remote access VPN (*OpenVPN Remote Access Configuration Example*). The differences are noted here.

Device Mode
tap

A bridged connection requires a **Device Mode** of *tap*.

Tunnel Network
Empty

Remove values from the IPv4 Tunnel Network and IPv6 Tunnel Network boxes so they are empty. The way a *tap* bridge OpenVPN functions it does not need a tunnel network as OpenVPN does not use the same address assignment techniques that it does for *tun* mode.

Bridge DHCP
When selected, OpenVPN passes DHCP through to the bridged interface configured later. In the most common scenario, this is *LAN*. Using this method connecting clients would receive IP addresses from the same DHCP pool used by directly wired LAN clients.

Bridge Interface
LAN

> **Warning:** This setting does not create the bridge, it only indicates to OpenVPN which interface will be a member of the bridge.

This controls which existing IP address and subnet mask OpenVPN will use for the bridge. Setting this to *none* will cause the **Server Bridge DHCP** settings below to be ignored.

Server Bridge DHCP Start/End
When using *tap* mode as a multi-point server, a DHCP range may optionally be configured to use on the interface to which this *tap* instance is bridged.

If these settings are left blank, OpenVPN will pass DHCP through to the bridge interface and it will ignore the interface setting above. This allows administrators to set aside a range of IP addresses

for use only by OpenVPN clients so they may be contained within a portion of the internal network rather than consuming IP addresses from the existing DHCP pool. Enter the **Server Bridge DHCP Start** and **Server Bridge DHCP End** IP address values as needed.

35.52.2 Creating the Bridge

Once the OpenVPN *tap* server has been created, the OpenVPN interface must be assigned and bridged to the internal interface.

Assign OpenVPN interface

The VPN interface must be assigned before it can become a bridge member. The procedure for assigning an OpenVPN interface is covered in *Assigning OpenVPN Interfaces*.

Create Bridge

Once the VPN interface has been assigned, create the bridge as follows:

- Navigate to **Interfaces > Assignments**, **Bridges** tab
- Click  **Add** to create a bridge
- Ctrl-click both the VPN interface and the interface to which it will be bridged (e.g. *LAN*)
- Click **Save**

See also:

More information on bridging can be found in *Bridging*.

35.52.3 Connect with Clients

Clients connecting to the VPN must also be set to use *tap* mode. Once that has been set, connect with a client such as one exported using the OpenVPN Client Export package. The clients will receive an IP address inside the internal subnet as if they were on the LAN.

Note: Bridged OpenVPN clients also receive broadcast and multicast traffic which can greatly increase the amount of traffic passing over the VPN.

35.53 OpenVPN Site-to-Site with Multi-WAN and OSPF

One way to configure a redundant OpenVPN deployment that uses multiple WAN interfaces for failover is by using a dynamic routing protocol such as OSPF.

See also:

- *Open Shortest Path First v2 (OSPF)*

35.53.1 Design

The general layout of this scenario is in Figure *Example OpenVPN Setup Involving OSPF Across Multiple WANs*. In this example, both sites have multiple WANs.

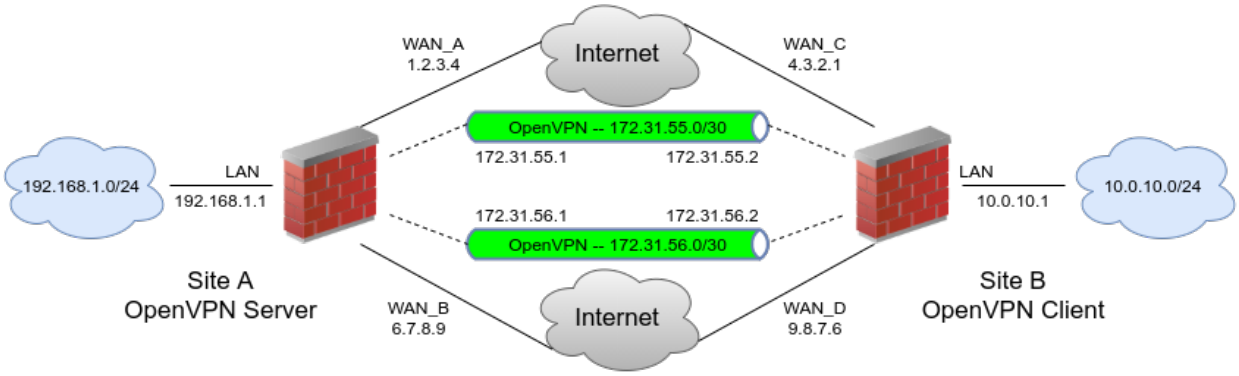


Fig. 84: Example OpenVPN Setup Involving OSPF Across Multiple WANs

35.53.2 OpenVPN Configuration

First, setup a site-to-site OpenVPN instance on each WAN for the remote sites using SSL/TLS with a /30 subnet (*OpenVPN Site-to-Site Configuration Example with SSL/TLS*).

- **Do not fill in** the **Remote Networks** fields on any of the server or client instances, only fill in **Tunnel Network** addresses
- Setup two servers on the local side, each on a different WAN and port

  Use two distinct, non-overlapping tunnel networks (e.g. `172.31.55.0/30` and `172.31.56.0/30`.)
- Setup two clients on the remote firewall, each paired up with one of the above servers, matching the IP addresses and port numbers involved
- Ensure the clients are set for their specific WAN

  Choose the interface from the drop-down menu or a CARP VIP on one of the WANs.
- Ensure these OpenVPN connections link up between client and server

  The tunnel address on both sides will respond to a ping when they are working correctly and appropriate firewall rules are in place. If the tunnels do not establish, see *Troubleshooting OpenVPN* for suggestions on troubleshooting the connection.
- Ensure the OpenVPN firewall rules allow all traffic or at least allow OSPF traffic from a source of the tunnel networks to a destination of any

  The destination on the traffic will be a multicast address, which firewall rules can use to filter specifically if needed, but there isn't much to be gained in the way of security if the source is locked down in the rules as the traffic cannot leave that segment.

35.53.3 FRR OSPF Configuration

Once both instances are connected, configure OSPF.

- Install the FRR package from **System > Packages**, **Available Packages** tab **on both firewalls**
- Navigate to **Services > FRR OSPF**, **Interfaces tab**
- Add each OpenVPN interface

  Set the cost to `10` on the primary link and `20` on the secondary, and so on.
- Add the LAN and other internal interfaces as **passive** interfaces
- Navigate to the **[Global Settings]** tab
- Enter a Master Password

  The content of the password does not matter significantly; FRR uses it internally, it is not used by administrators.
- Set the Router ID to an IP-address-like value, (e.g. `10.3.0.1`)

  The Router ID is unique on each device, which is why setting it to the LAN IP address of a router is a good practice.
- Set the Area ID which is also an IP-address-like value

  The Area ID is typically set to `0.0.0.0` or `0.0.0.1`, but any properly formatted value may be used. The Area ID is the **same** for **all** routers involved in this VPN
- Click **Save**

35.53.4 Validation and Testing

Once OSPF is active on all routers, they will attempt to form a neighbor relationship.

The **Status** tab in FRR will show a full peering with each instance on each wan if they connected properly. It will also list the routes obtained via OSPF. Once that happens, try unplugging and reconnecting WANs and refreshing the status while running test traffic across the VPN, such as an ICMP ping.

35.54 WireGuard Remote Access VPN Configuration Example

This recipe covers configuring a basic *WireGuard* remote access style VPN tunnel.

Note: Though WireGuard does not have a concept of "Client" and "Server" per se, in this style of deployment the firewall cannot initiate connections to remote peers. In this way the firewall acts like a "Server" and may be referred to as such in this documentation. Remote peers may also be referred to as "clients".

35.54.1 Required Information

The following basic information must be determined before starting the VPN configuration.

Item	Value
Design	Remote access, one tunnel+many peers
Firewall WAN	`198.51.100.6`
Listen Port	`51820`
Tunnel Subnet	`10.6.210.0/24`
Tunnel Address	`10.6.210.1/24`
Peer Addresses	`10.6.210.2` - `10.6.210.254`
Peer Endpoints	Dynamic

Generating Keys

WireGuard requires public/private key pairs for each peer, including this firewall.

Warning: Keys cannot be reused between clients, as WireGuard requires unique keys to identify clients and where to send their traffic.

Tunnel Keys

To generate keys for the firewall itself, click the **Generate** button when configuring a tunnel. The GUI will populate the private and public key fields automatically.

The peers will need the public key for their configuration.

Peer Keys

Each peer will need its own public/private key pair. The private key will be needed on the peer client software while the public key will be needed on the firewall itself for the peer definition.

These keys can be generated by the clients themselves, or via command line on a system which has the WireGuard utilities installed. This includes the firewall itself; these commands may be run from a console or SSH shell or from **Diagnostics > Command Prompt**.

From a command line, execute the following:

```
$ wg genkey | tee privatekey | wg pubkey > publickey
```

This command outputs files named `privatekey` and `publickey` which respectively contain a private key and its associated public key. This key pair can be used for a WireGuard peer.

To view the keys, inspect the contents of the files:

```
$ cat privatekey
WGpL3/ejM5L9ngLoAtXkSP1QTNp4eSD34Zh6/Jfni1Q=
$ cat publickey
b9FjbupGC7fomO5U4jL5Irt1ZV5rq4c+utGKj53HXgU=
```

Repeat the commands as needed as many times as is necessary for the number of peers required by this tunnel. Note the keys in a secure place.

Tip: Change the commands to output files named for their associated peer, then store the resulting files in a secure location.

Alternately, the keys can be output in one command without storing them persistently. This behavior is not be supported on all platforms, but is supported on the firewall itself.

```
$ wg genkey | tee /dev/stderr | wg pubkey
4BSH81zC3/OWl25XrzqWy7WnAiARXySHd+K+KFxNrWU=
rzWOC0zH9v2zF6r92uCbjs7JOmhqy8N+cUdA+GCynSM=
```

35.54.2 Tunnel Configuration

Now it's time to create the WireGuard tunnel.

- Navigate to **VPN > WireGuard > Tunnels**
- Click  **Add Tunnel**
- Fill in the options using the information determined earlier:

  Enable
  Checked

  Description
  `Remote Access`

  Listen Port
  `51820`

  Interface Keys
  Click **Generate** to create a new set of keys.

  Interface Addresses
  `10.6.210.1/24`

- Click **Save**

35.54.3 Peer Configuration

Peers can be added when editing a tunnel. To edit a tunnel:

- Navigate to **VPN > WireGuard > Peers**
- Click  **Add Peer**
- Fill in the options using the information determined earlier:

  Enable
  Checked

  Tunnel
  tun_wg<num> (Remote Access)

Description
The name of this client (e.g. The name of a person, device, username, or other uniquely identifying information.)

Dynamic Endpoint
Checked

Keep Alive
Typically left blank, but may be filled in if clients have problems traversing certain firewalls.

Public Key
The public key for this peer. Obtained from the key generation process earlier, or from the peer itself if it was generated by client software directly.

Pre-Shared Key
Not used in this example, but for additional security this pre-shared key can be generated and copied to the peer. Must match on the client and server.

Allowed IPs
The tunnel IP address for this peer, from the list determined above, with a `/32` CIDR mask. For example, the first peer will be `10.6.210.2/32`, the second will be `10.6.210.3/32`, and so on.

- Click **Save Peer**
- Repeat the steps to add additional peers as needed.

35.54.4 Firewall Rules

First add a rule to pass external WireGuard traffic on the WAN:

- Navigate to **Firewall > Rules**, **WAN** tab
- Click  **Add** to add a new rule to the top of the list
- Use the following settings:

Action
Pass

Interface
WAN

Protocol
UDP

Source
any

Destination
WAN Address

Destination Port Range
(other), `51820`

Description
`Pass traffic to WireGuard`

- Click **Save**
- Click **Apply Changes**

Next, add a rule to pass traffic inside the WireGuard tunnel:

- Navigate to **Firewall > Rules**, **WireGuard** tab
- Click  **Add** to add a new rule to the top of the list
- Use the following settings:

  Action
  Pass

  Interface
  WireGuard

  Protocol
  Any

  Source
  any

  Destination
  any

  Description
  `Pass VPN traffic from WireGuard peers`

- Click **Save**
- Click **Apply Changes**

35.54.5 Client Configuration

Client configuration varies by platform, see WireGuard documentation for details. This section covers a basic configuration.

This is an example configuration from a WireGuard client for a split-tunnel configuration:

```
[Interface]
PrivateKey = WGpL3/ejM5L9ngLoAtXkSP1QTNp4eSD34Zh6/Jfni1Q=
ListenPort = 51820
Address = 10.6.210.2/24

[Peer]
PublicKey = PUVBJ+zuz/0mRPEB4tIaVbet5NzVwdWMX7crGx+/wDs=
AllowedIPs = 10.6.210.1/32, 10.6.0.0/24
Endpoint = 198.51.100.6:51820
```

This is an example configuration from a WireGuard client for a full-tunnel configuration:

```
[Interface]
PrivateKey = WGpL3/ejM5L9ngLoAtXkSP1QTNp4eSD34Zh6/Jfni1Q=
ListenPort = 51820
DNS = 10.6.210.1, pfSense.home.arpa
Address = 10.6.210.2/24

[Peer]
PublicKey = PUVBJ+zuz/0mRPEB4tIaVbet5NzVwdWMX7crGx+/wDs=
AllowedIPs = 0.0.0.0/0
Endpoint = 198.51.100.6:51820
```

The fields in that file are as follows:

Interface
Settings for this client.

PrivateKey
The private key for this peer. Obtained from the key generation process earlier, or from the peer itself if it was generated by client software directly.

ListenPort
A static port to listen on, or omit the line to use a random port instead.

DNS
The DNS server(s) and search domain that should be used by the system when the tunnel is enabled.

Address
The tunnel address for this client. Not supported on all platforms, as some require configuring the address using command-line utilities. However, clients on Windows and Android, for example, support this directive.

This should use the same CIDR mask as the **Tunnel** address. In this example, the first peer is `10.6.210.2/24`.

Peer
Configuration for the firewall end of the tunnel.

PublicKey
The public key from the **Tunnel** configuration on the firewall.

AllowedIPs
The **Tunnel** address, and any additional networks which should be routed across the VPN in a comma-separated list. This could be a LAN subnet (e.g. `10.6.0.0/24`) or use `0.0.0.0/0` to route all traffic, including Internet traffic, across the tunnel.

Dynamnic Endpoint
Unchecked

Endpoint
The firewall WAN IP address and WireGuard **Listen Port**

Note: This only covers the basics, there are numerous other fields which can be used to control client behavior plus additional client options which vary by platform. For additional details, see the WireGuard documentation and the documentation for the WireGuard software used by a peer.

Transfer the resulting client configuration file to the peer in a secure manner. Methods vary by platform and client software.

35.54.6 Finish Up

After configuring the client and activating the VPN, the client should be able to pass traffic to the networks listed in the `AllowedIPs` list in its configuration.

- *WireGuard Site-to-Multisite VPN Configuration Example*
- *WireGuard VPN Client Configuration Example*

35.55 WireGuard Site-to-Site VPN Configuration Example

This recipe explains how to setup a VPN tunnel between two firewalls using *WireGuard*.

This example is a minimal configuration, more complicated scenarios are possible, see *WireGuard* for details.

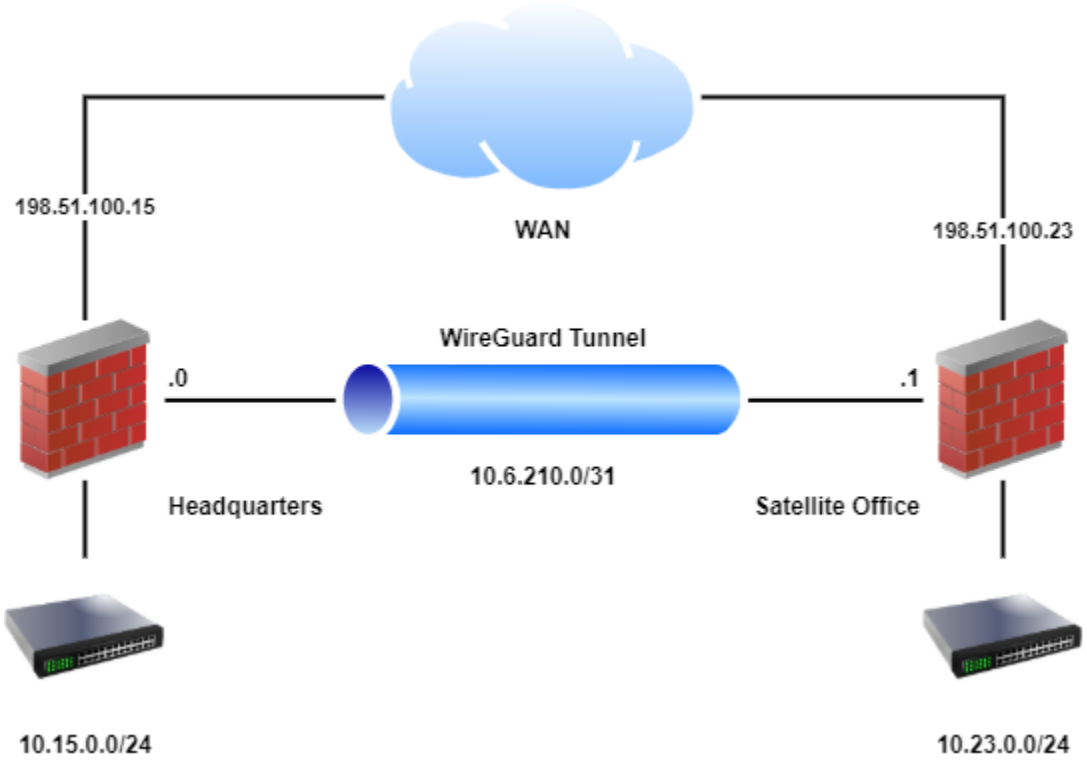

Fig. 85: WireGuard Example Site-to-Site Network

35.55.1 Required Information

General Values

Item	Value
Design	Site-to-Site, one peer per tunnel
Tunnel Subnet	`10.6.210.0/31`

HQ:

Item	Value
WAN IP Address	`198.51.100.15`
Tunnel Address	`10.6.210.0/31`
Listen Port	`51820`
LAN Subnet	`10.15.0.0/24`

Satellite Office:

Item	Value
WAN IP Address	`198.51.100.23`
Tunnel Address	`10.6.210.1/31`
Listen Port	`51820`
LAN Subnet	`10.23.0.0/24`

35.55.2 WireGuard Configuration

- Navigate to **VPN > WireGuard > Settings**
- Fill in the following options:

  Enable
  Checked

  Interface Group Membership
  Only Unassigned Tunnels

- Click **Save**

Tip: When allowing inbound connections from arbitrary remote networks, use rules only on assigned WireGuard interface tabs only to ensure proper return routing.

Note: Rules on assigned WireGuard interface tabs get `reply-to` which ensures that traffic entering a specific assigned WireGuard interface exits back out the same interface. Without that, return traffic will follow the default gateway.

35.55.3 Tunnel Configuration

First create the WireGuard tunnel on both sites:

- Navigate to **VPN > WireGuard > Tunnels**
- Click  **Add Tunnel**
- Fill in the options using the information determined earlier, with variations noted for each site:

  Enabled
  Checked

  HQ Settings

  Description
  `Satellite Office VPN`

  Satellite Office Settings

  Description
  `HQ VPN`

  Listen Port
  `51820`

  Interface Keys
  Click **Generate** to create a new set of keys.

- Copy the public key from each firewall and note which is which
- Click **Save**

35.55.4 Peer Configuration

The peer entry for the server can be added when editing the tunnel. Follow these steps on both sites, with the differences in settings noted inline.

Edit the tunnel:

- Navigate to **VPN > WireGuard > Tunnels**
- Locate the WireGuard tunnel for this VPN
- Click  at the end of the row for the tunnel

From the tunnel editing page, add a peer:

- Click  **Add Peer**
- Fill in the options using the information determined earlier, with variations noted for each site:

  HQ Settings

  Description
  `Satellite Office Peer`

  Dynamnic Endpoint
  Unchecked

Endpoint
`198.51.100.23` (the WAN IP address of the Satellite Office)

Endpoint Port
`51820`

Public Key
The public key *from the Satellite Office firewall*

Allowed IPs
`10.6.210.0/31` and `10.23.0.0/24` (Tunnel network and Satellite Office LAN)

Satellite Office Settings

Description
`HQ VPN Peer`

Dynamnic Endpoint
Unchecked

Endpoint
`198.51.100.15` (the WAN IP address of HQ)

Endpoint Port
`51820`

Public Key
The public key *from the HQ firewall*

Allowed IPs
`10.6.210.0/31` and `10.15.0.0/24` (Tunnel network and HQ LAN)

- Click **Save Peer**

35.55.5 Assign Interface

These steps should be done on both sites.

First, fix the default gateway so WireGuard isn't automatically selected before it's ready:

- Navigate to **System > Routing**
- Set **Default Gateway IPv4** to a specific gateway (e.g. *WANGW*) or group
- Set **Default Gateway IPv6** in a similar manner if this VPN will also carry IPv6 traffic
- Click **Save**
- Click **Apply Changes**

Next, assign the interface (*Assign a WireGuard Interface*):

- Navigate to **Interfaces > Assignments**
- Select the appropriate `tun_wg<number>` interface in the **Available network ports** list
- Click  **Add** to assign the interface as a new OPT interface (e.g. OPT1)
- Navigate to the Interface configuration page, **Interfaces > OPTx**
- Check **Enable**
- Enter an appropriate **Description** which will become the interface name (e.g. `VPN_HQ` or `VPN_SATELLITE`)

- Configure an appropriate **MTU** value for the WireGuard interface (e.g. `1420` for IPv4+IPv6 or `1440` for IPv4 only).

  For details on calculating the correct MTU, see in *Assign a WireGuard Interface*.

- Fill in the options for the **HQ** endpoint using the information determined earlier:

  IPv4 Configuration Type
  `Static IPV4`

  IPv4 Address
  `10.6.210.0/31`

  IPv4 Upstream Gateway

  - Click **Add a new gateway**
  - Fill in the options:

    Gateway Name
    `WG_VPN_SAT_V4`

    Gateway IPv4
    `10.6.210.1`

  - Click  **Add**

- Fill in the options for the **Satellite Office** endpoint using the information determined earlier:

  IPv4 Configuration Type
  `Static IPV4`

  IPv4 Address
  `10.6.210.1/31`

  IPv4 Upstream Gateway

  - Click **Add a new gateway**
  - Fill in the options:

    Gateway Name
    `WG_VPN_HQ_V4`

    Gateway IPv4
    `10.6.210.0`

  - Click  **Add**

- Click **Save**
- Click **Apply Changes**

35.55.6 Firewall Rules

First, add a rule to the WAN on both firewalls to allow traffic to reach WireGuard:

- Navigate to **Firewall > Rules**, **WAN** tab
- Click  **Add** to create a new firewall rule at the top of the list so that it matches before other rules
- Configure the firewall rule as follows:

  Action
  Pass

  Protocol
  UDP

  Source
  This can typically be left at *Any*, but it is more secure to fill in the IP address of the opposing firewall.

  Destination
  WAN Address

  Destination Port Range
  (other), `51820`

  Description
  `Pass traffic to WireGuard`

- Click **Save**
- Click **Apply Changes**

Next, add a rule to pass traffic inside the WireGuard tunnel on both firewalls:

- Navigate to **Firewall > Rules**
- Click the tab for the assigned WireGuard interface (e.g. **VPN_SATELLITE** or **VPN_HQ**)
- Click  **Add** to add a new rule to the top of the list
- Use the following settings:

  Action
  Pass

  Protocol
  Any

  Source
  any

  Destination
  any

  Description
  `Pass VPN traffic from WireGuard peers`

Note: This rule allows all traffic between sites, which is easy but not a secure practice. Traffic between the sites can be restricted as needed with less permissive rules.

- Click **Save**
- Click **Apply Changes**

35.55.7 Routing

Specific networks can be routed across the VPN by adding a static route for the network(s) under **System > Routing** on the **Static Routes** tab.

These steps should be done on both sites.

- Navigate to **System > Routing > Static Routes**
- Click **Add**
- Fill in the options using the information determined earlier, with variations noted for each site:

  HQ Settings

  Destinaton Network
  `10.23.0.0/24` (e.g. Satellite office LAN segment)

  Gateway
  `WG_VPN_SAT_V4`

  Satellite Office Settings

  Destinaton Network
  `10.15.0.0/24` (e.g. HQ LAN segment)

  Gateway
  `WG_VPN_HQ_V4`

- Click **Save**
- Click **Apply Changes**

See also:

As an alternative to static routing in this way, dynamic routing protocols can also work with WireGuard. See *WireGuard Routing* for more information.

Tip: These gateways can also be used for policy routing if needed.

35.55.8 Finish Up

The configuration is now complete! The two sites should now have full LAN-to-LAN connectivity.

35.56 WireGuard Site-to-Multisite VPN Configuration Example

This recipe explains how to setup a VPN tunnel between three firewalls in a site-to-multisite configuration using *WireGuard*.

This example is a minimal configuration, more complicated scenarios are possible, see *WireGuard* for details.

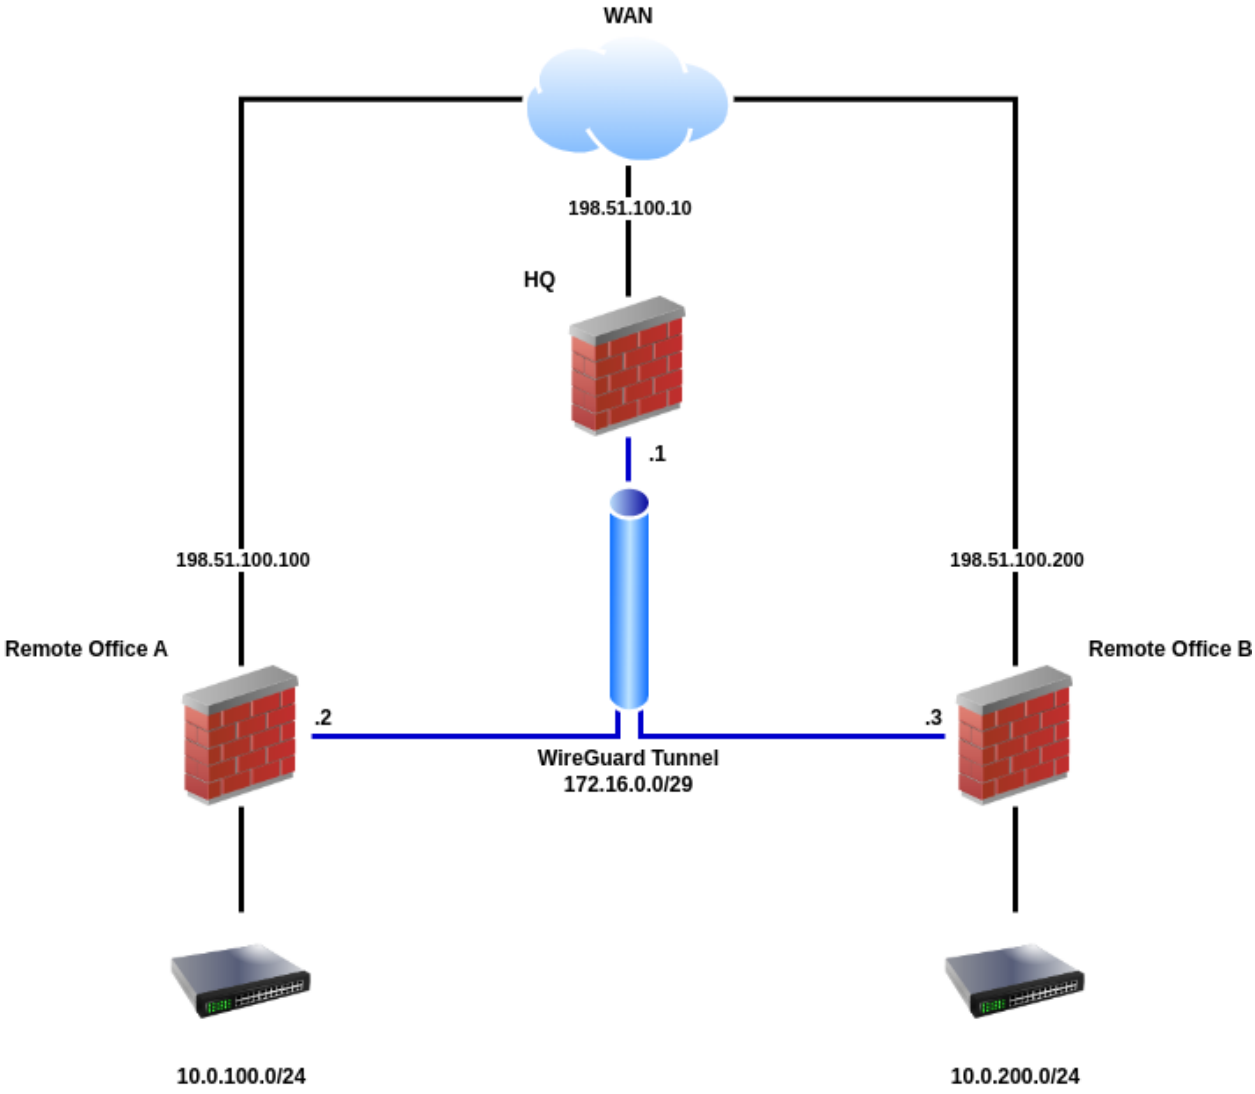

Fig. 86: WireGuard Example Site-to-Multisite Network

35.56.1 Required Information

General Values

Item	Value
Design	Site-to-Multisite, one peer per tunnel (spokes), multiple peers per tunnel (hubs)
Tunnel Subnet	`172.16.0.0/29`

HQ:

Item	Value
WAN IP Address	`198.51.100.10`
Tunnel Address	`172.16.0.1/29`
Listen Port	`51820`

Remote Office A:

Item	Value
WAN IP Address	`198.51.100.100`
Tunnel Address	`172.16.0.2/29`
Listen Port	`51820`
LAN Subnet	`10.0.100.0/24`

Remote Office B:

Item	Value
WAN IP Address	`198.51.100.200`
Tunnel Address	`172.16.0.3/29`
Listen Port	`51820`
LAN Subnet	`10.0.200.0/24`

35.56.2 WireGuard Configuration

- Navigate to **VPN > WireGuard > Settings**
- Fill in the following options:

  Enable
  Checked

  Interface Group Membership
  Only Unassigned Tunnels

- Click  **Save**

Tip: When allowing inbound connections from arbitrary remote networks, use rules only on assigned WireGuard interface tabs only to ensure proper return routing.

Note: Rules on assigned WireGuard interface tabs get `reply-to` which ensures that traffic entering a specific assigned WireGuard interface exits back out the same interface. Without that, return traffic will follow the default gateway.

35.56.3 Tunnel Configuration

First, create the WireGuard tunnel on all three sites:

- Navigate to **VPN > WireGuard > Tunnels**
- Click  **Add Tunnel**
- Fill in the options using the information determined earlier, with variations noted for each site:

  Enabled
  Checked

  HQ Settings

  Description
  `Remote Sites VPN`

  Remote Office A Settings

  Description
  `HQ VPN`

  Remote Office B Settings

  Description
  `HQ VPN`

  Listen Port
  `51820`

  Interface Keys
  Click **Generate** to create a new set of keys.

- Copy the public key from each firewall and note which is which
- Click  **Save Tunnel**

35.56.4 Peer Configuration

The peer entry for the server can be added when editing the tunnel. Follow these steps on both sites, with the differences in settings noted inline.

Edit the tunnel:

- Navigate to **VPN > WireGuard > Tunnels**
- Locate the WireGuard tunnel for this VPN
- Click  at the end of the row for the tunnel

From the tunnel editing page, add a peer:

- Click  **Add Peer**
- Fill in the options using the information determined earlier, with variations noted for each site:

HQ Settings

Description
`Remote Office A Peer`

Dynamnic Endpoint
Unchecked

Endpoint
`198.51.100.100` (the WAN IP address of Remote Site A)

Endpoint Port
`51820`

Public Key
The public key *from the Remote Office A firewall*

Allowed IPs
`172.16.0.2/32` and `10.0.100.0/24` (Remote Site A Tunnel Interface and LAN)

HQ Settings

Description
`Remote Office B Peer`

Dynamnic Endpoint
Unchecked

Endpoint
`198.51.100.200` (the WAN IP address of Remote Site B)

Endpoint Port
`51820`

Public Key
The public key *from the Remote Office B firewall*

Allowed IPs
`172.16.0.3/32` and `10.0.200.0/24` (Remote Site B Tunnel Interface and LAN)

Remote Office A Settings

Description
`HQ Peer`

Dynamnic Endpoint
Unchecked

Endpoint
`198.51.100.10` (the WAN IP address of HQ)

Endpoint Port
`51820`

Public Key
The public key *from the HQ firewall*

Allowed IPs
`172.16.0.0/29` and `10.0.200.0/24` (Tunnel Network and Remote Site B LAN)

Remote Office B Settings

Description
`HQ Peer`

Dynamnic Endpoint
Unchecked

Endpoint
`198.51.100.10` (the WAN IP address of HQ)

Endpoint Port
`51820`

Public Key
The public key *from the HQ firewall*

Allowed IPs
`172.16.0.0/29` and `10.0.100.0/24` (Tunnel Network and Remote Site A LAN)

- Click  **Save Peer**

35.56.5 Assign Interface

These steps should be done on all sites.

First, fix the default gateway so WireGuard isn't automatically selected before it's ready:

- Navigate to **System > Routing**
- Set **Default Gateway IPv4** to a specific gateway (e.g. *WANGW*) or group
- Set **Default Gateway IPv6** in a similar manner if this VPN will also carry IPv6 traffic
- Click  **Save**
- Click  **Apply Changes**

Next, assign the interface (*Assign a WireGuard Interface*):

- Navigate to **Interfaces > Assignments**
- Select the appropriate `tun_wg<number>` interface in the **Available network ports** list
- Click  **Add** to assign the interface as a new OPT interface (e.g. OPT1)
- Navigate to the Interface configuration page, **Interfaces > OPTx**
- Check **Enable**
- Enter an appropriate **Description** which will become the interface name (e.g. `VPN_HQ`, `VPN_SITEA`, or `VPN_SITEB`)
- Configure an appropriate **MTU** value for the WireGuard interface (e.g. `1420` for IPv4+IPv6 or `1440` for IPv4 only).

  For details on calculating the correct MTU, see in *Assign a WireGuard Interface*.
- Fill in the options using the information determined earlier, with variations noted for each site:

HQ Settings (VPN_HQ)

IPv4 Configuration Type
`Static IPV4`

IPv4 Address
`172.16.0.1/29`

Remote Office A Settings (VPN_SITEA)

IPv4 Configuration Type
`Static IPV4`

IPv4 Address
`172.16.0.2/29`

Remote Office B Settings (VPN_SITEB)

IPv4 Configuration Type
`Static IPV4`

IPv4 Address
`172.16.0.3/29`

- Click  **Save**
- Click  **Apply Changes**

35.56.6 Firewall Rules

First, add a rule to the WAN on both firewalls to allow traffic to reach WireGuard:

Note: Traffic flowing between peers is subject to firewall rules on the associated WireGuard interface.

- Navigate to **Firewall > Rules**, **WAN** tab
- Click  **Add** to create a new firewall rule at the top of the list so that it matches before other rules
- Configure the firewall rule as follows:

Action
Pass

Protocol
UDP

Source
This can typically be left at *Any*, but it is more secure to fill in the IP address of the opposing firewall.

Destination
WAN Address

Destination Port Range
(other), `51820`

Description
`Pass traffic to WireGuard`

- Click  **Save**
- Click  **Apply Changes**

Next, add a rule to pass traffic inside the WireGuard tunnel on both firewalls:

- Navigate to **Firewall > Rules**
- Click the tab for the assigned WireGuard interface (e.g. **VPN_HQ**, **VPN_SITEA**, or **VPN_SITEB**)
- Click  **Add** to add a new rule to the top of the list
- Use the following settings:

Action
Pass

Protocol
Any

Source
any

Destination
any

Description
`Pass VPN traffic from WireGuard peers`

Note: This rule allows all traffic between sites, which is easy but not a secure practice. Traffic between the sites can be restricted as needed with less permissive rules.

- Click  **Save**
- Click  **Apply Changes**

35.56.7 Routing

These steps should be performed on all sites:

- Navigate to **System > Routing > Gateways**
- Click  **Add**
- Fill in the options using the information determined earlier, with variations noted for each site:

HQ Settings

Interface
`tun_wg<number>`

Address Family
IPv4

Name
WG_SITEA_GW4

Gateway
172.16.0.2

HQ Settings

Interface
tun_wg<number>

Address Family
IPv4

Name
WG_SITEB_GW4

Gateway
172.16.0.3

Remote Office A/B

Interface
tun_wg<number>

Address Family
IPv4

Name
WG_HQ_GW4

Gateway
172.16.0.1

- Click  **Save**
- Click  **Apply Changes**

Specific networks can be routed across the VPN by adding a static route for the network(s) under **System > Routing** on the **Static Routes** tab.

These steps should be done on all sites.

- Navigate to **System > Routing > Static Routes**
- Click  **Add**
- Fill in the options using the information determined earlier, with variations noted for each site:

HQ Settings

Destinaton Network
10.0.100.0/24 (e.g. Remote Office A LAN segment)

Gateway
WG_SITEA_GW4

HQ Settings

Destinaton Network
`10.0.200.0/24` (e.g. Remote Office B LAN segment)

Gateway
`WG_SITEB_GW4`

Remote Office A Settings

Destinaton Network
`10.0.200.0/24` (e.g. Remote Office B LAN segment)

Gateway
`WG_HQ_GW4`

Remote Office B Settings

Destinaton Network
`10.0.100.0/24` (e.g. Remote Office A LAN segment)

Gateway
`WG_HQ_GW4`

- Click  **Save**
- Click  **Apply Changes**

See also:

As an alternative to static routing in this way, dynamic routing protocols can also work with WireGuard. See *WireGuard Routing* for more information.

Tip: These gateways can also be used for policy routing if needed.

35.56.8 Finish Up

The configuration is now complete! The two remote office sites should now have full LAN-to-LAN connectivity via HQ.

See also:

- *WireGuard*
- *Routing*
- *WireGuard Remote Access VPN Configuration Example*
- *WireGuard Site-to-Site VPN Configuration Example*
- *WireGuard VPN Client Configuration Example*

35.57 WireGuard VPN Client Configuration Example

This recipe explains how to setup *WireGuard* as a "client" to a remote VPN service through which Internet traffic will be routed.

Note: Though WireGuard does not have a concept of "Client" and "Server" per se, in this style of deployment the firewall initiates connections to a remote peer but the peer never initiates back to the firewall. In this way, the firewall behaves like a "Client" and may be referred to as such in this document. The remote peer may also be referred to as "server".

35.57.1 Required Information

The following basic information must be determined before starting the VPN configuration. This example information was obtained from a popular WireGuard VPN Provider.

Item	Value
Tunnel Addresses	`10.68.140.33/32` and `fc00:bbbb:bbbb:bb01::5:8c20/128`
Tunnel Private Key	ADRM6pyoYpofcDd0TkX4sb7UkR+Zj4AYeZOE2WWg2tI=
Peer Public Key	EPLh6pVel06dND8cE4Prix9GP4hGLYNhQhn5mSN2yzM=
Peer Endpoint	`86.106.143.236`
Peer Port	`51820`
Peer WG Address	Same as tunnel addresses for `/32` and `/128` routes
Peer DNS Server	`193.138.218.74`
Allowed IPs	`0.0.0.0/0` and `::0/0`

Hint: Start with configuring IPv4 connectivity first. Once IPv4 connectivity is established and working, then circle back and configure IPv6 connectivity if desired.

Some or all of these values must be obtained from the VPN provider or server administrator. Methods vary, but some may have a web-based portal which shows settings or generates a configuration file. Others may opt to send settings in a more secure manner.

Keys

In this role, the source of the keys can vary. Ideally, a private and public key set for this firewall should be generated by this firewall and the private key should never leave. The public key should be copied and submitted to the administrator of the server side so it can be used for this client.

Some providers insist on generating the keys themselves so they can preallocate addresses and other settings based on keys they already know. This also allows them to easily generate configurations for clients. It's less secure this way, but more convenient.

35.57.2 Tunnel Configuration

First create the WireGuard tunnel.

- Navigate to **VPN > WireGuard > Tunnels**
- Click  **Add Tunnel**
- Fill in the options using the information determined earlier:

  Enabled
  Checked

  Description
  `VPN Provider`

  Listen Port
  This does not likely matter unless the server requires a specific source port. In most cases it can be left blank or at the default `51820`.

  Interface Keys
  Enter the private key supplied by the provider `ADRM6pyoYpofcDd0TkX4sb7UkR+Zj4AYeZOE2WWg2tI=`.

  Note: Click **Generate** to generate a new key pair if the provider accepts user-generated keys.

- Click **Save**

35.57.3 Peer Configuration

The peer entry for the server can be added when editing the tunnel. To edit the tunnel:

- Navigate to **VPN > WireGuard > Tunnels**
- Locate the WireGuard tunnel for this VPN provider
- Click  at the end of the row for the tunnel

From the tunnel editing page, add a peer as follows:

- Click  **Add Peer**
- Fill in the options using the information determined earlier:

  Enable
  Checked

  Tunnel
  The WireGuard tunnel for this VPN provider.

  Description
  The name of this server or VPN provider.

  Dynamnic Endpoint
  Unchecked

  Endpoint
  The server hostname or IP address, `86.106.143.236` in this example.

Endpoint Port
The server WireGuard port, `51820` in this example.

Public Key
The public key for the **VPN provider endpoint**, given by the VPN provider `EPLh6pVel06dND8cE4Prix9GP4hGLYNhQhn5mSN2yzM=`.

Pre-Shared Key
Not used in this example, but for additional security this pre-shared key can be generated and copied to the peer. Must match on the client and server.

Most VPN providers are not utiizling pre-shared keys at this time.

Allowed IPs
List of networks to route to the remote side. Since this example will be sending all traffic through the VPN provider, enter `0.0.0.0/0` and `::0/0`.

- Click **Save Peer**

35.57.4 Confirm Handshakes

At this point it is possible to confirm basic connectivity with the VPN provider.

- Navigate to **VPN > WireGuard > Status**
- Click **Show Peers**
- Confirm peer connectivity and recent handshaking with the peer

35.57.5 Assign Interface

First, fix the default gateway so WireGuard isn't automatically selected before it's ready:

- Navigate to **System > Routing**
- Set **Default Gateway IPv4** to a specific gateway (e.g. *WANGW*) or group
- Set **Default Gateway IPv6** in a similar manner if this VPN will also carry IPv6 traffic
- Click **Save**
- Click **Apply Changes**

Next, assign the interface (*Assign a WireGuard Interface*):

- Navigate to **Interfaces > Assignments**
- Select the appropriate `tun_wg<number>` interface in the **Available network ports** list
- Click  **Add** to assign the interface as a new OPT interface (e.g. OPT1)
- Navigate to the Interface configuration page, **Interfaces > OPTx**
- Check **Enable**
- Enter an appropriate **Description** which will become the interface name (e.g. `WG_VPN`)
- Configure an appropriate **MTU** value for the WireGuard interface (e.g. `1420` for IPv4+IPv6 or `1440` for IPv4 only).

  For details on calculating the correct MTU, see in *Assign a WireGuard Interface*.

- Fill in the options using the information determined earlier:

  IPv4 Configuration Type
  `Static IPV4`

  IPv6 Configuration Type
  `Static IPv6`

  IPv4 Address
  `10.68.140.33/32`

  IPv4 Upstream Gateway

  - Click **Add a new gateway**
  - Fill in the options:

    Gateway Name
    `WG_VPN_v4`

    Gateway IPv4
    `10.68.140.33`

  - Click  **Add**

  IPv6 Address
  `fc00:bbbb:bbbb:bb01::5:8c20/128`

  IPv6 Upstream Gateway

  - Click **Add a new gateway**
  - Fill in the options:

    Gateway Name
    `WG_VPN_v6`

    Gateway IPv6
    `fc00:bbbb:bbbb:bb01::5:8c20`

  - Click  **Add**

- Click **Save**
- Click **Apply Changes**

35.57.6 Gateways and Groups

These gateways can be added to a gateway group for failover or load balancing of outbound traffic. This example assumes there are no existing groups. If there are groups already, the new gateway can be added to them like any other.

This example sets up a Gateway Group which prefers WireGuard and fails over to WAN. Traffic directed to this group will use WireGuard when it is up, and WAN when it is down. In practice this specific behavior may or may not be desirable, but can be used as a template for other scenarios.

Note: This will only function properly if gateway monitoring is possible. For that to work, edit the WireGuard interface gateways and fill in a different **Monitor IP** address which responds to ICMP echo (ping) requests over the WireGuard tunnel.

To create a new group:

- Navigate to **System > Routing**, **Gateway Groups** tab
- Click  **Add**
- Configure the group as follows:

  Group Name
  `Prefer_WireGuard_V4`

  Gateway Priority

  WG_VPN_v4
  Tier 1

  WANGW
  Tier 2

  Description
  `Prefer VPN, fail to WAN`

- Repeat for IPv6 if required
- Click **Save**
- Click **Apply Changes**

35.57.7 Outbound NAT

By default the VPN will not have outbound NAT applied to its traffic. Most VPN providers will require this, so that all traffic appears to originate from the address of the VPN interface, and not LAN.

To setup outbound NAT for the VPN:

- Navigate to **Firewall > NAT**, **Outbound** tab
- Set **Mode** to **Hybrid Outbound NAT**

  This example assumes the firewall starts out on **Automatic Outbound NAT**. If the firewall is using **Manual Outbound NAT**, there is no need to change the mode.
- Click **Save**
- Click | fa-turn-up| **Add** to create a new outbound NAT rule at the top of the list
- Configure the NAT rule as follows:

  Interface
  The assigned WireGuard interface (e.g. *WG_VPN*)

  Source
  The LAN subnet of this firewall (e.g. `192.168.1.0/24`)

  Description
  A description of the rule, if desired: `Outbound NAT for LAN to WireGuard VPN Provider`

  Leave all remaining options at their default values
- Repeat for IPv6 if required
- Click **Save**

- Click **Apply Changes**

35.57.8 Firewall Rules

This scenario should not require any firewall rules on the WAN or VPN interface. No connections will be made inbound on the WAN, only outbound. Traffic from the Internet will not be allowed back into the VPN interface.

35.57.9 Routing Traffic

Policy Routing

Rules can be added to local interfaces, such as LAN, for policy routing which utilize the gateway for the WireGuard interface.

For example, to policy route all traffic from a host on the LAN out through WireGuard:

- Navigate to **Firewall > Rules**, **LAN** tab
- Click  **Add** to create a new firewall rule at the top of the list so that it matches before other rules
- Configure the firewall rule as follows:

  Action
  Pass

  Interface
  LAN

  Protocol
  Any

  Source
  Set this to match the client whose outbound traffic will be routed across the VPN. For example:

  Address or Alias, `192.168.1.23`

  Destination
  Any

  Gateway
  WG_VPN_WGV4

  Note: Click **Display Advanced** to show this option.

  Leave all remaining options at their default values
- Repeat for IPv6 if required
- Click **Save**
- Click **Apply Changes**

This concept can be adapted for a number of different scenarios. For example, match all LAN traffic and send it across the VPN, or match traffic and use a gateway group to prefer the VPN, etc.

Static Routing

Specific networks can be routed across the VPN by adding a static route for the network(s) under **System > Routing** on the **Static Routes** tab.

Default Gateway

This is an optional step that some users may want to perform if they want all traffic from the firewall to cross the VPN, not only LAN client traffic.

Policy routing is the most flexible way to direct traffic over this type of connection, but it does not influence traffic from the firewall itself. To send traffic from the firewall across the VPN to Internet destinations, the VPN must be set as the default gateway.

To avoid a chicken-and-egg problem, a manual static route is required for the VPN provider peer endpoint address:

- Navigate to **System > Routing**, **Static Routes** tab
- Click  **Add**
- Configure the routes as follows:

  Destination network
  The VPN provider peer endpoint IP address. For this example, `86.106.143.236`. Use a CIDR mask of `32` (or `128` if the peer endpoint is an IPv6 address.)

  Gateway
  WANGW so that traffic for this endpoint is routed over WAN

  Description
  `Route to VPN provider endpoint`

- Click **Save**

With the peer route in place, now set the default gateway:

- Navigate to **System > Routing**, **Gateways** tab
- Set **Default Gateway IPv4** to *WG_VPN_V4*, or a gateway group which includes that gateway, such as the previously created *Prefer_WireGuard*.
- Set **Default Gateway IPv6** in a similar manner if the VPN also carries IPv6 traffic.
- Repeat for IPv6 if required
- Click **Save**
- Click **Apply Changes**

At this point, all traffic that doesn't match entries in the routing table will be sent across the VPN.

35.57.10 DNS Configuration

DNS privacy is also important, and there are a few factors to consider. For this example, DNS requests will be sent to a DNS server at the VPN peer, but without TLS.

See also:

Options such as *DNS over TLS* are covered elsewhere, but can help as well.

First, set the VPN provider DNS server:

- Navigate to **System > General**
- Remove any DNS servers present in the list under **DNS Server Settings**
- Set a DNS Server entry as follows:

  Address
  The address of the DNS server at the peer, in this example, `193.138.218.74`.

  DNS Hostname
  If this server supports DNS over TLS, enter its hostname here. Otherwise, leave it blank.

  Gateway
  Select the VPN gateway, *WG_VPN_V4*.

- *Uncheck* **DNS Server Override** to prevent this firewall from using DNS servers from dynamic WANs.
- Set **DNS Resolution Behavior** based on the requirements of this environment:

> **Warning:** This can help prevent DNS requests from leaking to other servers not using the VPN, but it can cause a chicken-end-egg scenario where DNS requests will fail unless the VPN is working. Ensure that DNS is not required to establish the VPN.

  Use local DNS, fall back to remote DNS Servers
  Use this option when using the DNS Resolver in forwarding mode and when the DNS server does not need DNS over TLS. This is the best fit for this example.

  Use local DNS, ignore remote DNS Servers
  Use this option when using DNS over TLS with the DNS Resolver in forwarding mode. This ensures that no DNS query will be sent without TLS.

  Use remote DNS Servers, ignore local DNS
  Use this option if the firewall itself shouldn't use the DNS Resolver, but communicate directly with the DNS server without TLS.

Next, configure the DNS Resolver for Forwarding mode:

- Navigate to **Services > DNS Resolver**
- *Uncheck* **Enable DNSSEC Support**
- *Check* **Enable Forwarding Mode**
- Repeat for IPv6 if required
- Click **Save**
- Click **Apply Changes**

Warning: If there are any **Custom Options** in the DNS Resolver, it is possible that switching to forwarding mode will change the context of the options. Add `server:` to the beginning of the **Custom Options** box content, above any existing options. If the **Custom Options** box is empty, it can remain empty.

35.57.11 Finish Up

The configuration is now complete! Depending on which sections were followed, the firewall should be able to at least communicate with the remote peer, networks, and clients should be able to pass traffic through the VPN provider out to the Internet.

Make any final adjustments or additional configurations as needed.

35.58 Accessing Port Forwards from Local Networks

By default, pfSense® software does not redirect internally connected devices to forwarded ports and 1:1 NAT on WAN interfaces. For example, if a client on LAN attempts to reach a service forwarded from WAN port `80` or `443`, the connection will hit the firewall web interface and not the service they intended to access. The client will be presented with a certificate error if the GUI is running HTTPS, and a DNS rebinding error since the GUI rejects access for unrecognized hostnames.

NAT Reflection employs techniques to redirect these connections. Split DNS is an alternate technique to accomplish the same goal. Split DNS is the best practice because it allows for retaining of the original source IP address and avoids unnecessarily looping internal traffic through the firewall. Both techniques are explained in this document.

35.58.1 Method 1: NAT Reflection

To access ports forwarded on the WAN interface from internal networks, NAT reflection must be enabled:

- Navigate to **System > Advanced**, **Firewall & NAT** tab
- Configure the following options in the **Network Address Translation** section of the page:

  NAT Reflection mode for port forwards
  Pure NAT

  Pure NAT mode is the best choice if NAT reflection must be activated, but it may not work for all scenarios. See *NAT Reflection mode for Port Forwards* for details on each of the NAT reflection modes.

  Enable NAT Reflection for 1:1 NAT
  Checked

Enable automatic outbound NAT for Reflection
Checked

- Click *Save*

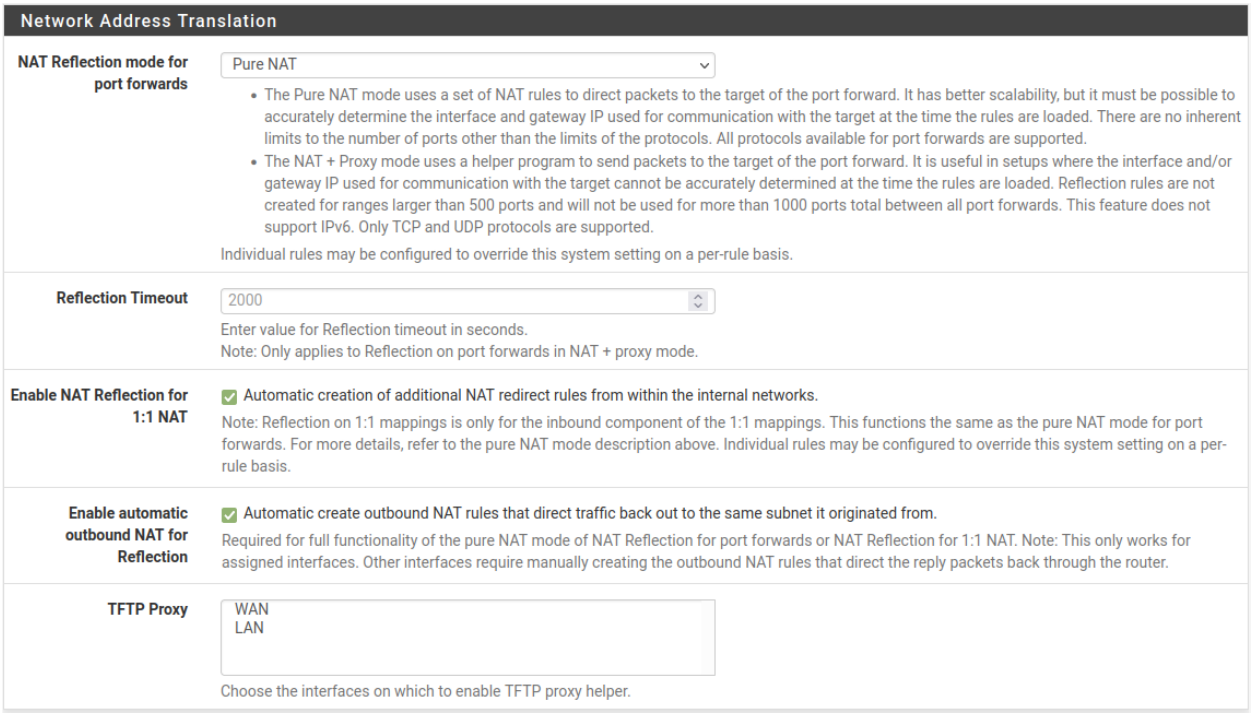

Fig. 87: NAT Reflection Settings

35.58.2 Method 2: Split DNS

Split DNS is the best practice to solve this problem and it is a much more elegant solution than NAT reflection. Split DNS is a configuration where internal and external clients resolve hostnames differently.

In this scenario, internal clients access resources by hostname, not IP address. Clients on the local network resolve that hostname to the actual LAN IP address of the server, and not the WAN IP address as others outside the network would see.

For this to work using the DNS Resolver or Forwarder in pfSense software, clients must use the IP Address of the firewall as their primary DNS server.

Note: If the clients all use some other internal DNS server not on the firewall, such as Active Directory, split DNS can still work. Configure the internal DNS server in a similar manner to what is described in this section.

Example:

- `www.example.com` resolves to public IP address `1.2.3.4`, which is the WAN IP address of the firewall
- The firewall is configured to forward port `80` on `1.2.3.4` to port `80` on `192.168.1.5`, the internal web server.
- Override `www.example.com` using **Services > DNS Resolver** (or **DNS Forwarder**, if that is active instead) and point `www.example.com` to `192.168.1.5`

Screenshots that show the above in practice:

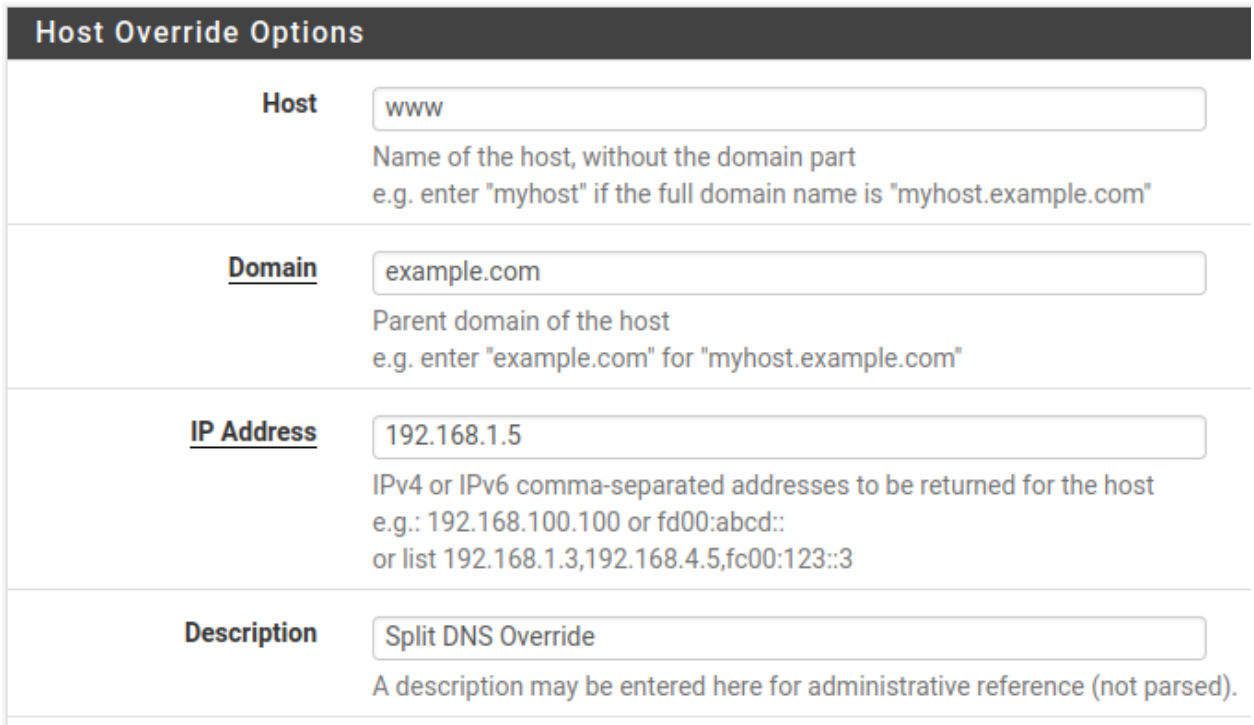

Fig. 88: Adding a DNS Resolver host override for split DNS

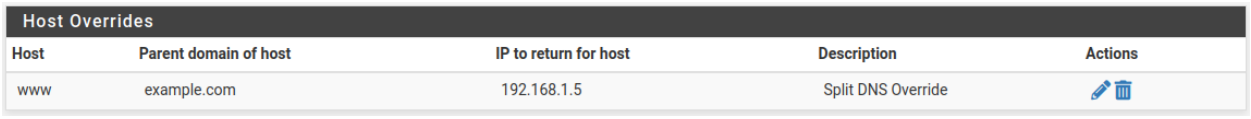

Fig. 89: Split DNS entry in the list of host overrides

35.59 Authenticating from Active Directory using RADIUS/NPS

Windows Servers can be configured as a RADIUS server using the Microsoft Network Policy Server (NPS). This allows a Windows Server to handle authentication for OpenVPN, Captive Portal, the PPPoE server, or even the firewall GUI itself. NPS can authenticate based on Windows Server local user accounts or Active Directory.

Note: While support for NPS has been present since Windows Server 2008, this document focuses on current versions of Windows Server software.

The options may vary slightly depending on the version of Windows Server software.

35.59.1 Choosing a server for NPS

NPS requires a minimal amount of resources and is suitable for addition to an existing Windows Server in most environments. Microsoft recommends installing it on an Active Directory domain controller to improve performance in environments where NPS is authenticating against Active Directory.

Tip: NPS can also be installed on a member server, which may be desirable in some environments to reduce the attack footprint of domain controllers. Each network-accessible service provides another potential avenue for compromising a server. NPS has a solid security record, especially compared to other services that must be running on domain controllers for Active Directory to function, so this isn't much of a concern in most network environments.

Most environments install NPS on one of their domain controllers. Microsoft recommends running it on each domain controller in the forest and using NPS proxies to share the load for a busy environment.

35.59.2 Installing NPS

- Open the Server Manager Dashboard
- Click **Add Roles and Features**

  This may be on the main screen or under the **Manage** menu.
- Click **Next** until the wizard displays the server selection screen
- Select this server from the list
- Click **Next** again
- Check **Network Policy and Access Services** on the list of roles
- Click **Add Features** if it appears
- Click **Next** on each screen until the end of the wizard
- Click **Finish** or **Install**, depending on the windows server version
- Click **Close** once the installation completes

35.59.3 Configuring NPS

To configure NPS, bring up the Server Manager and select the new role. The name varies on different versions of Windows Server but may be NPAS (2022), NAP (2012), Network Policy and Access Services, or a similar name.

First configure a RADIUS client for the firewall, then setup remote access policies.

Adding a RADIUS Client

- Open the **Server Manager** dashboard
- Click **NPAS** or its equivalent name (**NAP**, etc)
- Right click on this server in the server list
- Click **Network Policy Server**
- Expand **RADIUS Clients and Server**
- Click **RADIUS Clients**

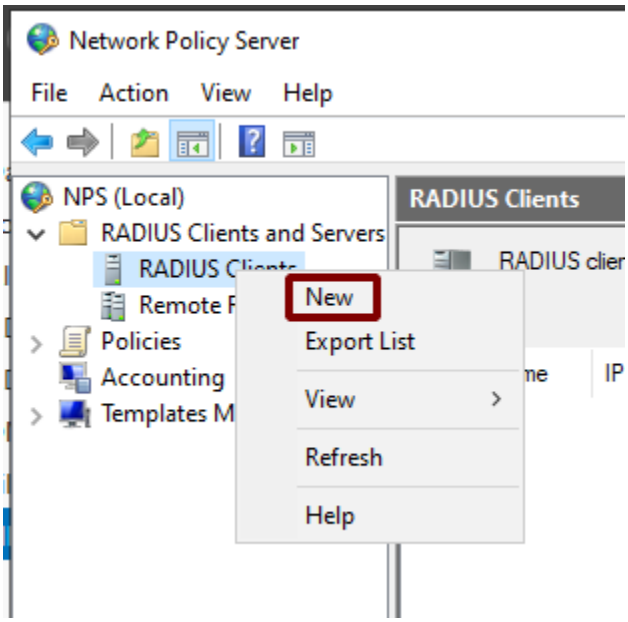

Fig. 90: Add New RADIUS Client

Add the new RADIUS client:

- Right click on **RADIUS Clients**
- Click **New**, as shown in Figure *Add New RADIUS Client*
- Enter a **Friendly name** for the firewall, as shown in Figure *Add New RADIUS Client Address*.

  This can be the hostname or an FQDN.
- Enter the **Address (IP or DNS)** for the firewall.

  This must be the IP address from which the firewall will initiate RADIUS requests or an FQDN which resolves to that IP address.

Note: This is the IP address of the firewall interface closest to the RADIUS server. If the RADIUS server is reachable via the firewall LAN interface, this will be the LAN IP address of the firewall. In deployments where the firewall is not the perimeter firewall, and the WAN interface resides on the internal network where the RADIUS server resides, the WAN IP address would be the correct address.

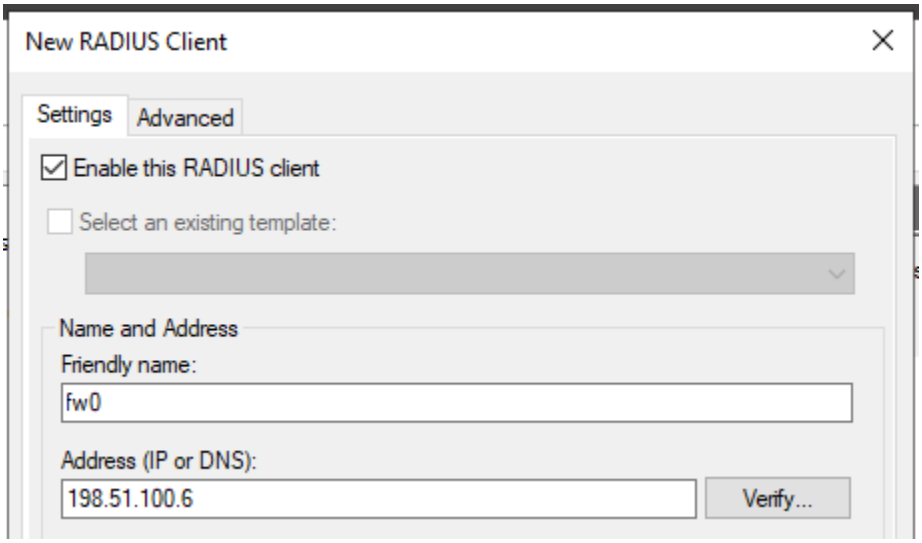

Fig. 91: Add New RADIUS Client Address

- Enter a **Shared secret**, as shown in Figure *Add New RADIUS Client Shared Secret*.

  This shared secret is used by the firewall to authenticate itself when making RADIUS access requests.

  Windows can automatically create a shared secret using the **Generate** option.

- Click OK.

The NPS configuration for the RADIUS client is now complete. The RADIUS Client is visible as in Figure *Listing of the RADIUS Client*.

Refer to other sections in this documentation describing the service to be used with RADIUS for more guidance on how to utilize the service. The *User Manager* can use NPS as an authentication server which also enables RADIUS for IPsec, OpenVPN, and *Captive Portal*. Other services such as the *PPPoE server* can use it directly as well.

Configuring Users and Network Policies

Network Policies control whether or not a user can authenticate via RADIUS. Using Network Policies, an administrator can place a user in a specific Active Directory group to allow VPN access and also offer more advanced capabilities such as time of day restrictions.

More information on remote access policies can be found in Microsoft's documentation at http://technet.microsoft.com/en-us/library/cc785236%28WS.10%29.aspx.

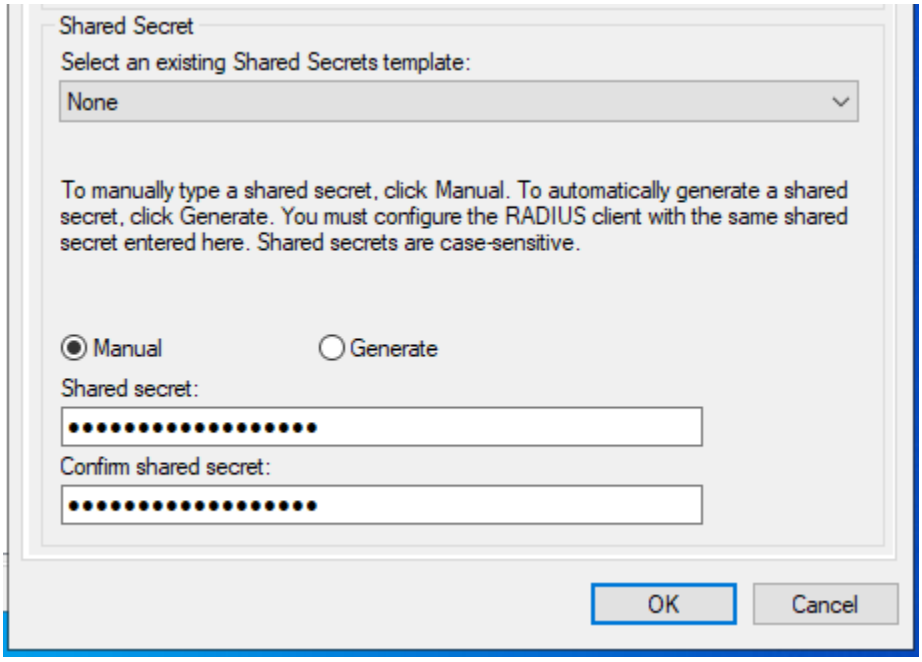

Fig. 92: Add New RADIUS Client Shared Secret

Fig. 93: Listing of the RADIUS Client

Adding a Network Policy

- Open the **Server Manager** dashboard
- Click **NPAS** or its equivalent name (**NAP**, etc)
- Right click on this server in the server list
- Click **Network Policy Server**
- Expand **NPS (Local)**, **Policies**, then **Network Policies**
- Right click on **Network Policies**
- Click **New**
- Enter `Allow from Firewall` in the **Policy name**
- Leave the **Type of network access server** set to *Unspecified*
- Click **Next**
- Click **Add** in the Specify Conditions window
- Select **Windows Groups**
- Click **Add**
- Enter or select the name of the user group which contains VPN users, e.g. `VPNUsers`
- Click **OK**
- Click **Next**
- Choose **Access granted**
- Click **Next**
- Add **EAP Types / Authentication Methods** as needed:
  - Leave existing authentication methods selected
  - Add or Select **Microsoft: Secured Password (EAP-MSCHAP v2)** if the firewall will use this policy for IPsec IKEv2 EAP-RADIUS authentication
  - Select **Encrypted Authentication (CHAP)**
  - Select **Unencrypted Authentication (PAP, SPAP)**
- Click **Next**
- Click **No** or **Decline** if the wizard prompts to view a help topic about security
- Configure any additional access constraints, if necessary
- Click **Next** on the remaining screens until the final screen is reached
- Click **Finish**

Editing an Existing Network Policy

Existing policies can be altered to change their constraints or other properties. For example, to edit an older policy to enable it for use by IPsec for IKEv2 EAP-RADIUS:

- Open the **Server Manager** dashboard
- Click **NPAS** or its equivalent name (**NAP**, etc)
- Right click on this server in the server list
- Click **Network Policy Server**
- Expand **NPS (Local)**, **Policies**, then **Network Policies**
- Edit the policy currently in use (e.g. right click, click **Properties**)
- Click the **Constraints** tab
- Click **Authentication Methods**
- Click **Add**
- Select **Microsoft: Secured Password (EAP-MSCHAP v2)**
- Click **OK**
- Click **Apply** to restart NPS
- Click **OK**

35.59.4 Check Users and Groups

These steps are only necessary if the use case for this setup requires group authentication on the firewall.

Before proceeding, ensure any users who must authenticate using NPS are members of the correct groups (e.g. `VPNUsers`).

Create a matching group with a remote scope on the firewall (*Manage Local Groups*).

Edit the NPS policy on the Windows server so it returns the group name:

- Open the **Server Manager** dashboard
- Click **NPAS** or its equivalent name (**NAP**, etc)
- Right click on this server in the server list
- Click **Network Policy Server**
- Expand **NPS (Local)**, **Policies**, then **Network Policies**
- Edit the policy currently in use (e.g. right click, click **Properties**)
- Click the **Settings** tab
- Click **Standard** under **RADIUS Attributes**
- Select **Class** from the list
- Click **Add**
- Select **String** for the attribute value type
- Enter a group name which matches a group on the firewall (e.g. `VPNUsers`)
- Click **OK**

- Click **Close**
- Click **Apply** to restart NPS
- Click **OK**

35.59.5 Add Authentication Server

Now that NPS is ready to accept authentication requests, the next step is to add an authentication server entry on the firewall.

See also:

RADIUS Authentication Servers

- Open the firewall GUI
- Navigate to **System > User Manager**, **Authentication Servers** tab
- Click  **Add** to create a new entry
- Enter the following settings:

  Descriptive name
  `Active Directory NPS`

  Type
  RADIUS

  Hostname or IP address
  `198.51.100.30` – Replace this with the IP address of the Windows server

  Shared Secret
  The password added to the NAS entry in NPS

  Services offered
  Authentication

  Authentication port
  `1812`

- Click **Save**

35.59.6 Test Authentication

On the firewall GUI, test the authentication:

- Navigate to **Diagnostics > Authentication**
- Set **Authentication Server** to the entry for NPS
- Enter a username and password for a user which should have access
- Click **Test**

If that test succeeded, then configure other services such as IPsec or OpenVPN to use the new RADIUS server and attempt authentication there.

35.59.7 Troubleshooting NPS

This section describes the most common problems users encounter with NPS.

Verify port

First ensure NPS is using the default port `1812`. If the NPS server was already installed, it may have be using a non-standard port.

- Open the **Server Manager** dashboard
- Click **NPAS** or its equivalent name (**NAP**, etc)
- Right click on this server in the server list
- Click **Network Policy Server**
- Right click on **NPS (Local)** at the top left of the console
- Click **Properties**
- Click the **Ports** tab
- Verify that the **Authentication** port set includes port `1812`

  NPS can use multiple ports separated with commas, as shown in figure *NPS Ports*.
- Verify the **Accounting** port set includes port `1813` (optional)

  This is only necessary if the use case requires RADIUS accounting.

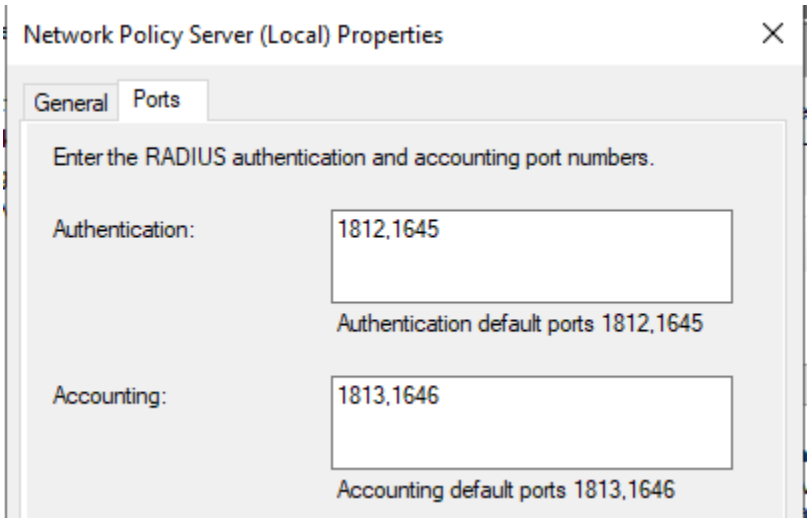

Fig. 94: NPS Ports

Check Event Viewer

When NPS handles a RADIUS authentication request it creates a log entry in the Security log in Event Viewer with the result of the authentication request. If it denies access, it logs the reason in the event log.

These log entries can be viewed in one of two ways:

View the **Security** log. This method is easier to identify success vs failure but on a busy server it may be difficult to isolate entries specific to NPS.

- Open Event Viewer on the Windows Server
- Expand **Windows Logs**
- Click **Security**
- Look for entries in the log which reference NPS

Use the custom view which only displays NPS log entries:

- Open Event Viewer on the Windows Server
- Expand **Custom Views**
- Expand **Server Roles**
- Click **Network Policy and Access Services**

Similar messages are available in both locations thought their format may vary slightly.

The contents of the log message contain a **Reason:** line which explains why authentication failed. The common two failures are:

- "Authentication failed due to a user credentials mismatch"

  This indicates that the user supplied an invalid username or password.

- "The Network Access Permission setting in the dial-in properties of the user account in Active Directory is set to Deny access to the user."

  Indicates that the user account is set to deny access or the network policies in NPS do not allow access for that user. For example, they may not be a member of the correct group.

If NPS is logging that authentication was successful, but the client is receiving a bad username or password message, ensure that the RADIUS secret configured in NPS and on the firewall match.

35.60 Allowing Remote Access to the GUI

Several ways exist to remotely administer a firewall running pfSense® software that come with varying levels of recommendation. They all work, but their use may vary for any number of reasons (Client restrictions, corporate policies, etc.)

35.60.1 Use a VPN

The safest way to accomplish the task is to setup a VPN that will allow access to the firewall and the network it protects. There are several VPN options available in pfSense software, such as

- *IPsec*
- *OpenVPN*
- *SSH tunneling*

Once a VPN is in place, reach the GUI safely using a local address on the firewall, such as the LAN IP address. The exact details vary depending on the VPN configuration.

35.60.2 Restricted Firewall Access

If the webGUI port must be accessible to the Internet, restrict it by IP address/range as much as possible. Ideally, if there is a static IP address at the location to manage from, allow traffic from that IP address or subnet and nowhere else. Aliases also help, and they can include fully qualified domain names as well. If the remote management clients have a dynamic DNS address, add it to a management alias.

35.60.3 Use HTTPS

The best practice is to always use HTTPS to encrypt access to the GUI port. Modern browsers may complain about the certificate, but an exception can usually be stored so it will only complain the first time.

To disable (or re-enable) HTTPS for the GUI, navigate to **System > Advanced**, under the **Admin Access** tab, using the **Protocol** option in the webConfigurator section. See *Admin Access* for details.

35.60.4 Move the GUI to an Alternate Port

Moving the GUI to a non-standard, random port is also beneficial. This does not improve the actual security of the GUI itself, but can potentially reduce the number of brute force attempts. The GUI can still be found by scanners unless the port is properly filtered.

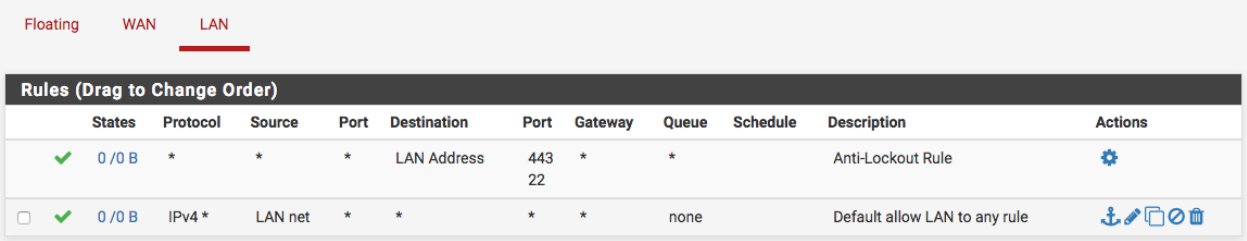
The port for the GUI can be changed under **System > Advanced**, **Admin Access** tab, using the *TCP Port* option in the **webConfigurator** section. Avoid common ports like `443`, `31337`, `8080`, `8888`, etc.

35.60.5 Strict Management

To enhance the security of a network, in many environments access to the firewall GUI is limited by firewall rules. Restricting access to the management interface is the best practice , for reasons as to why, see the blog post Securely Managing Web-administered Devices.

The default configuration of pfSense software allows management access from any machine on the LAN and denies it to anything outside of the local network. There is also an anti-lockout rule enabled by default that prevents firewall rules from being configured in a way that will lock the user out of the web interface.

To restrict management access first ensure the LAN rules allow access to the port used for the GUI. This depicts the default LAN rule, which allows access to the web interface.

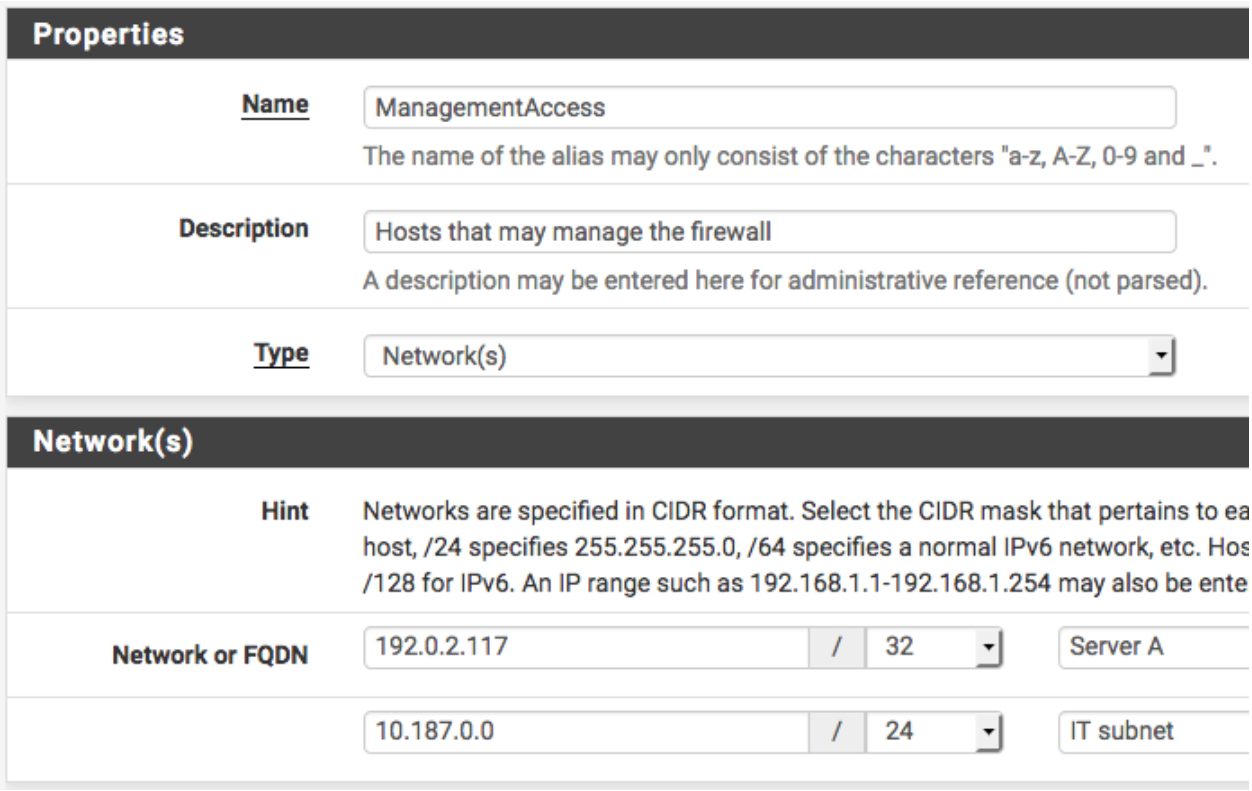


If a restrictive ruleset is in place on the LAN, make sure it permits access to the web interface before continuing.

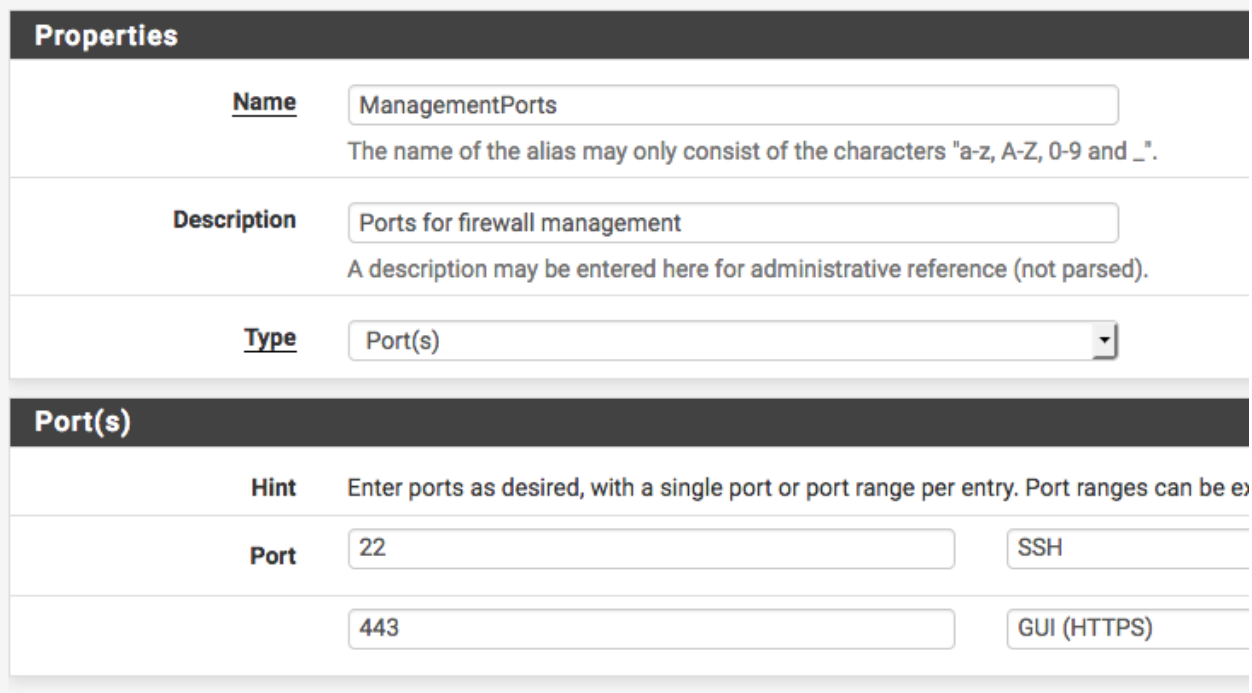
Now disable the anti-lockout rule. Navigate to **System > Advanced**, **Admin Access** tab and check **Disable webConfigurator anti-lockout rule**. Click **Save** and the rule will be removed.

Using a network alias for management access is another useful best practice. If both web and SSH administration are used, add an alias for those ports. The following are examples:

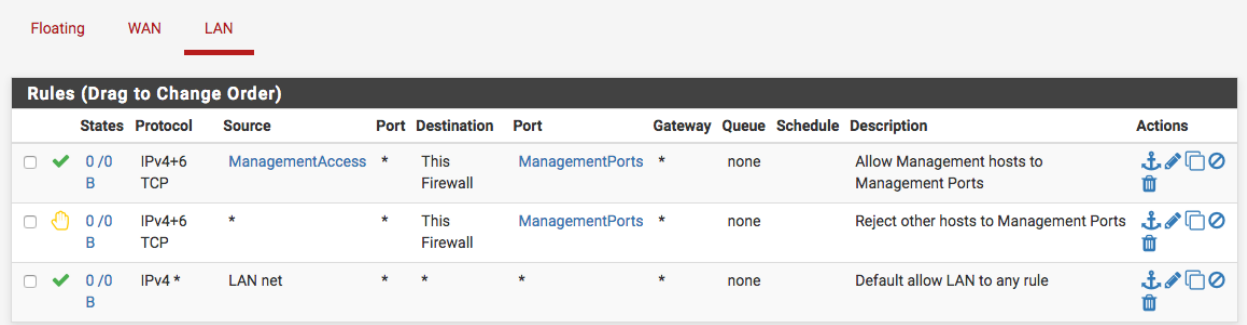
1. Example alias for networks allowed to access management interface



2. Example alias for ports allowed to access management interface



Now add a firewall rule allowing the sources defined in the management alias to the destination of the firewall, with the port used or alias created for those using multiple ports. **Make sure this rule is first in the list**. Then add a rule based on that rule (click  next to the rule), changing action to *block* or *reject* (reject is preferred on internal networks), source to *any*, and destination the same. When finished the ruleset should look like the following.



Click **Apply Changes** and the management interface is now restricted to only the defined hosts.

35.60.6 I Don't Care About Security, How Do I Open Access To The GUI?

To open the firewall GUI, create a firewall rule to allow remote firewall administration.

Note: Do not create a port forward or other NAT configuration.

Firewall > Rules, WAN Tab

Action
pass

Interface
WAN

Source
The IP address or subnet of the client, an alias containing management hosts/networks, or (as a last resort only) *Any*

Destination
WAN Address

Destination port range
HTTPS (Or the custom port)

Description
Allow remote management from anywhere (Dangerous!)

35.61 Preventing RFC 1918 Traffic from Exiting a WAN Interface

RFC 1918 addresses are blocks of network IP addresses reserved for private use. These addresses are commonly used behind firewalls to allow a single public IP address to be shared with multiple devices using NAT. The default pfSense® software installation assigns the `192.168.1.0/24` address space to the LAN interface, but RFC 1918 also defines other CIDR ranges for private use:

- `10.0.0.0/8`
- `172.16.0.0/12`
- `192.168.0.0/16`

As a general rule, it is good practice to prevent network traffic intended for RFC 1918 subnets from leaving the firewall via the WAN interface. This avoids unnecessary traffic on the WAN link and also provides a small security benefit by keeping information about the LAN network behind the firewall.

An example where this rule can be helpful is if a machine on the local LAN (e.g. `192.168.1.5`) is configured to access private LAN addresses that are routed across a VPN tunnel (e.g. `192.168.100.0/24`). If the VPN link were to go down, the firewall would no longer have an active route for `192.168.100.0/24` and a packet intended for `192.168.100.0/24` will be routed out the WAN interface using the default route. This could potentially provide information about the private LAN to someone with access to the ISP network. A malicious user could even set up an impostor machine on the WAN with a `192.168.100.0/24` address and pretend to be a machine on the inactive VPN link.

While the chance of this being a problem is small, the probability of unintentional RFC 1918 traffic routing through the WAN interface will increase for installations with more complex LAN topologies, a large number of users (typos, etc), or routes that may frequently change (VPN, etc). In these scenarios, it may be beneficial to add a firewall rule preventing RFC 1918 traffic from being routed out of the WAN interface.

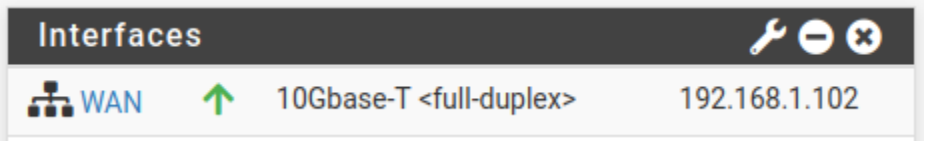
35.61.1 Scenarios where RFC 1918 addresses should NOT be blocked on the WAN interface

The default configuration of pfSense software will not block RFC 1918 addresses routed from the LAN subnet to the outside WAN because there are two common scenarios where blocking this traffic is not desirable:

ISP assigns a RFC 1918 address to end users
Some ISPs assign private network addresses to their customers and perform their own NAT for customer traffic to the public internet. Verify this by looking at the WAN interface IP address on the dashboard. If the assigned address is from one of the private IP ranges listed above, RFC 1918 traffic should NOT be blocked.

The firewall is behind another firewall or router
In this case, pfSense software performs NAT for devices connected to the LAN. The WAN interface forwards traffic to the upstream device where it undergoes a second NAT operation before entering the public internet. This is verified using the same steps as above – if the WAN IP address is from the RFC 1918 range, do NOT block this traffic from exiting the WAN

This is an example of an RFC 1918 address assigned to the WAN:



Warning: If either of these scenarios apply to this installation of pfSense software, do NOT add additional RFC 1918 traffic blocking to the WAN interface as this may prevent LAN users from accessing the WAN.

35.61.2 Steps to block RFC 1918 traffic from leaving the WAN interface

For installations where the above scenarios do not apply an additional firewall rule can be put in place to prevent RFC 1918 traffic from leaking out of the WAN interface. This provides a small increase in security and privacy by preventing information about the local LAN from being routed further upstream to the ISP.

To add a block rule for RFC 1918 traffic:

- Navigate to **Firewall > Aliases**
- Click **Add** to create a new alias
- Configure the alias with these settings:

  Name
  `private_networks` (Or another relevant name such as `RFC1918`)

  Description
  `RFC 1918 Private Networks`

  Type
  Network(s)

  Network or FQDN
  Add entries for each of the private RFC 1918 subnets:

  - `10.0.0.0/8`

- `172.16.0.0/12`
- `192.168.0.0/16`

- Click **Save**
- Navigate to **Firewall > Rules**, **Floating** tab
- Click  to add a new rule to the top of the list
- Configure the rule with these settings:

  Action
  Reject

  Quick
  Checked

  Interface
  WAN

  Optionally select multiple WAN interfaces or interface groups here, do NOT select the local LAN

  Direction
  out

  Address Family
  IPv4

  Protocol
  any

  Source
  any

  Destination
  Address or Alias, `private_networks`

- Click **Save**
- Click **Apply Changes**

Lastly, verify that local LAN and internet connectivity are still functional.

35.61.3 Notes

Adding this rule to the firewall will block access to bridge devices like cable modems or upstream routers outside of the WAN interface. For example, many cable modems use an IP address of `192.168.100.1` by default. This may or may not be desirable behavior for users. The RFC 1918 firewall rule needs to be bypassed with a specific pass rule above it, or disabled, if clients inside the LAN require access to this type of device.

On the interface options (**Interfaces > WAN**, for example) there is an option to *Block private networks*. This is a rule blocking **inbound** traffic, not outbound like the rule described here. As long as the firewall is not behind a WAN that uses private addressing, both types of rules are desirable and should be enabled.

35.62 Routing Public IP Addresses

This section covers the routing of public IP addresses where a public IP subnet is assigned to an internal interface on a single firewall deployment.

See also:

If a High Availability cluster is in use, see *High Availability Configuration Example without NAT*.

35.62.1 IP Assignments

At least two public IP subnets must be assigned by the ISP. One is for the WAN of the firewall, and one for the inside interface. This is commonly a /30 subnet for the WAN, with a second subnet assigned for the internal interface. This example will use a /30 on WAN as shown in Table *WAN IP Block* and a /29 public subnet on an internal OPT interface as shown in Table *Inside IP Block*.

Table 22: WAN IP Block

198.51.100.64/30	
IP Address	Assigned To
198.51.100.65	ISP router (pfSense® default gateway)
198.51.100.66	pfSense WAN interface IP address

Table 23: Inside IP Block

192.0.2.128/29	
IP Address	Assigned To
192.0.2.129	pfSense OPT interface
192.0.2.130	Internal hosts
192.0.2.131	
192.0.2.132	
192.0.2.133	
192.0.2.134	

35.62.2 Interface Configuration

First configure the WAN and OPT interfaces. The LAN interface can also be used for public IP addresses if desired. In this example, LAN is a private IP subnet and OPT1 is the public IP subnet.

Configure WAN

Add the IP address and gateway accordingly. Figure *WAN IP and Gateway Configuration* shows the WAN configured as shown in Table *WAN IP Block*.

Fig. 95: WAN IP and Gateway Configuration

Configure OPT1

Now enable OPT1, optionally change its name, and configure the IP address and subnet mask. Figure *Routing OPT1 Interface Configuration* shows OPT1 configured as shown in Table *Inside IP Block*.

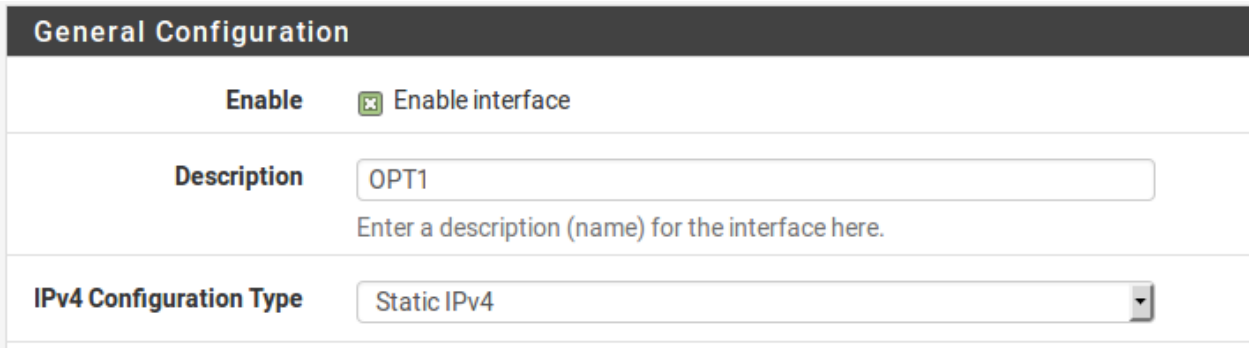


Fig. 96: Routing OPT1 Interface Configuration

Fig. 97: Routing OPT1 IP Address Configuration

35.62.3 NAT Configuration

The default of translating internal traffic to the WAN IP must be overridden when using public IP addresses on an internal interface.

- Browse to **Firewall > NAT**
- Click the Outbound tab
- Select Hybrid Outbound NAT rule generation
- Click **Save**
- Click  to add a new rule to the top of the list with the following settings:

Do not NAT
Checked, so that NAT will be disabled

Interface
WAN

Protocol
Any

Source
Network, enter the local public IP subnet, `192.0.2.128/29`

Destination
Any

- Click **Save**

This will override the default automatic rules which translate all traffic from local interfaces leaving the WAN interface to the WAN IP address. Traffic sourced from the OPT1 network `192.0.2.128/29` is not translated because of the manually added rule excluding it from NAT. This configuration maintains the automatic behavior for other internal interfaces, so that the advantages of automatic outbound NAT rules are not lost. This configuration is shown in Figure *Outbound NAT Configuration*.

If public IP addresses are used on **all** local interfaces, then set **Disable Outbound NAT** rather than using Hybrid mode.

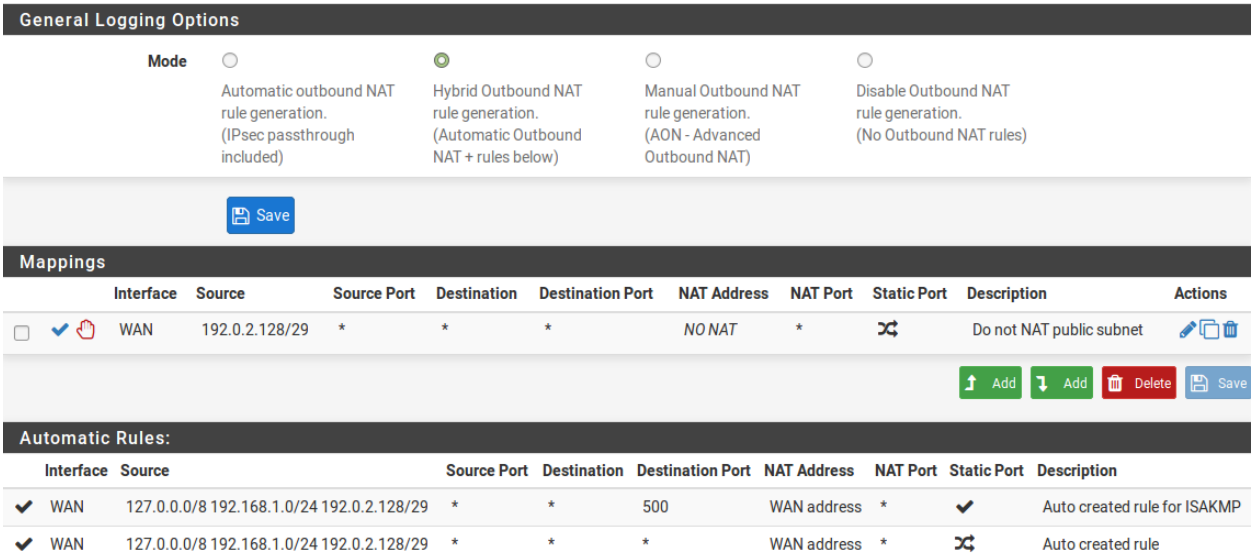

Fig. 98: Outbound NAT Configuration

35.62.4 Firewall Rule Configuration

The NAT and IP address configuration is now complete. Firewall rules will need to be added to permit outbound and inbound traffic. Figure *OPT1 Firewall Rules* shows a DMZ-like configuration, where all traffic destined for the LAN subnet is rejected, DNS and pings to the OPT1 interface IP address are permitted, and HTTP is allowed outbound.

To allow traffic from the Internet to the public IP addresses on an internal interface, add rules on the WAN using the public IP addresses as the **Destination**. Figure *WAN Firewall Rules* shows a rule that allows HTTP to 192.0.2.130, one of the public IP addresses on the internal interface as shown in Table *Inside IP Block*.

After configuring the firewall rules as desired, the setup is complete.

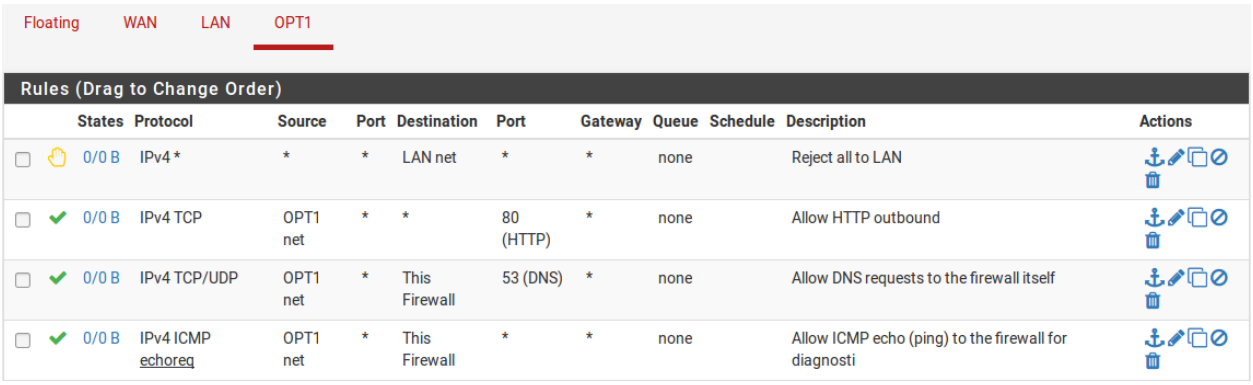

Fig. 99: OPT1 Firewall Rules

Fig. 100: WAN Firewall Rules

Note: Traffic will flow from LAN to this public subnet by default without NAT. If this behavior is not desired, adjust the LAN firewall and NAT rules accordingly. Additionally, policy routing may need to be bypassed to allow from LAN to this interface.

35.63 Accessing the Firewall Filesystem with SCP

Files may be transferred to and from the firewall with `scp`, which is part of the functionality that comes with having ssh access enabled.

See also:

- *Secure Shell (SSH)*
- *Granting Users Access to SSH*

To connect to the firewall with SCP for file transfers, use the `root` account with the same credentials as `admin`, or a user account with sufficient privileges.

Note: In most recent versions, the `admin` account can also be used for `scp`, but using `root` is still the best practice.

Users with shell access may transfer files, as well as users with the *User - System - Copy files* privilege.

Note: Users other than `root` can only transfer or write files for which their account has permission to read or modify.

Any SCP/SFTP-compatible program may be used to transfer files. Popular choices include `scp`, FileZilla, and WinSCP.

An example: Logged into a FreeBSD machine, copy a file from `/tmp` on a remote firewall to the current local working directory:

```
myuser@somebox:~/$ scp root@192.168.1.1:/tmp/lan-traffic.rrd-4h.png .
```

35.63.1 Troubleshooting

If `scp` is failing with the error `Illegal option -t` or printing a usage message, check that the connection is using the `root` account, as mentioned above.

35.64 Granting Users Access to SSH

This recipe explains how to enable *Secure Shell (SSH)* access to the firewall.

SSH is typically used for debugging and troubleshooting, but has many other useful purposes.

Note: The SSH daemon is not required by the firewall for operation, so it is disabled by default.

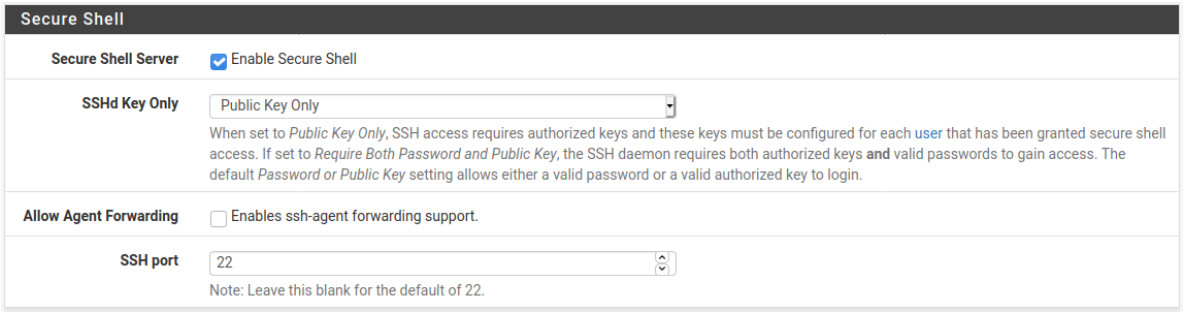
See also:

Secure Shell (SSH)

35.64.1 Enable SSH via GUI

This example enables SSH access using only public key authentication, which is more secure than allowing access by password alone.

- Navigate to **System > Advanced**, **Admin Access** tab
- Check **Enable Secure Shell**
- Set **SSHd Key Only** to *Public Key Only* to allow only key-based SSH authentication



- Enter a port number in **SSH Port** if the SSH daemon should listen on a non-default port

  Leave the field blank for the daemon to use port `22`

- Click **Save**

35.64.2 SSH Keys

When the SSH daemon is set for key-based authentication, it uses the keys defined on user accounts. Add keys to individual user accounts under **System > User Manager**. The `admin` user and `root` user share keys.

Warning: Do not attempt to manage keys from the shell directly.

See also:

Manage Local Users

35.64.3 Enable SSH via Console

Connect to the console (VGA or Serial) and use option `14` to enable or disable SSH.

To change the port number or key authentication options, use the GUI as directed above.

35.64.4 SSH Daemon Security

With a default ruleset, SSH may only be accessed by clients on the LAN. If SSH access must be allowed for clients the WAN, the best practice is to restrict access to Key-based authentication to avoid issues with brute force attacks. Moving the daemon to an alternate port is also a good practice, but moving the port alone is not sufficient protection.

The firewall will automatically block users who attempt to authenticate unsuccessfully. This behavior, and settings to control it, are described in *Login Protection*.

If password authentication is active, ensure that all user accounts with shell access have strong passwords that cannot be easily guessed.

See also:

See *Best Practices for SSH* for more on SSH security.

35.64.5 User Access

By default only `admin` and `root` have SSH access. Additional users with limited access may be granted the *User - System - Shell account access* privilege to login via SSH.

Note: Additional users do not have full root privileges in the shell, so the system does not display the console menu for those users. Many commands and other files are inaccessible as well. For a normal user to get much use from the shell, the *Sudo Package* can delegate additional privileges to run commands as *root* or other users.

35.64.6 SCP File Transfers

For information on using SCP file transfers via SSH, see *Accessing the Firewall Filesystem with SCP*.

35.65 Configuring Switches with VLANs

This section provides guidance on configuring a few varieties of switches for use with VLANs. This offers generic guidance that will apply to most if not all 802.1Q capable switches, then goes on to cover configuration on specific switches from Cisco, HP, Netgear, and Dell.

Note: This is the bare minimum configuration needed for VLANs to function, and it does not necessarily show the ideal secure switch configuration for any specific environment. An in depth discussion of switch security is outside the scope of this documentation.

35.65.1 Switch configuration overview

Generally three or four things must be configured on VLAN capable switches:

1. **Add/define the VLANs**

   Most switches have a means of defining a list of configured VLANs, and they must be added before they can be configured on any ports.

2. **Configure the trunk port**

   The port to which the firewall running pfSense® software will be connected must be configured as a trunk port, tagging all possible VLANs on the interface.

3. **Configure the access ports**

   Configure ports for internal hosts as access ports on the desired VLANs, with **untagged** VLANs.

4. **Configure the Port VLAN ID (PVID)**

   Some switches require configuring the PVID for access ports. This specifies which VLAN to use for the traffic entering that switch port. For some switches this is a one step process, by configuring the port as an access port on a particular VLAN, it automatically tags traffic coming in on that port. Other switches require this to be configured in one or two places. Check the switch documentation for details if it is not one detailed in this chapter.

35.65.2 Cisco IOS based switches

Configuring and using VLANs on Cisco switches with IOS is a fairly simple process, taking only a few commands to create and use VLANs, trunk ports, and assigning ports to VLANs. Many switches from other vendors behave similarly to IOS, and will use nearly the same if not identical syntax for configuration.

Create VLANs

VLANs can be created in a standalone fashion, or using VLAN Trunk Protocol (VTP). Using VTP may be more convenient, as it will automatically propagate the VLAN configuration to all switches on a VTP domain, though it also can create its own security problems and open up possibilities for inadvertently wiping out the VLAN configuration.

With VTP, to add another VLAN it only needs to be configured on a single switch, and then all other trunked switches in the group can assign ports to that VLAN. If VLANs are configured independently, they must be added to each switch by hand. Refer to Cisco's documentation on VTP to ensure a secure configuration use used, and that it is not prone to accidental destruction.

In a network with only a few switches where VLANs do not change frequently, VTP may be overkill and avoiding it will also avoid its potential downfalls.

Standalone VLANs

To create standalone VLANs:

```
sw# vlan database
sw(vlan)# vlan 10 name "DMZ Servers"
sw(vlan)# vlan 20 name "Phones"
sw(vlan)# exit
```

VTP VLANs

To setup a switch for VTP and VLANs, create a VTP database on the master switch and then create two VLANs:

```
sw# vlan database
sw(vlan)# vtp server
sw(vlan)# vtp domain example.com
sw(vlan)# vtp password SuperSecret
sw(vlan)# vlan 10 name "DMZ Servers"
sw(vlan)# vlan 20 name "Phones"
sw(vlan)# exit
```

Configure Trunk Port

For handing off VLANS to pfSense software a switch port not only has to be in trunk mode, but also must be using 802.1q tagging. This can be done like so:

```
sw# configure terminal
sw(config)# interface FastEthernet 0/24
sw(config-if)# switchport mode trunk
sw(config-if)# switchport trunk encapsulation dot1q
```

Note: On some newer Cisco IOS switches, the Cisco-proprietary ISL VLAN encapsulation method is deprecated and no longer supported. If a switch does not allow the `encapsulation dot1q` configuration option, it only supports 802.1Q and the encapsulation does not need to be specified.

Add Ports to the VLAN

To add ports to these VLANs, assign them as follows:

```
sw# configure terminal
sw(config)# interface FastEthernet 0/12
sw(config-if)# switchport mode access
sw(config-if)# switchport access vlan 10
```

35.65.3 Cisco CatOS based switches

Creating VLANs on CatOS is a little different, though the terminology is the same as using VLANs under IOS. Standalone VLANs and VTP are both possible to maintain the VLAN database:

```
# set vtp domain example mode server
# set vtp passwd SuperSecret
# set vlan 10 name dmz
# set vlan 20 name phones
```

Then configure a trunk port to automatically handle every VLAN:

```
# set trunk 5/24 on dot1q 1-4094
```

Then add ports to the VLAN:

```
# set vlan 10 5/1-8
# set vlan 20 5/9-15
```

35.65.4 HP ProCurve switches

HP ProCurve switches only support 802.1q trunking, so no configuration is needed for encapsulation. First, ssh or telnet into the switch and bring up the management menu.

Enable VLAN Support

First, VLAN support needs to be enabled on the switch if it is not already:

1. Choose **Switch configuration**
2. Choose **Advanced Features**
3. Choose **VLAN Menu...**
4. Choose **VLAN Support**
5. Set **Enable VLANs** to *Yes* if it is not already, and choose a number of VLANs. Each time this value is changed the switch must be restarted, so ensure it is large enough to support as many VLANs as necessary.
6. Restart the switch to apply the changes.

Create VLANs

Before the VLANs can be assigned to ports, The VLANs must be created. At the switch configuration menu:

1. Choose **Switch configuration**
2. Choose **Advanced Features**
3. Choose **VLAN Menu…**
4. Choose **VLAN Names**
5. Choose **Add**
6. Enter the **VLAN ID**, `10`
7. Enter the **name**, `DMZ`
8. Choose **Save**
9. Repeat the steps from **Add** to **Save** for any remaining VLANs

Assigning Trunk Ports to VLANs

Next, configure the trunk port for the firewall as well as any trunk ports going to other switches containing multiple VLANs.

1. Choose **Switch configuration**
2. Choose **VLAN Menu…**
3. Choose **VLAN Port Assignment**
4. Choose **Edit**
5. Find the port to assign
6. Press **space** on Default VLAN until it shows **No**
7. Move over to the column for each of the VLANs on this trunk port, and Press **space** until it shows **Tagged**. Every VLAN in use must be tagged on the trunk port.

Assigning Access Ports to VLANs

1. Choose **Switch configuration**
2. Choose **VLAN Menu…**
3. Choose **VLAN Port Assignment**
4. Choose **Edit**
5. Find the port to assign
6. Press **space** on **Default VLAN** until it shows **No**
7. Move over to the column for the VLAN to which this port will be assigned
8. Press **space** until it shows **Untagged**.

35.65.5 Netgear Managed Switches

This example is on a GS108Tv1, but other Netgear models are all very similar if not identical. There are also several other vendors including Zyxel who sell switches made by the same manufacturer, using the same web interface with a different logo. Log into the web interface of the switch to start.

Planning the VLAN configuration

Before configuring the switch, several items are required:

1. The number of VLANs to be configured
2. The IDs to use for the VLANs
3. How each switch port needs to be configured

For this example, an 8 port GS108Tv1 is used, and it will be configured as shown in Table *Netgear GS108T VLAN Configuration*.

Table 24: Netgear GS108T VLAN Configuration

Switch port	VLAN mode	VLAN assigned
1	trunk	*10* and *20*, tagged
2	access	*10* untagged
3	access	*10* untagged
4	access	*10* untagged
5	access	*20* untagged
6	access	*20* untagged
7	access	*20* untagged
8	access	*20* untagged

Enable 802.1Q VLANs

To configure the switch to use 802.1Q VLAN trunking:

- Navigate to the **System** menu on the left side of the page
- Click **VLAN Group Setting**, as indicated in Figure *VLAN Group Setting*.

Fig. 101: VLAN Group Setting

- Select IEEE 802.1Q VLAN (Figure *Enable 802.1Q VLANs*).

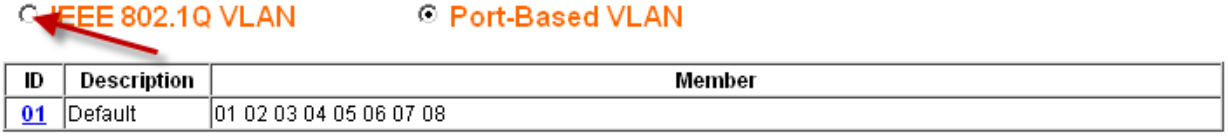


Fig. 102: Enable 802.1Q VLANs

- Click **OK** to confirm the switch to 802.1Q trunking, as shown in Figure *Confirm change to 802.1Q VLAN*.

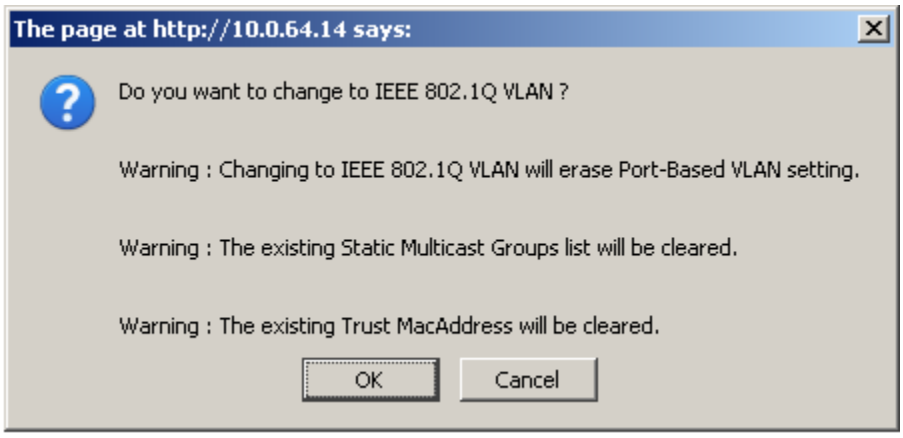

Fig. 103: Confirm change to 802.1Q VLAN

After clicking OK, the page will refresh with the 802.1Q VLAN configuration as shown in Figure *Default 802.1Q Configuration*.

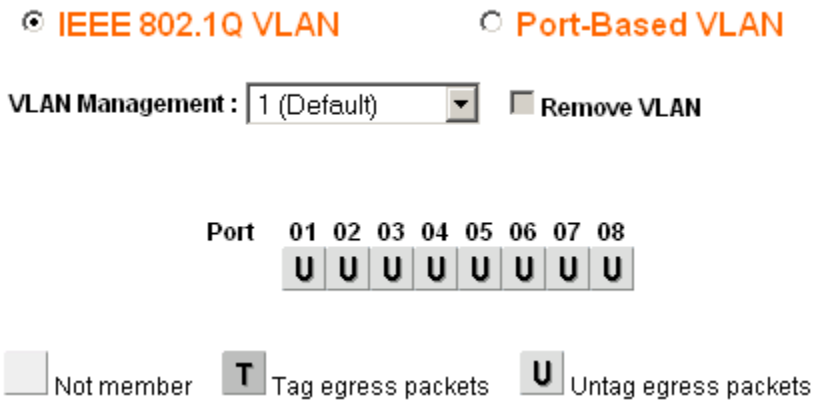

Fig. 104: Default 802.1Q Configuration

Add VLANs

For this example, two VLANs are added with IDs `10` and `20`.

To add a VLAN:

- Click the **VLAN Management** drop down
- Click **Add New VLAN** as shown in Figure *Add New VLAN*.
- Enter the VLAN ID for this new VLAN, such as `10`
- Click **Apply**. The VLAN screen is now ready to configure VLAN *10* (Figure *Add VLAN 10*).
- Click **Add New VLAN** again as shown in Figure *Add New VLAN* to add VLAN *20* (Figure *Add VLAN 20*).

Add as many VLANs as needed, then continue to the next section.

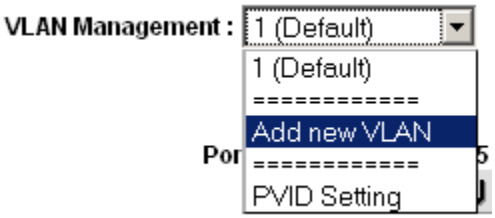

Fig. 105: Add New VLAN

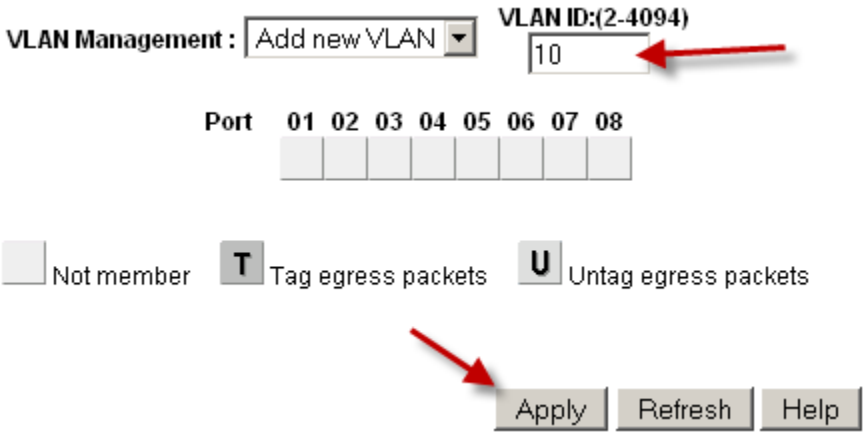

Fig. 106: Add VLAN 10

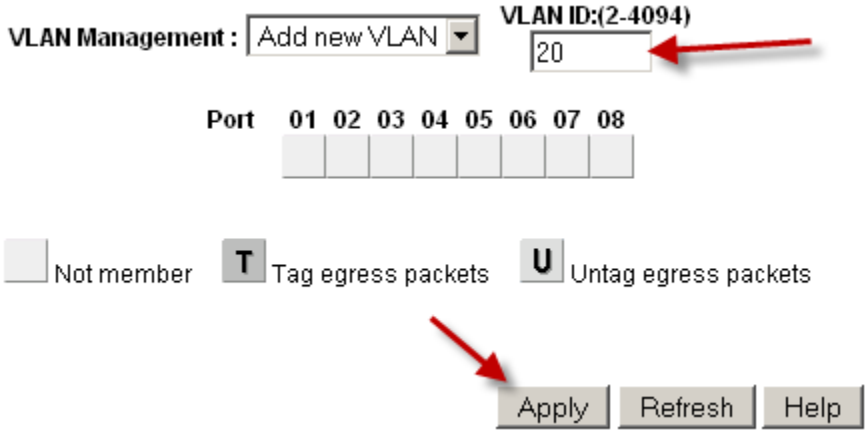

Fig. 107: Add VLAN 20

Configure VLAN tagging

When a VLAN is selected from the **VLAN Management** drop down, it shows how that VLAN is configured on each port:

- A **blank** box means the port is not a member of the selected VLAN.
- A box containing **T** means the VLAN is sent on that port with the 802.1Q tag.
- **U** indicates the port is a member of that VLAN and it leaves the port untagged.

The trunk port must have both VLANs added and tagged.

> **Warning:** Do not change the configuration of the port being used to access the web interface of the switch! This will lock the administrator out of the switch. The only means of recovery on the GS108Tv2 is using the **reset to factory defaults** button since it does not have a serial console. For the switches that have serial consoles, keep a null modem cable handy in case network connectivity with the switch is lost. Configuring the management VLAN is covered later in this section.

Click in the boxes beneath the port number as shown in Figure ref:*figure-toggle-vlan-membership* to toggle between the three VLAN options.

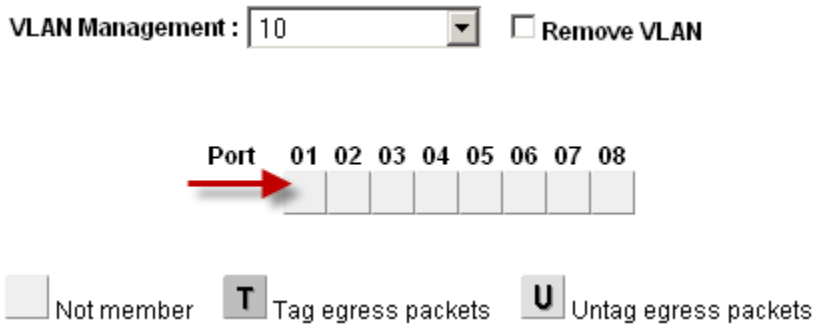

Fig. 108: Toggle VLAN Membership

Configure VLAN 10 membership

Figure *Configure VLAN 10 Membership* shows VLAN **10** configured as outlined in Table *table-netgear-gs108t-vlan-configuration*. The access ports on this VLAN are set to **untagged** while the trunk port is set to tagged.

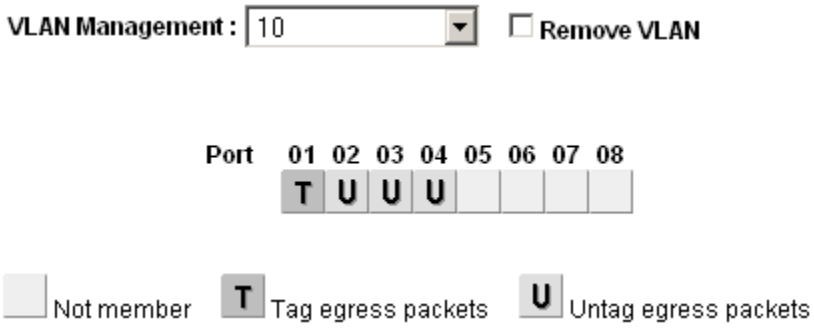

Fig. 109: Configure VLAN 10 Membership

Configure VLAN 20 membership

Select **20** from the VLAN Management drop down to configure the port memberships for VLAN **20**.

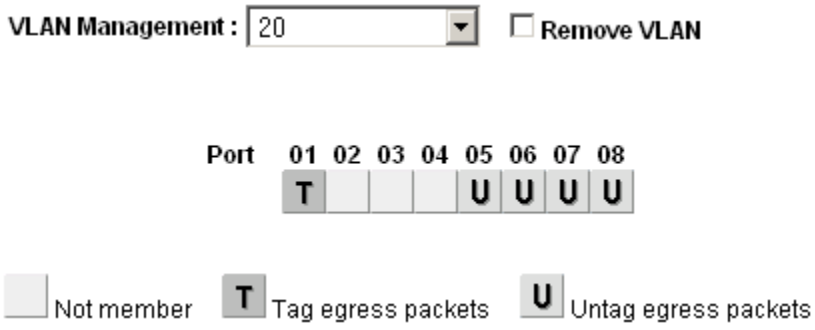

Fig. 110: Configure VLAN 20 Membership

Change PVID

On Netgear switches, in addition to the previously configured tagging settings, the PVID must also be configured to specify the VLAN used for frames entering a port:

- Select **PVID** from the VLAN Management drop down as shown in Figure *PVID Setting*.

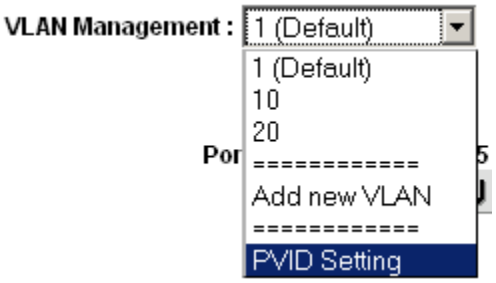

Fig. 111: PVID Setting

The default PVID setting is VLAN 1 for all ports as shown in Figure *Default PVID Configuration*.

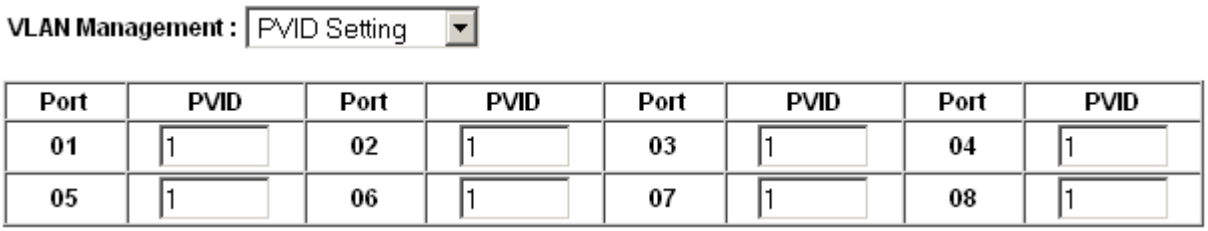

Fig. 112: Default PVID Configuration

- Change the PVID for each access port, but leave the trunk port and port used to access the switch management interface set to *1* .

Figure *VLAN 10 and 20 PVID Configuration* shows the PVID configuration matching the port assignments shown in Table *Netgear GS108T VLAN Configuration*, with port 8 being used to access the switch management interface.

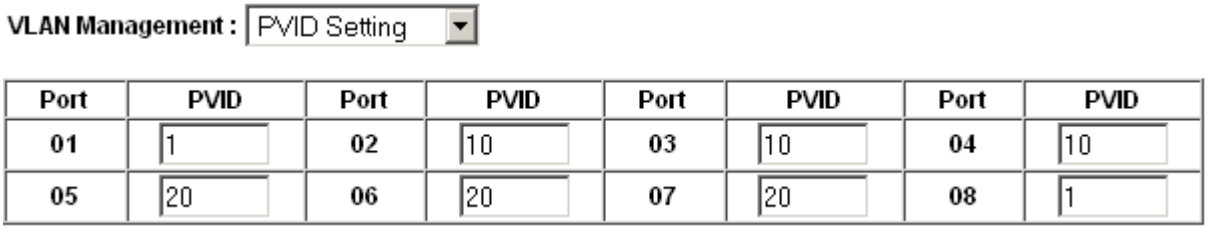

Fig. 113: VLAN 10 and 20 PVID Configuration

- Apply changes when finished

Remove VLAN 1 configuration

By default, all ports are members of VLAN 1 with untagged egress frames. To remove VLAN 1 from the other ports:

- Select *1 (Default)* from the **VLAN Management** drop down
- Remove VLAN 1 from all ports except the one used to manage the switch and the trunk port, to avoid being disconnected.

  In this example, port 8 is used to manage the switch. When finished, the screen will look like Figure *Remove VLAN 1 Membership*.

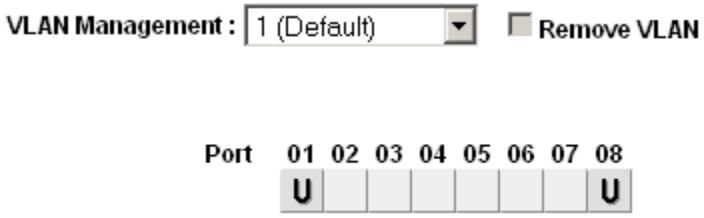

Fig. 114: Remove VLAN 1 Membership

- Apply changes when finished

Verify VLAN functionality

Configure VLANs on pfSense, including the DHCP server on the VLAN interfaces if needed. Plug systems into the configured access ports and test connectivity. If everything works as desired, continue to the next step. If things do not work as intended, review the tagging and PVID configuration on the switch, and the VLAN configuration and interface assignments on pfSense software.

35.65.6 Dell PowerConnect managed switches

The management interface of Dell switches varies slightly between models, but the following procedure will accommodate most models. The configuration is quite similar in style to Cisco IOS.

First, create the VLANs:

```
console# config
console(config)# vlan database
console(config-vlan)# vlan 10 name dmz media ethernet
console(config-vlan)# vlan 20 name phones media ethernet
console(config-vlan)# exit
```

Next, setup a trunk port:

```
console(config)# interface ethernet 1/1
console(config-if)# switchport mode trunk
console(config-if)# switchport allowed vlan add 1-4094 tagged
console(config-if)# exit
```

Finally, add ports to the VLANs:

```
console(config)# interface ethernet 1/15
console(config-if)# switchport allowed vlan add 10 untagged
console(config-if)# exit
```

35.66 Using the Shaper Wizard to Configure ALTQ Traffic Shaping

The easiest way to get started with traffic shaping is by using the wizard for the first time, which guides administrators through the shaper configuration process.

Tip: Due to the complexity of the shaper queues and rules, starting from scratch is quite complicated. If a firewall needs custom rules, step through the wizard and approximate the requirements, then make custom rules afterward.

Each step of the wizard sets up unique queues and rules that control what traffic is assigned into those queues. To configure everything manually, specify the WAN speed at the first screen, then click **Next** through all the remaining steps. The wizard requires options to be enabled on at least one step, but it does not matter which step.

Note: Completing the wizard and clicking **Finish** at the end will replace **all** existing shaper queues and floating rules created by the wizard, including those cloned from wizard rules, with the queues and rules from the new wizard configuration.

35.66.1 Choosing a Wizard

To get started with the Traffic Shaping Wizard, navigate to **Firewall > Traffic Shaper** and click the **Wizards** tab. This page displays a list of available traffic shaper wizards, including:

Multiple LAN/WAN
: Used when the firewall has one or more WANs and one or more LANs. This is the most common wizard and it covers most every scenario.

Dedicated Links
: Used when specific LAN+WAN pairings should be accounted for in the shaper configuration.

35.66.2 Starting the Wizard

Each wizard name is followed by the filename of the wizard, which is a link. Click the link to start the wizard. This example uses the **Multiple LAN/WAN** wizard, so click `traffic_shaper_wizard_multi_all.xml`.

Next, the wizard starts and the first step prompts for the number of WAN and LAN type connections on the firewall, as in Figure *Entering the Interface Count*.

- Enter the number of WAN-type connections on the firewall. These are connections with a gateway configured on the interface, or dynamic WAN type interfaces such as DHCP or PPPoE
- Enter the number of LAN type connections. These are local network interfaces without a gateway on the interface
- Click **Next** to proceed with the next step

In this example the firewall only has one WAN and one LAN interface.

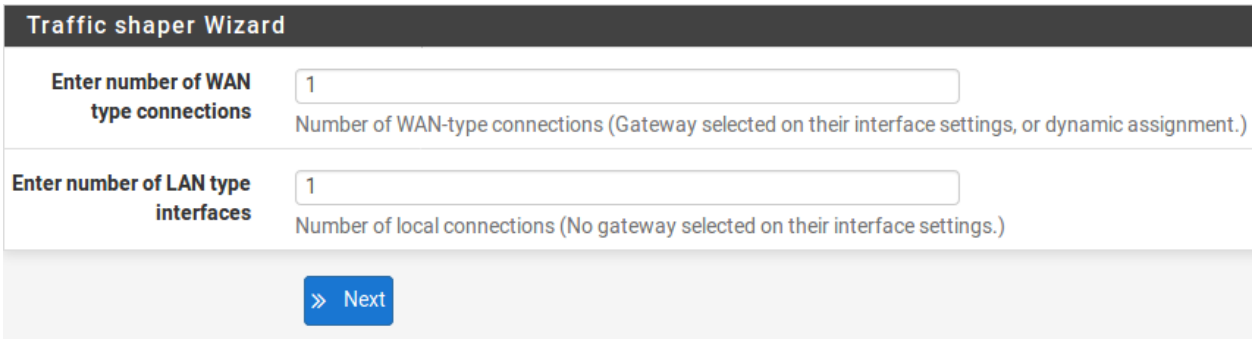

Fig. 115: Entering the Interface Count

35.66.3 Networks and Speeds

This step, shown in Figure *Shaper Configuration*, defines the network interfaces that will be the inside and outside from the point of view of the shaper, along with the **Download** and **Upload** speeds for a given WAN. When the firewall has more than one interface of a given type, the wizard displays multiple sections on the page to handle each one individually.

In addition to the interfaces and their speeds, select an ALTQ **Scheduler** (*ALTQ Scheduler Types*) for the WAN(s) and LAN(s). Use the same scheduler on every interface.

Depending on the connection type, the true link speed may not be the actual usable speed. In the case of PPPoE, the circuit has not only PPPoE overhead, but also overhead from the underlying ATM network link being used in most PPPoE deployments. By some calculations, between the overhead from ATM, PPPoE, IP, and TCP, the circuit may lose as much as 13% of the advertised link speed. When in doubt of what to set the speed to, be conservative. Reduce

by 10-13% and work it back up to larger values. If the firewall has a 3Mbit/s line, set it for about `2.7` Mbit/s and then test. The speed on the resulting parent queue can be edited later to adjust the bandwidth. If it has a low value, the connection will be maxed out at exactly the defined speed. Nudge it up higher until the firewall no longer sees any performance gains.

Interface speeds can be specified in *Kbit/s* , *Mbit/s* , or *Gbit/s* but use the same units on every page.

- Choose an **Interface** and **Scheduler** for each LAN-type interface (e.g. *LAN*, *PRIQ*)
- Choose an **Interface** and **Scheduler** for each WAN-type interface (e.g. *WAN*, *PRIQ*)
- Define the **Upload** speed and units for each WAN-type interface (e.g. `1`, *Mbit/s*)
- Define the **Download** speed and units for each WAN-type interface (e.g. `10`, *Mbit/s*)
- Click **Next** to proceed with the next step

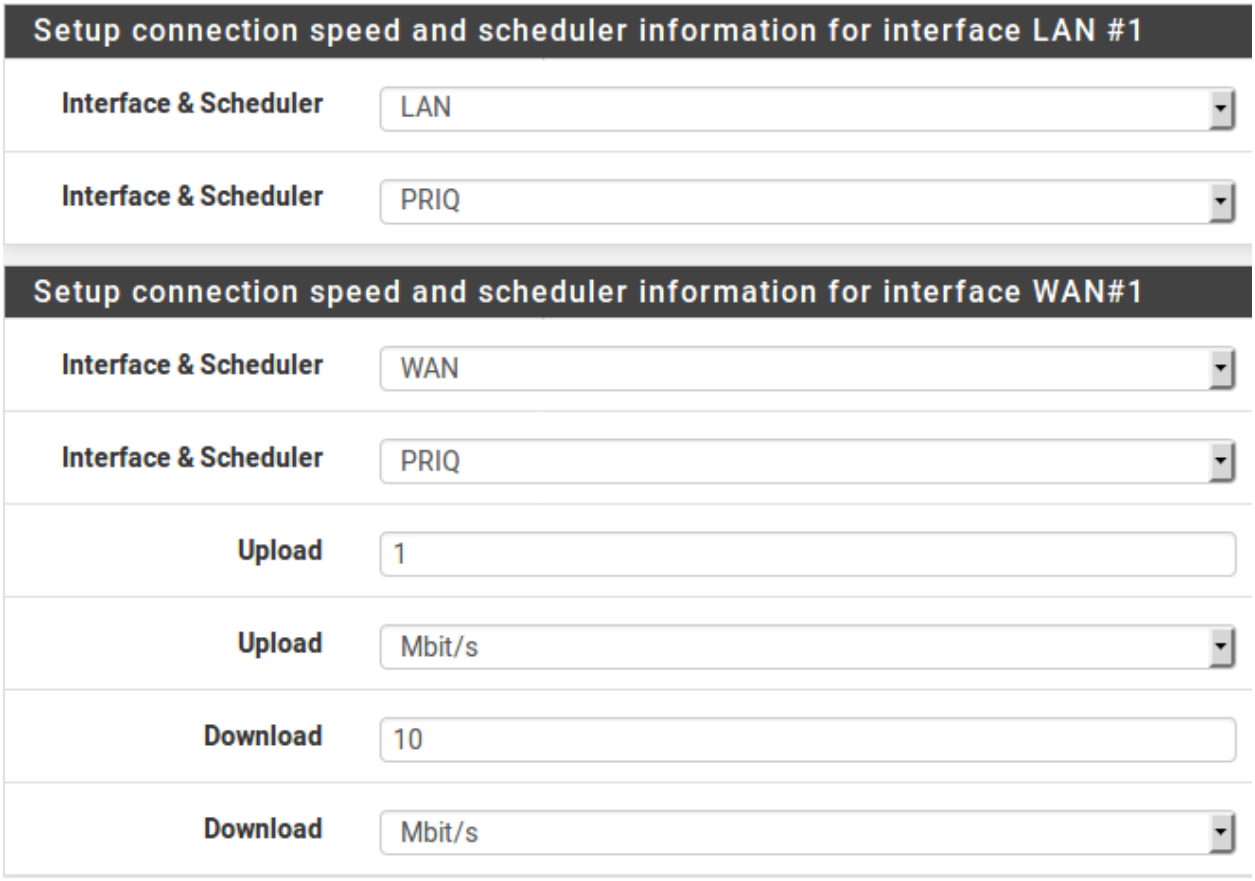

Fig. 116: Shaper Configuration

35.66.4 Voice over IP

The wizard contains several options for handling VoIP call traffic, shown in Figure *Voice over IP*. Prioritizing Voice over IP traffic sets up queues and rules to give priority to VoIP calls and related traffic. This behavior can be fine-tuned by the other settings on this step of the wizard.

Enable
A checkbox to enable the VoIP settings on this step. When unchecked, the options are disabled and these queues and rules will not be added by the wizard.

Provider
There are a few well-known providers including *Vonage*, *Voicepulse*, *PanasonicTDA*, and *Asterisk* servers. If the VoIP provider for this site is not in the list, choose *Generic*. This choice sets up rules based on the ports and protocols known to be used by these providers, rather than matching by address.

Note: This choice matches based on SIP and RTP ports, among others, therefore it can match traffic from other sources as well if they use the same ports as the selected service.

Upstream SIP Server
The IP of the upstream PBX or SIP trunk, or an alias containing the IP addresses or networks for the SIP trunk(s). When set, this overrides the **Provider** field and will instead match traffic based on these addresses.

Note: This choice matches all UDP traffic to and from the specified address(es). In most cases this is OK, but if there are other Non-VoIP UDP-based services on the same remote address, it could match that traffic as well. Such cases are rare, however, so this option tends to be more reliable than matching by port.

WAN Connection Upload
The amount of upload bandwidth to guarantee for VoIP devices. This will vary based on how many VoIP devices are on the network and how much bandwidth each session requires. This setting is used by HFSC and CBQ, and should be left blank for PRIQ.

Note: The bandwidth reservation for a service such as VoIP cannot exceed 30% of the available bandwidth on the link. For example, on a 10Mbit/s link, the shaper cannot reserve more than 3Mbit/s.

LAN Connection Download
The amount of download bandwidth to guarantee for VoIP devices. This setting is used by HFSC and CBQ, and should be left blank for PRIQ.

Note: The best practice is to use the **remote** SIP trunk or PBX address because otherwise the shaper may not be able to match traffic properly. For example, using the IP addresses of phones the shaper may only match traffic in one direction, or not at all. This is due to the way the shaper matches traffic with floating rules in an outbound direction. NAT applies before traffic is matched when exiting a WAN, so the shaper rules cannot match outbound connections based on local private IP addresses.

To use these options:

- Check **Prioritize Voice over IP traffic**
- Pick **ONE** of the following:

  - Choose a **Provider** from the list **OR**
  - Enter an **Upstream SIP Server** address or alias containing a **remote** SIP trunk or PBX
- Leave **Upload** and **Download** blank if using PRIQ, otherwise enter an appropriate **Upload** or **Download** value for each connection
- Click **Next** to proceed with the next step

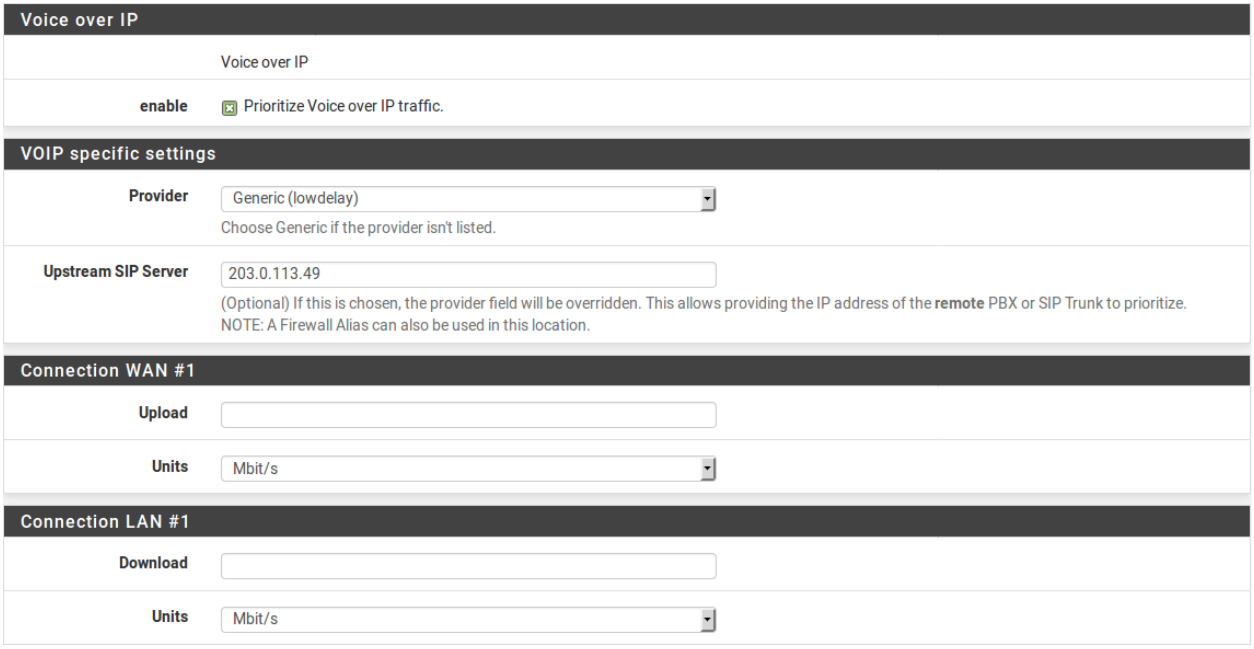

Fig. 117: Voice over IP

35.66.5 Penalty Box

The penalty box, depicted in Figure *Penalty Box*, is a place to relegate misbehaving users or devices that would otherwise consume undesirable amounts of bandwidth. These devices are assigned a hard bandwidth cap which they cannot exceed.

Enable
A checkbox to enable the Penalty Box settings on this step. When unchecked, the options are disabled and these queues and rules will not be added by the wizard.

Address
The IP address to penalize, or an alias containing multiple addresses to penalize.

Bandwidth
The amount of bandwidth that **Address** can consume, at most.

To use these options:

- Check **Penalize IP or Alias**
- Enter an IP address or Alias in the **Address** box
- Enter the **Bandwidth** limit
- Choose the correct units for the **Bandwidth** limit
- Click **Next** to proceed with the next step

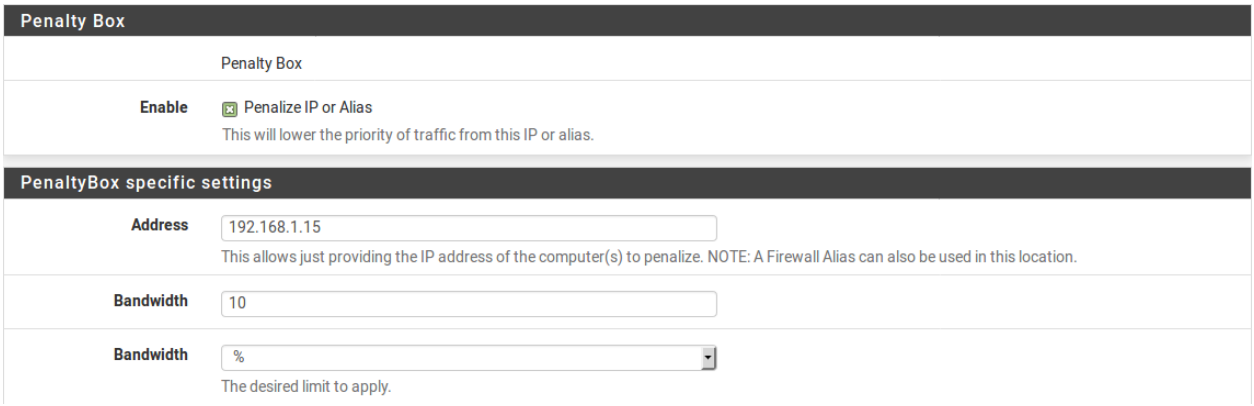

Fig. 118: Penalty Box

35.66.6 Peer-to-Peer Networking

The next step, shown in Figure *Peer-to-Peer Networking*, sets controls for many Peer-to-Peer (P2P) networking protocols. By design, P2P protocols will utilize all available bandwidth unless limits are put in place. If P2P traffic will be present on a network, the best practice is to ensure it will not degrade other traffic.

Note: P2P protocols deliberately attempt to avoid detection. Bittorrent is especially guilty of this behavior. It often utilizes non-standard or random ports, or ports associated with other protocols. Identifying all P2P traffic can be difficult or impossible.

Enable
A checkbox to enable the P2P traffic settings on this step. When unchecked, the options are disabled and these queues and rules will not be added by the wizard.

Peer-to-Peer Catch All
Causes any unrecognized traffic to be assumed as P2P traffic, and such traffic will have its priority lowered accordingly.

Bandwidth
The amount of bandwidth that unclassified traffic can consume, at most, when P2P Catch All is active.

> **Warning:** This option effectively takes over the **Default** traffic shaping queue and lowers its priority. When this option is active, it is critical for all legitimate traffic to be matched by rules that set a priority higher than the priority of the P2P catch all queue.
>
> The **Raise / Lower Other Applications** step of the wizard can help here, but ultimately accomplishing this task frequently requires additional manual rules.

Enable/Disable specific P2P protocols
These options identify various known P2P protocols. The firewall will assign ports and protocols associated with each enabled option as P2P traffic.

To use the options in this step:

- Check **Lower priority of Peer-to-Peer traffic**
- Optionally enable the **p2p Catch All** feature

  - Enter the **Bandwidth** limit for **p2p Catch all**, if enabled
  - Choose the correct units for the **Bandwidth** limit
- Select protocols for the firewall to classify as P2P traffic
- Click **Next** to proceed with the next step

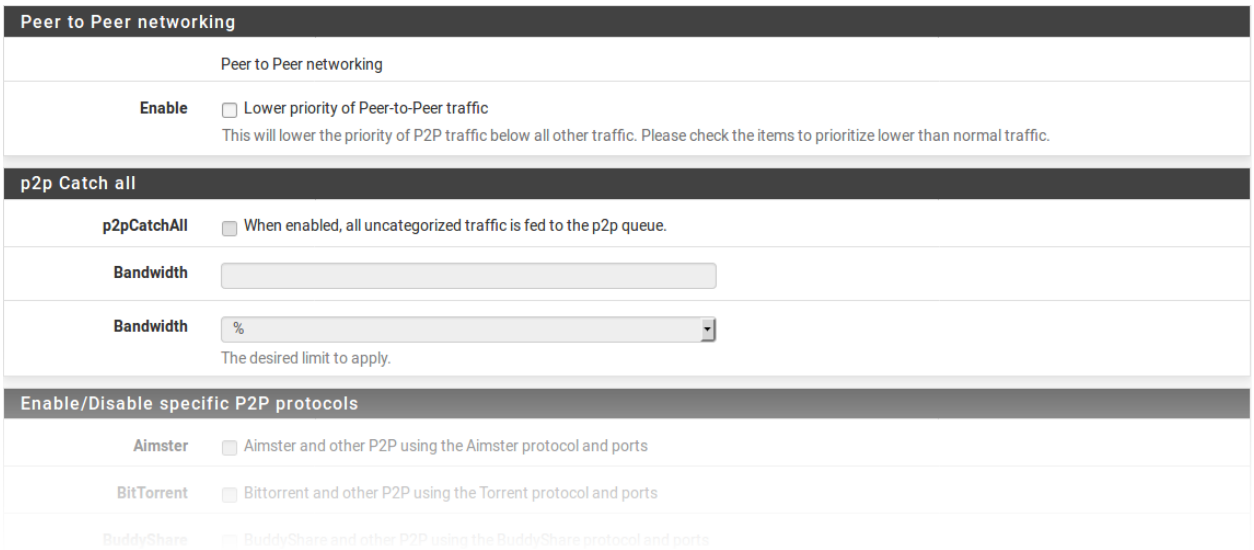

Fig. 119: Peer-to-Peer Networking

35.66.7 Network Games

Online games typically rely on low latency for acceptable player experiences. If a user on the network attempts to download large files or game patches while playing, that traffic can easily drown out the packets associated with the game itself and cause lag or disconnections. If the firewall gives gaming traffic priority, it can ensure that traffic will be delivered first and fastest.

Enable
A checkbox to enable the gaming traffic settings on this step. When unchecked, the options are disabled and these queues and rules will not be added by the wizard.

Enable/Disable specific game consoles and services
These options match traffic for entire game consoles or online services which use common ports and protocols across all, or at least a majority, of their games.

Enable/Disable specific games
These options match traffic for specific games which deviate from the general categories in the previous section.

Tip: To prioritize a game that is not listed, check any other game from the list so that the wizard will create the queues and rules to use as a reference base. After completing the wizard, edit the resulting rules to match the unlisted game.

To use the options in this step:

- Check **Prioritize network gaming traffic**
- Select any games consoles on the network from the list in **Enable/Disable specific game consoles and services**

- Select any games on the network from the list in **Enable/Disable specific games**
- Click **Next** to proceed with the next step

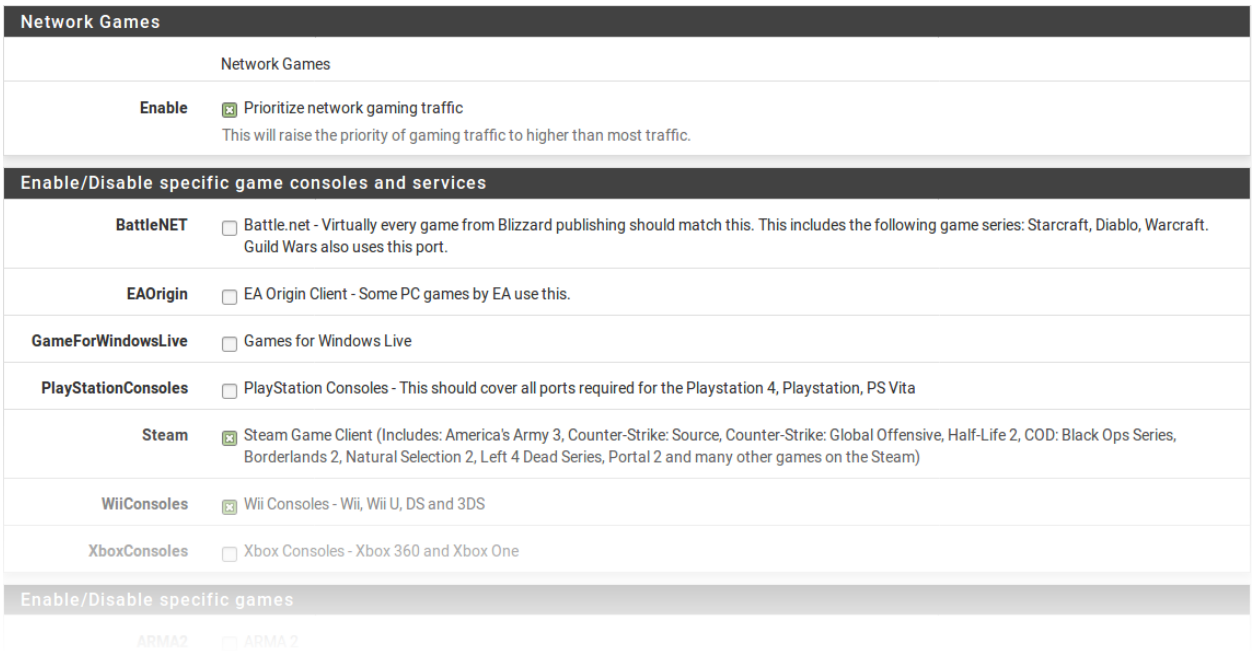

Fig. 120: Network Games

35.66.8 Raising or Lowering Other Applications

The last configuration screen of the shaper wizard, seen in Figure *Raise or Lower Other Applications*, lists a number of other commonly available applications and protocols.

The needs of a particular network dictate how the firewall should handle each protocol. For example, in a corporate environment management may want to lower the priority of non-interactive traffic such as e-mail where a reduction in speed is not usually noticed by users, and they may also want to raise the priority of interactive services like RDP where poor performance is an impediment for employees. In a home, multimedia streaming may be more important, and other services can have their priority lowered by the shaper.

Tip: As with other steps of this shaper wizard, if a protocol is not listed, select a similar protocol and then adjust the rules after completing the wizard.

Enable
A checkbox to enable the settings on this step. When unchecked, the options are disabled and these queues and rules will not be added by the wizard.

Protocol Categories
Each section contains well-known protocols, grouped by their general function.

There are more than 40 protocols to choose from, and each can be given a *Higher priority*, *Lower priority*, or left at the *Default priority*.

Tip: If **p2pCatchAll** is active, the best practice is to use this step to ensure that these other protocols

are recognized and treated normally, rather than penalized by the default p2pCatchAll rule.

To use the options in this step:

- Check **Other networking protocols**
- Locate specific protocols in the list to alter priority.
- For each protocol, choose one of *Higher priority*, *Lower priority*, or leave it at the *Default priority*.
- Click **Next** to proceed with the next step

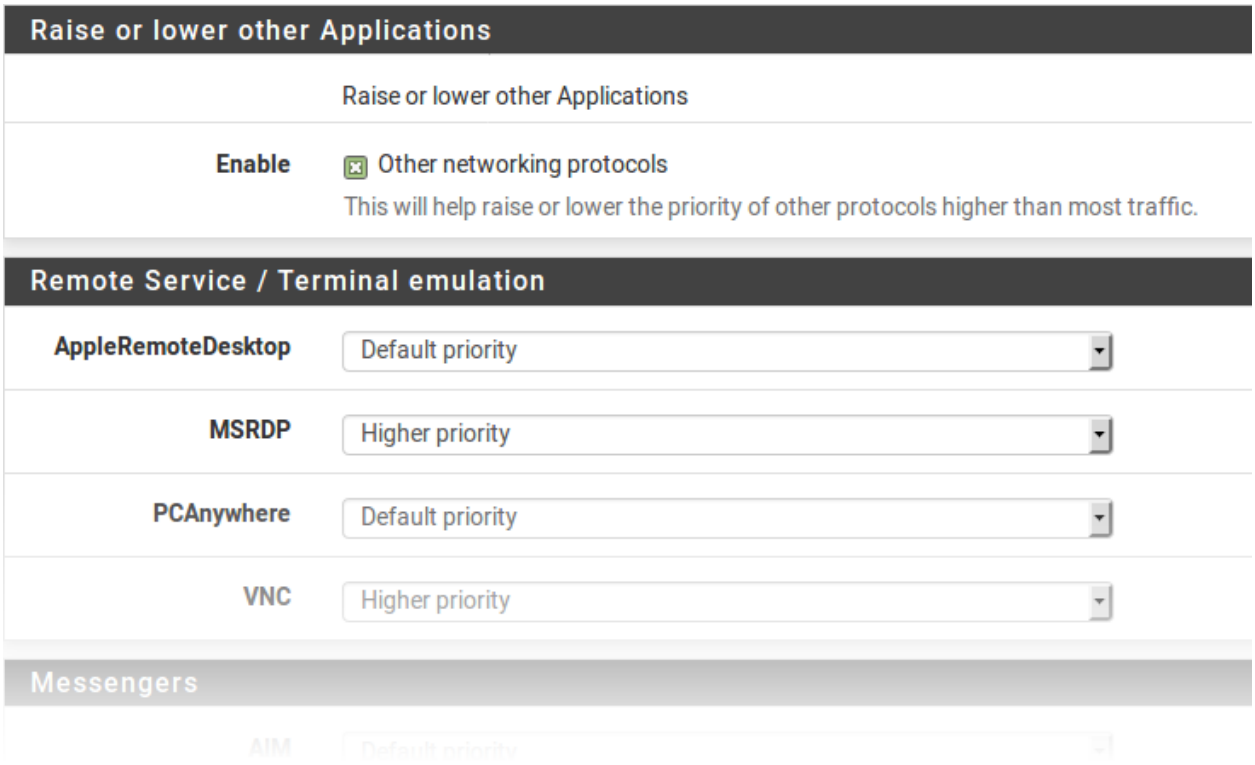

Fig. 121: Raise or Lower Other Applications

35.66.9 Finishing the Wizard

Click **Finish** to complete the wizard. The firewall will then create all of the rules and queues for enabled options, and then it will reload the ruleset to activate the new traffic shaper settings.

Due to the firewall operating in a stateful manner, the firewall can only apply changes in traffic shaping to new connections. In order for the new traffic shaping settings to be fully active on all connections, clear the states.

To reset the state table contents:

- Navigate to **Diagnostics > States**
- Click the **Reset States** tab
- Check **Reset the firewall state table**
- Click **Reset**

35.66.10 Shaper Wizard and IPv6

The shaper wizard creates rules for IPv4 traffic only. Rules can be manually adjusted or cloned and set for IPv6.

35.67 Configuring CoDel Limiters for Bufferbloat

The FQ_CODEL limiter scheduler can help alleviate the effects of Bufferbloat. The CoDel algorithm and bufferbloat are discussed in the ALTQ chapter at *CoDel Active Queue Management* and the same concepts apply to FQ_CODEL with limiters as well.

Before starting, use a Bufferbloat Test Site to determine if changes are necessary. If the firewall already receives a high score the circuit may not be prone to bufferbloat and thus may not require these limiters.

This configuration requires a limiter and queue for both download and upload, plus a floating rule to apply the limiters to outgoing traffic.

35.67.1 Create Download Limiter and Queue

The first task is to create a download limiter and queue:

- Navigate to **Firewall > Traffic Shaper**, **Limiters** tab
- Click  **New Limiter**
  - Configure the limiter with the following settings:

    Enable
    Checked

    Name
    `WANDown`

    Bandwidth
    Set equal to WAN download bandwidth (confirm via speed test first)

    Mask
    None

    Description
    `WAN Download`

    Queue Management Algorithm
    Tail Drop

    Scheduler
    FQ_CODEL

    The page will display FQ_CODEL options and their default values after saving this limiter, but leave them at defaults.

    Queue Length
    Can vary depending on the speed of the link, but `1000` should be a safe default for most high speed WANs (100Mbit/s). For very high speed WANs (e.g. 1Gbit/s+), consider increasing further to `3000-5000`.

    ECN
    Checked

  - Click **Save**

- Click  **Add New Queue** under WANDown
  - Configure the queue with the following settings:

    Enable
    Checked

    Name
    `WANDownQ`

    Mask
    None

    Description
    `WAN Download Queue`

    Queue Management Algorithm
    Tail Drop
  - Leave the other fields at their default values
  - Click **Save**

35.67.2 Create Upload Limiter and Queue

- Navigate to **Firewall > Traffic Shaper**, **Limiters** tab

- Click  **New Limiter**
  - Configure the limiter with the following settings:

    Enable
    Checked

    Name
    `WANUp`

    Bandwidth
    Set equal to WAN upload bandwidth (confirm via speed test first)

    Mask
    None

    Description
    `WAN Upload`

    Queue Management Algorithm
    Tail Drop

    Scheduler
    FQ_CODEL

    The page will display FQ_CODEL options and their default values after saving this limiter, but leave them at defaults.

    Queue Length
    Can vary depending on the speed of the link, but `1000` should be a safe default for most high speed WANs (100Mbit/s). For very high speed WANs (e.g. 1Gbit/s+), consider increasing further to `3000-5000`.

ECN
Checked

– Click **Save**

- Click  **Add New Queue** under WANUp
  – Configure the queue with the following settings:

Enable
Checked

Name
`WANUpQ`

Mask
None

Description
`WAN Upload Queue`

Queue Management Algorithm
Tail Drop

  – Leave the other fields at their default values
  – Click **Save**
- Click **Apply Changes**

35.67.3 Create Floating Rule

- Navigate to **Firewall > Rules**, **Floating** tab
- Click  **Add** to create a new rule at the bottom of the list
  – Configure the rule as follows:

Action
Pass

Quick
Checked

Interface
WAN

Direction
Out

Address Family
IPv4

Note: If the WAN can carry both IPv4 and IPv6, make a separate rule for each address family.

Protocol
Any

Source
WAN Address

> **Warning:** It is important not to match too loosely on the source, especially when a firewall has multiple WANs. In certain cases with multiple WANs, if traffic meant to exit an alternate non-default WAN matches this kind of floating rule, the traffic will end up dropped as pf may still process that traffic outbound on the default WAN before redirecting out the correct interface.

Destination
Any

Description
`CoDel Limiters`

Gateway
Must be set to the gateway for this WAN interface

In / Out Pipe
WANUpQ / *WANDownQ*

> **Note:** On WAN floating rules in the outbound direction, "in" traffic is upload, and "out" traffic is download, from the perspective of LAN clients.

- Save

- Apply Changes
- Reset states to force all traffic to use new limiters

35.67.4 Test Again

Use a Bufferbloat Test Site again and compare score now to the score before the test was run. In most cases, the new score should be an A or higher.

If the score does not improve, or gets worse, there is likely a problem with the configuration. First, go back and compare all of the settings with the suggested values on this document.

If the configuration matches, the settings may need further adjustment. For example, the bandwidth values may be higher than the circuit is capable of delivering, the queue sizes may need increased, or the CoDel parameters may need changed. Post on the Netgate Forum for assistance with diagnosing the problem.

35.67.5 Notes

Certain configurations may require alterations to the suggested procedure above.

Multiple WANs

For multiple WANs make a complete set of queues for **each** WAN and make a **separate** floating rule for each WAN. Ensure the rules do not match the source IP address(es) of the other WANs.

For example:

- Pass quick out WAN1 from WAN1 Address to any, gateway WAN1GW, In/Out Pipe WAN1UpQ/WAN1DownQ
- Pass quick out WAN2 from WAN2 Address to any, gateway WAN2GW, In/Out Pipe WAN2UpQ/WAN2DownQ

Multiple Addresses/VIPs

If there are multiple IP addresses on a WAN (e.g. VIPs, routed subnets), create an alias with all of the necessary addresses and use it as the source of the floating rule.

35.68 Copy Files to a USB Drive

On occasion it may be necessary to copy files to or from the firewall using a USB flash drive.

Note: This procedure assumes the drive is formatted with FAT or FAT32 (Also known as "DOS") partitions.

At this time it is not possible to use drives formatted as exFAT or NTFS.

This procedure assumes the user is *connected to the firewall console* or *using SSH* and *connected using an SSH client*.

35.68.1 Locate Drive and Partition Name

Mounting the drive requires knowing the device name of the USB flash drive and the name of the FAT partition.

There are a couple different methods to determine these values.

Using Device Labels

The most convenient way to mount a drive is by its device label, if it is known. This is the name given by the user in Windows when formatting the drive or by altering the drive properties.

With the drive connected, look at the list of available device labels for DOS partitions:

```
: ls -l /dev/msdosfs/
crw-r-----  1 root  operator  0x93 Jul  8 13:56 MYDRIVE
crw-r-----  1 root  operator  0x65 Jul  8 11:30 EFISYS
```

In this example, the drive is named `MYDRIVE` and when mounting the full name of `/dev/msdosfs/MYDRIVE` is valid for use by `mount`.

> **Warning:** On UEFI systems the `EFISYS` label is the system EFI boot partition, do not mount or alter the content of that partition!

Using gpart

The most definitive way to locate the correct drive and partition is to use `gpart` and look for a `fat32` entry.

This example system has two multiple disks, but only one of them is a USB thumb drive with a FAT32 partition:

```
: gpart list | egrep 'Name:| type:'
1. Name: mmcsd0p1
   type: efi
2. Name: mmcsd0p2
   type: freebsd-boot
3. Name: mmcsd0p3
   type: freebsd-swap
4. Name: mmcsd0p4
   type: freebsd-zfs
1. Name: mmcsd0
1. Name: da0s1
   type: fat32
1. Name: da0
```

In this example the target partition is `da0s1` as it's the name corresponding to the `fat32` type entry.

This next example system has a USB drive containing multiple partitions, but only one of them is FAT32:

```
: gpart list | egrep 'Name:| type:'
1. Name: da0s1
   type: efi
2. Name: da0s2
   type: fat32
3. Name: da0s3
   type: freebsd
1. Name: da0
1. Name: da0s3a
   type: freebsd-zfs
1. Name: da0s3
```

Based on the above output the target partition is `da0s2`.

System Log and Device List

This method is not as accurate but may be good enough for the majority of use cases.

Monitor the console or watch the system log when inserting the USB drive (e.g. `tail -F /var/log/system.log`). This will contain output similar to the following:

```
ugen0.2: <USB Flash Disk> at usbus0
umass0 on uhub0
umass0: <USB Flash Disk, class 0/0, rev 2.00/11.00, addr 1> on usbus0
da0 at umass-sim0 bus 0 scbus0 target 0 lun 0
da0: <USB Flash Disk 1100> Removable Direct Access SPC-2 SCSI device
da0: Serial Number FBG1204030507369
da0: 40.000MB/s transfers
da0: 1912MB (3915776 512 byte sectors)
da0: quirks=0x2<NO_6_BYTE>
```

This output indicates the correct drive is `da0` but it does not help determine the correct partition on that drive.

Next, look at the list of devices in `/dev/` to see which partitions are present on the drive:

```
: ls -l /dev/da0*
crw-r-----  1 root  operator  0x91 Jul  8 13:56 /dev/da0
crw-r-----  1 root  operator  0x92 Jul  8 13:56 /dev/da0s1
```

For a USB drive containing only a single FAT32 partition, `da0s1` is likely the correct partition.

35.68.2 Mount the Partition

Before mounting, create a directory to use as the mountpoint. The directory `/mnt` can be used for this purpose but a safer practice is to create a custom directory:

```
: mkdir -p /root/usb
```

The next step is to mount the drive using the full path to the label or partition and the mount point:

Label example:

```
: mount -t msdosfs /dev/msdosfs/MYDRIVE /root/usb
```

Partition device example:

```
: mount -t msdosfs /dev/da0s1 /root/usb
```

Warning: Remember to *unmount the drive* before removing it from USB!

35.68.3 Copy the Files

With the drive mounted, files can be copied to or from the drive using the mountpoint directory, `/root/usb` in this example.

Copy/Move files from the firewall to the USB drive:

```
: cp /conf/config.xml /root/usb/config-backup.xml
: mv /tmp/status_output.tgz /root/usb/
```

Copy files from the USB drive to the firewall:

```
: cp /root/usb/myscript.sh /root/bin/
```

35.68.4 Unmount and Clean Up

After copying files, the drive **must** be unmounted:

```
: umount /root/usb/
```

With the drive unmounted it is now safe to remove the USB device from the firewall.

Warning: Failing to unmount the drive before removing the USB device can result in a kernel panic and reboot!

Next, remove the mountpoint directory if it is no longer necessary:

```
: rmdir /root/usb/
```

Note: This is optional. The mountpoint directory may be left in place for future use.

Warning: Do not use `rm -rf` or similar on the mountpoint! If the device was still mounted, this would destroy files on the device. Using `rmdir` ensures the operation will only have an effect if the directory is empty.

35.68.5 Full Example

```
# Insert the USB drive

# Find the label
: ls -l /dev/msdosfs/
crw-r-----  1 root  operator  0x93 Jul  8 13:56 MYDRIVE

# Create the mountpoint
: mkdir /root/usb

# Mount the drive
: mount -t msdosfs /dev/msdosfs/MYDRIVE /root/usb

# Copy files
: cp /conf/config.xml /root/usb/config-backup.xml

# Unmount the drive
: umount /root/usb/

# Remove the mountpoint
: rmdir /root/usb/

# Remove the USB drive
```

35.69 Virtualizing pfSense Software with VMware vSphere / ESXi

This article is about building a pfSense® virtual machine on vSphere / ESXi. Article explains how to install any major pfSense software version on VMware vSphere.

> **Warning:** Depending on the version of pfSense software in use, there may be specific vSphere / ESX version requirements as well. For example, versions of pfSense software based on FreeBSD 12.x require ESX 6.7 or later while versions based on FreeBSD 14.x require ESX 7.0 or later. Typically the VM hardware version must also be at that level or greater. While older versions may work, they may be unstable.
>
> Refer to both *Versions of pfSense software and FreeBSD* and the VMware Guest OS Compatibility Guide to find the base OS and requirements for each version.

The article does not cover how to install vSphere or how to configure pfSense software to do any of the many amazing things it can. A basic, working, virtual machine running pfSense software will exist by the end of this document.

Note: If the pfSense software instance will be running as a perimeter firewall for an organization and the "attack surface" should be minimized, many will say it is preferable to run it unvirtualized on stand-alone hardware. That is a decision for the user and/or organization to make, however. Now back to the topic.*

This guide starts at the point with a vanilla ESXi install connected using the vSphere client. If other VMs are already running on ESXi, then it is not likely necessary to follow the networking steps too closely. However, skim through it to see what is suggested before building the pfSense software virtual machine.

35.69.1 Assumptions

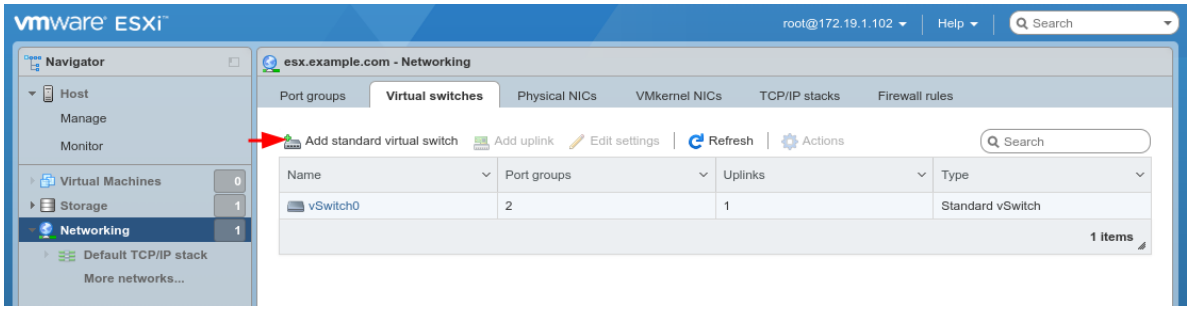
- vSphere host is up and running and the user can login to the web interface through its management network adapter.
- The reader has an understanding of network addressing.
- vSphere host has a working datastore.
- The pfSense software installation `.iso` image is present in a datastore.

The following steps include the necessary vSphere web client configuration required to get a VM for pfSense software running.

35.69.2 Basic vSphere web client networking setup

Before creating a new VM in vSphere web client, create two virtual switches and two port groups. First, create Virtual switches for WAN and LAN and after that two port groups for the WAN and LAN. If there are existing virtual switches in the environment which can be used for this VM, skip this step.

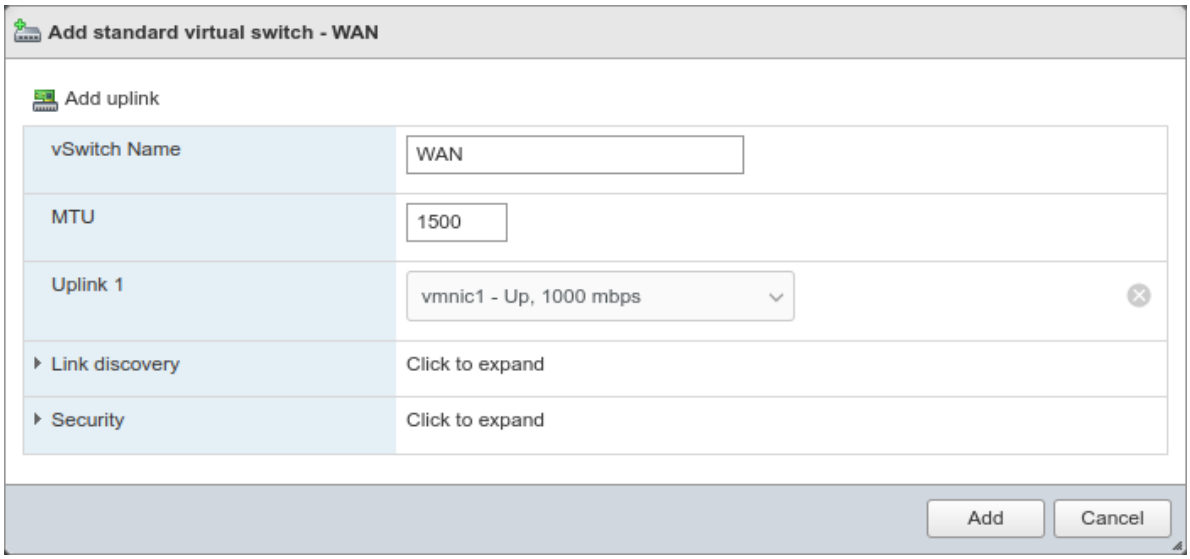
- Open the vSphere web interface
- Click **Networking**, **Virtual switches** tab
- Click **Add standard virtual switch**



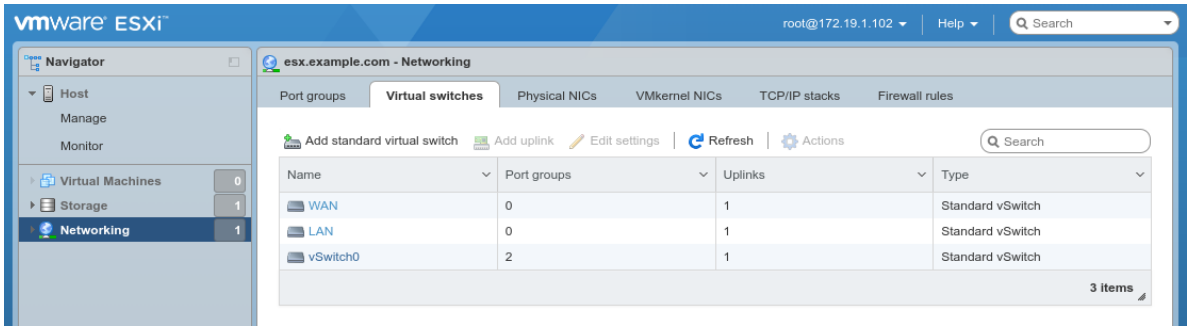
- Configure the vSwitch as follows:

  vSwitch Name
  `WAN`

  Uplink 1
  vmnic1



- Click **Add**
- Repeat the process and add another vSwitch named `LAN` for *vmnic2*



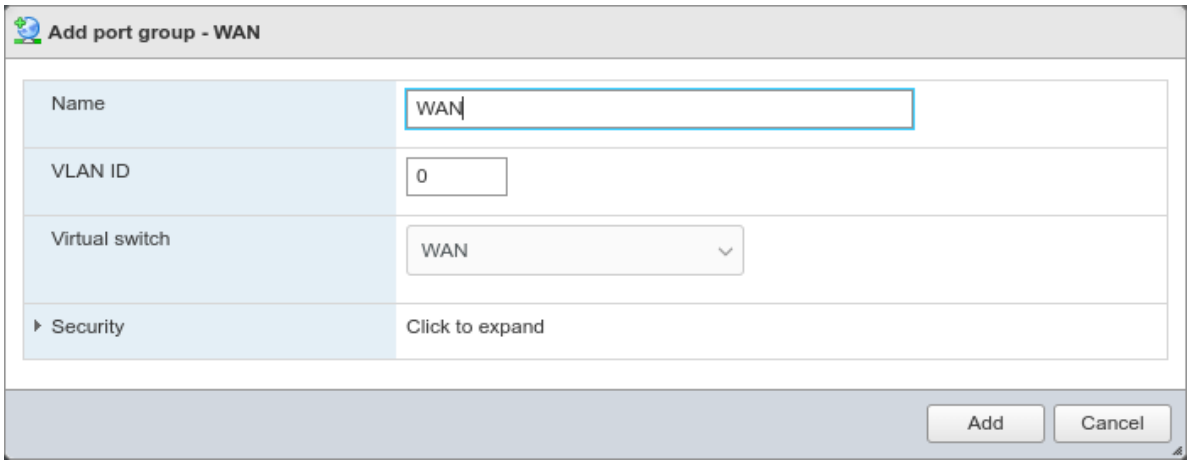
35.69.3 Creating port groups

After creating Virtual switches, now create port groups. If there are existing port groups in the environment which can be used for this VM, skip this step.

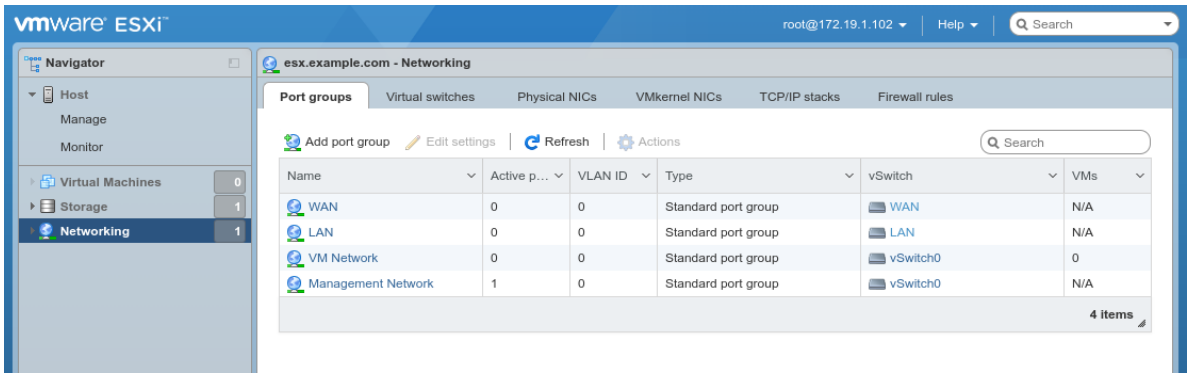
- Click **Networking**, **Port groups** tab
- Click **Add port group**
- Configure the port group as follows:

  Name
  `WAN`

  Virtual switch
  WAN



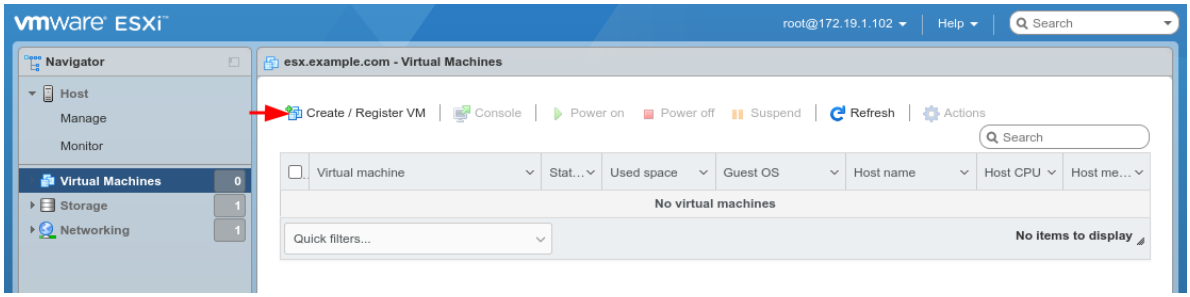
- Click **Add**
- Repeat the process and add another port group named `LAN` for the *LAN* vSwitch.



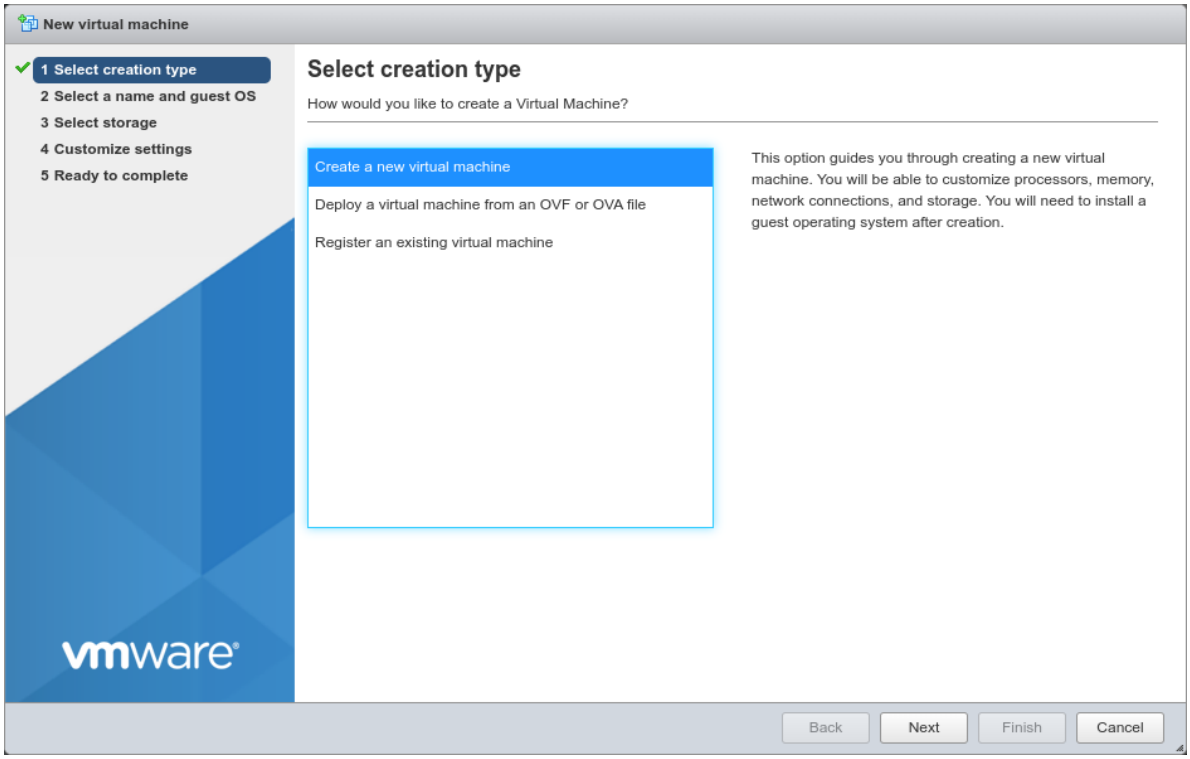
35.69.4 Creating a Virtual Machine

With the required networking configured, the next step is to create a virtual machine.

- Click **Virtual Machines** on the left Navigator pane
- Click **Create/Register VM**



- Select **Create a new virtual machine** on the first wizard



- Click **Next**
- Configure the **Select a name and guest OS** screen of the wizard as follows:

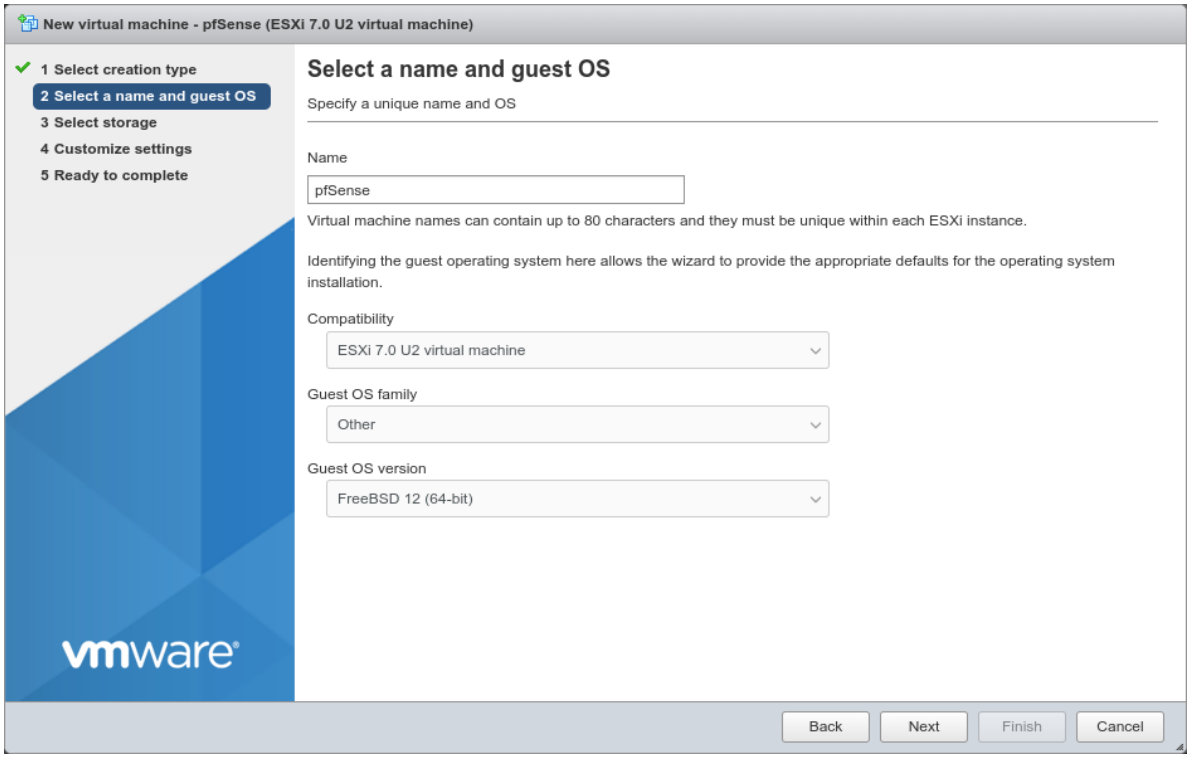
  Name
  `pfSense` or another meaningful name, such as `firewall`.

  Compatibility
  The latest version available (e.g. *ESXi 7.0 U2 virtual machine*)

  Guest OS Family
  Other

  Guest OS Version

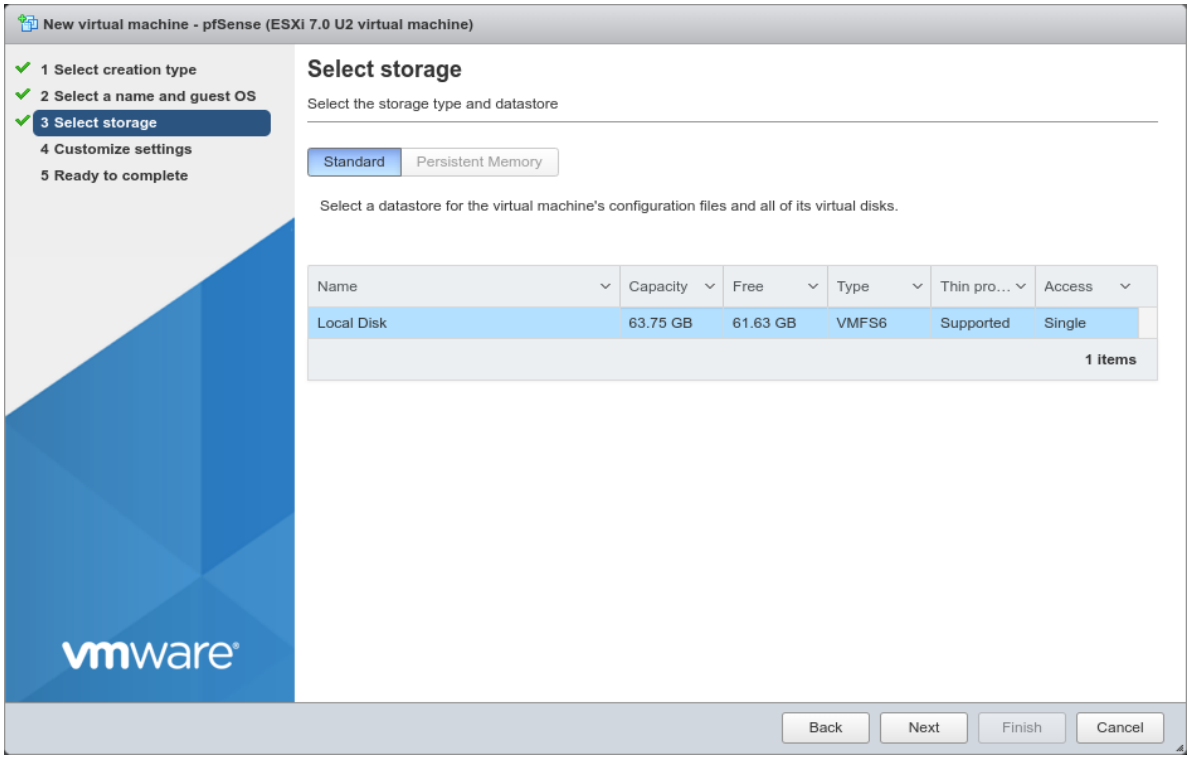
FreeBSD 12 (64-bit) or whichever version best matches the version of FreeBSD used by the chosen version of pfSense software. See *Versions of pfSense software and FreeBSD* for a list.



- Click **Next**
- Select the datastore where the VM disk will live

  This is where ESX will allocate storage to hold the configuration and operating files for the virtual machine. There may be multiple datastores available to ESX, local or even remote NFS volumes.

  Local disks are faster and more reliable, but pfSense software does not require a fast disk in most use cases, so in those environments it can run off an NFS disk if necessary.



- Click **Next**
- Click **Add network adapter** to create a second NIC
- Configure the items on the **Customize settings** screen as follows:

  CPU
  Use a single CPU socket.

  If the hypervisor host has sufficient cores available, click to expand the CPU options and set a higher **Cores per socket** count.

  Memory
  Depending on the number and type of packages that will be installed on the pfSense software, a basic firewall VM should run comfortably in 1024MB of RAM. For deployments which require more or larger packages, increase the RAM as needed.

  Hard Disk 1
  Give the VM at least 16 GB of space, more for larger packages.

  SCSI Controller 0
  The default *LSI Logic SAS* is compatible, leave it as-is.

  Network Adapter 1
  Select the *WAN* port group.

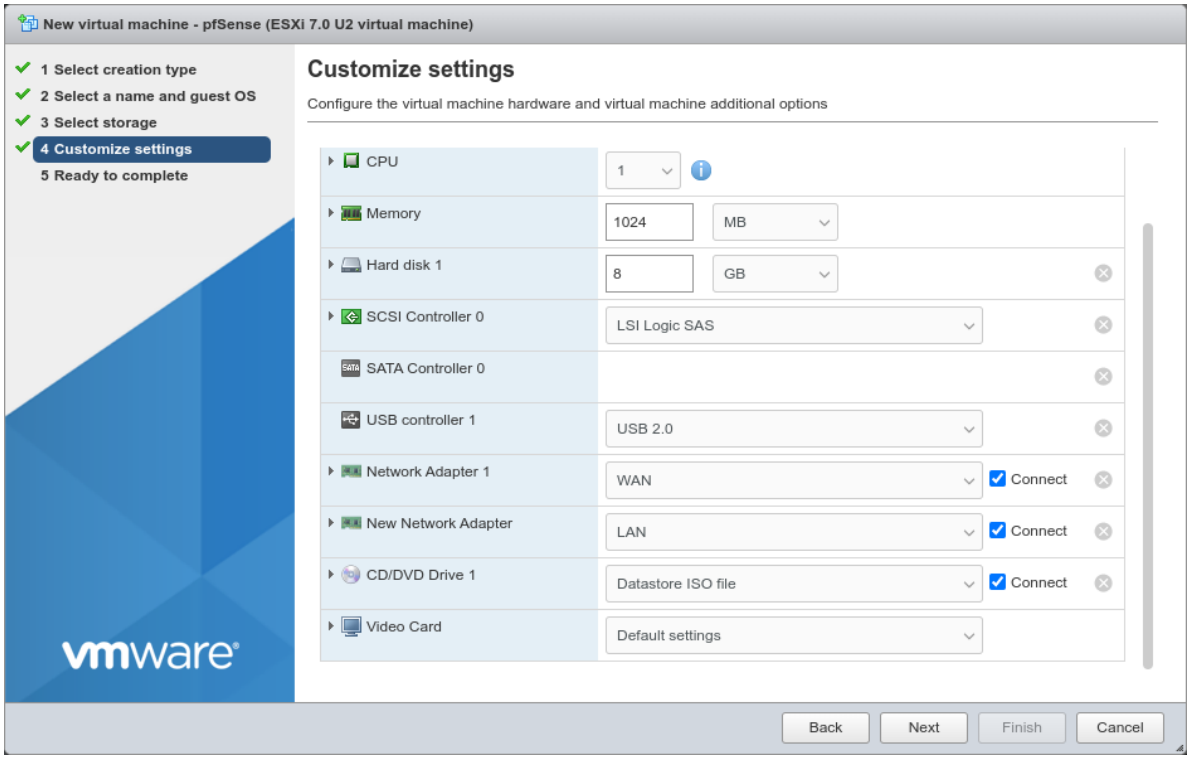
  For best performance, use VMXNET 3 type of adapters which is the current default in vSphere 7.x. Click to expand the interface options and ensure it's set to VMXNET 3.

  New Network Adapter
  Select the *LAN* port group.

  Click to expand the interface options and ensure it's set to VMXNET 3.

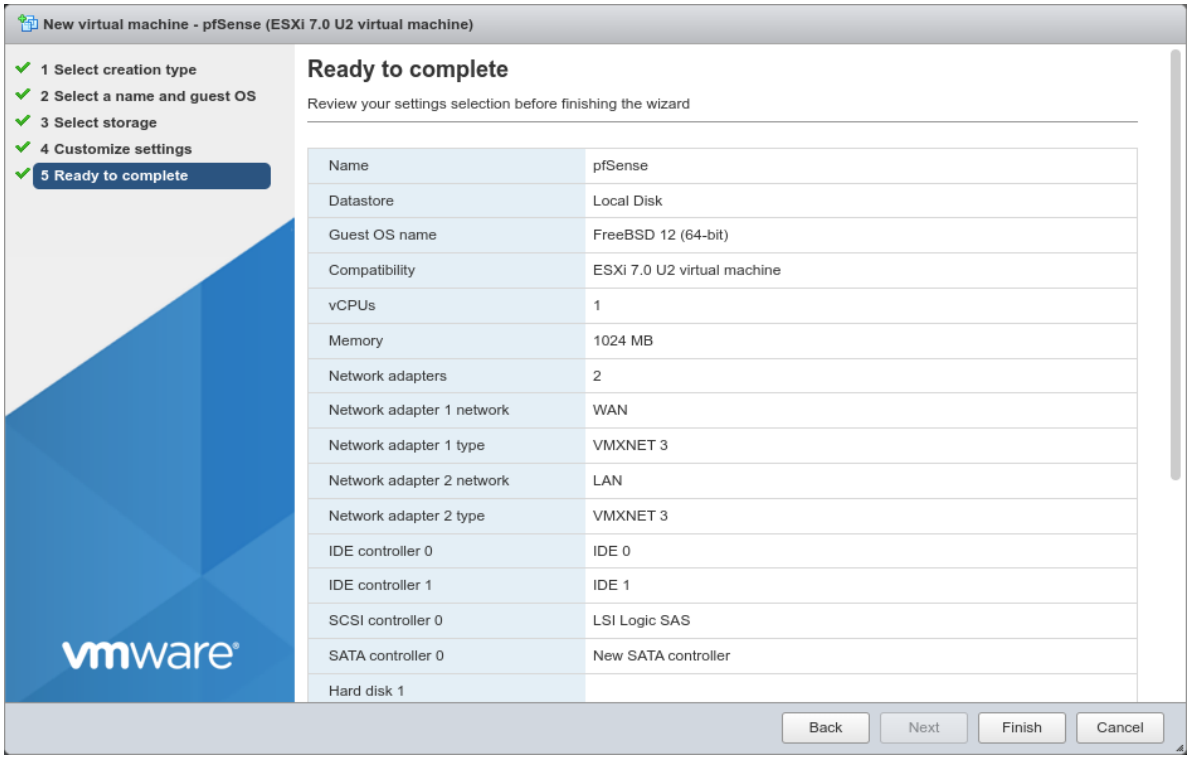
  CD/DVD Drive 1
  Select *Datastore ISO file** and then browse to and pick the pfSense software installer ISO.

The remaining options can remain at their default values, or change to suit the needs of the environment.



- Click **Next**
- Review the settings for the VM

  If anything is incorrect, go back to the previous screens and correct it.

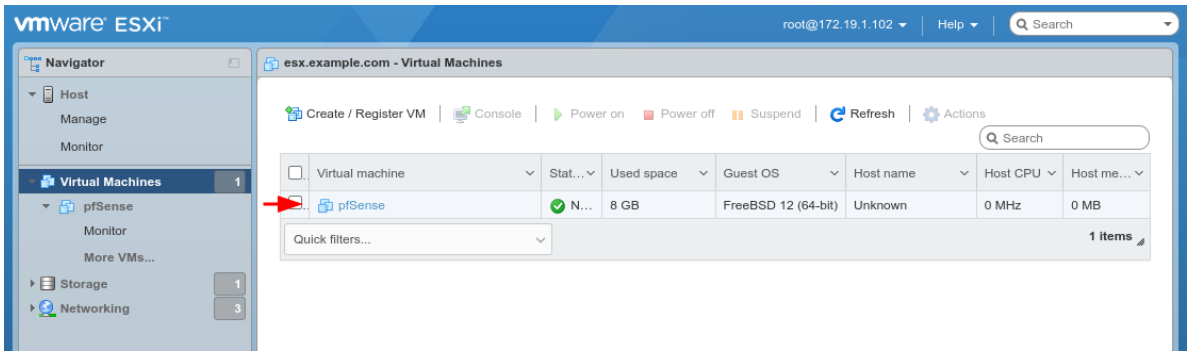


- Click **Finish**

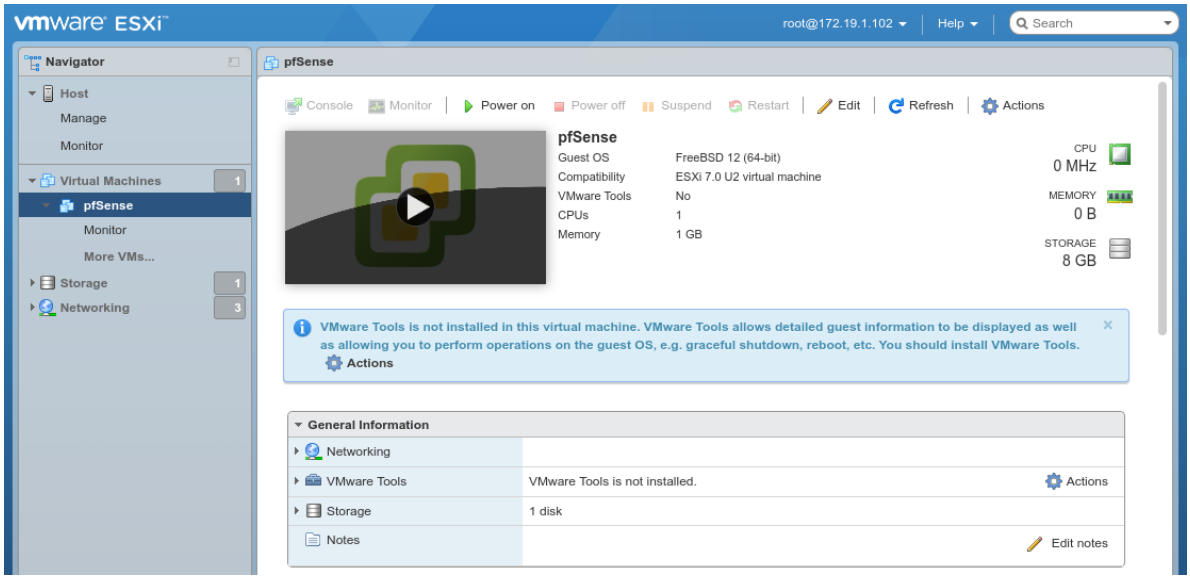
35.69.5 pfSense software installation

The vSphere web interface will now have an entry for the new VM.

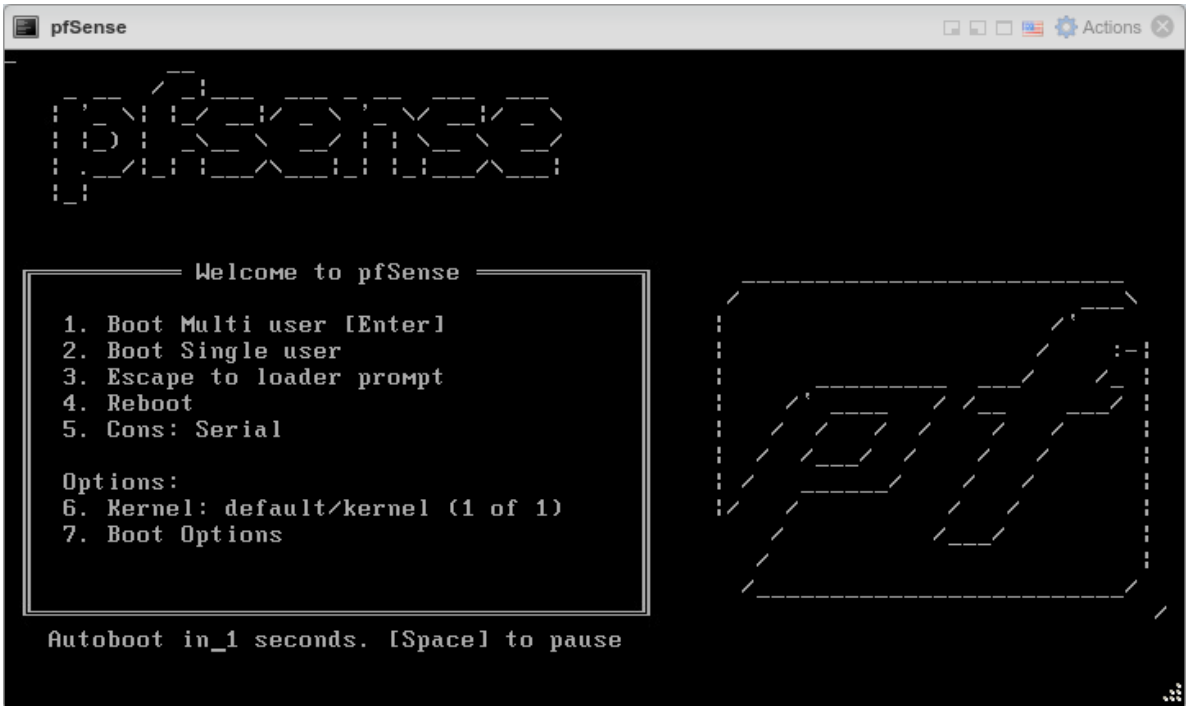
- Click **Virtual Machines** in the **Navigator** panel on the left



- Click the name of the VM in the list to open it



- Click **Power on** to start the VM
- Click inside the console window to open the console view to continue the installation.



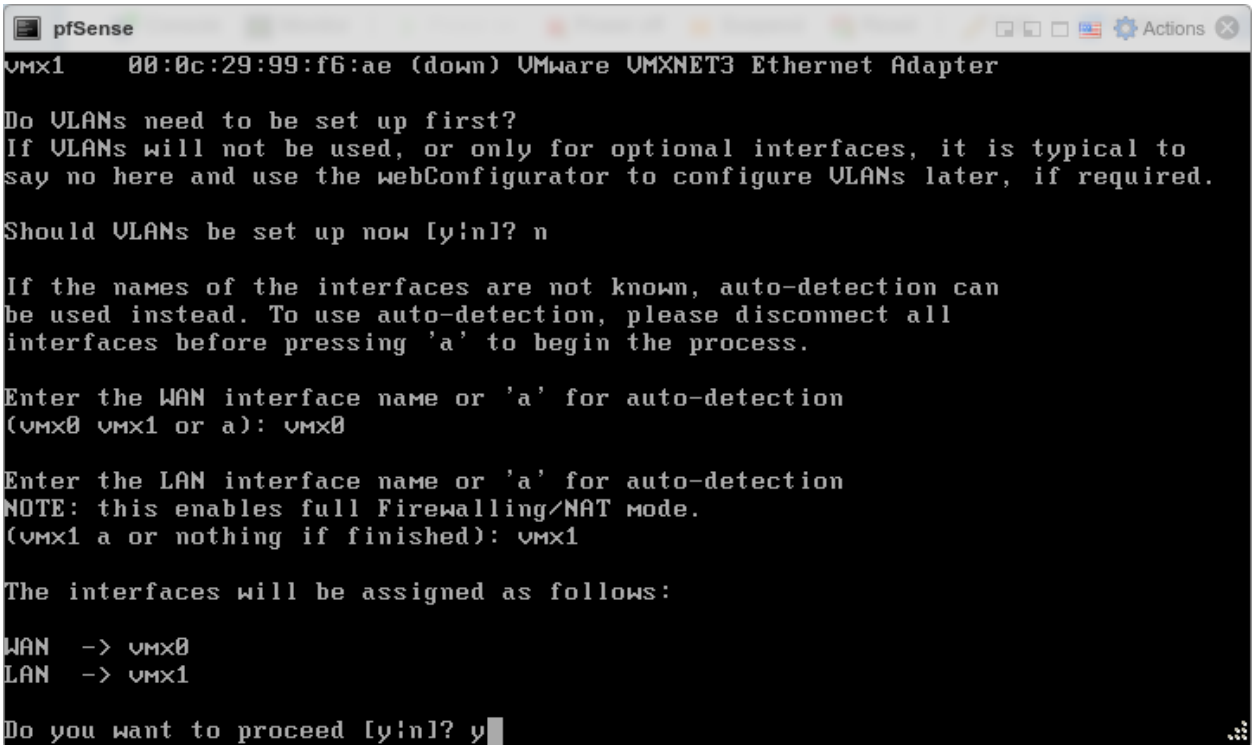
When the VM starts it will boot into the installer automatically. From there, follow the installation steps as usual, and reboot when finished.

See also:

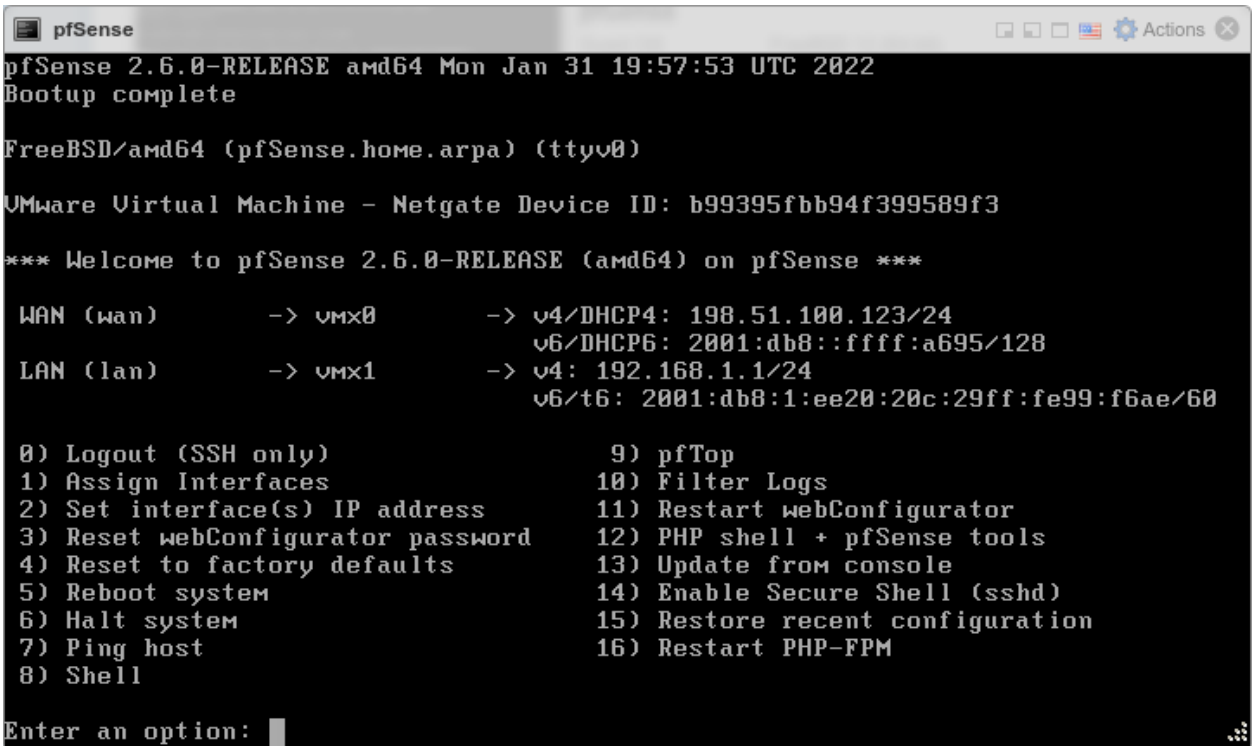
See *Installation Walkthrough* for a detailed walkthrough of the installation process.

After the virtual machine boots back up, the console will stop at an interfaces assignment prompt.

- Type `n` and press `Enter` to skip VLAN configuration
- Enter `vmx0` for WAN
- Enter `vmx1` for LAN
- Press `Enter` if prompted for additional interfaces
- Type `y` and press `Enter` to complete the interface assignment



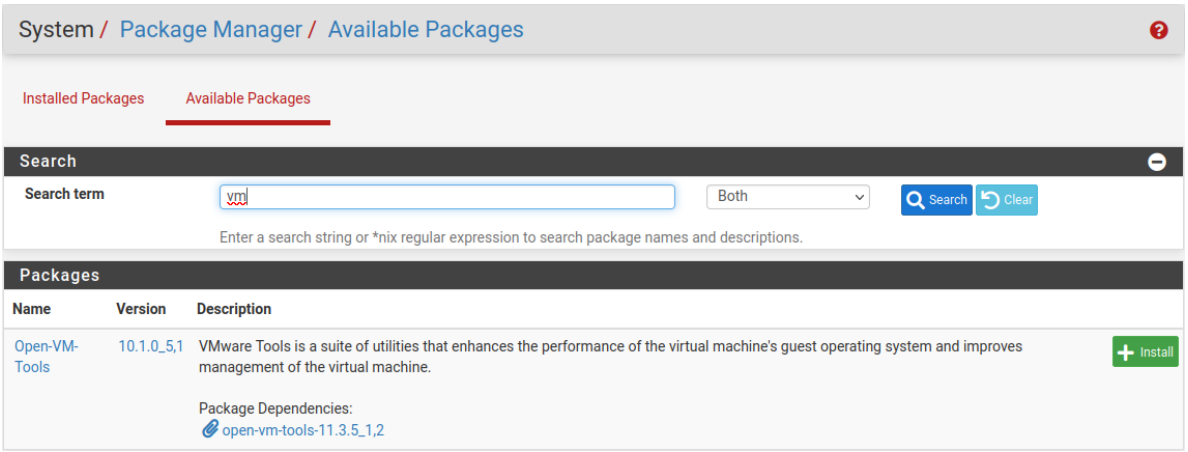
After assigning the interfaces the VM will complete the boot process. It is now ready to configure like any other firewall running pfSense software.



Installing Open-VM-Tools

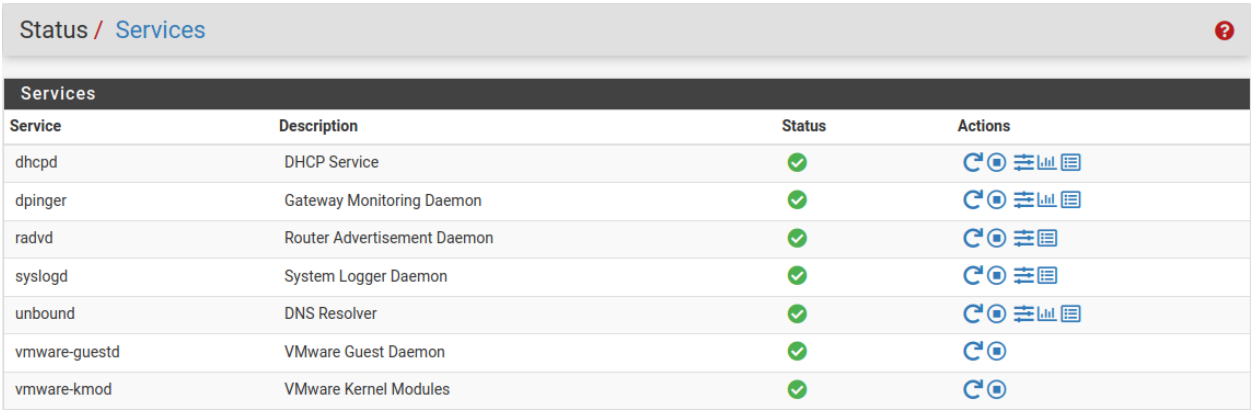
Once the pfSense software installation is complete, upon first boot install the Open-VM-Tools.

- Navigate to **System > Packages**, **Available Packages** tab
- Find **Open-VM-Tools** in the list or search for it



- Click  **Install**
- Confirm the installation

Make sure the Open-VM-Tools service is running under **Status > Services**.



Congratulations, the installation of pfSense software on ESXi is complete!

35.69.6 Additional Information and Tips

Dedicated Management Network

The best practice is to separate the ESXi Management network from other networks. The example in this recipe uses a dedicated management network, which is common in well-designed networks. Separation can be accomplished using VLANs or an additional NIC on the ESXi host dedicated only for ESXi management. The vSphere client PC may need additional routing or networking connections to reach the dedicated management network.

Identifying Interfaces

If multiple physical interfaces are available in the ESXi host, it can be a bit of a struggle to work out which one has been identified as `vmnic1`, `vmnic2` and so on. If the MAC address of each NIC is noted down along with the slot it occupied when it was installed in the machine, look at the Network Adapters screen under the Configuration tab to match up the MAC addresses. However, having that foresight is rare, so lacking that information the easiest way to match physical NICs to `vmnic` entries is to plug a PC or switch into them, one at a time. The speed and duplex on the Networking or Network Adapters screens should change as the interface comes up. Click **Refresh** to update the list.

35.70 Virtualizing pfSense Software with Hyper-V

This article is about running pfSense® software in a virtual machine under Microsoft Hyper-V. The guide applies to any Hyper-V version, desktop or server (this includes the standalone Hyper-V Server). The guide explains how to install any major pfSense software version under Hyper-V. Article covers the Hyper-V networking setup and pfSense software virtual machine setup process. The guide does not cover how to install Hyper-V or Windows Server. A basic, working, pfSense software virtual machine will exist by the end of this article.

Note: If pfSense software will be used as a perimeter firewall for an organization and the attack surface should be minimized, the best practice is typically to run the firewall non-virtualized on stand-alone hardware. That is a decision for the user and/or organization to make, however.

This guide starts at a point with a Windows and the Hyper-V role installed. If other VMs are already running on Hyper-V, then it is not likely necessary to follow the networking steps too closely. However, skim through it to see what is suggested before building the pfSense software virtual machine part.

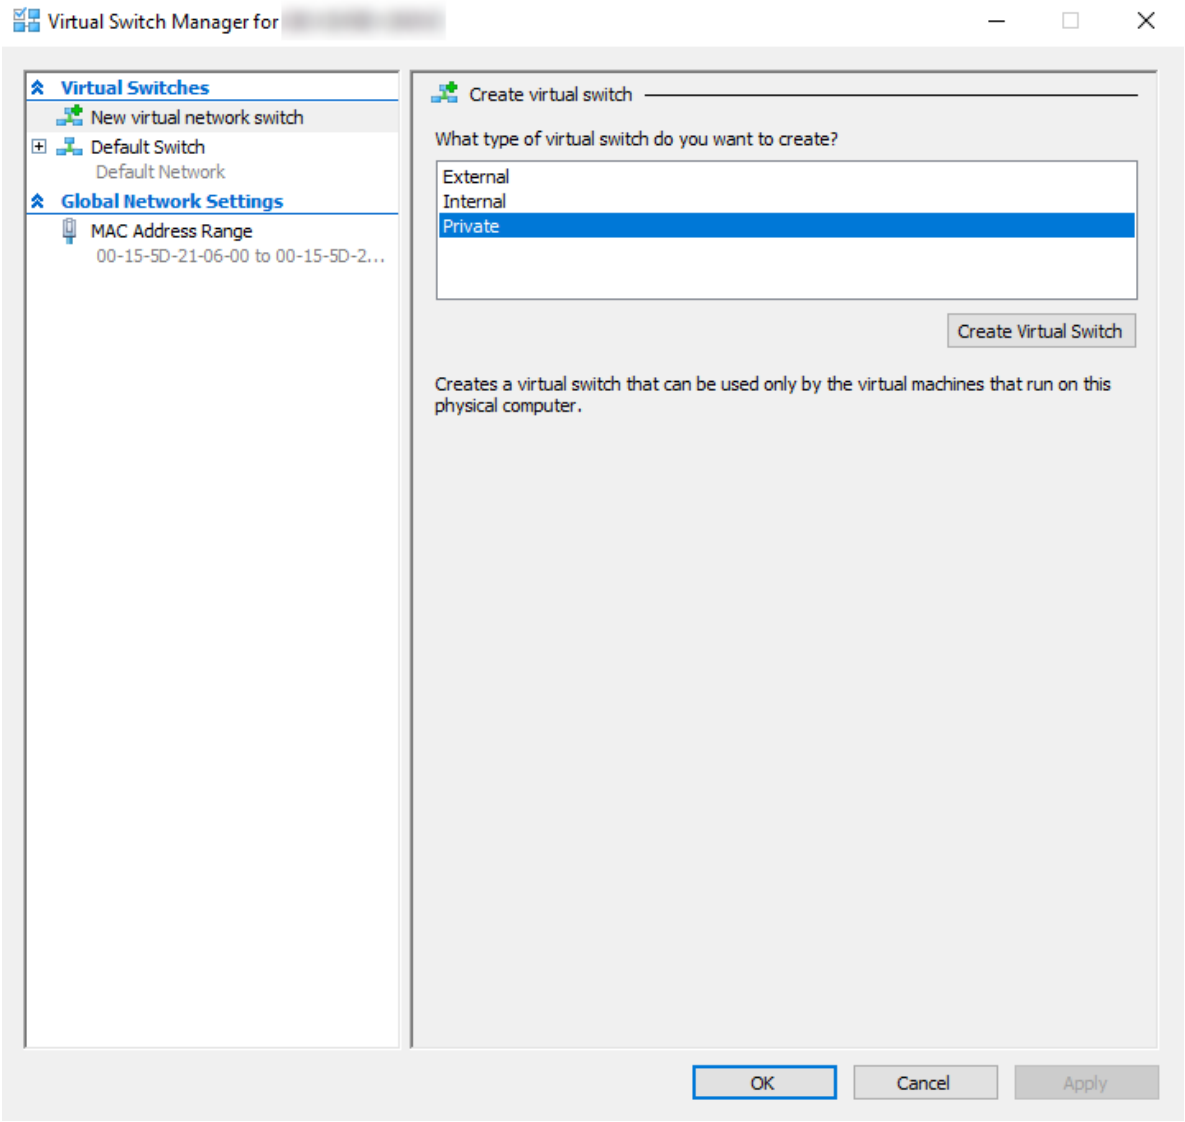
35.70.1 Assumptions

- Hyper-V host is up and Hyper-V role/feature has been installed
- The reader has an basic understanding of networking and Hyper-V virtualization

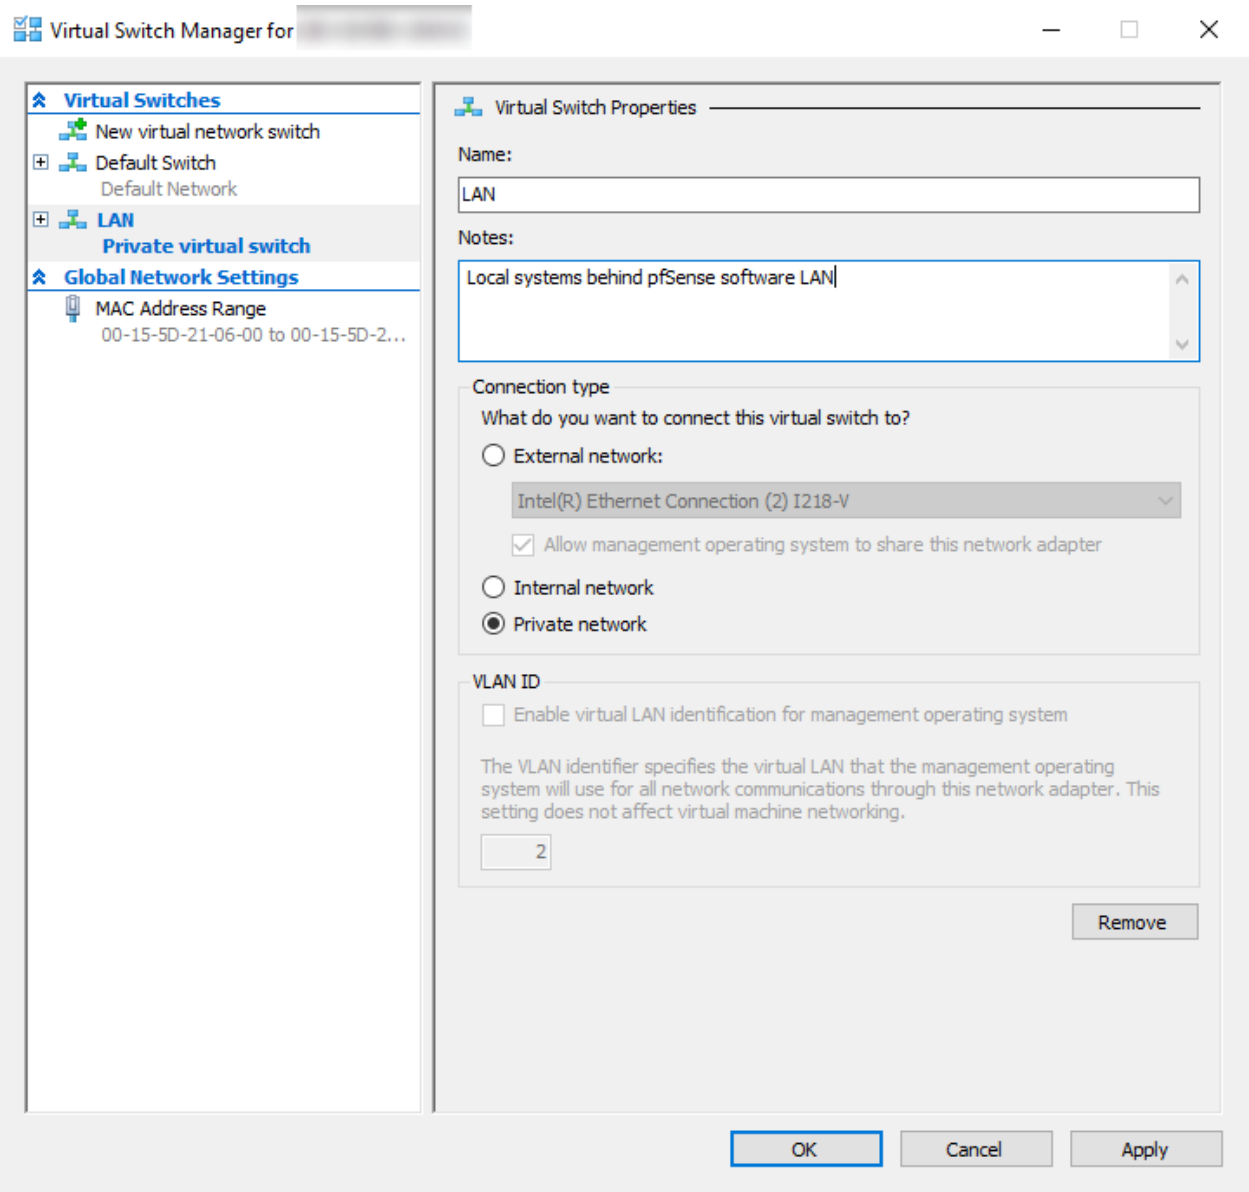
35.70.2 Basic Hyper-V Networking

To virtualize pfSense software, first create two **Virtual Switches** via Hyper-V Manager.

- Open the Hyper-V Manager
- Click **Virtual Switch Manager** from the **Actions** menu
- Select **Private** for the type of virtual switch
- Click **Create Virtual Switch**



- Set the **Name** for the newly added switch to `LAN`
- Set an appropriate description in the **Notes** field
- Ensure the **Connection type** is set to *Private network*
- Click **Apply**



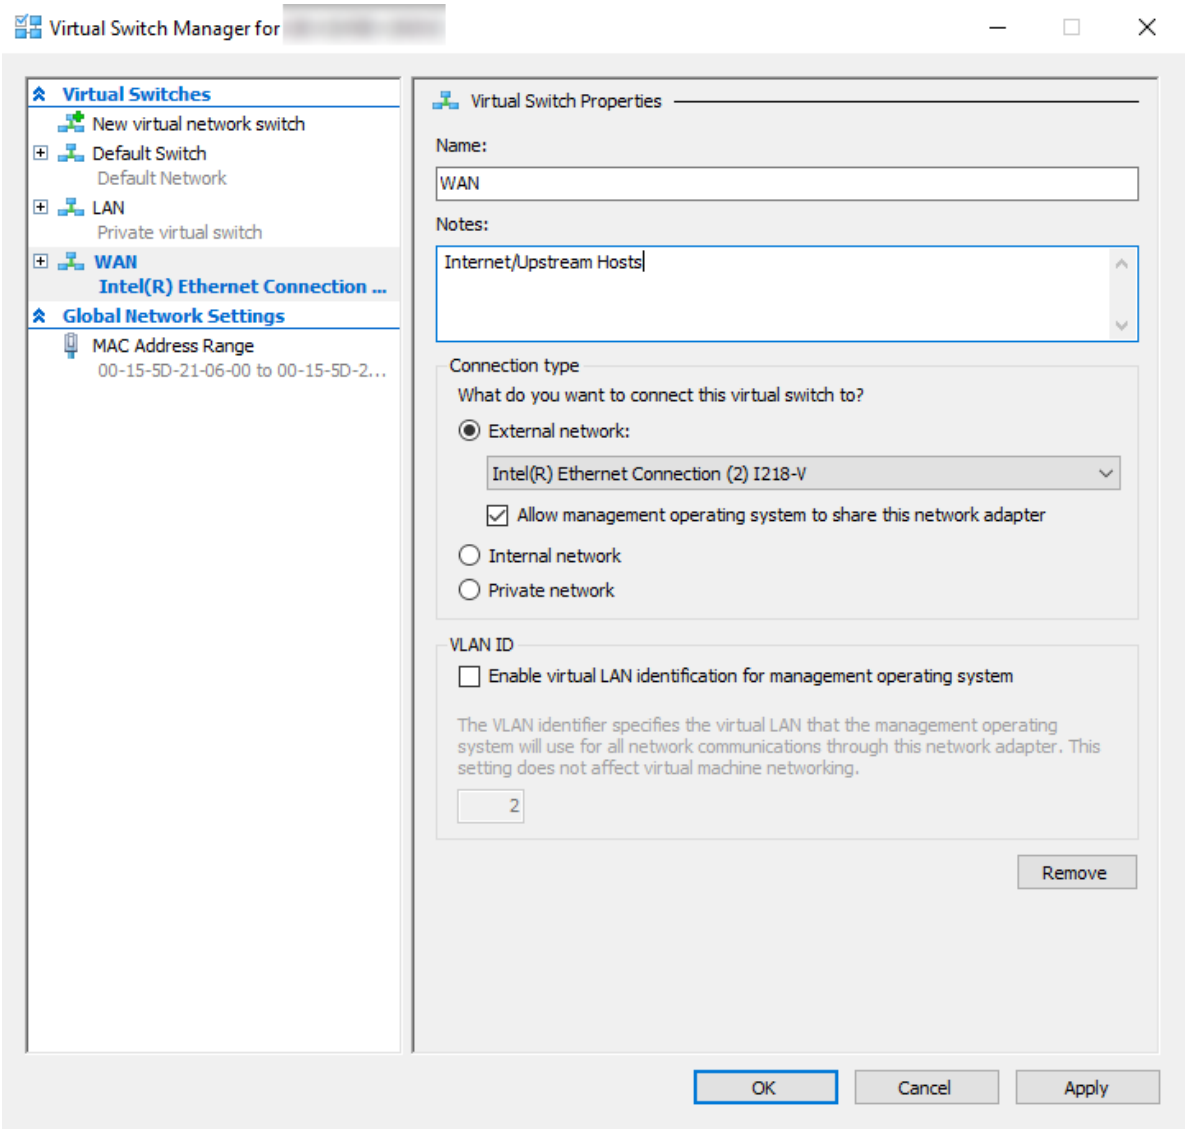
Now create a switch for the WAN/Upstream networks:

- Click **New virtual network switch**
- Select **External** for the type of virtual switch
- Click **Create Virtual Switch**
- Set the **Name** for the newly added switch to `WAN`
- Set an appropriate description in the **Notes** field
- Select the appropriate interface for the **External network**

  This is the interface on the Windows host which connects to the upstream/WAN switch/CPE or similar uplink.
- Uncheck **Allow management operating system to share this network adapter** if the hypervisor host has a dedicated interface for WAN.

  For the purpose of this guide the management was allowed, however production use requires a separate NIC for

WAN.



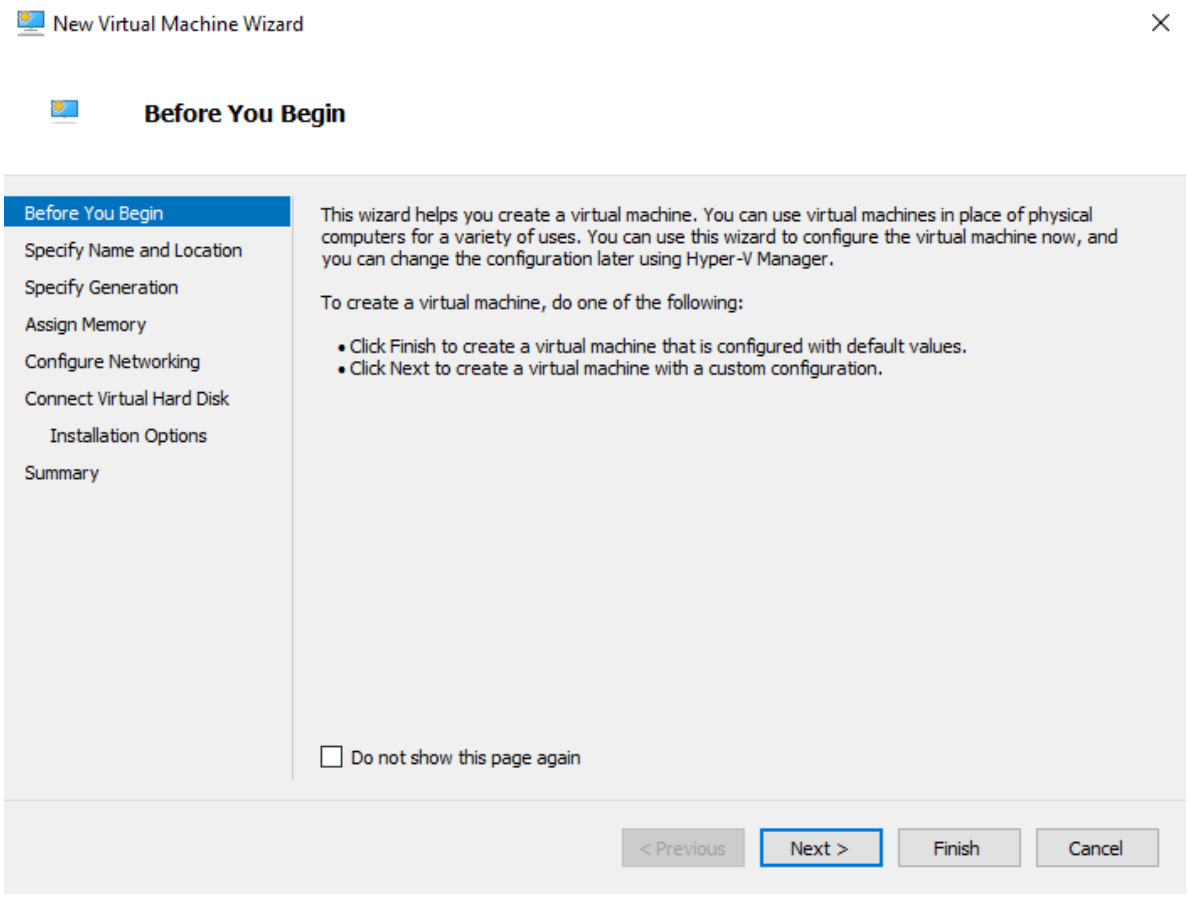
- Click **OK** to complete the switch setup

35.70.3 Creating the virtual machine

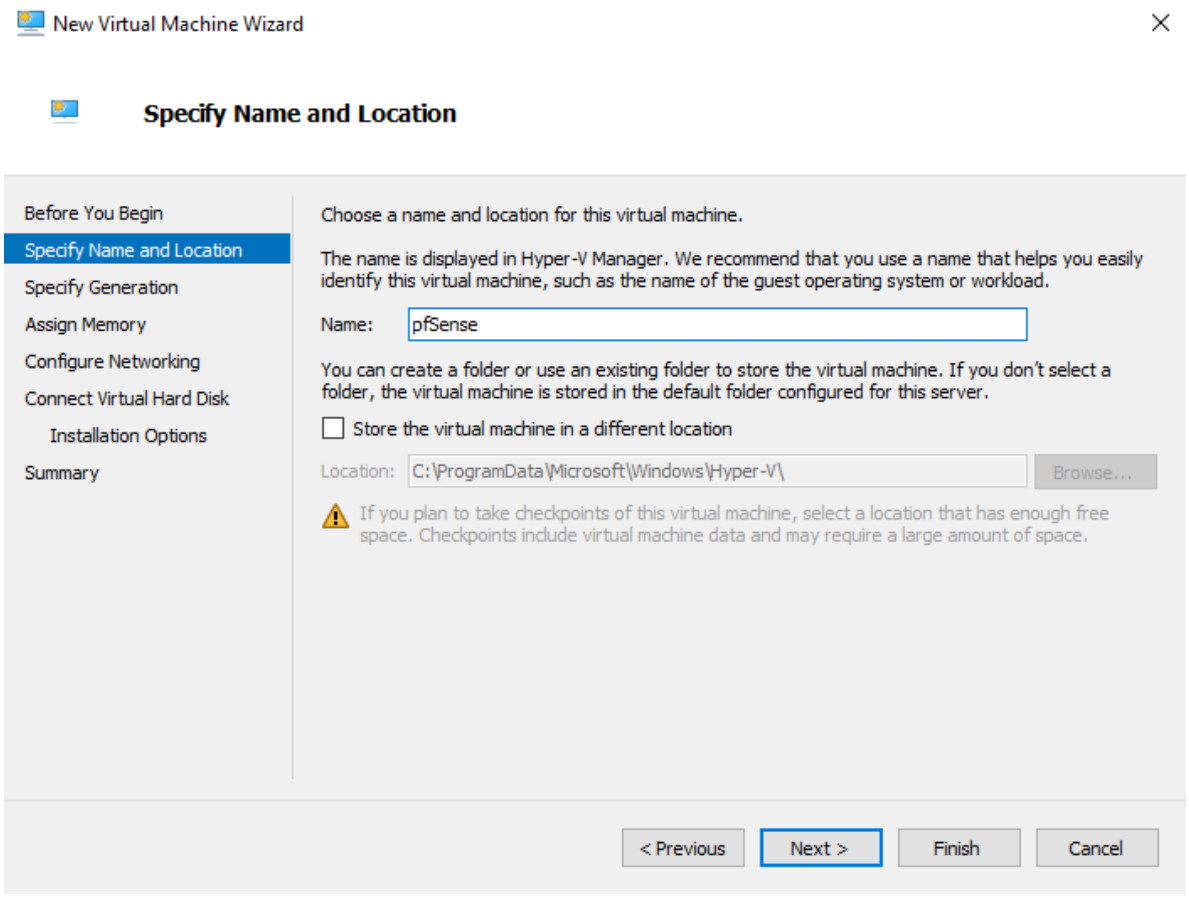
After creating WAN and LAN switches, move to virtual machine creation.

- Click **New > Virtual Machine** from the **Actions** list

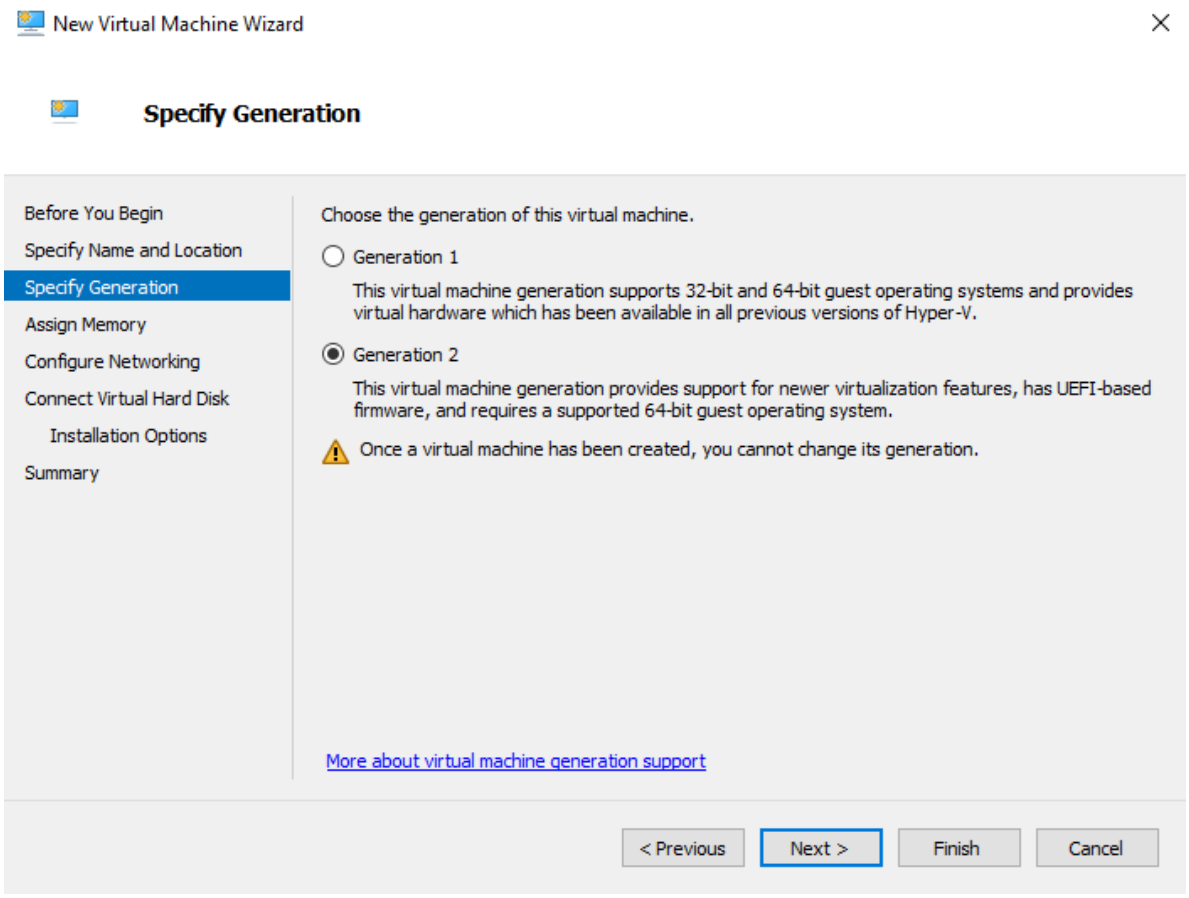
  This starts the new virtual machine wizard.



- Click **Next** and proceed to the **Specify Name and Location** step
- Enter a **Name** for the virtual machine, such as `pfSense`

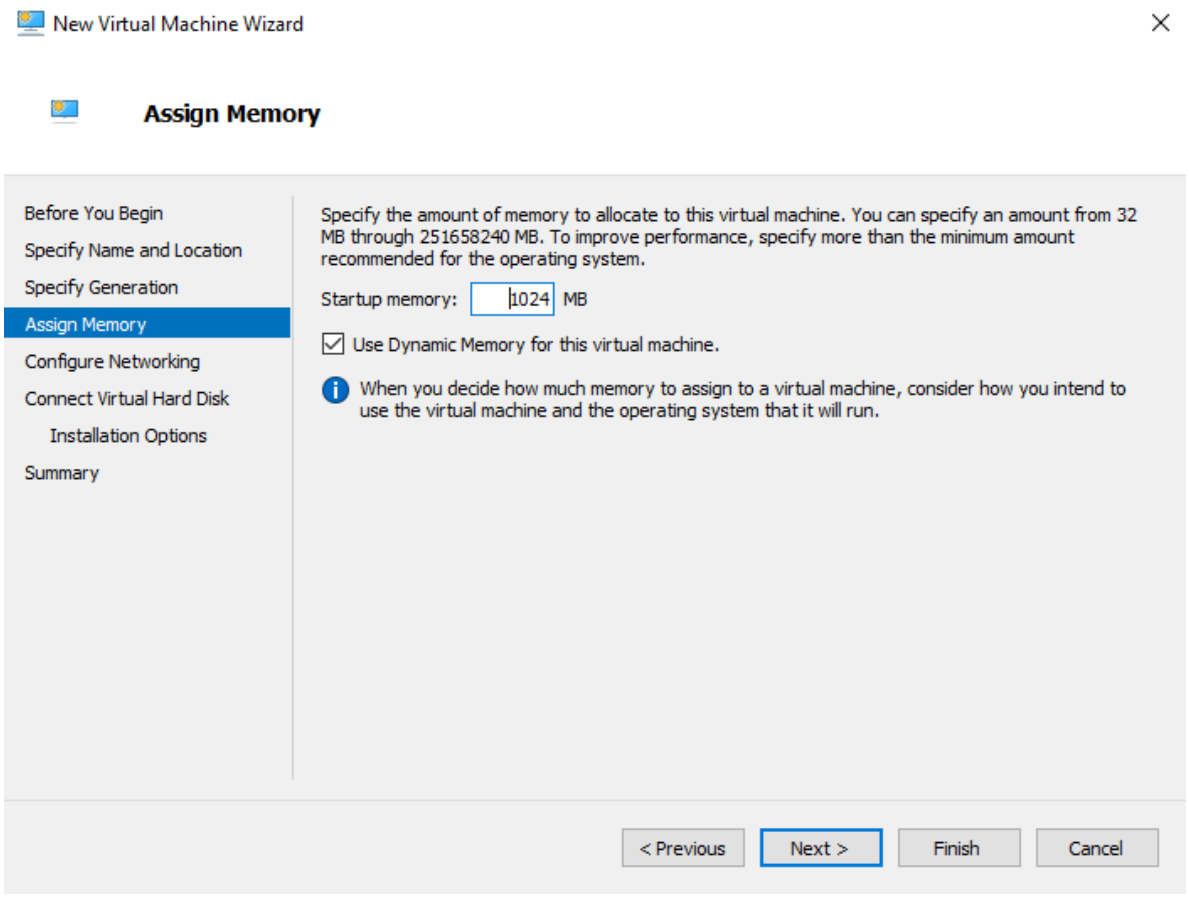


- Click **Next** and proceed to the **Specify Generation** step
- Select the appropriate virtual machine generation: *Generation 2*



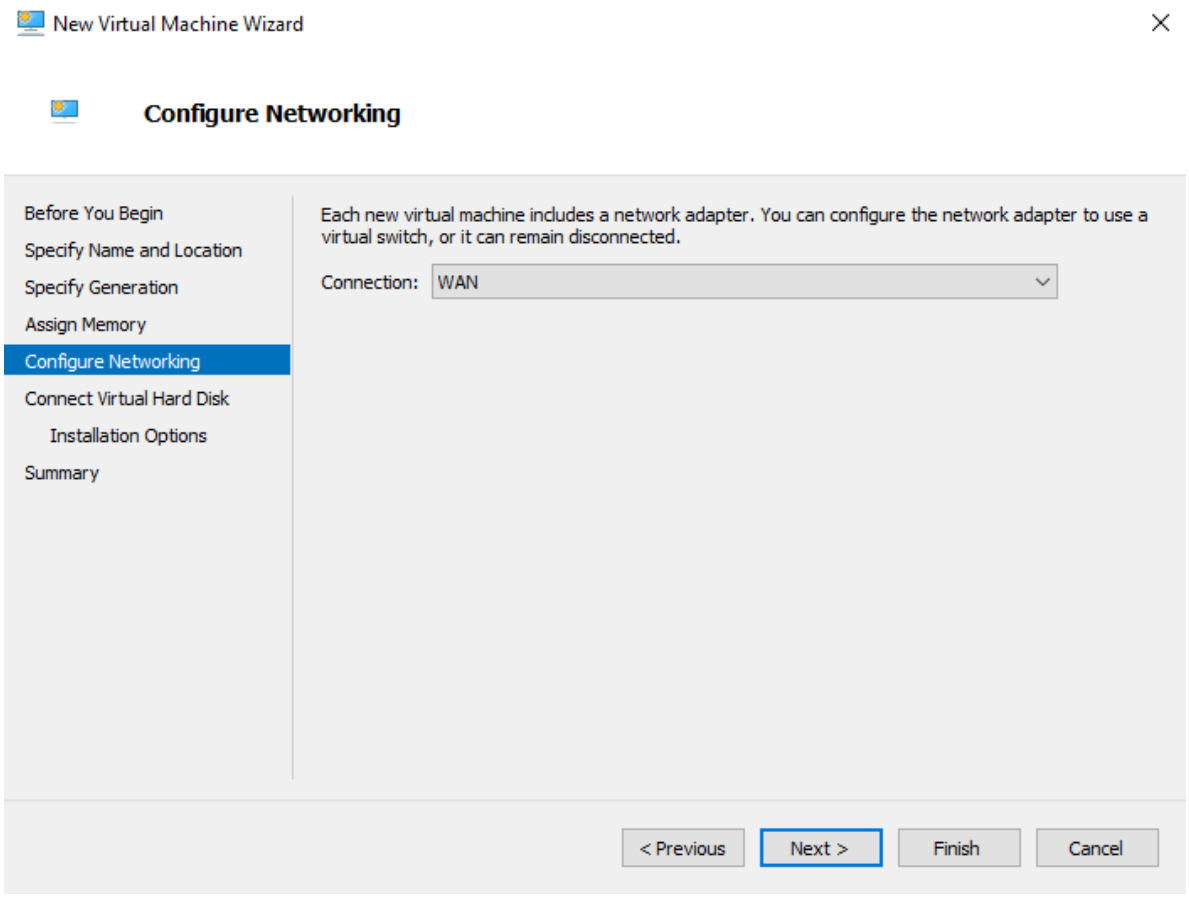
- Click **Next** and proceed to the **Assign Memory** step
- Add enough RAM to meet the requirements of this environment

  This guide uses 1GB (`1024` MB). 2GB is better if this VM will run multiple packages.



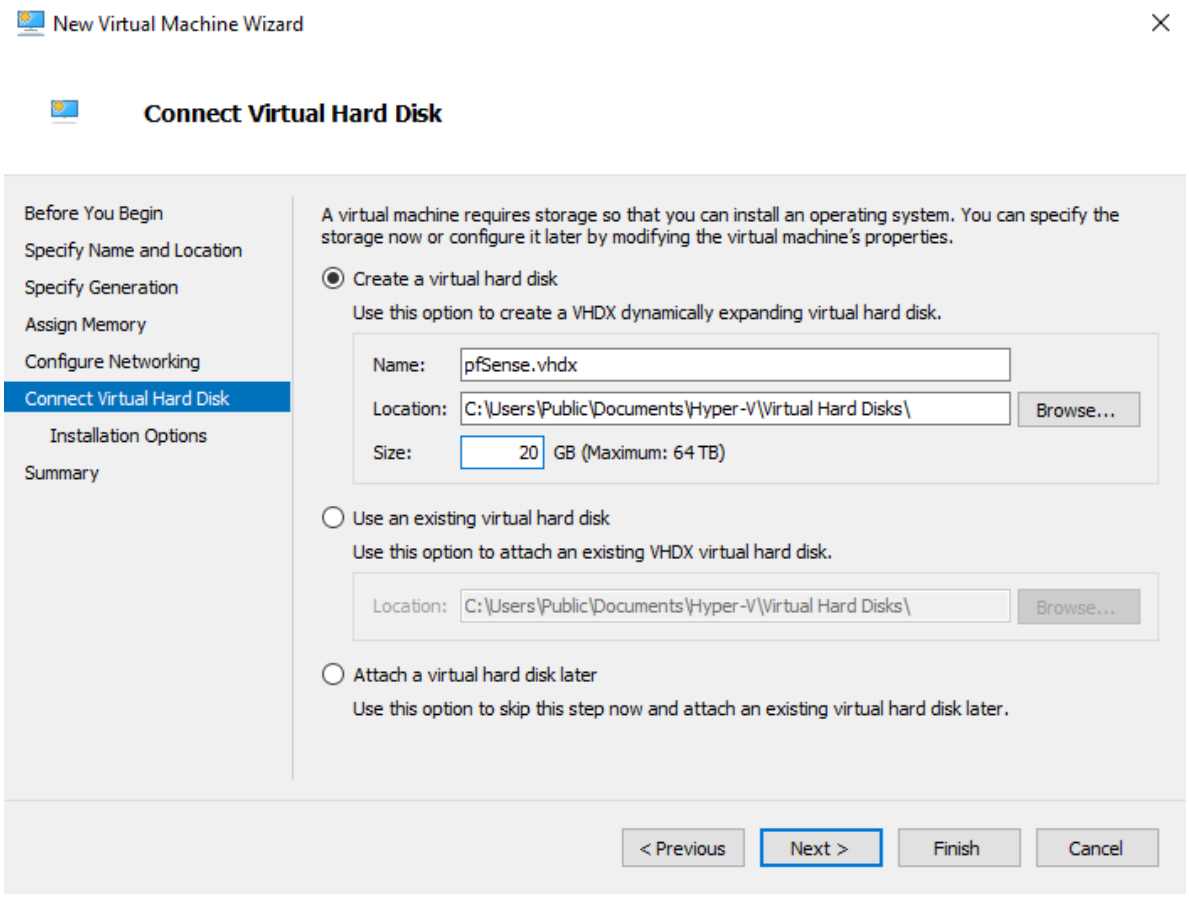
- Click **Next** and proceed to the **Configure Networking** step
- Select WAN from **Connection** drop-down menu

  The LAN will be added later after completing the wizard.

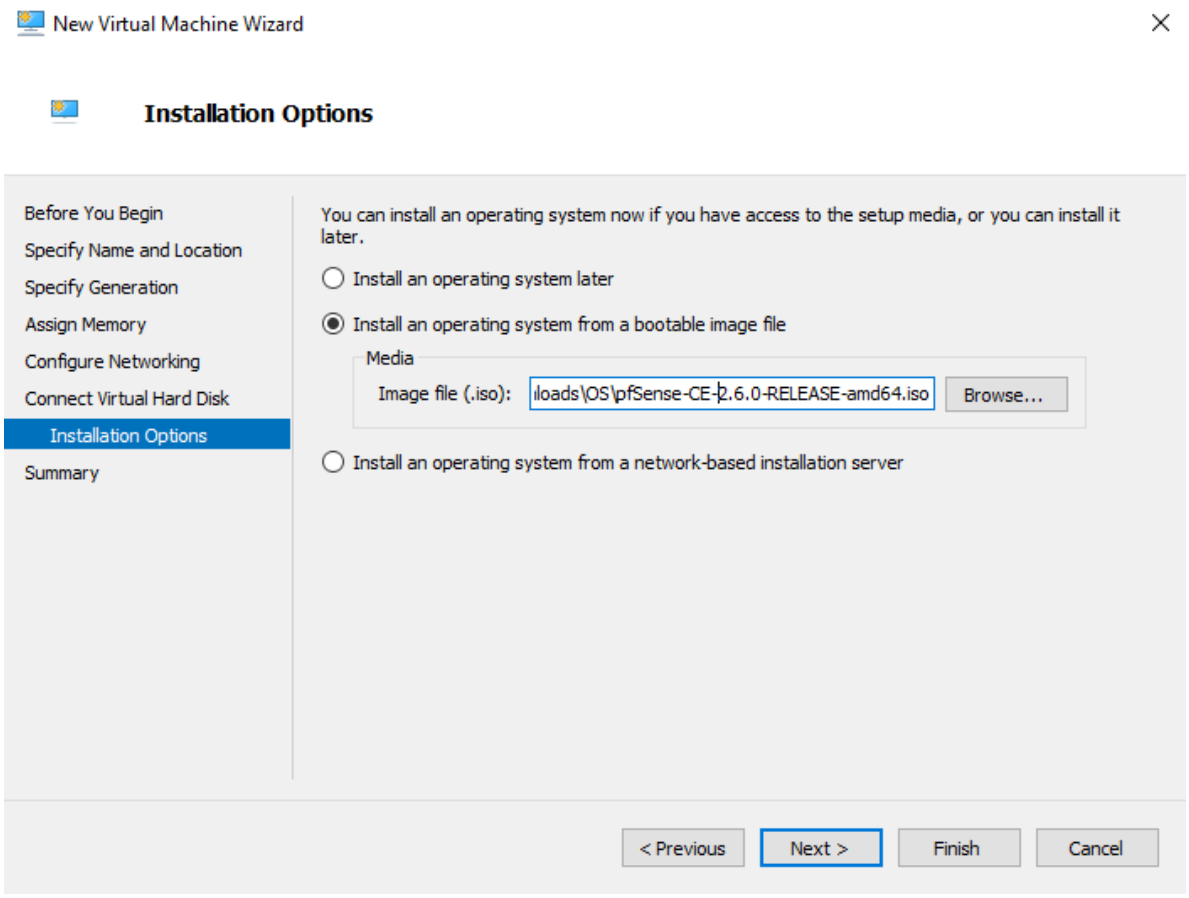


- Click **Next** and proceed to the **Connect Virtual Hard Disk** step
- Select **Create a virtual hard disk**
- Assign `10` to `20` GB for the VM disk

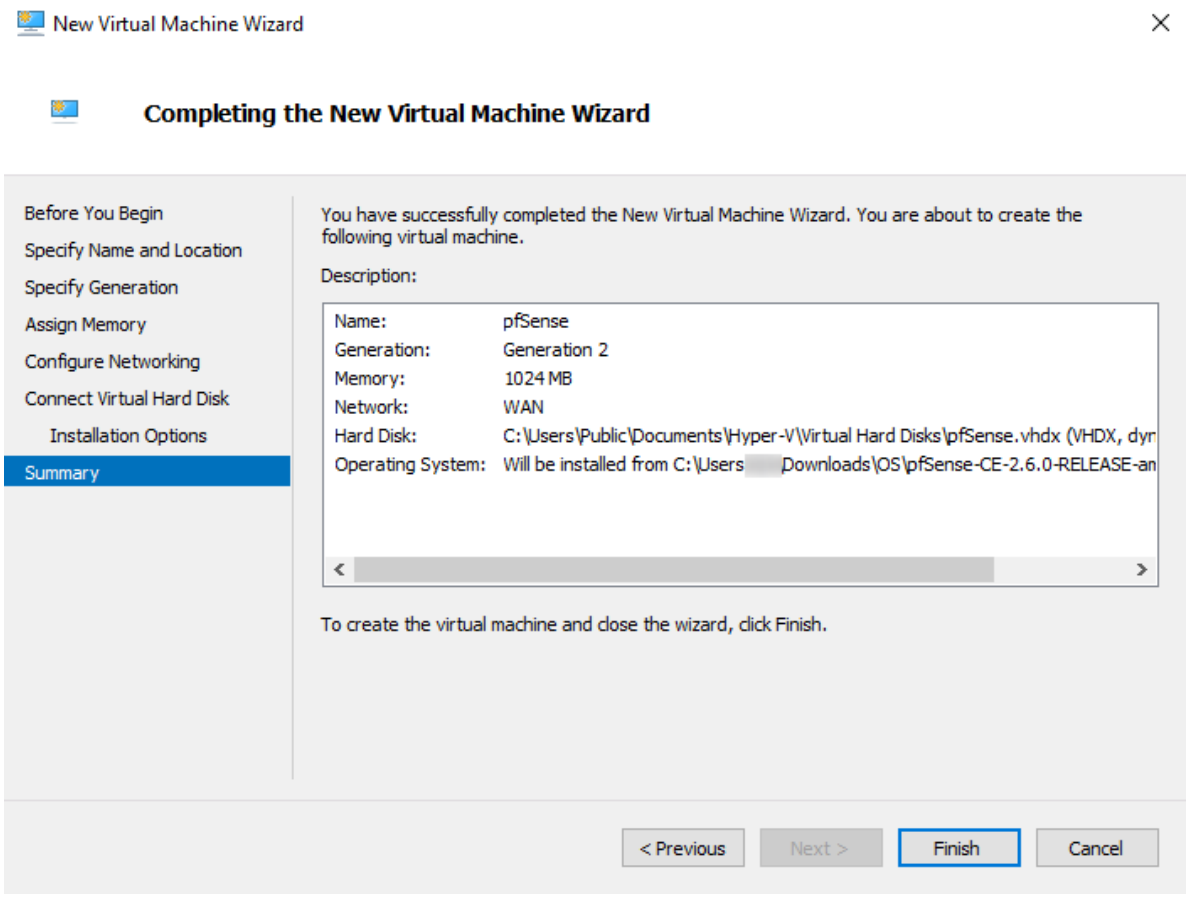
  Disk-intensive tasks such as packages for IDS/IPS or proxies may require larger disk sizes.



- Click **Next** and proceed to the **Installation Options** step
- Select **Install an operating system from a bootable image file**
- Browse to the pfSense software installer ISO image



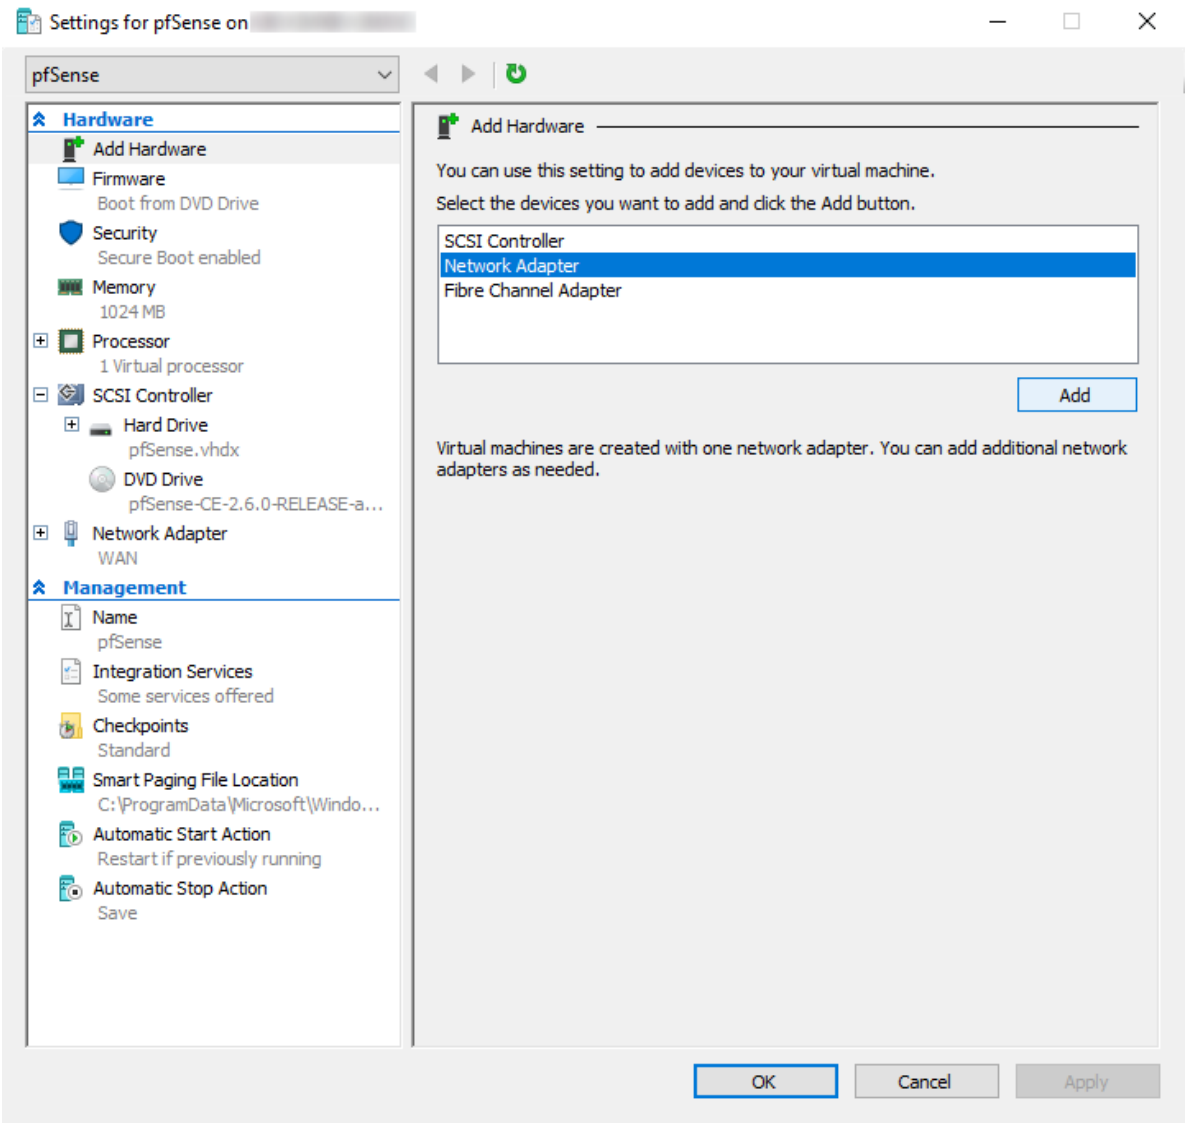
- Click **Next** to display the summary at the end of the wizard
- Review the virtual machine information



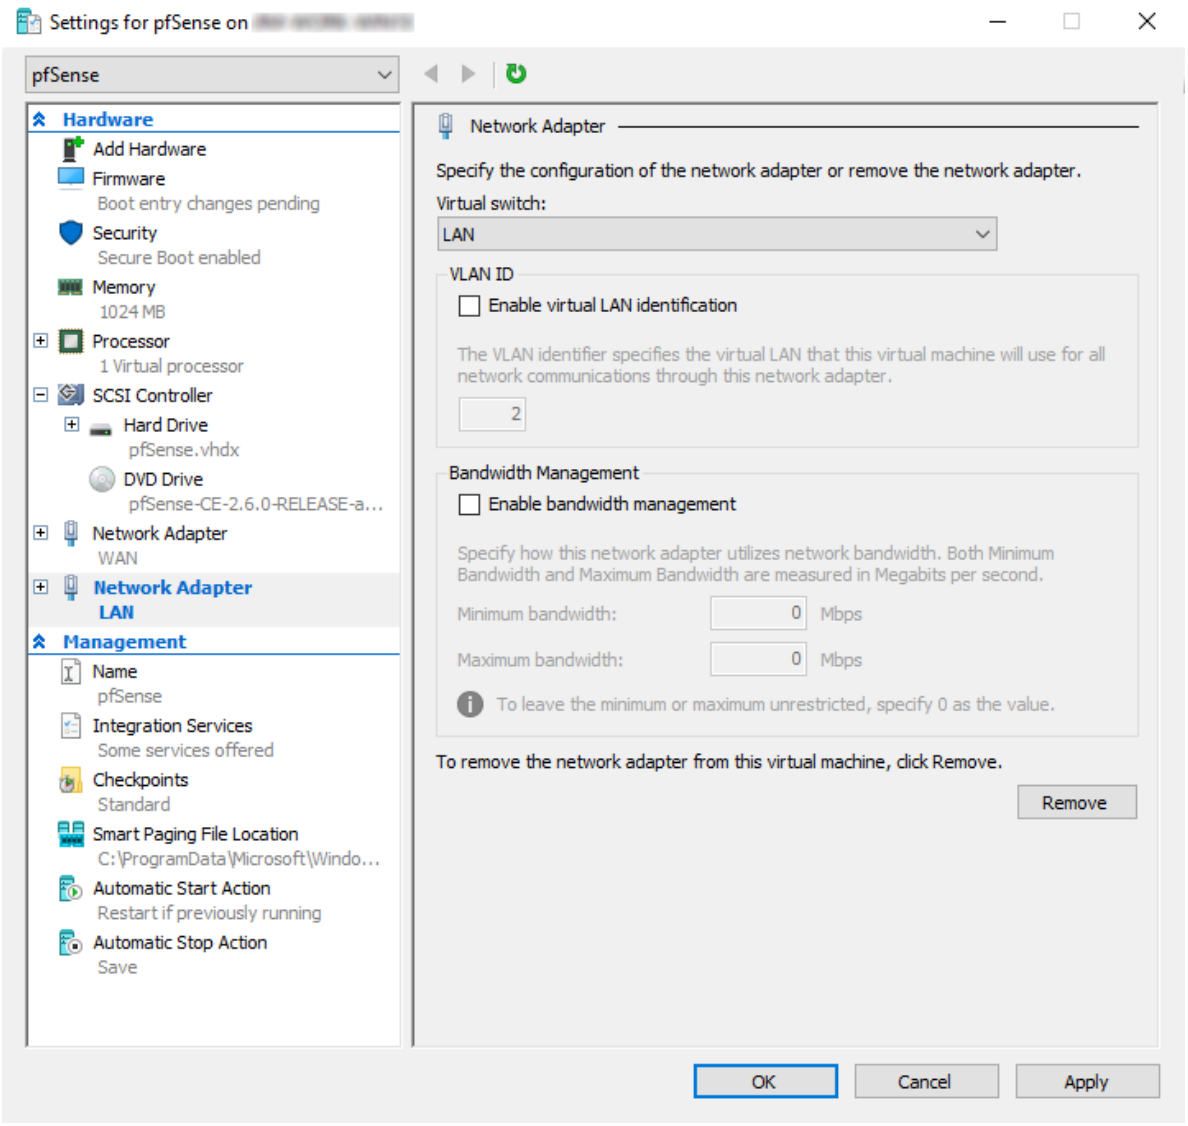
- Click **Finish** if all of the information is correct

This completes the wizard but there are several items which must be set on the VM for it to successfully install and boot pfSense software.

- Select the VM in the **Virtual Machines** list in the Hyper-V Manager
- Click **Settings** on the **Actions** panel for this VM
- Select **Add Hardware** under **Hardware** in the left side panel
- Select **Network Adapter**

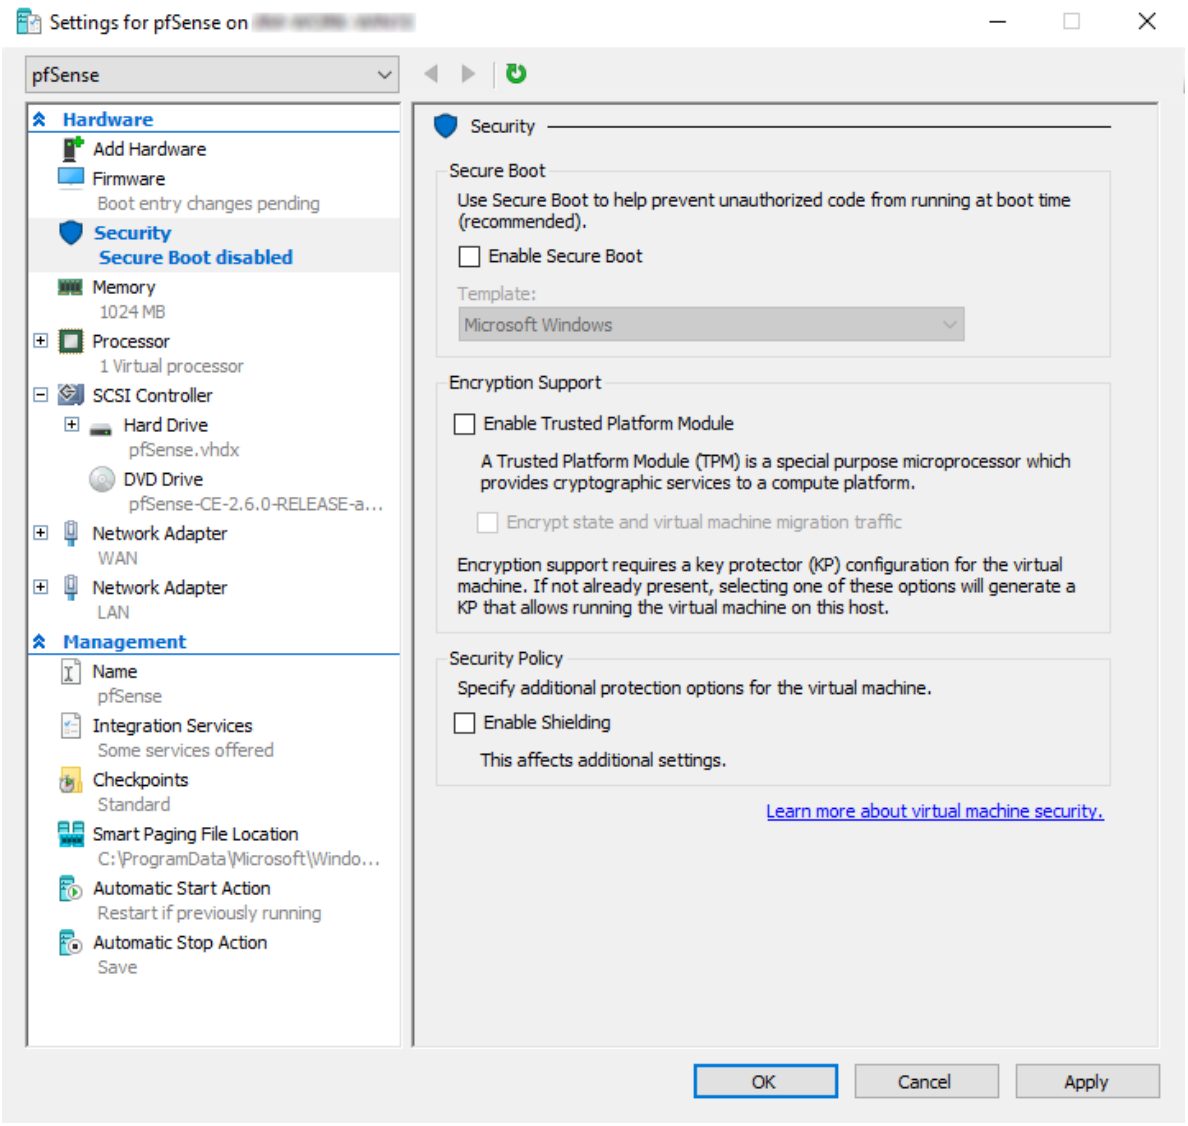


- Set the **Virtual Switch** to the *LAN* switch created earlier

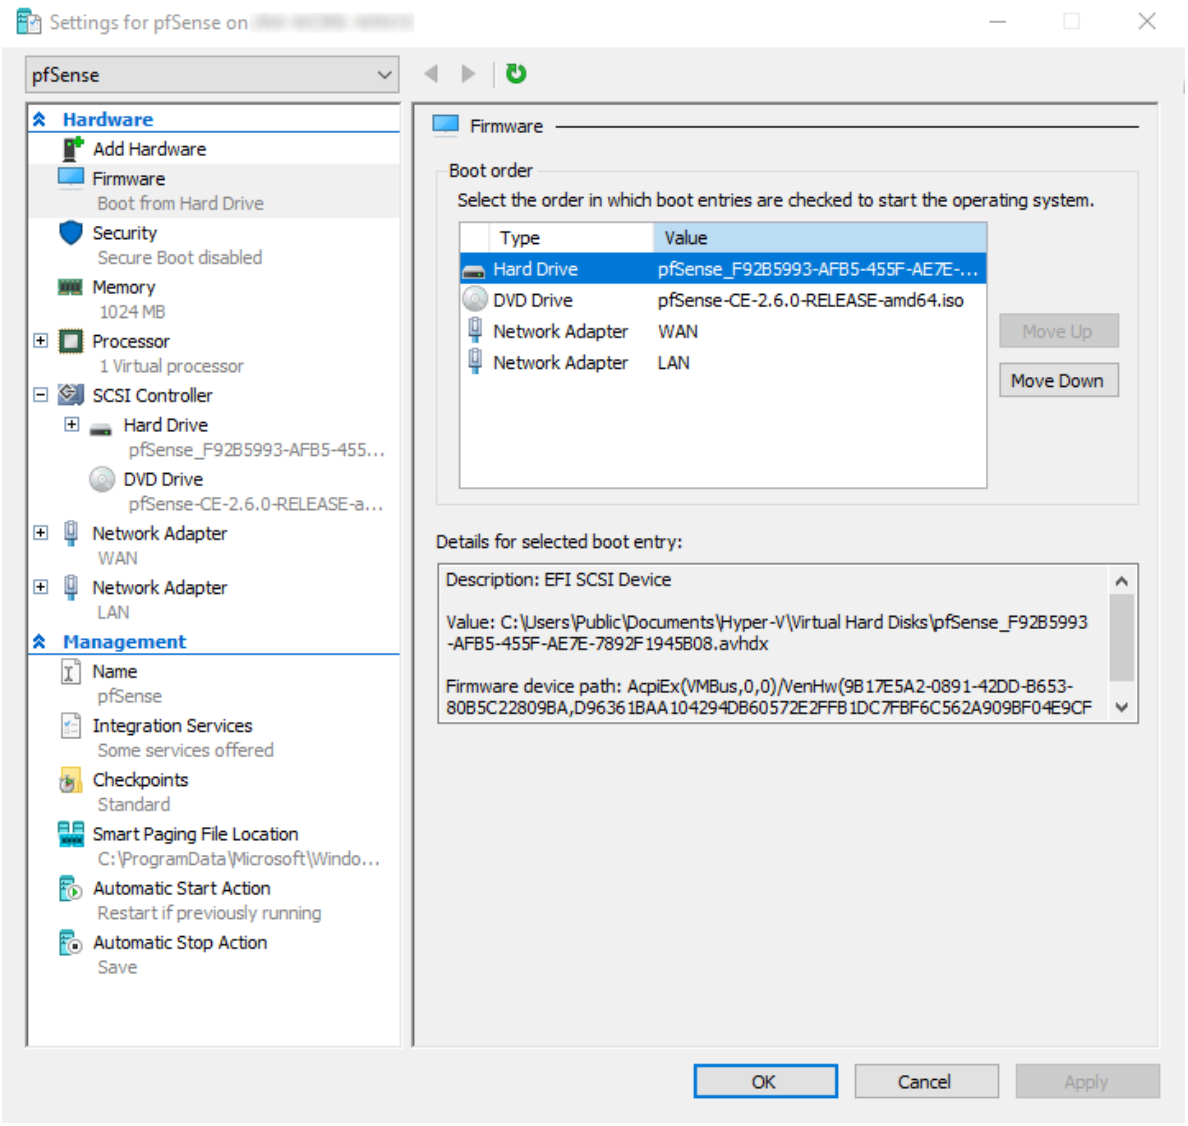


- Click **Apply**
- Select **Security** under **Hardware** in the left side panel
- Uncheck **Enable Secure Boot**

> **Warning:** Secure boot must be disabled for the VM to boot pfSense software.



- Click **Apply**
- Select **Firmware** under **Hardware** in the left side panel
- Select the **Hard Drive** entry in the **Boot Order** list
- Click **Move Up** until the **Hard Drive** entry is at the *top* of the list

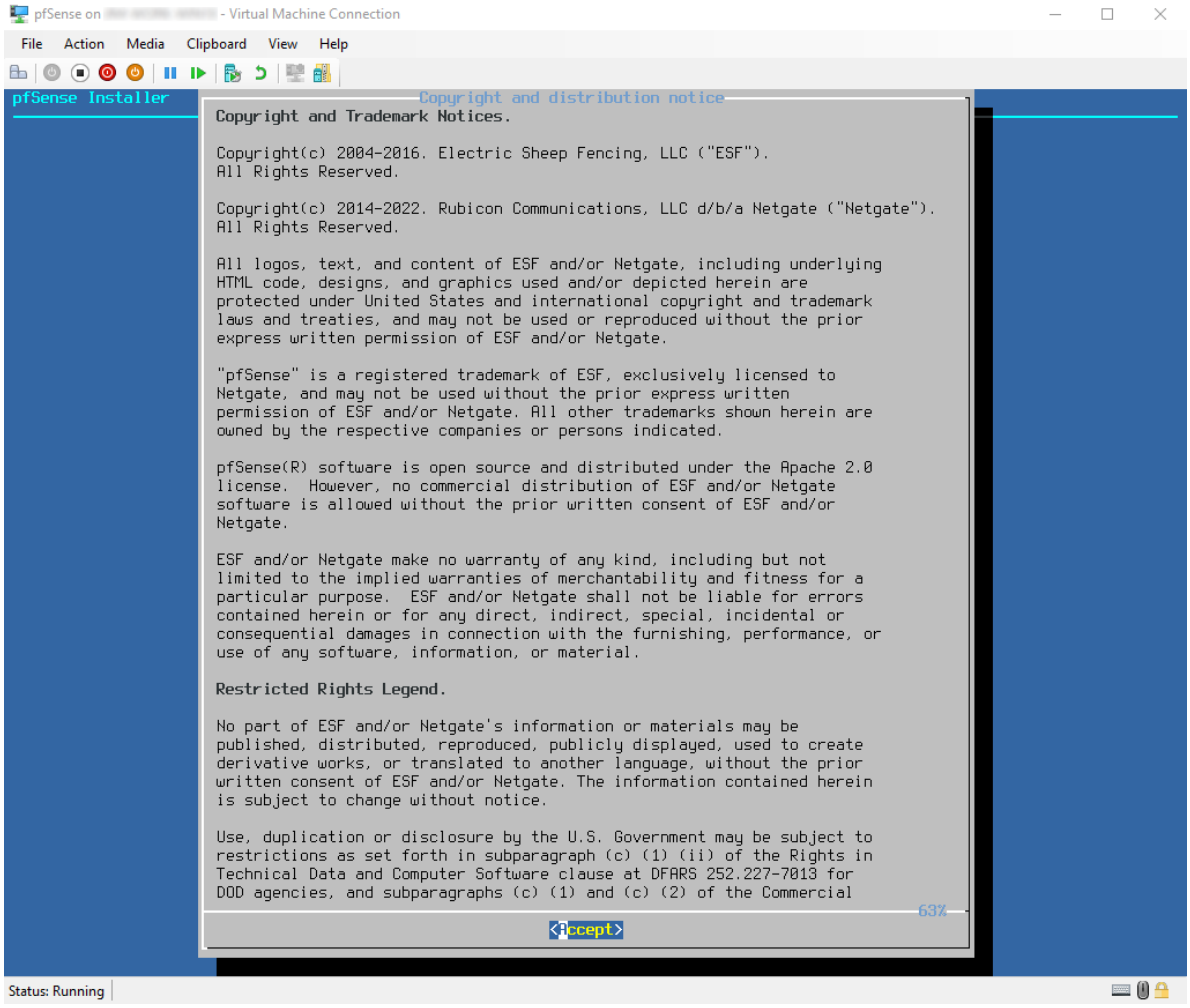


- Click **Apply**
- Review the other VM settings and make the WAN and LAN switches are selected under the respective network adapters
- Click **OK**

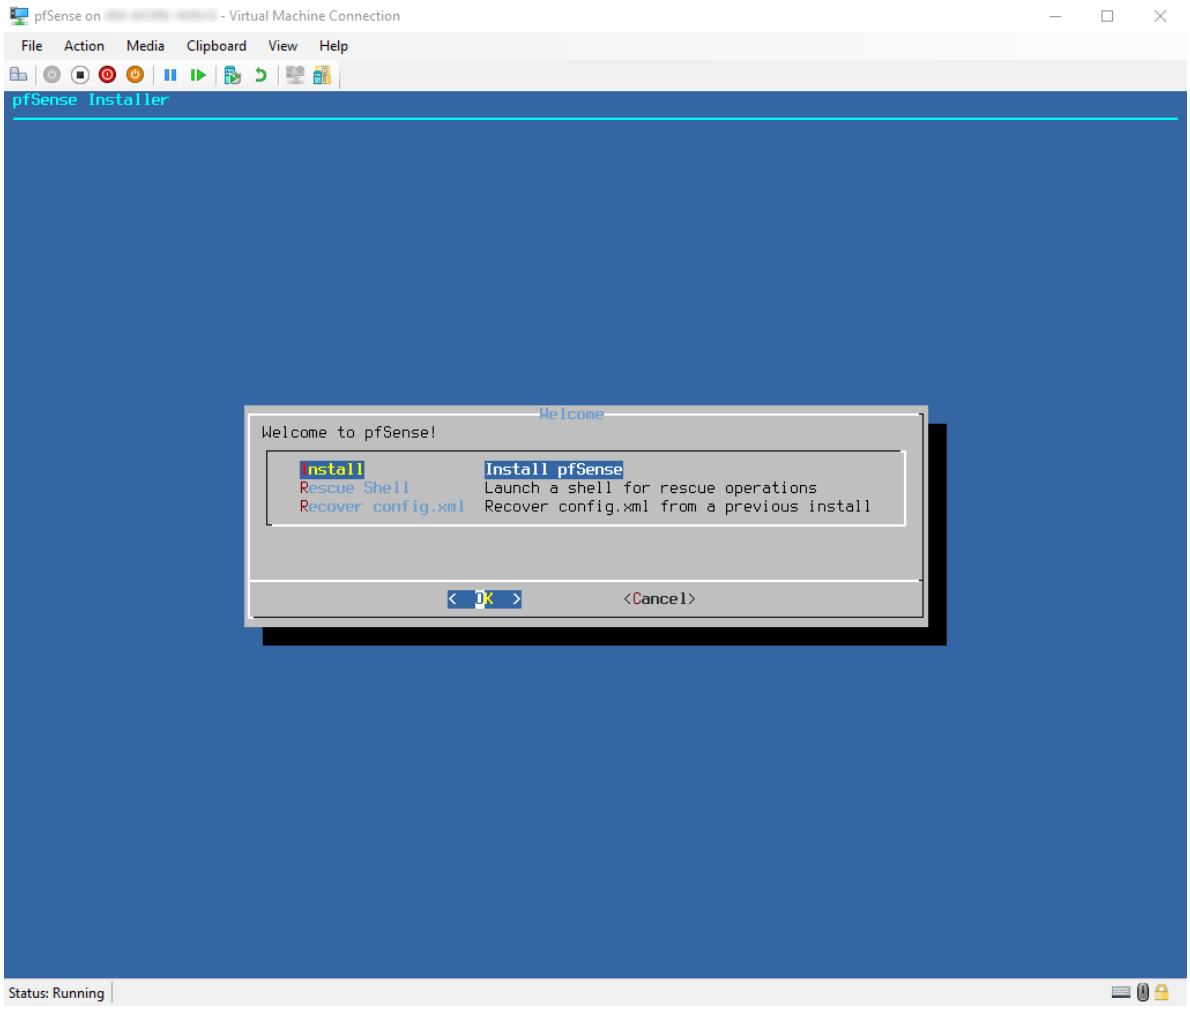
35.70.4 Installing pfSense Software

After successfully creating and configuring the pfSense software virtual machine, it's time to start it.

- Select the VM in the **Virtual Machines** list in the Hyper-V Manager
- Click **Start** from the VM menu in the **Actions** panel
- Click **Connect…** from the VM menu to open a console for the VM
- Wait for the virtual machine to boot and launch the installer



- Read and accept the EULA to display the installation menu



- Proceed through the installation as usual.

  See also:

  See *Installation Walkthrough* for a detailed walkthrough of the installation process.

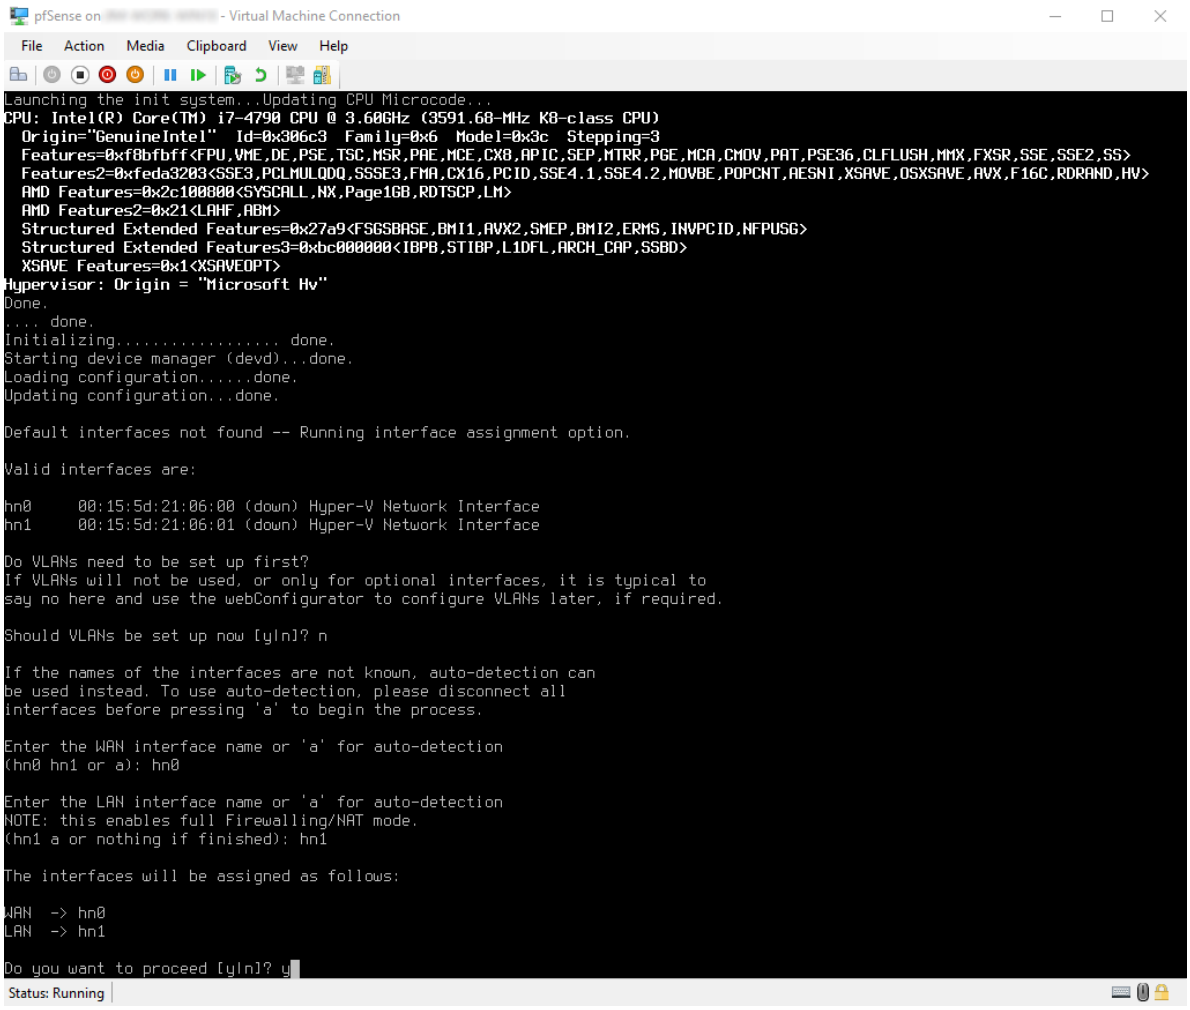
- Finish the installation, select reboot, and eject the ISO from the **Media** menu of the VM console

The VM will restart and begin its first boot.

35.70.5 First boot and interfaces assignment

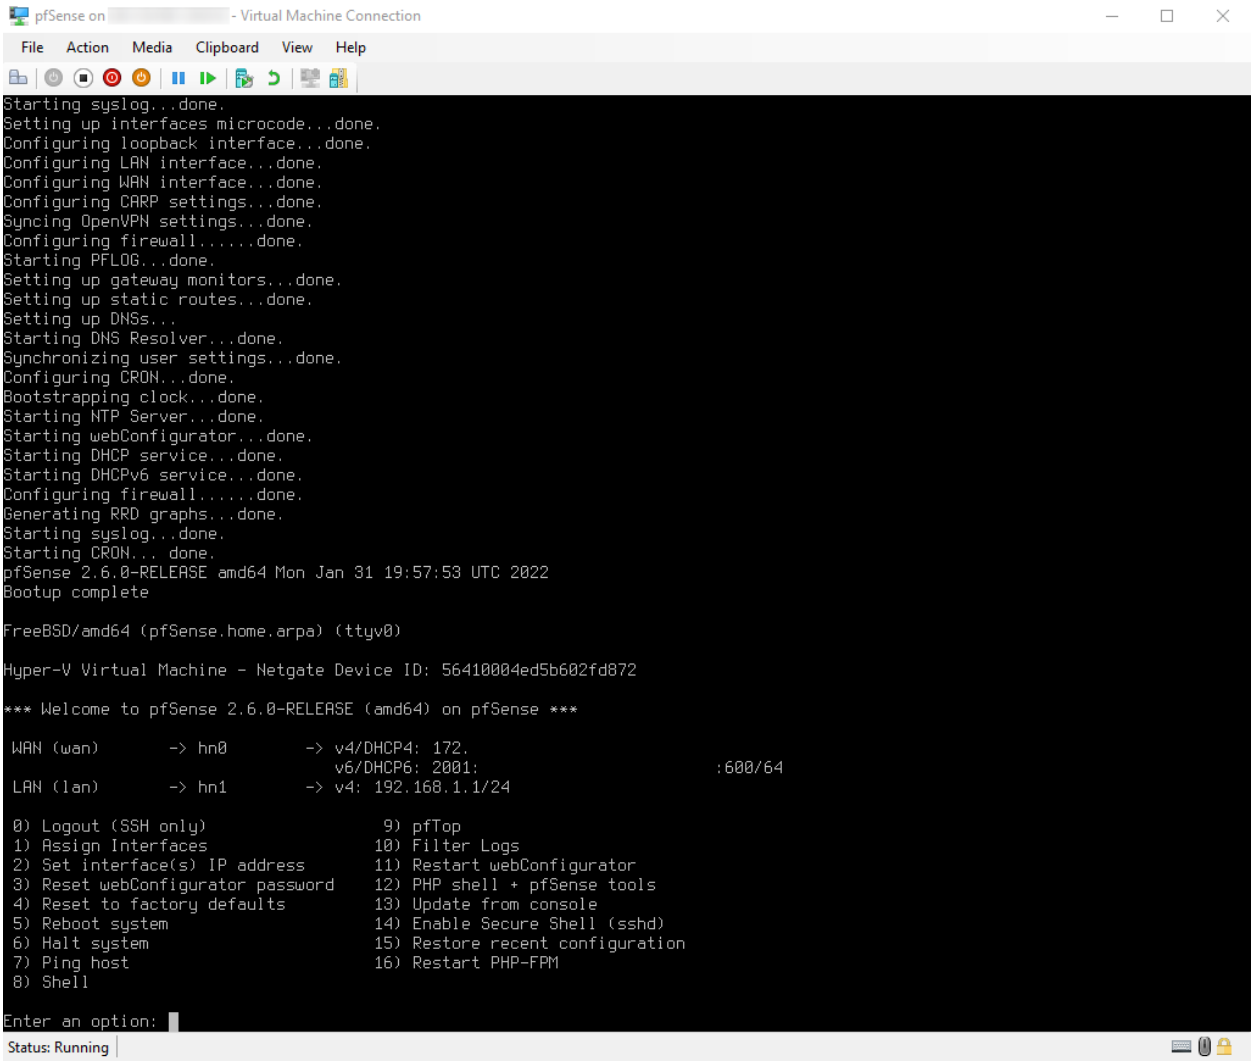
The pfSense software virtual machine should boot up quickly and prompt for interface assignments.

- Enter `n` and press the `Enter` key to skip the VLAN setup
- Enter `hn0` and press the `Enter` key when prompted for the name of the WAN interface
- Enter `hn1` and press the `Enter` key when prompted for the name of the LAN interface
- Enter `y` and press the `Enter` key to proceed



Tip: The MAC addresses printed on the console can be verified against the virtual machine settings to confirm which interface is which.

After assigning interfaces, pfSense software will finish the boot-up. Verify both interfaces have the correct IP addresses.



Congratulations! The virtual machine is now running pfSense software on Microsoft Hyper-V.

From here, proceed through the configuration process for pfSense software as usual. See *Configuration* for details.

35.71 Virtualizing with Proxmox® VE

This following article is about building and running pfSense® software on a virtual machine under Proxmox Virtual Environment (VE). The guide also applies to any newer Proxmox VE version. Article covers Proxmox VE networking setup and firewall virtual machine setup process. The guide does not cover how to install Proxmox VE.

A basic, working, virtual machine will exist by the end of this article.

35.71.1 Assumptions

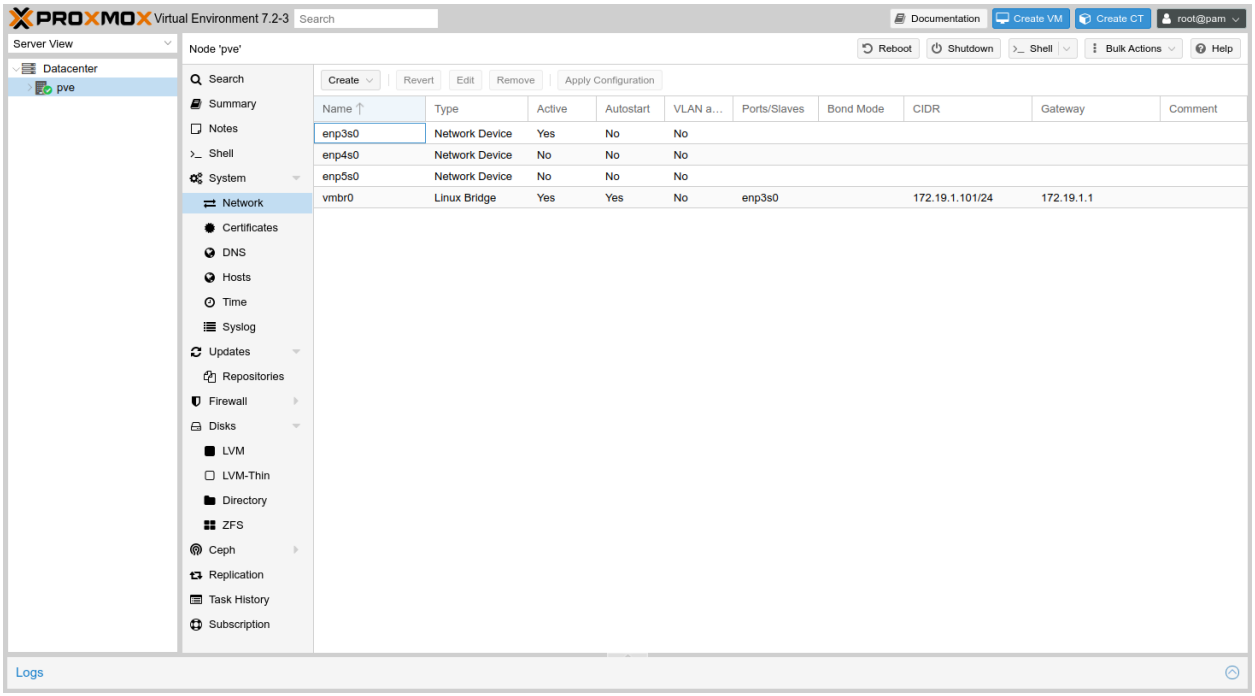
- Proxmox VE host is up and running
- Host has at least two network interfaces available for WAN and LAN.
- pfSense software ISO image is present on the Proxmox VE host

35.71.2 Basic Proxmox VE networking

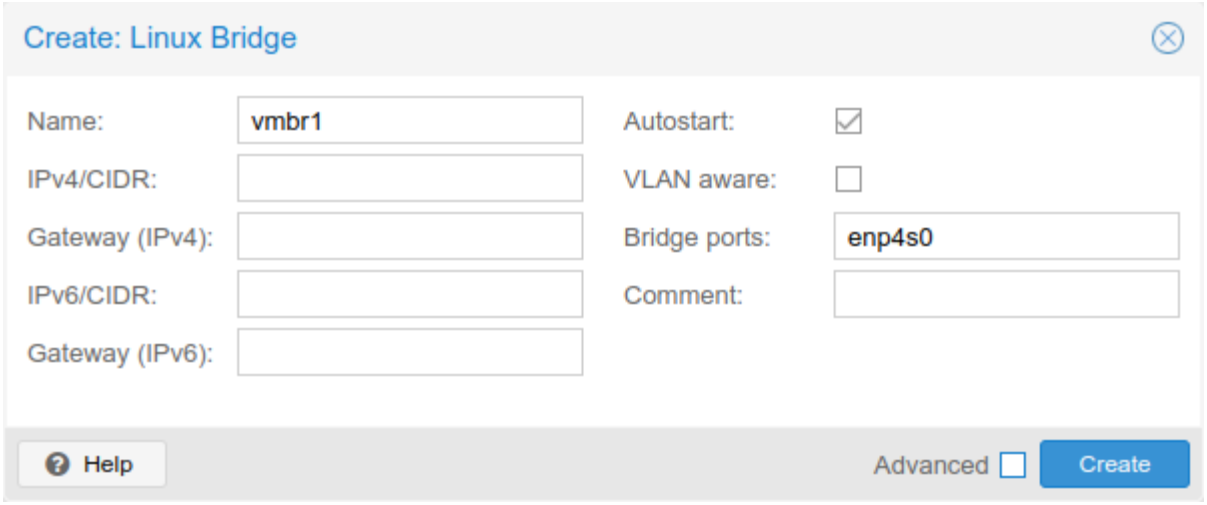
First create two Linux Bridges on Proxmox VE, which will be used for LAN and WAN on the firewall VM.

- Select the host from the server view
- Navigate to **System > Network**

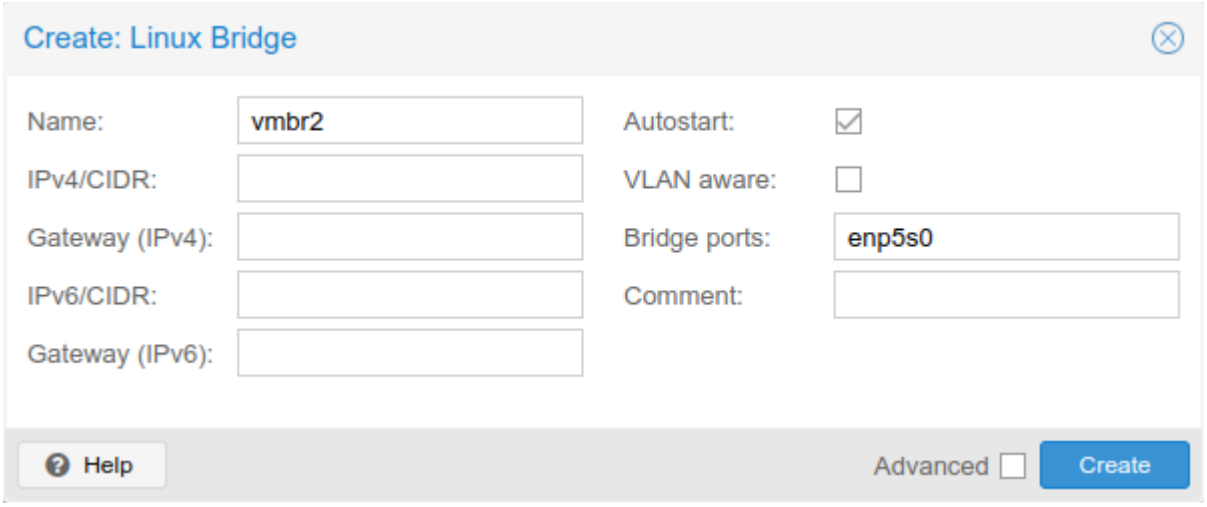
This example uses `enp4s0` and `enp5s0` interfaces for the firewall, while `enp3s0` is for Proxmox VE management. The naming of interfaces will vary depening on the hardware involved (interface type, bus location, etc.).



- Click **Create**
- Select Linux Bridge
- Enter `enp4s0` under **Bridge ports**



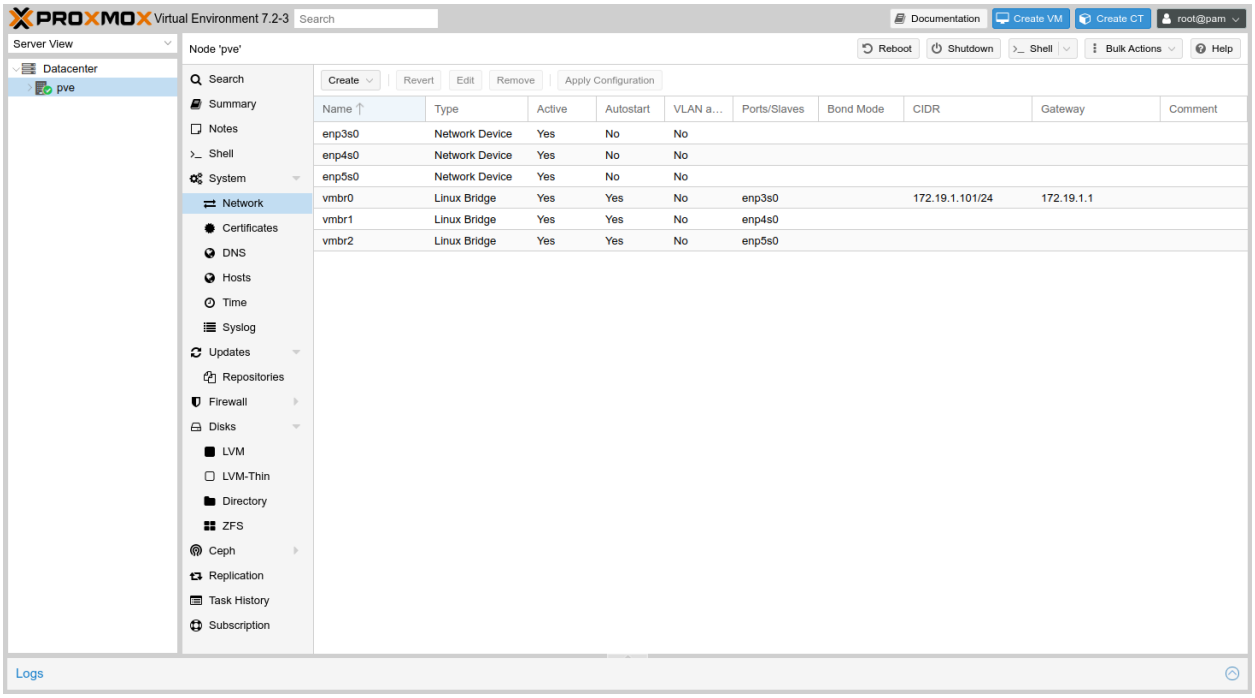
Repeat the process to add another Linux Bridge, this time add `enp5s0` under **Bridge ports**.



- Click **Apply Configuration** to configure the new interfaces in the OS
- Click **Yes** to confirm the action

Proxmox VE networking should now display two Linux bridges like on the following screenshot.

Note: If the interfaces do not show as **Active**, reboot the Proxmox VE host.



35.71.3 Creating a Virtual Machine

After creating WAN and LAN Linux bridges, now proceed to create a new virtual machine.

- Click **Create VM** from the top right section to display the new virtual machine wizard
- Navigate to the **General** tab
- Enter a **Name** for the VM (e.g. `firewall`)
- Navigate to the **OS** tab
- Set the following options:

  Use CD/DVD disc image file
  Selected

  Storage
  local

  ISO image
  Select the previously uploaded ISO image

  Guest OS Type
  Other

- Navigate to the **System** tab
- Set the following options:

  Graphic card
  SPICE

  Note: The SPICE console uses less CPU when idle and supports more advanced console features than the default console. It is compatible with the VNC Proxmox VE console as well as the more

advanced virt-viewer console application.

- Navigate to the **Hard Disk** tab
- Set the following options:

  Bus/Device
  VirtIO Block

  Disk Size
  Enter an appropriate disk size, no less than `8` GB.

- Navigate to the **CPU** tab
- Set the following options:

  Socket
  `1`

  Cores
  `1` or more cores as needed

  Type
  Host to match the CPU on the hypervisor hardware.

  Extra CPU Flags
  These settings adjust the CPU capabilities and behavior of the guest. If using **Host** for **Type** these can likely be left at the default.

  When setting a CPU type other than **Host**, consider setting the **AES** flag to **+** (**On**) which allows the guest to use AES-NI (*Cryptographic Accelerator Support*).

- Navigate to the **Memory** tab
- Set the following options:

  Memory
  At least `1024` MB

- Navigate to the **Network** tab
- Set the following options:

  Bridge
  vmbr1

  Model
  VirtIO (paravirtualized)

- Navigate to the **Confirm** tab
- Review the settings and make any final corrections if necessary
- Click **Finish**
- Wait for the VM creation process to finish

Now add another network adapter to the VM:

- Expand the **Server View** list on the left to show the contents under **Datacenter** and the name of this hypervisor node (e.g. **pve**, **proxmox**, etc.)
- Select the newly created virtual machine from list
- Click **Hardware** in the right pane

- Click **Add**
- Click **Network Device**
- Set the following options:

  Bridge
  vmbr2

  Model
  VirtIO (paravirtualized)

- Click **Add**

Review the hardware list for the VM and confirm it now contains two network interfaces.

35.71.4 Starting and configuring the virtual machine

After creating a new virtual machine and adding network interfaces, it is time to start the virtual machine.

- Expand the **Server View** list on the left to show the contents under **Datacenter** and the name of this hypervisor node (e.g. **pve**, **proxmox**, etc.)
- Select the newly created virtual machine from list
- Click **Start**
- Click **Console** on the left, under **Summary**

Note: The **Console** button at the top will launch the console in a new window, which depending on the settings may require an additional client installation such as virt-viewer.

When the VM starts it will boot into the installer automatically. From there, follow the installation steps as usual, and reboot when finished.

See also:

See *Installation Walkthrough* for a detailed walkthrough of the installation process.

After the virtual machine reboots, the console will stop at an interfaces assignment prompt.

- Type `n` and press `Enter` to skip VLAN configuration
- Enter `vtnet0` for WAN
- Enter `vtnet1` for LAN
- Press `Enter` if prompted for additional interfaces
- Type `y` and press `Enter` to complete the interface assignment

After interfaces have been assigned, the VM will complete the boot process.

35.71.5 Disable Hardware Checksums with Proxmox VE VirtIO

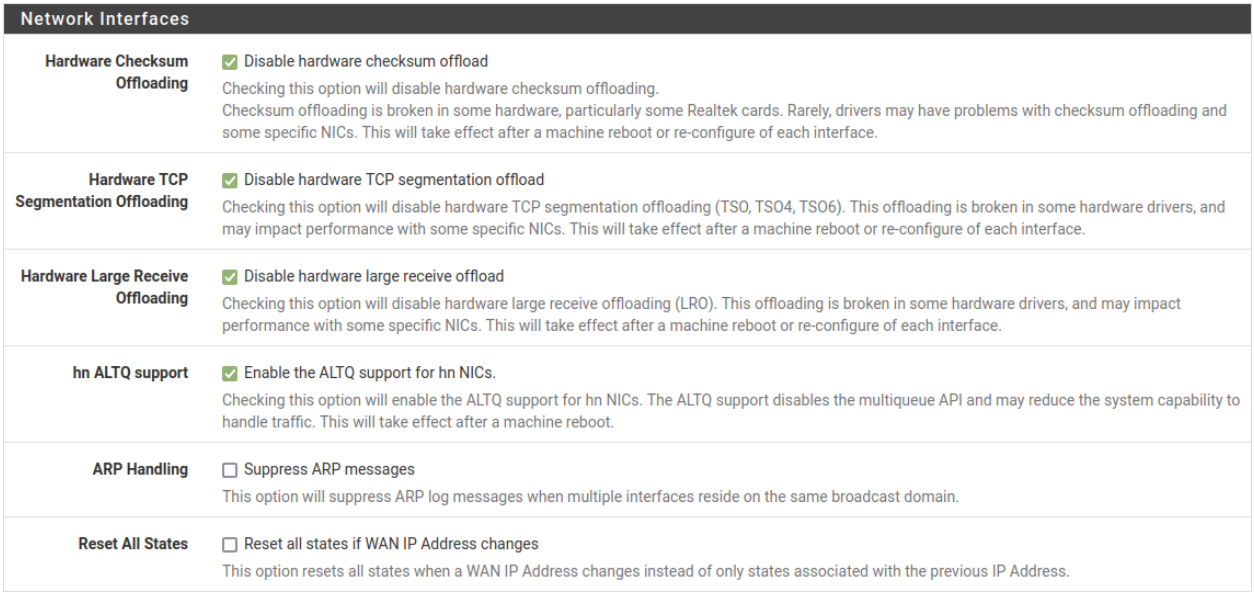
When using VirtIO interfaces in Proxmox VE, network interface hardware checksum offloading **must** be disabled. Current versions of pfSense software attempt to disable this automatically for `vtnet` interfaces, but the best practice is to double check the setting in case changes in Proxmox VE result in the automatic process failing.

> **Warning:** Do not skip this step, otherwise the virtual machine will not properly pass traffic. Accessing the firewall may be sluggish at first, but changing this setting will correct that as well.

After the installation and interfaces assignment processes are complete, connect to the assigned LAN port from another computer or VM on the LAN-side bridge.

To disable hardware checksum offload:

- Navigate to **System > Advanced**, **Networking** tab
- Locate the **Networking Interfaces** section
- Check **Disable hardware checksum offload**
- Click Save
- Reboot the firewall from **Diagnostics > Reboot** or the console menu



Congratulations, the virtual machine installation and configuration on Proxmox VE is now complete.

35.71.6 Booting UEFI

pfSense software can boot UEFI in a Proxmox VE guest but doing so requires a few extra steps.

When creating the VM:

- Set **Machine** to **q35**
- Set **BIOS** to **OVMF (UEFI)**
- Add an EFI disk when prompted

- Pick the storage for the EFI disk, other settings can remain at defaults

---

Note: An existing non-UEFI VM can be reconfigured to boot UEFI with these settings on its **Hardware** but the process is more error prone. For example, the EFI disk is a separate manual process and not semi-automated as it is when creating a VM.

After creating the VM:

- Edit the VM Hardware and add a serial port device

  Note: On some versions of pfSense software the EFI boot process for a ProxMox VE VM works more reliably with a serial port present in the VM hardware, even if the OS is not actively using the port.

On the first boot, go into the boot settings and disable secure boot:

- Hit `Esc` while the boot splash screen is visible
- Select **Device Manager**
- Select **Secure Boot Configuration**
- Uncheck **Attempt Secure Boot**
- Press `F10` to save
- Press `Esc` to exit
- Reset the VM

With secure boot disabled the VM can now boot with UEFI from the ISO as well as after installation.

35.72 General

- *Basic Firewall Configuration Example*
- *Blocking Web Sites*
- *Using an External Wireless Access Point*
- *Using Software from FreeBSD*
- *Using NAT and FTP without a Proxy*
- *Configuring pfSense Software for Online Gaming*
- *Migrating an Assigned LAN to LAGG*
- *Accessing a CPE/Modem from Inside the Firewall*
- *Exporting NetFlow with softflowd*
- *Configuring Switches with VLANs*
- *Using the Shaper Wizard to Configure ALTQ Traffic Shaping*
- *Configuring CoDel Limiters for Bufferbloat*
- *Copy Files to a USB Drive*
- *Diagnostic Data for Support*
- *Changing Credentials and Keys*

- *WAN Connectivity with 802.1X Authentication Bridging and VLAN 0 PCP Tagging*

35.73 DNS

- *Configuring DNS over TLS*
- *Configuring BIND as an RFC 2136 Dynamic DNS Server*
- *Blocking External Client DNS Queries*
- *Redirecting Client DNS Requests*

35.74 Authentication

- *Accessing the Firewall Filesystem with SCP*
- *Granting Users Access to SSH*
- *External User Authentication Examples*
- *Authenticating Users with Google Cloud Identity*
- *Using EAP and PEAP with FreeRADIUS*
- *Using Mobile One-Time Passwords with FreeRADIUS*
- *Authenticating from Active Directory using RADIUS/NPS*

35.75 Firewall/NAT

- *Allowing Remote Access to the GUI*
- *Preventing RFC 1918 Traffic from Exiting a WAN Interface*
- *Accessing Port Forwards from Local Networks*
- *Configuring NAT for a VoIP PBX*
- *Configuring NAT for VoIP Phones*
- *Configuring NAT64 for IPv6-only Clients*

35.76 Routing

- *Dynamic Routing Protocol Basics*
- *Configuring IPv6 Through A Tunnel Broker Service*
- *Configuring Multi-WAN for IPv6*
- *Routing Public IP Addresses*

35.77 High Availability

- *High Availability Configuration Example*
- *Converting High Availability DHCP from ISC to Kea*
- *High Availability Configuration Example with Multi-WAN*
- *High Availability Configuration Example without NAT*

35.78 IPsec

- *IPsec Site-to-Site VPN Example with Pre-Shared Keys*
- *IPsec Site-to-Site VPN Example with Certificate Authentication*
- *IPsec Remote Access VPN Example Using IKEv2 with EAP-MSCHAPv2*
- *IPsec Remote Access VPN Example Using IKEv2 with EAP-RADIUS*
- *IPsec Remote Access VPN Example Using IKEv2 with EAP-TLS*
- *Configuring IPsec IKEv2 Remote Access VPN Clients*
- *IPsec Remote Access VPN Example Using IKEv1 with Xauth*
- *IPsec Remote Access VPN Example Using IKEv1 with Pre-Shared Keys*
- *Routing Internet Traffic Through a Site-to-Site IPsec Tunnel*

35.79 L2TP/IPsec

- *L2TP/IPsec Remote Access VPN Configuration Example*
- *Connecting to L2TP/IPsec from Android*

35.80 OpenVPN

- *OpenVPN Site-to-Site Configuration Example with SSL/TLS*
- *OpenVPN Site-to-Site Configuration Example with SSL/TLS and DCO*
- *OpenVPN Site-to-Site Configuration Example with Shared Key*
- *OpenVPN Remote Access Configuration Example*
- *Adding OpenVPN Remote Access Users*
- *Installing OpenVPN Remote Access Clients*
- *Authenticating OpenVPN Users with FreeRADIUS*
- *Authenticating OpenVPN Users with RADIUS via Active Directory*
- *Connecting OpenVPN Sites with Conflicting IP Subnets*
- *Routing Internet Traffic Through A Site-To-Site OpenVPN Tunnel*
- *Bridging OpenVPN Connections to Local Networks*

- *OpenVPN Site-to-Site with Multi-WAN and OSPF*

35.81 WireGuard

- *WireGuard Remote Access VPN Configuration Example*
- *WireGuard Site-to-Site VPN Configuration Example*
- *WireGuard Site-to-Multisite VPN Configuration Example*
- *WireGuard VPN Client Configuration Example*

35.82 Virtualization

- *Virtualizing pfSense Software with VMware vSphere / ESXi*
- *Virtualizing pfSense Software with Hyper-V*
- *Virtualizing with Proxmox® VE*

CHAPTER

THIRTYSIX

MENU GUIDE

36.1 System

The **System** menu contains choices for the firewall itself, general and advanced options, updates, add-on packages, users, and routing.

Advanced
Advanced settings for the firewall, hardware, SSH, notifications, tunables, and many others.

See *Advanced Configuration Options*.

Certificates
Manage Certificate Authorities, Certificates, and Certificate Revocation Lists (x.509).

See *Certificate Management*.

General Setup
General settings such as hostname, domain, and DNS servers.

See *General Configuration Options*.

High Availability
Controls how nodes running pfSense® software in a High Availability (HA) cluster synchronize states and configuration.

See *High Availability Synchronization Settings*.

Logout
Logs out of the GUI, returning the user back to the login screen.

See *User Management and Authentication*.

Package Manager
Additional software add-ons for pfSense software to expand its functionality.

See *Packages*.

Routing
Manage gateways, static routes, and gateway groups for using multiple WANs.

See *Routing*.

Setup wizard
The Setup Wizard performs the basic initial configuration.

See *Setup Wizard*.

Update
Upgrade pfSense software to the latest version.

See *Upgrading using the GUI*.

User Manager
Manage users, groups, and authentication servers (RADIUS or LDAP) for GUI access, VPN access, etc.

See *User Management and Authentication*.

User Password Manager
Self-service user password manager. Allows GUI users to change their own password.

See *User Password Manager*

User Settings
If per-user settings are enabled, this page provides a way for users to override default behavior options found under **General Setup**.

36.2 Interfaces

The **Interfaces** menu contains an entry for assigning interfaces along with entries for each currently assigned interface. Menu entries for assigned interfaces use the configured names, or the standard names if they have not been changed (e.g. WAN, LAN, OPTx)

Assignments
Assign interfaces to logical roles (e.g. WAN, LAN, OPT), and create/maintain VLANs and other types of virtual interfaces.

See *Interface Configuration*, *Interface Types and Configuration*, and *Virtual LANs (VLANs)*.

WAN
Configure the WAN interface.

See *Interface Configuration*.

LAN
Configure the LAN interface.

See *Interface Configuration*.

OPTx
Configure any additional optional interfaces.

See *Interface Configuration*.

36.3 Firewall

The **Firewall** menu entries configure firewall rules, NAT rules, and their supporting structure.

Aliases
Manages collections of IP addresses, networks, or ports to simplify rule creation and management.

See *Aliases*.

NAT
Manages NAT rules that control port forwards, 1:1 NAT, and Outbound NAT behavior.

See *Network Address Translation*.

Rules
Configures firewall rules. This page contains one tab for each configured interface, plus tabs for groups and different VPN types, when enabled.

See *Introduction to the Firewall Rules screen*.

Schedules
Manages time-based rule schedules.

See *Time Based Rules*.

Traffic Shaper
Manages traffic shaping/Quality of Service (QoS) settings.

See *Traffic Shaper*.

Virtual IPs
Configure Virtual IP addresses which allow pfSense® software to handle traffic for more than one IP address per interface, typically for NAT rules or High Availability.

See *Virtual IP Addresses*.

36.4 Services

The **Services** menu contains items which control services provided by daemons running on the firewall.

See also:

Services

Auto Config Backup
Configures the automatic configuration backup service which optionally uploads encrypted configuration backups for secure off-site backups.

See *Automatic Configuration Backup Service*.

Captive portal
Controls the Captive Portal service which directs users to a web page for authentication before permitting Internet access.

See *Captive Portal*.

DHCP relay
Configures the DHCP relay service which proxies DHCP requests from one network segment to another.

See *DHCPv4 & DHCPv6 Relay*.

DHCP server
Configures the DHCP service which provides automatic IP address configuration for clients.

See *DHCPv4 Server*.

DHCPv6 Relay
Configures the DHCP relay service for IPv6 which proxies DHCPv6 requests from one network segment to another.

See *DHCPv4 & DHCPv6 Relay*.

DHCPv6 Server
Configures the DHCP service for IPv6 which provides automatic IPv6 address configuration for clients.

See *DHCPv6 Server*.

DNS Forwarder
Configures the built-in caching DNS forwarder.

See *DNS Forwarder*.

DNS Resolver
Configures the built-in caching DNS resolver.

See *DNS Resolver*.

Dynamic DNS
Configures Dynamic DNS services ("dyndns") which updates a remote name server when the WAN IP address of this firewall changes.

See *Dynamic DNS*.

IGMP Proxy
Configures the Interior Group Management Protocol proxy for passing multicast traffic between interfaces.

See *IGMP Proxy*.

NTP
Configures the Network Time Protocol server daemon.

See *NTPD*.

PPPoE Server
Configures the PPPoE server which accepts and authenticates connections from PPPoE clients on local networks.

See *PPPoE Server*.

Router Advertisement
Configures IPv6 Router Advertisement behavior which provides IPv6 routing and address configuration for clients.

See *IPv6 Router Advertisements*.

SNMP
Configures the Simple Network Management Protocol (SNMP) daemon to allow network-based collection of statistics from this firewall.

See *SNMP*.

UPnP IGD & PCP
Configures the Universal Plug and Play (UPnP IGD) & Port Control Protocol (PCP) service which automatically configures NAT and firewall rules for devices which support the UPnP IGD or PCP standards. This menu entry only appears when the firewall contains more than one assigned interface.

See *UPnP IGD & PCP*.

Wake on LAN
Configures Wake on LAN entries which remotely wake up local client devices.

See *Wake on LAN*.

36.5 VPN

The **VPN** menu contains items pertaining to Virtual Private Networks (VPNs), including IPsec, OpenVPN and L2TP.

See also:

Virtual Private Networks

IPsec
Configure IPsec VPN tunnels, mobile IPsec, and IPsec settings.

See *IPsec*.

L2TP
Configure L2TP services and users.

See *L2TP VPN*.

OpenVPN
Configure OpenVPN servers and clients, as well as client-specific configuration.

See *OpenVPN*.

36.6 Status

The **Status** menu entries display status information and logs for various system components and services.

Captive Portal
When Captive Portal is enabled, this entry shows user and voucher status.

See *Captive Portal Status*.

CARP (failover)
Shows the status of CARP IP addresses on this firewall, such as MASTER/BACKUP state for each CARP VIP. Also has controls for HA maintenance mode.

See *CARP Status*.

Dashboard
A shortcut back to the main page of the firewall GUI, which displays general system information.

See *Dashboard*.

DHCP leases
Shows a list of all IPv4 DHCP leases assigned by this firewall and provides controls based on those leases, such as adding static mappings.

See *DHCPv4 Leases*.

DHCPv6 leases
Shows a list of all IPv6 DHCP leases assigned by this firewall.

See *DHCPv6 Status*.

DNS Resolver
Shows the contents of the DNS resolver infrastructure cache.

See *DNS Resolver Status*.

Filter Reload
Shows the status of the last filter reload request, including active reload actions. Also provides a means to force a filter reload, and to force an XMLRPC configuration sync when HA is configured.

See *Filter Reload Status*.

Gateways
Shows the status of gateways, and gateway groups for multiple WANs.

See *Gateway Status*.

Interfaces
Shows the hardware status for network interfaces, equivalent to using `ifconfig` on the console.

See *Interface Status*.

IPsec
Shows the status of any configured IPsec tunnels.

See *IPsec Status*.

Monitoring
Shows graphed data for system statistics such as bandwidth used, CPU usage, firewall states, etc.

See *Monitoring Graphs*.

NTP
Shows the status of the Network Time Protocol server daemon.

See *NTP Daemon Status*.

OpenVPN
Shows the status of any configured OpenVPN instances.

See *OpenVPN Server and Client Status*.

Queues
Shows the status of traffic shaping queues.

See *ALTQ Traffic Shaper Queue Monitoring*.

Services
Shows the status of system and package service daemons.

See *Service Status*.

System logs
Shows logs from the system and system services such as the firewall, DHCP, VPNs, etc.

See *System Logs*.

Traffic graph
Displays a dynamic real-time traffic graph for an interface.

See *Traffic Graphs*.

UPnP IGD & PCP
Shows a list of any currently active UPnP IGD & PCP port forwards. This entry is only present when the firewall contains more than one interface.

See *UPnP IGD & PCP Status*.

Wireless
Shows a list of any currently available wireless networks in range, along with signal levels. This menu entry is only present if the firewall has an assigned wireless interface.

See *Wireless Status*.

36.7 Diagnostics

Items under the **Diagnostics** menu perform various diagnostic and administrative tasks.

ARP Table
Displays a list of devices as seen locally by the firewall. The list includes an IP address, MAC address, Hostname, the Interface where the device was seen, and other related information.

See *ARP Table*.

Authentication
Tests authentication to a defined RADIUS or LDAP server.

See *Troubleshooting Authentication*.

Backup & Restore
Backup and restore configuration files.

See *Backup and Recovery*.

Command Prompt
Execute shell commands or PHP code, and upload/download files to/from the firewall.

> **Warning: Use with caution**

See *Command Prompt*.

DNS Lookup
Executes a DNS lookup to resolve hostnames for diagnostic purposes, and to test connectivity to DNS servers.

See *DNS Lookup*.

Edit File
Edit a file on the firewall filesystem.

See *Editing Files on the Firewall*.

Factory defaults
Resets the configuration back to default. Be aware, however, that this does not alter the filesystem or uninstall package files; it only changes configuration settings.

See *Resetting to Factory Defaults*.

GEOM Mirrors
If the firewall contains a GEOM disk mirror, this page shows the status of the mirror and provides controls for managing the mirror.

Halt system
Shuts down the firewall and turns off the power where possible.

See *Halting and Powering Off the Firewall*.

Limiter Info
Shows the status of any Limiters and the traffic flowing inside them.

See *Checking Limiter Usage*.

NDP Table
Shows a list of local IPv6 devices as seen by the firewall. The list includes an IPv6 address, MAC address, hostname (if known to the firewall), and the interface.

See *NDP Table*.

Packet Capture
Perform a packet capture to inspect traffic, and then view or download the results.

See *Packet Capture GUI*.

pfInfo
Displays statistics about the packet filter, including general traffic rates, connection rates, state table info, and various other counters.

See *pfInfo*.

pfTop
Displays a list of the top active connections by a selectable metric such as bytes, rate, age, etc.

See *pfTop*.

Ping
Sends ICMP echo requests to a given IP address, sent via a chosen interface.

See *Ping Host*.

Reboot
Reboots the firewall. This can take several minute to complete, depending on the hardware and enabled features.

See *Rebooting the Firewall*.

Routes
Shows the contents of the routing table.

See *Route Table Contents*.

SMART Status
Displays diagnostic information about disk drives, if supported by the hardware. Can also run drive tests.

See *S.M.A.R.T. Hard Disk Status*.

Sockets
Displays a list of processes on the firewall that are bound to network ports, listening for connections or making connections outbound from the firewall itself.

See *Viewing Active Network Sockets*.

States
Shows the currently active firewall states.

See *Viewing Firewall States in the GUI*.

States Summary
Displays information about the state table, to see activity summarized by IP address.

See *Firewall States Summary*.

System Activity
Shows memory usage and a list of active processes and system threads on the firewall, the output is from `top -aSH`.

See *System Activity (Top)*.

Tables
Displays and edits the contents of various firewall tables and aliases.

See *Firewall Table Contents*.

Test Port
Performs a simple TCP connection test from the firewall to determine if a remote host is accepting connections on a specified port.

See *Testing a TCP Port*.

Traceroute
Trace the route taken by packets between this firewall and a remote system.

See *Traceroute*.

This section is a guide to the standard menu choices available in pfSense® software. This guide will help to quickly identify the purpose of a given menu option, and refer to places in the documentation where those options are discussed in further detail.

Packages can add items to any menu, so check each menu or consult the documentation for a package to locate its menu entries. Typically, packages install entries under the **Services** menu, but there are numerous exceptions.

CHAPTER

THIRTYSEVEN

GLOSSARY OF TERMS

DNS
An acronym for Domain Name System.

ICMP
An acronym for Internet Control Message Protocol.

HTTP
An acronym for Hypertext Transfer Protocol.

IP
An acronym for Internet Protocol.

LAN
An acronym for Local Area Network.

NAT
An acronym for Network Address Translation.

SSH
An acronym for Secure Shell.

TCP
An acronym for Transmission Control Protocol.

UDP
An acronym for User Datagram Protocol.

WAN
An acronym for Wide Area Network.

VM
An acronym for Virtual Machine.

VPN
An acronym for Virtual Private Network.

Note: Though technically abbreviations read letter by letter are initialisms, not acronyms, this document refers to both as acronyms to be more accessible to readers.

CHAPTER

THIRTYEIGHT

DEVELOPMENT

These articles cover advanced topics related to developing on or with pfSense® software.

38.1 General Development Information

38.1.1 Software Release Schedule

pfSense Plus software typically targets 3 releases per year but the schedule varies based on complexity of development for a given release.

Releases for pfSense® CE software are made when they are ready. A public schedule is not available at this time, but release announcements and progress messages are made on the Netgate Blog.

See also:

Some information on upcoming releases can be found in *Versions of pfSense software and FreeBSD*.

Netgate provides maintenance releases of pfSense CE software as needed, typically a couple per year. These include primarily bug fixes and security updates.

To follow the progress of a release, visit the pfSense Redmine.

38.1.2 Reporting Issues with pfSense Software

This page serves as a guide for providing legitimate bug reports with pfSense® software. Most of the bug reports from outside users are not bugs at all, but incorrect configurations. Often user reports do not contain nearly enough information for a developer to replicate the problem. If a bug report does not contain the appropriate information to verify a legitimate bug, developers have no choice but to reject the report.

> **Attention:** The pfSense Redmine site is not a discussion platform and is never to be used for support requests.

The first step is typically to ask about the problem using one of the available support resources, such as the Netgate Forum. An issue report can be opened If a specific bug is found that can be reproduced by developers.

An example of an invalid bug report is `XYZ doesn't work!` without appropriate accompanying detail. An alternative, to make that a legitimate bug report, is:

```
Subject:
  Feature XYZ generates an invalid configuration for option A on
  ``thispage.php``
```

(continues on next page)

(continued from previous page)

```
Description:
  The underlying @xyz.conf@ has @option1=1@ where it should be @option1=5@
  when option A is checked on @thispage.php@ in the web interface.
```

See also:

How to report bugs effectively.

Where to submit

For anything that is not a confirmed, specific, detailed bug report, post to the Netgate Forum first. The forum is a platform where the problem can be discussed and the specifics required to replicate the issue can be identified.

After discussion and confirmation of a specific, legitimate bug report on the Netgate Forum, please open a ticket in the pfSense Redmine, including a link back to the discussion in question.

Attention: The pfSense Redmine site is not a discussion platform and is never to be used for support requests.

What to Include

When submitting a bug report to the pfSense Redmine site, fill out the report completely and include enough supporting information to reproduce the issue.

Use the following guidelines when completing the issue report.

File issues with the base system under pfSense and issues with packages under pfSense Packages.

Note: Not all fields will be available to all users.

Tracker
Use the appropriate issue tracker type, following these guidelines:

Bug
Problems, unexpected behavior, crashes, or when the other categories do not apply.

Regression
A function that worked previously but failed during development or when upgrading to a more recent release.

Feature
Feature requests or changes in (working) behavior.

Todo
Tasks or work that need to be completed that are not specifically bugs or features.

Subject
A brief but complete and accurate description of the problem. If the problem is specific to one page or file, prefix the subject with that page filename.

Example:

```
Save and Force Update button does not perform any action on ``services_
↪rfc2136_edit.php``
```

Description
A full description of the problem. Include any relevant detail, supporting evidence such as log entries, and if possible a complete recount of how to reproduce the bug that includes every necessary step.

> **Warning: Information in this issue tracker is public!** Do not include any personal information such as usernames, passwords, private certificates, keys, e-mail addresses, IP addresses, and so on. In the rare case when such information is helpful in diagnosing a problem, it can be transmitted privately.

- Please use appropriate formatting, such as `<pre>` tags around log data or command output. Attach lengthy output in a text file rather than including it inline in the description.
- Attach files with supporting information, such as logs or crash dumps, if relevant. Check for personal data before attaching files and obfuscate/mask info as needed.

Status
Leave this as *New*.

Priority
Leave this as *Normal* or set lower for minor issues.

> **Warning: Higher priorities must only be set by developers when appropriate**.

Assignee
Leave this **empty** unless directed by a developer to assign it to them directly.

Category
Pick the closest relevant category for the issue, if possible, or a generic category such as "Web Interface" for GUI issues and "Operating System" for OS issues.

Target Version/Plus Target Version
Leave this **empty** unless directed by a developer to assign a specific target.

> **Warning:** Developers will assign a target version after evaluating the issue.

Affected Version
Pick the version number of the firewall experiencing the issue.

Affected Architecture
Pick *All* unless the issue is known to only affect a single architecture.

Leave other fields **blank**, such as **Parent Task**, **Start/End Date**, and so on.

38.1.3 Obtaining Panic Information for Developers

Crash dump functionality is built into every kernel on current versions of pfSense® software, but behavior varies based on architecture. Crash dumps are automatically saved on installations with swap space, or printed to the console on other platforms (e.g. ARM).

Viewing and Submitting a Crash Dump

After a panic or crash leading to a reboot, the operating system attempts to recover the contents of the crash dump while booting back up.

If the OS was able to read and process the contents of the crash dump, it converts the crash dump into a crash report. The GUI then displays a prompt on the dashboard to view the contents of the crash report.

Note: For privacy reasons, crash reports cannot be automatically submitted to Netgate for review.

Download the report or copy the contents from the GUI, and review the included data to ensure there is no private or identifiable information inside. If the data is OK, create a post on the Netgate Forum with the contents of the crash report. Attaching the crash report archive file(s) from the GUI is the best practice as that yields the most information in the easiest format to read.

Note: At a minimum, include the backtrace portion of `ddb.txt` from the crash dump archive. The backtrace is located after `db:0:kdb.enter.default> bt` in that file.

Crash Dump Format

The crash dumps are in FreeBSD textdump format and held in `/var/crash` after the OS recovers the data.

Crash dump archives are named `textdump.tar.<n>` where `<n>` starts at `0` and is incremented if older archives are still present in `/var/crash`.

Crash dump archives contain the following files:

`config.txt`
: The kernel configuration file

`ddb.txt`
: The output from the debugger scripts run during the crash dump

`msgbuf.txt`
: The contents of the kernel message buffer (`dmesg`)

`panic.txt`
: The panic message, if available. Typically a more detailed version of this is found at the end of `msgbuf.txt`.

`version.txt`
: The kernel version string

Serial Console Crash Dump

On hardware with a serial console, connect to the serial console and record the scrollback buffer when a crash happens, or there may not be a way to retrieve the crash dump otherwise.

Install without Swap Space

If the installation does not contain any swap space, it may not be able to take a crash dump or automatically restart, and may stop at a `db>` prompt on the console. Capture the output there, and also the output of the `bt` command at that prompt, then manually reboot.

38.1.4 FreeBSD Issue Policy

The pfSense® team relies on the work provided by the FreeBSD project as the base operating system of pfSense software. On occasion, pfSense software users will run into problems with FreeBSD that are outside of the scope with which Netgate can help. This page provides basic guidance on what to do in these scenarios.

Most frequently, these issues are driver or hardware-specific bugs. Netgate developers are most familiar with hardware sold by Netgate, and drivers for that hardware in FreeBSD. Thus, that is the only hardware for which Netgate can offer assistance.

When pfSense software users encounter driver problems on third party hardware, the best practice is to install a stock FreeBSD release on the hardware, replicate the problem, and report it to the appropriate FreeBSD list. This is likely the only way such problems will get resolved in future releases of FreeBSD. Alternatively, use different hardware known to work well with pfSense software, such as hardware from the Netgate Store.

If an installation of pfSense software encounters a kernel panic, Netgate developers may be able to help analyze the backtrace. Post the crash dump contents on the Netgate Forum.

See also:

See: *Obtaining Panic Information for Developers*

The primary exception to this is for issues that affect a large number of pfSense software users and/or Netgate hardware customers. Examples of this could be problems with PF, CARP, IPsec, or any number of other components. In these cases, Netgate will track and work to resolve issues of this nature. However, Netgate cannot coordinate testing and fixes for one off issues and edge cases encountered by single users.

38.1.5 Requesting New pfSense Features

To request new pfSense® features first submit a feature request on pfSense Redmine.

If the feature request is approved, develop the functionality and submit a pull request to the applicable pfSense repositories.

38.1.6 System Patches Package

The System Patches package manages patches which change the behavior of pfSense® software. These patches may be bundled with the package, fetched from the official code repository, pasted in, or even uploaded from other sources.

This package makes it simple obtain official recommended security patches and bug fixes from Netgate between releases, as well as to test and deploy custom changes.

Installing the package

This package is available in the package repository:

- Navigate to **System > Packages**, **Available Packages** tab.
- Find **System Patches** in the list, or search for it.
- Click  **Install** at the end of its row
- Click  **Confirm** to confirm the action and complete the installation.

Once the installation finishes, Patches may be managed at **System > Patches**.

Recommended System Patches

The System Patches package is bundled with recommended patches for specific versions of pfSense software. This list is below the custom system patches area on **System > Patches**. The list of recommended patches is different for each version and typically includes security patches and important bug fixes. The list only displays patches relevant to the current version of pfSense software running on the device.

Note: Not every release has recommended patches! In most cases a brand new release would not have any entries in the recommended patches list unless a significant issue was discovered after the release was published.

The list of recommended patches includes a brief description of the patch and what it fixes or changes. There are typically links to relevant Redmine issues, Security Advisories, or similar sources. There may also be special notes or instructions to follow for patch entries.

Managing Recommended Patches

Applying and reverting recommended patches works the same way as it does for manual patch entries, as described in *Managing Patch Entries*. There are a few differences, however. Options not relevant to recommended patches are not available for entries in the recommended patches area. This includes the "Fetch" action as well as the ability to reorder, edit, add, or delete entries.

In most cases administrators will want to click  **Apply All Recommended** which will do as it says and apply all of the currently unapplied patches in the recommended patches list. Recommended patches may also be applied or reverted one at a time.

Warning: Occasionally a recommended patch also requires a manual action, such as restarting a service or rebooting the device. Read the description of each recommended patch entry carefully for such notes and follow the suggested steps after applying the patch.

Warning: There is no need to take any action with these patches before a upgrading pfSense software. Newer releases will already contain the older patches, and the entries in the list will be different after the release.

Updating Recommended Patches

Recommended patches are bundled within the System Patches package itself, so updating the package will also update the list of available recommended patches.

Warning: Take care when checking for package updates when there is a newer release of pfSense software available. Ensure the device is set to use its current version update branch under **System > Updates** rather than the branch for the new version.

Patch Settings

When creating or editing a Custom System Patch entry, the following settings are available:

Description
Text identifying the patch for reference.

URL/Commit ID
A Git commit ID for the pfSense CE software repository on Github, or the full URL to a patch file.

After saving the patch, use the **Fetch** button to download the patch content to the firewall.

Patch Contents
The contents of the patch in unified diff format.

When using a URL or commit ID, this should be blank when first saving but will contain the patch content after fetching.

Patch File Upload
A button to populate the **Patch Contents** by selecting a file on the client computer.

Path Strip Count
The number of path components to remove from the paths in patch metadata.

GitHub commit IDs and URLs should be count of `2` (default and fixed automatically on save). Patches from other sources will need to be set appropriately.

For example, if a path like `a/src/etc/inc/filter.inc` is in the patch header, the package should strip off the `a/src` so a strip count of `2` is needed. If it's deeper, such as `home/me/patches/etc/inc/filter.inc`, strip however many levels are necessary, which in this example would be `3`.

Base Directory
The package assumes a base directory of `/` for patches by default, but an alternate base may be applied if a patch does not supply a full path to the file it is patching (e.g. `/usr/local/www`).

Ignore Whitespace
Whether or not the patching process should ignore whitespace differences in the patch data.

Patches from GitHub should work with either whitespace setting, patches from other sources may need the option set to ignore whitespace, especially if they contain DOS line endings rather than UNIX or if the patch content lost tabs when copying and pasting.

Auto Apply
Whether or not the package will attempt to apply this patch on each boot of the firewall.

For patches which are included in future releases of pfSense software this is unnecessary as the appropriate fixes are included in the new release and need not be applied again. For manual custom changes this may be necessary to ensure these customizations are restored after upgrades.

The patches may be reordered in the list to arrange them so they apply in a specific order automatically, in case one patch depends on a previous patch.

Patch ID
When editing an existing patch, the GUI displays its unique ID in this field.

Managing Patch Entries

Manage patch entries at **System > Patches**.

The **Custom System Patches** list is for patches added manually by firewall administrators. The list has the following functions:

Select/Move
Selects entries to move or delete.

Clicking the  icon moves selected patches to this position, altering the order of patches. This may be relevant with auto-apply if one patch depends upon another.

Description
Text describing the patch, for reference.

Fetch
A button to download the patch content from its source, either a custom URL or a Github commit ID.

Apply
Attempt to apply this patch.

Revert
Attempt to revert this patch.

View
View the contents of the patch data.

Debug
Test the patch and interpret the results, this will display information about why a patch may not apply or restore cleanly. The output will include a detailed analysis of the results and can optionally display full detail of patch failures.

Auto Apply
A read only indication of whether this patch entry has the auto-apply option enabled.

Edit

The  icon edits this patch entry.

Delete

The  icon deletes this patch entry.

Add New Patch
Creates a new patch entry.

Delete Patches
Deletes all selected patch entries.

Note: The GUI does not display buttons unless they are relevant.

The lower section contains **Recommended System Patches** for the specific running version of pfSense software as described earlier in this document under *Recommended System Patches*. The controls in this section are limited as there is no need to edit the entries or alter the list.

Warning: There is typically no need to revert Custom or Recommended patch entries before or after upgrading pfSense software. Newer releases may contain the same fix as an older patch, which means the patch may appear to be applied after upgrading. Reverting such patches will **remove** the fix from the new release, bringing back the old bug. As such, the best course of action is to delete outdated Custom System Patch entries without reverting them.

Adding a Custom Patch

- Navigate to **System > Patches**
- **Read the text and warnings!**
- Click  **Add New Patch** under the **Custom System Patches** section
- Enter *Patch Settings* as described previously using one of the following styles:
  - Commit ID (e.g. `4573641589d50718b544b778cea864cfd725078a`) in the **URL/Commit ID** field
  - GitHub commit URL (e.g. `https://github.com/pfsense/pfsense/commit/4573641589d50718b544b778cea864cfd725078a`) in the **URL/Commit ID** field
  - GitHub Pull Request (PR) URL with '.diff' appended, such as `https://github.com/pfsense/pfsense/pull/XXXX.diff` where XXXX is the PR number

    Set Path Strip = `2` if it does not adjust automatically
  - Full URL to a patch from another source (e.g. `https://redmine.pfsense.org/attachments/594/0001-Add-support-for-aliases-in-DNS-Forwarder-fixes-2410.patch`) in the **URL/Commit ID** field
  - Leave **URL/Commit ID** blank and paste the contents of a patch into **Patch Contents** text area or upload a patch file
- Click **Save**

Applying/Reverting a patch

If a URL or commit ID was entered for a patch, the entry in the patch list will have a **Fetch** button.

Click **Fetch** and firewall will retrieve the patch content. This **does not** apply the patch.

To apply the patch, click **Apply**. The package will then apply the patch. The available link for the patch will then change to say **Revert** instead.

To revert, click **Revert**.

See also:

Managing Patch Entries

Troubleshooting

- It is normal for an already-applied patch to show only a revert button. Similarly, if an older patch is present on a newer release which includes the fix, it will appear as already applied.

  Warning: Do not revert these patches after upgrading! – Doing so will undo the fix and cause problems on the new release.

- If one patch relies upon another patch being applied first, their usual actions may not appear unless taken in the proper order. For example, patch 2 may not show an Apply button until after patch 1 is applied. Likewise for reverting.
- Click  **Re-Fetch** for remote patches to make sure the package has a clean copy of the patch content.
- Click **Debug** to run a test and then click **Detail** next to either the apply or revert line to get the full patch output
- If the above test output mentions **No file to patch**, double check the **Path Strip Count** and/or the **Base Directory**.
- If every part of a patch fails, try toggling **Ignore Whitespace**.

Known issues

See also:

The pfSense bug tracker contains a list of known issues with this package.

Package Support

This package is currently supported by Netgate TAC to those with an active support subscription.

38.1.7 Using the PHP Shell

Using the PHP developer shell on pfSense® software allows manipulation of the firewall configuration directly without using the GUI. Using this mechanism also allows rapid deployment of pfSense software and/or the setup of exotic configurations.

The shell can be started from console menu option `12` or from the CLI by executing `pfSsh.php`.

Example Session

The following shows an example session, with the text coming from the `help` command in the PHP shell.

Follow each line or group of lines to run with `exec;`:

```
*** Welcome to pfSense ***

 WAN (wan)       -> vmx0       -> v4/DHCP4: 198.51.100.3/24
                                  v6/DHCP6: 2001:db8::ffff:22d6/128
 LAN (lan)       -> vmx1       -> v4: 10.3.0.1/24
                                  v6/t6: 2001:db8:1:eee0:20c:29ff:fe45:260/60
```

(continues on next page)

(continued from previous page)

 1) Assign Interfaces                 10) Filter Logs
 2) Set interface(s) IP address       11) Restart GUI
 3) Reset admin account and password  12) PHP shell + pfSense tools
 4) Reset to factory defaults         13) Update from console
 5) Reboot system                     14) Disable Secure Shell (sshd)
 6) Halt system                       15) Restore recent configuration
 7) Ping host                         16) Restart PHP-FPM
 8) Shell

Enter an option: 12

Starting the pfSense developer shell....

Welcome to the pfSense developer shell

Type "help" to show common usage scenarios.

Available playback commands:
     changepassword disablecarp disabledhcpd disablerefererchеck enableallowallwan␣
↪enablecarp
     enablesshd externalconfiglocator generateguicert gitsync installpkg listpkg␣
↪removepkgconfig
     removeshaper restartdhcpd restartipsec svc uninstallpkg

pfSense shell: help

     Enter a series of commands and then execute the set with "exec".

     For example:
     echo "foo"; // php command
     echo "foo2"; // php command
     ! echo "heh" # shell command
     exec

     Example commands:

     record <recordingfilename>
     stoprecording
     showrecordings

     parse_config(true);  # reloads the $config array

     $temp = print_r($config, true);
     more($temp);

     /* to output a configuration array */
     print_r($config);

     /* to output the interfaces configuration portion of config.xml */
     print_r($config['interfaces']);
```

(continues on next page)

(continued from previous page)

```
    /* to output the dhcp server configuration */
    print_r($config['dhcpd']);

    /* to exit the  developer shell */
    exit

    /* to output supported wireless modes for an interface */
    print_r(get_wireless_modes(\"ath0\"));

    /* to enable SSH */
    $config['system']['enablesshd'] = true;

    /* change OPTX to the OPT interface name such as BACKHAUL */
    $config['interfaces']['optx']['wireless']['standard'] = "11a";
    $config['interfaces']['optx']['wireless']['mode'] = "hostap";
    $config['interfaces']['optx']['wireless']['channel'] = "6";

    /* to enable dhcp server for an optx interface */
    $config['dhcpd']['optx']['enable'] = true;
    $config['dhcpd']['optx']['range']['from'] = "192.168.31.100";
    $config['dhcpd']['optx']['range']['to'] = "192.168.31.150";

    /* to disable the firewall filter */
    $config['system']['disablefilter'] = true;

    /* to enable an interface and configure it as a DHCP client */
    $config['interfaces']['optx']['disabled'] = false;
    $config['interfaces']['optx']['ipaddr'] = "dhcp";

    /* to enable an interface and set a static IPv4 address */
    $config['interfaces']['wan']['enable'] = true;
    $config['interfaces']['wan']['ipaddr'] = "192.168.100.1";
    $config['interfaces']['wan']['subnet'] = "24";

    /* to save out the new configuration (config.xml) */
    write_config();

    /* to reboot the system after saving */
    system_reboot_sync();
```

Playback Scripts

There are several pre-defined playback scripts for the PHP Shell that automate simple tasks or enable access to the GUI.

These scripts are run from within the PHP shell like so:

```
pfSense shell: playback scriptname
```

Warning: The PHP shell is not designed to run multiple playback scripts in a single session. After executing a playback script, exit the PHP shell and start it again. Otherwise subsequent scripts may fail to run. Alternately, run

the playback scripts using the CLI method.

The scripts can also run from the command line:

```
# pfSsh.php playback scriptname
```

Warning: This must be run from an actual shell prompt over SSH or at the console. Do not attempt to run this through the GUI.

changepassword

This script changes the password for a user, and also prompts to reset the account properties if it is disabled or expired.

cryptconfig

This script can encrypt or decrypt configuration backups using the same method as doing so in the GUI when creating or restoring backups.

In either case, the script will prompt for the encryption passphrase. When decrypting, this passphrase must exactly match the passphrased used to encrypt the configuration file.

Usage:

```
# pfSsh.php playback cryptconfig <action> <input filename> <output filename>
```

To encrypt a configuration file:

```
# pfSsh.php playback crypt encrypt /conf/config.xml /root/config-backup.xml
```

To decrypt a configuration file:

```
# pfSsh.php playback crypt decrypt /root/config-backup.xml /root/config.xml
```

disablecarp / enablecarp

These scripts disable and enable CARP high availability functions, and will deactivate CARP type Virtual IP addresses.

This action **does not** persist across reboots.

disablecarpmaint / enablecarpmaint

These scripts disable and enable CARP maintenance mode, which leaves CARP active but demotes this unit so the other node can assume control.

This maintenance mode **will** persist across reboots.

disabledhcpd

This script removes all DHCP configuration from the firewall, effectively disabling the DHCP service and completely removing all of its settings.

disablerefercheck

This script disables the `HTTP_REFERER` check mentioned in *Browser HTTP_REFERER enforcement*. This can help gain access to the GUI if a browser session is triggering this protection.

enableallowallwan

This script adds an allow all rule for IPv4 and IPv6 to the WAN interface.

> **Warning:** Be extremely careful with this option, it is meant to be a **temporary** measure to gain access to services on the WAN interface of the firewall in situations where the LAN is not usable. Once proper access rules are put in place, remove the rules added by this script.

enablesshd

This script enables the SSH daemon, the same as the console menu option or GUI option.

externalconfiglocator

This script looks for a `config.xml` file on an external device, such as a USB thumb drive, and will move it in place for use by the firewall.

gatewaystatus

This script prints the current gateway status and statistics. It also accepts an optional parameter `brief` which prints only the gateway name and status, omitting the addresses and statistical data.

generateguicert

This script creates a new self-signed certificate for the firewall and activates it for use in the GUI. This is useful in cases where the previous certificate is invalid or otherwise not usable. It fills in the certificate details using the firewall hostname and other custom information.

gitsync

This complex script synchronizes the PHP and other script sources with files from the pfSense CE software Github repository. It is most useful on CE development snapshots to pick up changes from more recent commits.

> **Warning:** This script can be dangerous to use in other circumstances. Only use this under the direction of a knowledgeable developer or support representative.

> **Warning:** This script is not currently compatible with pfSense Plus software.

If the script is run without any parameters it prints a help message outlining its use. More information can be found at *Using gitsync to Update pfSense® Software Between Snapshots*.

installpkg / listpkg / uninstallpkg

These scripts interface with the package system in a similar way to the GUI. These are primarily used for debugging package issues, comparing information in `config.xml` compared to the package database.

pfanchordrill

This script recursively searches through `pf` anchors and prints any NAT or firewall rules it finds. This can help track down unexpected behavior in areas such as UPnP or Captive Portal which rely on rules in anchors that are not otherwise visible in the GUI.

pftabledrill

This script prints the contents of all `pf` tables, which contain addresses used in firewall aliases as well as built-in system tables for features such as bogon network blocking, snort, and GUI/SSH lockout. This script is useful for checking if a specific IP address is found in any table, rather than searching individually.

removepkgconfig

This script removes all traces of package configuration data from the running `config.xml`. This can be useful if a package has corrupted settings or has otherwise left the packages in an inconsistent state.

removeshaper

This script removes ALTQ traffic shaper settings, which can be useful if the shaper configuration is preventing rules from loading or is otherwise incorrect and preventing proper operation of the firewall.

resetwebgui

This script resets the GUI settings for widgets, dashboard columns, the theme, and other GUI-related settings. It can return the GUI, particularly the dashboard, to a stable state if it is not functioning properly.

restartallwan

This script disables and re-enables each WAN-type interface, which reapplies the interface configuration.

restartdhcpd

This script stops and restarts the DHCP daemon.

restartipsec

This script rewrites and reloads the IPsec configuration for strongSwan.

svc

This script controls the services running on the firewall, similar to interacting with services at **Status > Services**.

The general form of the command is:

```
# pfSsh.php playback svc <action> <service name> [service-specific options]
```

The **action** can be `stop`, `start`, or `restart`.

The **service name** is the name of the services as found under **Status > Services**. If the name includes a space, enclose the name in quotes.

The **service-specific options** vary depending on the service, they are used to uniquely identify services with multiple instances, such as OpenVPN or Captive Portal entries.

Examples:

Stop miniupnpd:

```
# pfSsh.php playback svc stop miniupnpd
```

Restart OpenVPN client with ID 2:

```
# pfSsh.php playback svc restart openvpn client 2
```

Start the Captive Portal process for zone “MyZone”:

```
# pfSsh.php playback svc start captiveportal MyZone
```

upgradeconfig

Runs the current configuration, or optionally an arbitrary configuration file, through the configuration upgrade process.

The general form of the command is:

```
# pfSsh.php playback upgradeconfig [<input filename> <output filename>]
```

To force the current running configuration through the upgrade process:

```
# pfSsh.php playback upgradeconfig
```

To run the configuration upgrade process on a different configuration file:

```
# pfSsh.php playback upgradeconfig /root/oldconfig.xml /root/newconfig.xml
```

Warning: Some configuration upgrade steps may contain a directive to write the configuration which may unintentionally replace the current running configuration with the copy being upgraded at that step. After running this script on an arbitrary file, visit the configuration history (*Configuration History*) and roll back to the correct configuration if it was replaced. The upgrade process does not apply settings, so no additional action should be necessary.

Recording and Playback

Aside from the predefined scripts, users may create their own playback scripts by recording sessions.

This can easily automate a number of commands to repeat them later, saving time and effort.

Recording a session

```
# pfSsh.php
[...]

pfSense shell: record resetrrd
Recording of resetrrd started.
pfSense shell: require_once("filter.inc");
pfSense shell: require("shaper.inc");
pfSense shell: require_once("rrd.inc");
pfSense shell: ! rm /var/db/rrd/*.rrd
pfSense shell: enable_rrd_graphing();
pfSense shell: setup_gateways_monitor();
pfSense shell: stoprecording
Recording stopped.
pfSense shell: exit
```

Playing back a session

```
# pfSsh.php
[...]

pfSense shell: playback resetrrd

Playback of file resetrrd started.

pfSense shell: exit
```

Warning: The PHP shell is not designed to run multiple playback scripts in a single session. After executing a playback script, exit the PHP shell and start it again. Otherwise subsequent scripts may fail to run. Alternately, run the playback scripts using the CLI method.

Sessions can be played back directly from the command line as well:

```
# pfSsh.php playback resetrrd
```

38.2 pfSense Software Development

38.2.1 Getting Started with pfSense® Software Development

There is no single specific starting point for joining the pfSense® software development effort, but the following items are helpful in getting started:

- Review the *Developer Style Guide*
- Become familiar with the pfSense CE software git repositories and GitHub in general)

  Current repositories used for developing pfSense software and its dependencies include:

  pfSense
  : The main source repository for pfSense CE software, containing the GUI code, builder code, and related scripts.

  FreeBSD-src
  : OS source code used to build pfSense CE software.

  FreeBSD-ports
  : Build information for supporting software used in pfSense CE software, and code for custom programs, daemons, modules, and packages.

- Review the list of open bug reports and other issues.
- Submit changes as *pull requests on GitHub*.

Netgate developers will review submissions, offer feedback, and merge the changes if they are acceptable.

38.2.2 PHP 8.x and Later Development

PHP 7.x is at its end of life, and so development is moving to PHP 8.x on future releases of pfSense software, such as pfSense Plus software version 23.01 and pfSense CE software version 2.7.x.

Migrating to PHP 8.1 introduces some backward incompatible changes from 7.x in how some expressions are evaluated.

Configuration Access

One of the more pervasive idioms in the pfSense code base and its packages that is now problematic is the method by which code historically traverses the configuration tree. The problematic method indexes the configuration data into multiple levels of nested associative arrays, e.g.:

```
$foo = $config['section']['subsection']['item'];
```

The configuration array tree is not fully populated with all possible keys, therefore any of the keys in the expression above may not exist in the array being indexed. The evaluation of an expression indexing an associative array with a key that it does not contain results in an empty string. Expressions indexing a string are allowed in PHP 7.4, and in the case that the key is a string the expression evaluates to an empty string again. However, in PHP 8.1 these expressions now raise errors and terminate the evaluation of PHP code. To correct these errors and to progress toward decoupling the implementation of the runtime configuration store from the rest of the code base, the development tree now includes utility functions to access the `$config` variable instead of accessing it directly. These functions are defined in `/etc/inc/config.lib.inc`.

Reading Configuration Values

The following function should be used to read values from the configuration:

```
config_get_path(string $path, $default = null)
```

Given a path with the separator /, look for an item by indexing into the configuration tree by the identifiers in the path.

Returns `$default` if the item or any intermediary in the path cannot be found.

Examples

Basic example accessing one value nested inside a section:

PHP 7.x Style:

```
$foo = $config['section']['item'];
```

PHP 8.x Style:

```
$foo = config_get_path('section/item');
```

More complicated example accessing a value inside a subsection multiple levels deep:

PHP 7.x Style:

```
init_config_arr('section', 'subsection');
if ($config['section']['subsection']['item']) {
    $foo = $config['section']['subsection']['item'];
} else {
    $foo = "Not Found";
}
```

PHP 8.x Style:

```
$foo = config_get_path('section/subsection/item', "Not Found");
```

Testing if Settings are Enabled

A common way to mark options and features as enabled or disabled in the configuration is via "presence" style variables. Where if the value is present in the configuration, the option is enabled. If the value is missing, it's disabled.

There is a new shortcut for testing these options:

```
config_path_enabled($path, $enable_key = "enable")
```

This function determines if `$enable_key` is a key into the array at path `$path`, and the value is non-null. This is used to obtain the same semantics as checking if the value is present in the configuration, but in a safe manner.

Note: Some sections of the configuration use different semantics for indicating if a feature is enabled which `config_path_enabled()` does not interpret at this time. Only use `config_path_enabled()` to replace `isset()` style expressions.

Examples

This first example is for an option which is enabled or disabled based on the presence of a configuration element named default "enable":

PHP 7.x Style:

```
$bar_enabled = isset($config['foo']['bar']['enable']);
```

PHP 8.x Style:

```
$bar_enabled = config_path_enabled('foo/bar');
```

This next example tests whether or not the element "baz" is present in the configuration at the same level of the previous example.

PHP 7.x Style:

```
$baz_enabled = isset($config['foo']['bar']['baz']);
```

PHP 8.x Style:

```
$baz_enabled = config_path_enabled('foo/bar', 'baz');
```

Writing Configuration Values

This function sets an item at a given the configuration path:

```
config_set_path(string $path, $value, $default = null)
```

If any intermediate section in the path cannot be found, or is an empty value, the function creates an array for it. If any intermediary in the path is unexpectedly a scalar value, the function returns the `$default` value to indicate an error.

Examples

This basic example sets a value in the configuration and then writes the changes:

PHP 7.x Style:

```
$config['foo']['bar']['item'] = 'newvalue';
write_config('Update settings');
```

PHP 8.x Style:

```
config_set_path('foo/bar/item', "newvalue");
write_config('Update settings');
```

This slightly more complex example reads a value from the configuration, updates the option with a new value, then stores the results.

PHP 7.x Style:

```
$bar = &$config['foo']['bar'];
/* ... */
$bar['item'] = 'newvalue';
/* ... */
write_config('Update settings');
```

PHP 8.x Style:

```
$bar = config_get_path('foo/bar');
/* ... */
$bar['item'] = 'value';
/* ... */
config_set_path('foo/bar', $bar);
write_config('Update settings');
```

Deleting Configuration Values

To unset (delete) a value from the configuration, use this function:

```
config_del_path(string $path)
```

This function completely removes a path from the configuration tree by running `unset()` on the array element, if it exists.

This is obtains the same semantic as `unset()` in a safe manner.

Examples

PHP 7.x Style:

```
unset($config['foo']['bar']['item']);
```

PHP 8.x Style:

```
config_del_path('foo/bar/item');
```

Array Access Functions

The configuration-based functions utilize more general array functions which can be used directly for similar tasks on any array.

```
array_get_path(array &$arr, string $path, $default = null)
array_set_path(array &$arr, string $path, $value, $default = null)
array_path_enabled(array &$arr, string $path, $enable_key = “enable”)
array_del_path(array &$arr, string $path)
```

String to Number Comparison

In the past, PHP would return `true` when comparing `0` to an empty string (`''`) but now it returns `false`. If the code in question must test against an empty string to know if a value is usable, do not cast the value to `int` or take other equivalent actions. Along the same lines, if the value must be compared numerically, cast it to `int` after first checking if it's an empty or otherwise usable value.

Note: While the behavior of comparing `0` to an empty string has changed, the result of `empty(0)` and `empty('0')` are still `true` on PHP 8.x.

Before:

```
$varusersamountoftime = ($users['varusersamountoftime'] ?: '');
$varusersamountoftime = (int) $varusersamountoftime * 60;
/* ... */
if ($varusersamountoftime != '') {
    /* ... */
}
```

In this example the value of the variable is always cast to `int` which means that an empty value is changed to `0`. On PHP 7.x, the later `if` would evaluate to `false` if the value was `0` but on PHP 8.x, the test will evaluate to `true`.

After:

```
if ($users['varusersamountoftime']) {
    $varusersamountoftime = (int) $users['varusersamountoftime'] * 60;
} else {
    $varusersamountoftime = '';
}
/* ... */
if ($varusersamountoftime != '') {
    /* ... */
}
```

This code will evaluate the same on both PHP 7.x and 8.x because it only changes the value to `int` when the variable is set and has a non-zero value, and it is an empty string otherwise.

Practical Examples

Iterating over Arrays of Items in the Configuration

Previously, one or more checks would have to be made to see if the array in the configuration is present, checking the value with `isset()` or `is_array()`. With the config interface, a suitable default value of an empty array can be specified in a call to `config_get_path()`, and the result can be directly iterated. The resulting code is more concise.

This example iterates over aliases in the configuration:

PHP 7.x Style:

```
if (isset($config['aliases']) &&
    is_array($config['aliases']) &&
    isset($config['aliases']['alias']) &&
    is_array($config['aliases']['alias'])) {
```

(continues on next page)

(continued from previous page)

```
    foreach ($config['aliases']['alias'] as $aliased) {
        if ($aliased['name'] == $alias_name) {
            return filter_generate_nested_alias($aliased['name']);
        }
    }
}
```

The above example needs multiple safety checks to ensure that each level exists and is an array before it attempts to iterate over the array. Some of this can be bypassed by running a `init_config_arr()` or similar but it still requires wrapping it in a test before iterating.

Contrast that with this much simpler example using the new utility function:

PHP 8.x Style:

```
foreach (config_get_path('aliases/alias', []) as $aliased) {
    if ($aliased['name'] == $alias_name) {
        return filter_generate_nested_alias($aliased['name']);
    }
}
```

This next example demonstrates a common method used to check all OpenVPN server and client instances:

PHP 7.x Style:

```
init_config_arr(array('openvpn'));
foreach (array('server', 'client') as $mode) {
    if (is_array($config['openvpn']["openvpn-{$mode}"])) {
        foreach ($config['openvpn']["openvpn-{$mode}"] as $id => $setting) {
            /* ... */
        }
    }
}
```

This becomes much simpler and does not require the extra initialization or tests:

PHP 8.x Style:

```
foreach (array('server', 'client') as $mode) {
    foreach (config_get_path("openvpn/openvpn-{$mode}", []) as $id => $setting) {
        /* ... */
    }
}
```

This example iterates over all installed packages. This requires extra checks because the user may not have any packages installed, or may even not have a section in the configuration with package settings.

PHP 7.x Style:

```
if (is_array($config['installedpackages']) &&
    is_array($config['installedpackages']['package'])) {
    foreach ($config['installedpackages']['package'] as $pkg) {
        if ($pkg['name'] == $package_name) {
            return $pkg['descr'];
        }
```

(continues on next page)

(continued from previous page)

```
    }
}
```

PHP 8.x Style:

```
foreach (config_get_path('installedpackages/package', []) as $pkg) {
   if ($pkg['name'] == $package_name) {
      return $pkg['descr'];
   }
}
```

Replacing isset() to Determine if an Item is Enabled

As with other configuration accesses, using `config_path_enabled()` is safe if any part of the path does not exist, and will return `false` if that is the case. If the array key for the element that indicates something is enabled is not the default `enable`, the name can be passed as another parameter.

PHP 7.x Style:

```
$assignedif = convert_real_interface_to_friendly_interface_name($vlanif);
if ($assignedif) {
    if (isset($config['interfaces'][$assignedif]['enable'])) {
        interface_configure($assignedif, true);
    }
}
```

PHP 8.x Style:

```
$assignedif = convert_real_interface_to_friendly_interface_name($vlanif);
if ($assignedif) {
    if (config_path_enabled("interfaces/{$assignedif}")) {
        interface_configure($assignedif, true);
    }
}
```

This example checks if an option is enabled the same way, but using a specific key name:

PHP 7.x Style:

```
if (!isset($config['system']['ipv6allow'])) {
    /* ... */
}
```

PHP 8.x Style:

```
if (!config_path_enabled('system','ipv6allow')) {
    /* ... */
}
```

Accessing Items from Variable Paths

Before, extra care needed to be taken to initialize multi-level arrays and to check before accessing certain areas, for example:

```
init_config_arr(array('captiveportal'));
$a_cp = &$config['captiveportal'];
/* ... */
if ($a_cp[$cpzone]) {
    /* ... */
    $pconfig['certref'] = $a_cp[$cpzone]['certref'];
    /* ... */
}
```

Now this can be done safely without the extra steps:

```
$pconfig['certref'] = config_get_path("captiveportal/{$cpzone}/certref");
```

Note: Note the use of double quotes in the path to allow variable substitution.

Default Values

One of the primary benefits of this new style is the ability to easily accommodate default values without a lot of extra logic. There are examples of this in previous sections above where a default array is returned (`[]`) to ensure that a returned value is always an array.

In this example, a value is populated either from the configuration or using a globally defined default:

PHP 7.x Style:

```
init_config_arr('syslog');
$syslogcfg = $config['syslog'];
$log_size = isset($syslogcfg['logfilesize']) ? $syslogcfg['logfilesize'] : $g['default_
↪log_size'];
```

PHP 8.x Style:

```
$log_size = config_get_path('syslog/logfilesize', $g['default_log_size']);
```

38.2.3 Referencing Tickets in Commit Messages

By placing a special keyword in a commit message the issue tracking system (pfSense Redmine) can associate a commit with a specific ticket automatically, creating a link in the ticket to the relevant commits.

When using these keywords immediately follow them by a `#` and then the ticket number, such as `Ticket #1234`. They are not case sensitive.

The following keywords will reference a ticket but take no action on the ticket status:

- `refs`, `references`, `IssueID`, `ticket`, `bug`, `feature`, `todo`, `redmine`

The following keywords will not only reference the ticket, but automatically move the ticket to a feedback state:

- `fix`, `fixes`, `fixed`, `close`, `closes`, `closed`, `resolve`, `resolves`, `resolved`, `implement`, `implements`, `implemented`, `finish`, `finishes`, `finished`

Keep this in mind when submitting changes in GitHub pull requests for existing issues.

38.2.4 Submitting a Pull Request via GitHub

Submitting a Pull Request (PR) via GitHub is the fastest and best way to contribute source code changes to the pfSense® CE project.

Using a PR allows developers to easily review and comment on changes, allows easy testing via patches from the *System Patches* Package, and allows the changes to be easily merged into the project.

Creating a PR is a relatively straightforward process but there are a few guidelines and suggestions to follow when submitting contributions:

- Ensure the bug or feature has an entry on the pfSense Redmine

  Create a new entry if one does not exist.

  The only exceptions to this are for very minor typo/wording fixes.

- Read through and follow the *Developer Style Guide*
- Read through the GitHub documentation on pull requests
- Create a fork of the correct repository (e.g. pfSense/pfSense for the base system, or pfSense/FreeBSD-ports for packages)
- Always submit pull/merge requests to the `master` branch of the `pfSense/pfSense` repository or the `devel` branch of `pfSense/FreeBSD-ports`.

  The exception to this is when making PRs for multiple branches due syntax or other differences which require variations that prevent a regular cherry-pick or similar action from copying the commit to other branches

- When making commits to the fork, *reference the relevant Redmine entry*
- When ready to submit the changes, create a pull request from the fork to the appropriate branch
  - The PR title should be a short summary of the changes and include a reference to the relevant Redmine issue number(s)
  - The PR description should include a longer explanation of the proposed changes and link to the relevant Redmine issue number(s)
- After submitting the pull request, add a link to the PR on the related Redmine issue to cross-reference the entries.

38.2.5 Checking the Current FreeBSD Version

Versions of pfSense software and FreeBSD contains a table of the versions used in various releases of pfSense® software and FreeBSD.

Alternately, inspect the version on a running firewall manually using one of the following methods.

Dashboard

From the Dashboard in the webGUI, look at the **System Information** widget. The widget displays the FreeBSD version under the **Version** section.

Command Line

In the *SSH console* or *Execute Shell Command* field in the GUI, run the following command:

```
uname -mrs
```

38.2.6 Creating Dashboard Widgets

Getting Started

Creating widgets is simple. First, create the html code for the widget, save it to a file named `widget_name.widget.php`, and put it into the `/usr/local/www/widgets/widgets` directory on the firewall.

Do not include any `<body>`, `<html>`, or `$pgtitle` definitions, etc. Only include basic HTML code for what needs to be displayed. Examine the current widget source code for examples.

The file must be named in the `my_name.widget.php` format. No spaces are allowed in the filename. The name the GUI displays is the name of the file. For example the Traffic Graphs widget file is named `traffic_graphs.widget.php`.

And that's it! The dashboard handles the rest of the widget behavior (e.g. buttons, border, dragging, sequence, etc.) automatically.

To include custom code into the widget upon rendering:

PHP
: Create a file named `widget_name.inc` and place the `.inc` file in the `/usr/local/www/widgets/include` directory.

JavaScript
: Create a file named `widget_name.js` and place the `.js` file in the `/usr/local/www/widgets/javascript` directory.

Saving Data

Saving configuration data for a widget requires more work and is beyond the scope of this document. Look at the source code for existing widgets which have settings and follow their example, including:

- The form for the settings and all related fields, save button, etc.
- Input validation
- Storing settings by writing the configuration
- Redirect the user back to the dashboard

Customizing the Title and Linking to page

By default the name of the widget file is what is shown on the Widget in the dashboard. This title can be changed and also have a link to another page inserted.

To configure the widget to use a certain name other than the name of the file, create an `.inc` file with the same base name as the widget and place that file into the `/usr/local/www/widgets/include` directory.

For example if a widget is named `abc.widget.php`, the include file must be `abc.inc`.

In this `.inc` file use the following code:

```
<?php //set variable for custom title
$abc_title = "A B C custom";
$abc_title_link = "abc.php";
?>
```

Use the widget name in the variable names as shown in the example.

An example of these values can be taken from the `interfaces.inc` file for the Interfaces widget:

```
<?php [...]
$interfaces_title = gettext("Interfaces");
$interfaces_title_link = "status_interfaces.php";
?>
```

38.2.7 Enabling Additional PHP Modules

In certain cases, such as packages or customized Captive Portal code, additional PHP extensions may be required that are not enabled.

There are a handful of PHP extensions available in the package repository which are not included in the base distribution of pfSense® software.

The extensions included and activated vary by pfSense software version, look in `/usr/local/lib/php/` to see which extensions are present, and check the output of `php -m` to see what is enabled on a firewall already.

Examples of additional extensions available to install may include:

- `mysqli`
- `pdo_mysql`
- `pgsql`

To activate one of these, install the appropriate version-specific package from the command line, for example:

```
# pkg search php
<locate the desired package>
# pkg install -y php74-mysqli
# /etc/rc.php-fpm_restart; /etc/rc.restart_webgui
# php -m | grep mysqli
mysqli
```

A reboot would also fully activate the module, but should not be necessary.

38.2.8 Executing Commands at Boot

There are three primary options for executing custom commands at boot time: `shellcmd`, `earlyshellcmd`, and shell scripts.

The shellcmd package can manage the `shellcmd` and `earlyshellcmd` tags in the GUI, so `config.xml` values need not be edited by hand.

At boot time the firewall executes the `earlyshellcmd` entries first and the `shellcmd` entries much later in the boot process. Shell scripts are executed at the very end of the boot process when initializing packages.

The `shellcmd` and `earlyshellcmd` options are preferable as they are contained within in the configuration file. As such they do not typically require additional modifications should the storage medium be replaced and reinstalled, or if the configuration is restored to a different piece of hardware.

shellcmd option

The hidden `config.xml` option <shellcmd> makes the firewall run a command towards the end of the boot process.

To add a `shellcmd` to a configuration, either use the `shellcmd` package or edit `config.xml` by hand (*XML Configuration File*).

To edit the `config.xml`:

- Back it up via **Diagnostics > Backup/restore**
- Open the XML backup file in a text editor that properly handles UNIX line endings.
- Add a new line above the </system> line such as the following:

```
<shellcmd>mycommand -a -b -c 123</shellcmd>
```

  Where `mycommand -a -b -c 123` is the command to run.

- Save the changes to the configuration
- Restore the modified configuration

Multiple lines may be added to execute multiple commands.

earlyshellcmd option

The hidden `config.xml` option <earlyshellcmd> makes the firewall run a command at the beginning of the boot process.

Note: In most cases <shellcmd> is more appropriate, though this may be necessary in some circumstances.

The process to add an <earlyshellcmd> tag is the same as <shellcmd>. Either use the `shellcmd` package or edit it in by hand.

This should result in a tag such as the following in the configuration:

```
<earlyshellcmd>mycommand -a -b -c 123</earlyshellcmd>
```

Multiple <earlyshellcmd> lines can be present to execute multiple commands.

Shell script option

Any shell script can be placed in the `/usr/local/etc/rc.d/` directory.

The filename must end in `.sh` and it must be marked as executable (`chmod +x myscript.sh`).

The firewall will execute every shell script ending in `.sh` in this directory at boot time and also during certain system events (e.g. interface link changes, IP address changes, and gateway events).

38.2.9 Using a Debug Kernel

pfSense® software has debug symbols for the kernel and modules that can be added to aid in debugging. To install the debug symbols, use the following command:

```
pkg install pfSense-kernel-debug
```

38.2.10 Using gitsync to Update pfSense® Software Between Snapshots

Most often upgrading to a new development snapshot is the best way to get updated code when tracking a development version of pfSense® software (alpha, beta, RC, etc).

However, since new snapshots are only built once per day in most cases, one can often get by with pulling new code from the `pfSense` CE Git repository instead of reloading a whole new snapshot. This is useful for testing code changes committed since the last snapshot. This process is known as a `gitsync`.

Warning: This process is not compatible with pfSense Plus software.

Warning: A `gitsync` only synchronizes PHP changes without any binary changes. At times, PHP changes require associated binary changes that only come from an upgrade using a snapshot or other upgrade image.

Unless development is followed closely and the ramifications of all changes are understood, or unless breakage is not a concern, do not use this!

For most users, this action should only be taken if directed to do so by a developer.

This only works with code or files that are not compiled. For example: PHP Code, configuration files, GUI pages, etc.

There are two ways to perform a `gitsync`, both perform the same function:

Method 1:

From the console menu, press option 12 to start a developer shell, then type:

```
> playback gitsync master
```

Method 2:

From a normal shell (console menu option 8), type the following command:

```
# pfSsh.php playback gitsync master
```

Warning: This must be run from an actual shell prompt over SSH or at the console. Do not attempt to run this through the GUI.

The `master` part of the command tells the gitsync process to grab the code for the `master` branch, a.k.a. HEAD, main, etc. That can be replaced with a version-specific branch such as `RELENG_x_y_z`.

For example, on 2.8.0-RELEASE, to sync post-release code changes, use:

```
# pfSsh.php playback gitsync RELENG_2_8_0
```

Troubleshooting

The `gitsync` script attempts to install `git` automatically. However, if an error occurs the `git` package may need to be added manually. This can be done from a shell prompt:

```
# pkg install git
```

Git Protocol changed/URL Moved

Occasionally something on GitHub changes and renders an old clone of the repository broken. The most recent change was a change to disable certain protocols in favor of only using HTTPS. In this case it's necessary to delete the old clone so that `gitsync` can create a fresh copy.

```
# rm -rf /root/pfsense/
# pfSsh.php playback gitsync master
```

38.2.11 Development Branch Names

During the development cycle of pfSense® software work happens on specific branches for specific purposes.

HEAD (master)

HEAD, also known as -HEAD, `master`, `plus-master`, `devel`, `plus-devel`, or `main`, refers to the latest bleeding edge development version of pfSense software, where all new features are first added. The specific branch name varies depending on the repository.

When a release nears, this branch of a given repository is branched to create a RELENG (Release Engineering) branch. This follows the FreeBSD project's development model.

RELENG_x_y_z

A branch with a complete version number, such as `RELENG_x_y_z` (CE) or `plus-RELENG_yy_mm` (Plus) is a maintenance branch for a specific release, x.y.z (CE) or yy.mm (Plus). This may be updated after a release and eventually become the next patch release, if necessary.

Others

For links to other branches, past and present, see *Versions of pfSense software and FreeBSD*.

- *Developer Style Guide*

38.3 pfSense Package Development

38.3.1 Developing Packages

Developers familiar with FreeBSD, pkg, and PHP, will find it fairly straightforward to create packages for pfSense® software. End users and organizations can benefit from developing a package that does not exist.

To submit a new package, create a *pull request* on GitHub for the pfSense software FreeBSD-Ports Repository so Netgate can evaluate the work for inclusion into the package repository for access by all users.

When developing packages, always target the latest development version of pfSense software first.

pfSense Software Package System

On pfSense software, every pfSense software package is also a FreeBSD port. These are installed and managed via `pkg`, even when using the GUI to add or remove packages. Binary packages from FreeBSD are added as dependencies of the pfSense software package, so they are installed automatically as well, along with any of their own required dependencies.

The basic idea is to make packages for pfSense software similar to FreeBSD packages, but with customization. One way this is achieved is by adding metadata about packages to the firewall configuration when it is installed, and also creating the configuration screen of an application using XML. pfSense software provides an optional framework to create the web interface and to store it in the XML configuration file of the firewall. The package writer is expected to convert the data from XML to the native format of the application.

Package System

pfSense software packages are typically composed of:

- A Manifest File
- Package configuration file(s)
- Supporting files (`.inc` files, additional `.php` web interface files, etc.)

See also:

See *Package Port Directory Structure* for a more in-depth list of files and their locations in the package structure.

Manifest File

The manifest file is located inside the package's port directory:

```
<category>/pfSense-pkg-<package name>/files/usr/local/share/pfSense-pkg-<package name>/
↪info.xml
```

For example:

```
sysutils/pfSense-pkg-Cron/files/usr/local/share/pfSense-pkg-Cron/info.xml
```

This file contains basic information about the package. The format of the manifest XML file is as follows:

```
<pfsensepkgs>
    <package>
        <name>someprogram</name>
        <descr><![CDATA[Some cool program.]]></descr>
        <version>%%PKGVERSION%%</version>
        <configurationfile>someprogram.xml</configurationfile>
    </package>
</pfsensepkgs>
```

Note: The `version` entry is updated automatically, use the template as shown.

Package Configuration Files

The manifest specifies a Package Configuration File for the package using the `config_file` tag. The convention is to keep this file inside the `files/usr/local/pkg/` directory inside the port structure for the package.

The easiest way to get a feel for the format is to look at existing packages and how they use these configuration files, how their fields look, how the code behaves, and so on.

The format is:

```
<?xml version="1.0" encoding="utf-8" ?>
<packagegui>
  <copyright></copyright>
  <name></name>
  <title></title>
  <include_file></include_file>
  <aftersaveredirect></aftersaveredirect>
  <menu>
    <name></name>
    <section></section>
    <configfile></configfile>
    <tooltiptext></tooltiptext>
    <url>/pkg.php?xml=package.xml</url>
  </menu>
  <tabs>
    <tab>
      <text></text>
      <url></url>
```

(continues on next page)

(continued from previous page)

```
      <active/>
      <tab_level/>
    </tab>
  </tabs>
  <service>
    <name></name>
    <rcfile></rcfile>
    <executable></executable>
    <description></description>
  </service>
  <plugins>
    <item>
      <type>plugin_name</type>
    <item>
  </plugins>
  <adddeleteeditpagefields>
    <columnitem>
      <fielddescr></fielddescr>
      <fieldname></fieldname>
    </columnitem>
  </adddeleteeditpagefields>
  <fields>
    <field>
      <fielddescr></fielddescr>
      <fieldname></fieldname>
      <description></description>
      <size></size>
      <type></type>
    </field>
  </fields>
  <custom_php_global_functions><!-- PHP function call --></custom_php_global_functions>
  <custom_php_install_command><!-- PHP function call --></custom_php_install_command>
  <custom_php_pre_deinstall_command><!-- PHP function call --></custom_php_pre_deinstall_
↪command>
  <custom_php_deinstall_command><!-- PHP function call --></custom_php_deinstall_command>
  <custom_add_php_command><!-- PHP function call --></custom_add_php_command>
  <custom_add_php_command_late><!-- PHP function call --></custom_add_php_command_late>
  <custom_delete_php_command><!-- PHP function call --></custom_delete_php_command>
  <custom_php_resync_config_command><!-- PHP function call --></custom_php_resync_config_
↪command>
  <start_command><!-- PHP function call --></start_command>
  <custom_php_service_status_command><!-- PHP function call --></custom_php_service_

  <custom_php_validation_command><!-- PHP function call --></custom_php_validation_
↪command>
  <custom_php_after_head_command><!-- PHP function call --></custom_php_after_head_
↪command>
  <custom_php_command_before_form><!-- PHP function call --></custom_php_command_before_
↪form>
  <custom_php_after_form_command><!-- PHP function call --></custom_php_after_form_
↪command>
</packagegui>
```

Field types

interfaces_selection
Combo/list box with interfaces list:

```
<field>
  <filddescr>Interface Selection</filddescr>
  <fieldname>interfaces</fieldname>
  <type>interfaces_selection</type>
  <description>Select interfaces to listen on</description>
  <multiple/><!-- (optional) -->
  <size>10</size><!-- (optional) -->
  <hideinterfaceregex>(wan|loopback)</hideinterfaceregex><!-- (optional) -->
  <showvirtualips/><!-- (optional) -->
  <showips/><!-- (optional) -->
  <showlistenall/><!-- (optional) -->
</field>
```

checkbox
Field with text description and a enable/disable checkbox:

```
<field>
  <filddescr>Enable</filddescr>
  <fieldname>enable_package</fieldname>
  <type>checkbox</type>
  <description>Select this option to enable this config</description>
</field>
```

input
Single line text edit element

```
<field>
  <filddescr>username</filddescr>
  <fieldname>username</fieldname>
  <type>input</type>
  <description>Enter package username</description>
</field>
```

password
Special input element for passwords, all input will be masked with * symbol on GUI but clear text on xml config file:

```
<field>
  <filddescr>password</filddescr>
  <fieldname>password</fieldname>
  <type>password</type>
  <description>Enter password</description>
</field>
```

textarea
Multi-line text edit element:

```
<field>
  <filddescr>Custom options</filddescr>
```

(continues on next page)

(continued from previous page)

```
  <fieldname>custom_options</fieldname>
  <type>textarea</type>
  <description>Paste custom config here</description>
  <encoding>base64</encoding><!-- (optional) -->
</field>
```

select

Combo Box with drop-down list items:

```
<field>
  <fielddescr>Some Choice</fielddescr>
  <fieldname>some_choice</fieldname>
  <description><![CDATA[Select a choice]]></description>
  <type>select</type>
    <options>
    <option><name>Choice A</name><value>a</value></option>
    <option><name>Choice B</name><value>b</value></option>
    </options>
  <multiple/><!-- (optional) -->
  <size>10</size><!-- (optional) -->
</field>
```

info

Information text without any options to select:

```
<field>
  <fielddescr>Additional info</fielddescr>
  <fieldname>just_info</fieldname>
  <type>info</type>
  <description>show info text on package GUI</description>
</field>
```

button

Additional buttons to take additional actions on packages:

```
<field>
 <fielddescr>Reload config</fielddescr>
 <fieldname>reload</fieldname>
 <type>button</type>
 <description>click to force a config reload</description>
 <placeonbottom/><!-- Use this option to place the button besides save default␣
↪button -->
</field>
```

In package `.inc` file, to check what button was selected, use:

```
if (($_POST['Submit'] == 'Save') {
   /* Do save stuff */
}
if (($_POST['Submit'] == 'Reload') ||
    !isset($_POST['Submit'])) {
   /* Do reload stuff */
}
```

Field groups

combinefields
Several options can be combined into a single row as an option group using <combinefields>

For example this block groups three options onto a single row:

```
<field>
        <fielddescr>Option 1</fielddescr>
        <fieldname>option1</fieldname>
        <description>Option 1</description>
        <type>input</type>
        <combinefields>begin</combinefields>
</field>
<field>
        <fielddescr>Option 2</fielddescr>
        <fieldname>option1</fieldname>
        <description>Option 2</description>
        <type>input</type>
<field>
        <fielddescr>Option 3</fielddescr>
        <fieldname>option3</fieldname>
        <description>Option 3</description>
        <type>input</type>
        <combinefields>end</combinefields>
</field>
```

rowhelper
Used in pkg_edit.php to add multiple config lines like a table on package GUI. Inside rowhelper, add any field type described above:

```
<field>
<fielddescr><![CDATA[Lists]]></fielddescr>
<fieldname>none</fieldname>
<description><![CDATA['Format' - Choose the file format that url will retrieve or␣
↪local file format.]]></description>
<type>rowhelper</type>
  <rowhelper>
    <rowhelperfield>
    <fielddescr>Format</fielddescr>
    <fieldname>format</fieldname>
    <type>select</type>
      <options>
      <option><name>gz</name><value>gz</value></option>
      <option><name>txt</name><value>txt</value></option>
     </options>
    </rowhelperfield>
    <rowhelperfield>
      <fielddescr>URL or local file</fielddescr>
      <fieldname>url</fieldname>
      <type>input</type>
      <size>75</size>
    </rowhelperfield>
  </rowhelper>
```

(continues on next page)

(continued from previous page)

```
</field>
```

adddeleteeditpagefields
: Used with `pkg.php` to have multiple config of the same xml page. Useful to access lists, users lists, multi daemon configurations, etc:

```
<adddeleteeditpagefields>
  <columnitem>
    <fielddescr>Alias</fielddescr>
    <fieldname>aliasname</fieldname>
  </columnitem>
  <columnitem>
    <fielddescr>Description</fielddescr>
    <fieldname>description</fieldname>
  </columnitem>
  <columnitem>
    <fielddescr>Action</fielddescr>
    <fieldname>action</fieldname>
  </columnitem>
  <columnitem>
    <fielddescr>Update Frequency</fielddescr>
    <fieldname>cron</fieldname>
  </columnitem>
</adddeleteeditpagefields>
```

Binaries from FreeBSD

The actual binaries are normal FreeBSD package binaries for that particular program. Once listed as a dependency for a pfSense package in its *Makefile*, the builders compile the dependencies automatically and copy them to the pfSense software package servers. There is no need to specify these in XML.

Updating Packages

When updating a package is it important to bump the version in its *Makefile* otherwise the package will not be rebuilt and made available to others.

Repository Branches

When submitting changes, they are typically submitted to the `devel` branch of the FreeBSD-Ports Repository. In order to show to all users, the changes must be placed in the current release branch as well, such as RELENG_2_8_0.

Ideally, the changes should be submitted to the development branches and tested on systems pulling packages from the development repository. Once the changes have been tested, they can be placed into the release branch for deployment to a wider audience.

Testing/Building Individual Packages

Archive files from pkg may be copied to the firewall and added with pkg directly. The good thing about using pkg is that the GUI packages and CLI packages are all the same. Files for pfSense software packages are all kept together inside the archive, dependencies such as FreeBSD packages are in separate archives.

The package may be compiled on a local FreeBSD 15.0-CURRENT@bf06074106cf builder, then `pkg delete` the old version and then `pkg add` the new one or use any other pkg operations needed.

For example, a basic package like Cron is `pfSense-pkg-Cron-0.3.3`, so if a new copy is built and put on the firewall:

```
# pkg add /path/to/file/pfSense-pkg-Cron-0.3.3.txz
```

It will also work with `pkg add` and a URL to an `http` or `https` web server.

The process for making a package is:

- Check out the FreeBSD-Ports Repository.
- *Locate the port directory*
- Make changes
- Run `make package`:

```
$ git clone git@github.com:pfsense/FreeBSD-ports.git pfSense-ports
$ cd pfSense-ports/blah/pfSense-pkg-foo/
[hack, hack, hack]
$ make package  (might need sudo)
$ scp work/pkg/pfSense-pkg-foo* root@myfirewall:.
```

And then on the firewall:

```
# pkg add pfSense-pkg-foo-<version>.txz
```

Poudriere could also be setup for a custom repository but in most cases that will be overkill.

There are additional considerations when adding files, like updating the *plist*, and crafting a new pfSense package from scratch may be tricky if there is no prior knowledge of how the FreeBSD ports tree works.

38.3.2 Package Port Directory Structure

The directory structure of a package for pfSense® software is similar to that of a traditional FreeBSD port.

or more information on working with FreeBSD Ports, see bsd.port.mk.

This page uses the simple Cron package as an example, many other packages are similar. See *FreeBSD Ports Used for Packages* for links to existing packages to copy/clone from.

Category
: First is the category, which roughly lines up with the category for the package with the caveat that if a pfSense package is based on a FreeBSD port, it should be in the same location (e.g. `haproxy` is under `net/haproxy`)

  In the case of Cron this is `sysutils`:

```
FreeBSD-ports/sysutils/
```

Main package directory
: Inside of the category directory, it is always prefixed with `pfSense-pkg-`:

```
FreeBSD-ports/sysutils/pfSense-pkg-Cron/
```

Note: From here on, the `FreeBSD-ports` prefix will be omitted for brevity.

`Makefile`

Includes version information, information about binaries, dependencies, install procedures, where to copy files, and so on. Copy an existing one for a similar package and adjust as needed (but do so carefully):

```
sysutils/pfSense-pkg-Cron/Makefile
```

pfSense software standard package `install/deinstall` scripts

Note: These files are identical for all packages. Copy the contents from another existing package.

```
sysutils/pfSense-pkg-Cron/files/pkg-deinstall.in
sysutils/pfSense-pkg-Cron/files/pkg-install.in
```

Description

A brief text description of the package:

```
sysutils/pfSense-pkg-Cron/pkg-descr
```

Packing List

A list of files installed by the package, for specifics on the format, see the links above:

```
sysutils/pfSense-pkg-Cron/pkg-plist
```

Files Directory

The directory where custom files are placed which will be copied to the firewall:

```
sysutils/pfSense-pkg-Cron/files/
```

The structure under the `files/` directory should follow the same conventions as files on the pfSense installation, which typically follows hier(7) from FreeBSD. For example, executable scripts would go under `files/usr/local/bin/`

Privileges

An optional file containing privilege information:

```
sysutils/pfSense-pkg-Cron/files/etc/inc/priv/cron.priv.inc
```

Package Code and Configuration

The include files and XML files for the package:

```
sysutils/pfSense-pkg-Cron/files/usr/local/pkg/cron.inc
sysutils/pfSense-pkg-Cron/files/usr/local/pkg/cron.xml
```

XML Metadata

```
sysutils/pfSense-pkg-Cron/files/usr/local/share/pfSense-pkg-Cron/info.xml
```

GUI-Accessible Files

Files that go into the main directory of the web server:

```
sysutils/pfSense-pkg-Cron/files/usr/local/www/
```

Note: The Cron package uses a subdirectory under /usr/local/www for its files - - this is optional.

```
sysutils/pfSense-pkg-Cron/files/usr/local/www/packages/cron/cron.php
sysutils/pfSense-pkg-Cron/files/usr/local/www/packages/cron/cron_edit.php
sysutils/pfSense-pkg-Cron/files/usr/local/www/packages/cron/index.php
```

38.3.3 FreeBSD Ports Used for Packages

The list of packages in the pfSense® software copy of FreeBSD-ports includes:

- ACME (security/pfSense-pkg-acme)
- apcupsd (sysutils/pfSense-pkg-apcupsd)
- arping (net/pfSense-pkg-arping)
- arpwatch (net-mgmt/pfSense-pkg-arpwatch)
- Avahi (net/pfSense-pkg-Avahi)
- Backup (sysutils/pfSense-pkg-Backup)
- bandwidthd (net-mgmt/pfSense-pkg-bandwidthd)
- bind (dns/pfSense-pkg-bind)
- Cellular (net/pfSense-pkg-cellular)
- Cron (sysutils/pfSense-pkg-Cron)
- Darkstat (net-mgmt/pfSense-pkg-darkstat)
- filer (sysutils/pfSense-pkg-filer)
- FreeRADIUS3 (net/pfSense-pkg-freeradius3)
- FRR (net/pfSense-pkg-frr)
- FTP Client Proxy (ftp/pfSense-pkg-FTP_Client_Proxy)
- HAProxy (net/pfSense-pkg-haproxy)
- HAProxy-devel (net/pfSense-pkg-haproxy-devel)
- iperf (benchmarks/pfSense-pkg-iperf)
- LADVD (net/pfSense-pkg-LADVD)
- LCDproc (sysutils/pfSense-pkg-LCDproc)
- Lightsquid (www/pfSense-pkg-Lightsquid)
- lldpd (net-mgmt/pfSense-pkg-lldpd)
- Mail Reports (mail/pfSense-pkg-mailreport)
- MTR (net/pfSense-pkg-mtr-nox11)
- NET-SNMP (net-mgmt/pfSense-pkg-net-snmp)
- Netgate Firmware Upgrade (sysutils/pfSense-pkg-Netgate_Firmware_Upgrade)

- nmap (security/pfSense-pkg-nmap)
- Node Exporter (sysutils/pfSense-pkg-node_exporter)
- Notes (sysutils/pfSense-pkg-Notes)
- nrpe (net-mgmt/pfSense-pkg-nrpe)
- ntopng (net/pfSense-pkg-ntopng)
- NUT (sysutils/pfSense-pkg-nut)
- Open-VM-Tools (emulators/pfSense-pkg-Open-VM-Tools)
- OpenVPN Client Export (security/pfSense-pkg-openvpn-client-export)
- pfBlockerNG (net/pfSense-pkg-pfBlockerNG)
- PIMD (net/pfSense-pkg-pimd)
- RRD Summary (sysutils/pfSense-pkg-RRD_Summary)
- Service Watchdog (sysutils/pfSense-pkg-Service_Watchdog)
- shellcmd (sysutils/pfSense-pkg-Shellcmd)
- siproxd (net/pfSense-pkg-siproxd)
- snmptt (net-mgmt/pfSense-pkg-snmptt)
- Snort (security/pfSense-pkg-snort)
- softflowd (net-mgmt/pfSense-pkg-softflowd)
- Squid (www/pfSense-pkg-squid)
- SquidGuard (www/pfSense-pkg-squidGuard)
- Status_Traffic_Totals (net/pfSense-pkg-Status_Traffic_Totals)
- stunnel (security/pfSense-pkg-stunnel)
- Sudo (security/pfSense-pkg-sudo)
- Suricata (security/pfSense-pkg-suricata)
- syslog-ng (sysutils/pfSense-pkg-syslog-ng)
- System Patches (sysutils/pfSense-pkg-System_Patches)
- Telegraf (net-mgmt/pfSense-pkg-Telegraf)
- tftpd (ftp/pfSense-pkg-tftpd)
- tinc (security/pfSense-pkg-tinc)
- WireGuard (net/pfSense-pkg-WireGuard)
- Zabbix-Agent (net-mgmt/pfSense-pkg-zabbix-agent)
- Zabbix-Proxy (net-mgmt/pfSense-pkg-zabbix-proxy)
- Zeek (security/pfSense-pkg-zeek)

Note that each package is under a category and prefixed with `pfSense-pkg-`.

See *Package Port Directory Structure* for details about the structure of files inside each package directory.

38.3.4 Compiling Software on the Firewall

pfSense® software intentionally does not include a full environment for compiling software (make, headers/includes, sources, etc) on the installed firewall. Those tools are left out for security reasons.

A virtual machine or separate system can be setup to compile software, and then the compiled binaries/packages/software can be moved over to the firewall.

When doing this, install a version of FreeBSD that matches up with the version of pfSense software currently in use. A list can be found here: *Versions of pfSense software and FreeBSD*

Alternately, install pre-compiled FreeBSD packages as described here: *Installing FreeBSD Packages*

CHAPTER

THIRTYNINE

REFERENCES

These documents are for reference purposes and may be about general topics that do not fit into other categories or topics about the documentation itself.

39.1 Typographic Conventions

Throughout this documentation the authors use conventions to denote certain concepts, information, or actions. The following list gives examples of how to format these items in the documentation.

Menu Selections
: **Firewall > Rules**

GUI Item Labels/Names
: **Destination**

Buttons
:  **Add**

Prompt for input
: **Proceed?**

Input from the user (text)
: `Rule Description`

Input from the user (selection)
: *WAN*

File Names
: `/boot/loader.conf`

Names of commands or programs
: `gzip`

Commands Typed at a shell prompt

```
# ls -l
```

Long shell command-line examples may be split using the backslash (\) for shell line continuation.

Command Output

```
-rw-r--r--  2 root  wheel   887 Apr 12 09:49 .cshrc
```

The list above also servers as an example of a "definition list" used to define sets of terms or options and their meanings.

39.2 Documentation Quality Guidelines

39.2.1 Overview

This document aims to give an idea of what types of information should be in articles to keep them as useful as possible for other users of the documentation.

For information about style and formatting, see *Style Guide*.

39.2.2 What to include in articles

- Concise, detailed information – the more accurate the information, the more useful it is.
- Good spelling and grammar
- Good formatting (*Style Guide*)
- Proper categories to classify the article. For example, place the new article in the correct area of the documentation site (e.g. articles about OpenVPN go under `source/vpn/openvpn/`).

39.2.3 What not to include in articles

- Poor grammar
- Inconsistent or poor backing data
- Disparaging comments
- Ambiguity – try to make articles clear so there is no confusion
- Avoid creating a new directory or category for a single article if possible. If more will be added, then it is OK.
- Redundant information already covered in other documents. Especially in recipes.

- Do not start a recipe with installing pfSense software or other basic tasks. Make assumptions and link to other articles for topics already covered elsewhere. There is no need to reinvent the wheel and have multiple overlapping copies of the same information. This helps keep recipes as concise as possible!

39.2.4 Where to see why an article was flagged

Articles flagged for cleanup should have corresponding issues on GitHub discussing the required changes.

39.3 Style Guide

To make this documentation easier for users, the style of articles should be consistent and clear. The following guidelines are best practices and strong suggestions. Text found to not be following these Language Style/Grammar guidelines may be edited and corrected at any time.

See also:

See *Documentation Quality Guidelines* for information about how entries in the documentation should be written and what they should contain.

39.3.1 Trademarks

- The first use of `pfSense®` **must** have the ® symbol on each and every page.
- Trademarks, such as "pfSense®", are proper adjectives and **not** verbs or nouns.

  In most cases this means that a reference must be phrased as "pfSense® software" instead of "pfSense®" on its own.
- Include "Plus" or "CE" when referring to specific builds of pfSense software. If a topic applies to any build, then this extra reference is not necessary.

  Example: "pfSense® Plus software", "pfSense® CE software"
- Be respectful of Trademarks, including those of third parties.
- Where feasible, try to include relevant marks for third parties or use their preferred nomenclature, phrasing, formatting, and so on.

  For example, use "Proxmox® VE" and not "Proxmox" when referring to the Proxmox Virtualization Environment as that is the way Proxmox Server Solutions GmbH prefers others to reference the product.

Examples:

Firewalls

- Good: Firewall running pfSense® software
- Bad: pfSense® firewall, pfSense® box

Versions

- Good: pfSense® Plus software version 23.01
- Bad: pfSense® 23.01

Installations

- Good: Installation of pfSense® software
- Bad: pfSense® install

39.3.2 Referring to items involving pfSense software

Refer to a firewall running pfSense as a "firewall" or "node". Avoid other similar terms ("router", "system", "box", etc.) for clarity and consistency.

39.3.3 Capitalization

Capitalize terms correctly! Especially **pfSense**!

No other capitalization of "pfSense" may be used except in a URL which is acceptable as lowercase (e.g. https://www.pfsense.org). If a sentence begins with "pfSense" the first letter must remain lowercase.

Note: If any other usage of "pfSense" or a misspelling of same is present in a document ("PFsense", "PFSense", "pfSence", etc), fix it immediately.

Other special notes for capitalization:

- WebGUI, IPsec, OpenVPN, Internet, Ethernet, VPN, DNS, PPPoE, IPv4, IPv6, NPt, strongSwan, pfsync, pftop, JavaScript, WireGuard.

39.3.4 What to Avoid

Avoid addressing the user directly ("you", "your", etc.)
Rewrite sentences to avoid addressing the user when found. Exceptions may be made for quoted/cited text or other unavoidable circumstances.

Avoid references to the writer ("I", "we")
Except when making specific recommendations, which is OK to avoid using passive voice. "We recommend" is better than "It is recommended", though the ideal phrasing would be "the best practice is".

Avoid the use of words such as "should", "could", "might"
Words that do not commit to a specific action/result are undesirable. For example "This should happen" or "That might appear". Some instances are expected/required when making recommendations, but reword where feasible.

Avoid the use of Weasel words
See Weasel Words for reference.

Avoid redundant phrases
This especially includes acronym references that duplicate words: "WAN Network", "LAN Network", "DUID Identifier", "6RD Rapid Deployment". Remove the redundant word(s) and/or use alternate phrasing ("WAN Subnet" or "Network on the WAN interface" rather than "WAN Network")

Avoid unnecessary abbreviations and shortening of words
This creates ambiguity, for example:

- Avoid using "IP" or "IPs" to refer to IP addresses. Use the full form "IP address" instead to remove ambiguity.
- Avoid using "config" when "config.xml" or "configuration" is more clear.
- Avoid using "ovpn" to mean "OpenVPN" except in cases when the OS-level interfaces are being referenced (`ovpncX` is OK, "Use OVPN instead" is not.)

Avoid using "here" for links
Do not make links for "here", "click here", or similar phrasing. They provide no context for the link, cause redundancy in phrasing, and cause problems for users that require accessibility functions such as screen readers.

See also:

See recommendations from W3C Tips and uxmovement.

Avoid awkward possessive references
For example: "firewall's", "pfSense's".

Avoid gender-specific pronouns
Example: "his", "hers"

Avoid leaving out necessary hyphens
Example: "howto" should be "how-to"

Avoid "Britishisms" or other non-en_US style spellings
Use "Flavor", not "Flavour". Use "Specialize", not "Specialise"

Avoid confusing bandwidth specifications

- Avoid confusing bits and bytes. Use Big **B** for bytes, little **b** for bits.
- Avoid ambiguity when specifying bandwidth measurements. Bandwidth should always have *time* component, such as *per second*. "5 Mbit/s" is much clearer than "5 Mbps", "5 Mb", or "5MB".

Avoid passive voice when necessary
When it makes more sense to do so, try to make it clear who is taking an action in a sentence, and use active voice instead of passive voice where possible in these cases.

- Bad: "When a packet is routed"
- Okay: "When a packet is routed by the firewall"
- Better: "When the firewall routes a packet"

There are times when the person or item taking an action isn't as important as the receiver of the action. The performer of the action may be unknown, assumed, or unimportant. In these cases the passive voice is acceptible. For example when describing GUI interactions, "When X is clicked" may be less awkward than repeating "When the user clicks X".

39.3.5 Crafting Instructions

When forming lists of instructions, start each item with an action word when possible: Click x, Select x, Enter x, Navigate to x.

When instructing a user to reach a specific page or place in the GUI, reference this action as "Navigate to".

39.3.6 Example Text

When offering examples, keep the following in mind:

- Domain names should use `example.com` or another reserved name from RFC 2606.
- IP address examples should be taken from subnets reserved for documentation in RFC 6890: `192.0.2.0/24`, `198.51.100.0/24`, `203.0.113.0/24` or the traditional RFC 1918 networks `192.168.0.0/16`, `172.16.0.0/12`, or `10.0.0.0/8` if the documentation subnets are not sufficient.
  - In some cases where additional unique examples are needed, use the benchmarking subnet `198.18.0.0/15`.

39.3.7 High Availability / CARP References

- Refer to the cluster as a "High Availability Cluster" or "HA Cluster" and **not** as a "CARP Cluster".
- Use the term "node" as in "cluster node" for referencing an individual unit.
- Use the term "primary" for the primary node, never "master" as this can be confused with the CARP VIP status.
- Use the term "secondary" for the secondary node, never "backup" or "slave" as this is outdated terminology and can be confused with the CARP VIP status.
- Use the terms "Sync interface" or "Interconnect interface" when referring to the dedicated interface between HA Cluster nodes. **Never refer to that interface as a "CARP interface"**.

39.4 Formatting Guide

The pfSense® software documentation is built using Sphinx/reStructuredText. The formatting is similar in some ways to Markdown, but has significant differences. To get a feel for the formatting, and read through this document.

Tip: Test out how different markup is rendered using the Online reStructuredText editor. Additional information can be found at A primer on reStructuredText and reST/Sphinx cheat sheet.

39.4.1 Filenames

When adding new pages or images use all lowercase letters and hyphens instead of spaces for the filename. This is commonly referred to as a slug, or a slugified version of the text. For example, this file is named `formatting-guide.rst`. When possible, try to find a meaningful single word for the filename instead of using lengthy names.

Tip: Use an online slug generator.

39.4.2 Text

In general try to keep text in logical paragraphs wrapped at 80 characters. This ensures the source is easy for everyone to read no matter where it is being edited. For long pages with several sections that may only be relevant to some users, split the page into several smaller documents.

Basic Inline Formatting

Add basic inline formatting to the text as follows:

- one asterisk: `*text*` for *emphasis* (italics),
- two asterisks: `**text**` for **strong emphasis** (boldface), and
- backquotes: ``` ``text`` ``` for `code samples`.
- To start a block of literal formatted text such as code, console input/output, log data, etc., use `.. code-block::` followed by a blank line. Prefix each line inside the block with three spaces:

```
.. code-block::

   code
```

These can be applied to text in various ways within the documentation:

- Menu references use bold text and ">" with spaces in between to separate menus from menu items: **System > General**
  - Navigation that also refers to a tab name should be formatted like so: **System > Advanced**, **Miscellaneous** tab.
- GUI text references and option names use bold text: **Description**
- Text to be entered or replaced by the user uses backquotes: Enter `192.168.1.1` for the **IPv4 Address**.
- Options selected by the user from a list or drop-down are italic: Select *WAN* for the **Interface**.
- File names and paths use backquotes: `/root`
- Commands names inline with other text use backquotes, "The `sudo` command ...".
- Shell commands being demonstrated or directed use code blocks. Start a code block as usual and then use # followed by a space to simulate a command prompt:

```
# ls -l /root
```

- Program output also uses code blocks. Blank lines in output can either be blank so that a line does not contain only whitespace:

```
# someprogram
Output:

Foo
```

- Do not leave any trailing whitespace on lines or any lines containing only whitespace.
- Lines should be indented with spaces, not tabs. Tabs may be used inside literal blocks.
- Use UTF-8 encoding.

39.4.3 Headings

Headings consist of text and a line of characters underneath ("underline") the **same length** as the text. The specific characters must be consistent to denote sections of the same depth in a single file. Parts and chapters also use a similar row of characters above the text ("overline").

- `####` with overline, for parts
- `****` with overline, for chapters
- `====`, for sections
- `----`, for subsections
- `~~~~`, for subsubsections
- ```` ```` ````, for paragraphs

Example:

```
This is a Section Heading
=========================
```

The specific characters are not as important as being consistent. The parser considers **each file separately** so there is no need to track and be consistent across multiple files even if they are in the same chapter/section/etc.

Note: The headings are also how the "On This Page" section is generated. When possible, use headings that create an outline of the content, making it easy for the reader to scan.

39.4.4 Lists

Sphinx supports several types of item lists suitable for various purposes.

Unordered Lists

Place an asterisk followed by a space at the start of a paragraph and indent two additional spaces for any lines that wrap.

```
* This is a bulleted list.
* It has two items, the second
  item uses two lines.
```

Which renders as:

- This is a bulleted list.
- It has two items, the second item uses two lines.

Ordered lists

Ordered lists are auto-numbered by prefixing a line with `#.` followed by a space. Indent lines that wrap with three additional spaces:

```
#. This is a numbered list.
#. It has two items too.
   This second item has two lines, too.
```

Which renders as:

1. This is a numbered list.
2. It has two items too. This second item has two lines, too.

Nested lists

Nested lists are possible, but be aware that they must be separated from the parent list items by blank lines:

```
* this is
* a list

  * with a nested list
  * and some subitems

* and here the parent list continues
```

Which renders as:

- this is
- a list
  - with a nested list
  - and some subitems
- and here the parent list continues

Definition lists

Definition lists are created as follows:

```
term (up to a line of text)
  Definition of the term, which must be indented

  and can even consist of multiple paragraphs

next term
  Description.
```

Note: The term itself cannot have more than one line of text.

Which renders as:

term (up to a line of text)
Definition of the term, which must be indented

and can even consist of multiple paragraphs

next term
Description.

> **Warning:** These lists cannot be nested more than **three** levels deep in ordered, unordered, definition, or field lists or it breaks PDF building.

Field Lists

Field lists are perfect for lists of options. They start with the field name starting and ending with a colon, followed by text describing the field. The content should start on a new line under the field name and should be indented two space. Though starting on a new line is optional in the parser, starting on a blank line makes the formatting cleaner and easier to follow.

```
:Option Name:
  What it does.
:Option 2:
  Another option. This is a long description that wraps to the next line,
  with two spaces indentation.
:Third Option:
  Something else.
```

Which renders as:

Option Name
What it does.

Option 2
Another option. This is a long description that wraps to the next line, with two spaces indentation.

Third Option
Something else.

> **Warning:** These lists cannot be nested more than **three** levels deep in ordered, unordered, definition, or field lists or it breaks PDF building.

39.4.5 Links

External Link

Separate the link and the target definition, like this:

```
This is a paragraph that contains `a link`_.
```

```
.. _a link: http://example.com/
```

Place the target definition at the bottom of the page in alphabetical order.

Note: If the link text will contain a colon, escape it in both the link text and the definition, for example:

```
See `Link\: Stuff`_.
```

```
.. _Link\: Stuff: http://example.com/stuff
```

Cross Reference to Section of Document

To make a cross reference to another document, first create a label immediately before the section title:

```
.. _label-some-section:

Some Section
------------
```

And then in the other document, reference it using `:ref:` and the given label:

```
See :ref:`label-some-section` for more information
```

Cross Reference to Entire Document

If a cross-reference will instead reference an entire document rather than a specific section, use the `:doc:` method instead.

For example, to reference this entire document, `/references/style-guide.rst`, use the following text, omitting the file extension:

```
:doc:`/references/style-guide`
```

39.4.6 Images

Images

Place images in the `source/_static` directory in the same folder structure as the page that the image is going to be posted on. For example, an image within `source/references/fomatting-guide.rst` would go in `source/_static/references/image.png`.

```
.. image::
   /_static/filename.*
   :align:
     center
   :alt:
     Alternative text that describes the image
   :target:
     /_static/filename.png
```

Note: `:target:` is optional and only necessary if it is a large image.

Figures

Place figures in the `source/_static` directory in the same folder structure as the page that the image is going to be posted on. For example, an image within `source/references/fomatting-guide.rst` would go in `source/_static/references/image.png`.

Figures are similar to images, but need a unique label and a caption for proper in-text references.

```
.. _figure-my-stuff:
.. figure::
   /_static/stuff.*
   :figclass:
     align-center
   :target:
     /_static/stuff.png

   This is the caption
```

Note: `:target:` is optional and only necessary if it is a large image.

Which can be referred to using the following:

```
An example is shown in Figure :ref:`figure-my-stuff`.
```

Warning: The indention is important! The caption *must* be aligned properly with the other attributes!

Inline Images

Inline images (no breaks above or below, aka inline with the text) require using a substitution. Since inline images are typically inserted on many pages, inline image files can be placed in the root of `source/_static` or an appropriate subdirectory.

Many common icon substitutions are available in a common substitutions file which is automatically included in all source files and usable as follows:

```
To add a blah, click |fa-plus|.
```

To do this in a one-off fashion, use a substitution within the same file:

```
Click |image_icon_edit| to edit the entry
<rest of page>
.. |image_icon_edit| image:: _static/icons/fa-pencil.*
```

39.4.7 Tables

Grid Tables

The grid must be "painted", they look like this example:

```
+------------------------+------------+----------+----------+
| Header row, column 1   | Header 2   | Header 3 | Header 4 |
| (header rows optional) |            |          |          |
+========================+============+==========+==========+
| body row 1, column 1   | column 2   | column 3 | column 4 |
+------------------------+------------+----------+----------+
| body row 2             | ...        | ...      |          |
+------------------------+------------+----------+----------+
```

Simple Tables

These are easier to write, but are limited: they must contain more than one row, and the first column cells cannot contain multiple lines. They look like this:

```
=====  =====  =======
A      B      A and B
=====  =====  =======
False  False  False
True   False  False
False  True   False
True   True   True
=====  =====  =======
```

39.4.8 Table of Contents

Every file has to a part of a `toctree` or **Table of Contents** tree, as this is how the side navigation is built.

Reference RST files by their filenames without their `.rst` extension. It is also possible to link to external resources if necessary, as shown with the YouTube link:

```
.. toctree::
   :maxdepth:
     2

   filename1
   filename2
   sub-directory/index
   Example YouTube Video <https://youtu.be/Cwz7vWu_KO0>
```

Local Table of Contents

Sometimes it is useful to add the table of contents of the current page:

```
.. contents::
   :depth:
     2
```

39.4.9 Admonitions (Colored Boxes)

Admonitions are text, distinguished in formatted boxes, that bring attention to important items.

Admonitions are similar to other directives, starting with two periods and a space followed by the admonition name and then two colons, e.g. `.. note::`.

Though the parser allows the text to start after the directive, the best practice is to start the text content on a line **under** the admonition which makes the formatting easier to follow and wrap consistently.

The most common example is a "Note" box:

```
.. note::
   This is a note, it will be surrounded by a note box when it is built.
```

Which renders as:

Note: This is a note, it will be surrounded by a note box when it is built.

Admonitions are available for a wide variety of types, including:

- `note`
- `tip`
- `warning`
- `attention`
- `caution`
- `danger`
- `error`
- `hint`
- `important`
- `seealso`

39.4.10 Substitutions

reST substitutions are pieces of text and/or markup which the parser will replace with another (usually longer) string or element. Substitutions are referred to in the text by `|name|`.

Substitutions are useful for inline images, links or references to be used in many documents, or even commonly repeated strings which may need to change over time. Rather than finding and replacing every reference so such items manually, they can be managed from a shared source.

Substitutions are defined like footnotes with explicit markup blocks, for example:

```
.. |name| replace:: replacement *text*
```

or this:

```
.. |caution| image:: warning.png
              :alt:
                Warning!
```

To use substitutions for multiple documents, put them into a separate file and include it into all documents where they will be used, using the `include` directive. Give the include file a file name extension differing from that of other source files, such as `.rsti`, to avoid Sphinx finding it as a standalone document.

Note: The common substitutions file is automatically included in all documents. Check that file before adding more substitutions in other files. Substitutions which will be widely used in many documents should be placed there.

39.4.11 Literal (code) Blocks

Briefly described earlier, literal or "code" blocks allow for pre-formatted text, most commonly used for source code, shell commands, command output, and so on.

A code block for general use, such as for log data, shell input/output, or command examples should be started with `.. code-block::` followed by a blank line. Prefix each non-blank line inside the block with three spaces.

```
.. code-block::

   code
```

The lines inside the code block must be indented to the same level, usually three spaces.

For an blank line inside the code block, use a completely empty line, not a line containing only whitespace.

For more complex examples, syntax highlighting can be used for source code using the `code-block` directive followed by the type of content inside the block:

```
.. code-block::
   html
   :linenos:

   <b>some html</b>
```

Which renders as:

```
1 <b>some html</b>
```

39.5 Updating Documentation

The primary avenue to make Netgate aware of problems in the documentation is to open an Issue on Redmine. In addition to requesting corrections, this may also be used to request new content or to propose other changes.

When creating an issue, please be specific and reference documents by filename where appropriate.

39.6 Developer Style Guide

This page covers rules and styles to be used when submitting code for inclusion in pfSense® software.

39.6.1 Modularity and Organization

Historically pfSense software, and before it M0n0wall, have placed all of the functionality required to obtain configuration data, display it, edit it, validate it, format it, and save it in a single PHP file (web page). Much use was made of global variables to allow functions access to the required data. These are both undesirable strategies.

The "everything in one file" approach leads to large, difficult to manage files. Functions declared in PHP web pages cannot be accessed from outside that page leading to duplication, bloat and maintenance headaches. Global variables are fragile and often mysterious, particularly when the variable is declared in another file. What does `global $p_interface_remote;` mean? What type is it, who/what sets it, where is it declared, is it multi-user safe, etc?

pfSense software functionality, particularly in PHP web pages, should adhere to MVC methodologies. The PHP web page file should contain only the code to display and edit information. The code to retrieve it, validate it, update it and save it should be provided in discrete functions included ("required") from a separate file (preferably in `/usr/local/pfSense/include/www`).

All functions should be organized in a modular fashion with clearly defined inputs and return values documented in the comments. The use of global variables should be minimized. Globals such as `$g`, `$config` and `$input_errors` etc are unavoidable and so acceptable, but where possible values should be passed in either directly or by reference.

- https://en.wikipedia.org/wiki/Modular_programming
- https://en.wikipedia.org/wiki/Model%E2%80%93view%E2%80%93controller

39.6.2 Developer Rules

- Never commit untested code.
- If a developer breaks the code, they fix it, even if their code breaks another subsystem. This is not glamorous but it is the right thing to do (or back the code out until a proper fix can be obtained).
- If a developer commits a kernel change that requires a userland configuration change of any type, then that developer must also make sure there is PHP code to control the userland change as needed (different sysctls, different means of configuring something, upgrade code etc.). This could be done by the same person or coordiated with other developers so all the changes go in at the same time.
- Internal developers (employees, etc.) should use branch development and merge requests, do not commit directly to master branch or equivalent where possible.
- Avoid changing the XML configuration structure whenever possible. Where that is infeasible, do not commit code that changes the XML configuration structure without adding configuration upgrade code at the same time.

- Never push a commit to any branch that knowingly causes a regression.
- Any major or high risk changes must first be done in a git clone (community contributors), branch (employees/internal developers) and reviewed by another committer before merging into the `master` branch.

  Using a *pull request* or merge request for this workflow is acceptable, and is how every change from those outside the development team is handled.
- Mention relevant ticket numbers in commit messages so that Redmine can associate the changes. See *Referencing Tickets in Commit Messages*.
- When possible, compose and format commit messages similar to entries in the change logs. For example:
  - Brief first sentence that describes the commit
  - Start with an action word describing the nature of the change ("Adds…", "Changes…", "Improves…", "Corrects…")
  - Reference the ticket number in the first sentence (see previous bullet point)
  - Examples:
    - "Change X to Y which fixes #1234"
    - "Correct check for XYZ in some_page.php to prevent badthing. Fixes #2345"
    - "Add coolnewthing to some_page.php. Implements #3456"
  - Add a blank line after the first sentence.
  - Longer, more detailed explanations can be placed in the body of the commit message.
- Always use full paths when calling an executable (e.g. `/usr/bin/grep` NOT `grep`)

39.6.3 HTML Specific Rules

Note: Incorrect HTML code is treated as broken code. Breaking the code is not allowed. A C compiler for example would complain in most cases if a developer breaks the code syntactically. Web browsers may ignore invalid code, but this does not mean that the code is not broken. The broken code must be fixed by the person who committed the invalid code.

---

pfSense software uses the XHTML doctype in the GUI code. The doctype enforces code against the following ruleset:

- Use lower case tag names and not a mix of uppercase and lowercase tag names
- Breaks must be closed (`<br />`)
- Image tags must be closed (`<img />`)
- An image tag *always* has an alt attribute, though it may contain no value
- Horizontal rule tags must be closed (`<hr />`)
- HTML form fields must be closed (`<input />`)
- Ampersands in a URL (e.g. within a href attribute) must be coded as a HTML entity (e.g. `&amp;`)
- Special characters (e.g. umlauts) must be coded as HTML Entities:
- A `<table />` tag does not have a name attribute
- A `<div />` tag does not have a name attribute
- A `<ul />` tag does not have a name attribute

- A tag does not have a name attribute
- Checkbox checked attributes must be coded as checked="checked"
- HTML field disabled attributes must be coded as disabled="disabled"
- HTML field readonly attributes must be coded as readonly="readonly"
- Any HTML <input /> field has a type attribute (e.g. type="text")
- Opening , <b> tags must have a matching closing tag (e.g.)
- <table /> tags do not contain a <form /> tag
- The type attribute of a <form /> tag must contain a lower case value (e.g. type="post" or type="get")
- The language=JavaScript attribute for <script /> tags is deprecated. Use the type="text/javascript" attribute instead.
- Always use lowercase attribute names for calling JavaScript events (e.g. onclick="foobar();")
- The <embed /> tag is deprecated, use <object /> instead
- If a style attribute is assigned to an HTML element it must be enclosed by quotes, for example: element.style.borderTop = "2px solid #990000";

It is possible to syntax check code in Firefox with the HTML validator plugin, or use the W3C validator. The latter is supported by Opera even for RFC 1918 networks.

39.6.4 PHP Specific Rules

Rule #1: Any time a rule is broken, there must be proper justification and documentation.

General rules

- All php files must start with a header block in English
- Use descriptive variable names in English
- Use lowercase variable names ($my_very_long_var_name) or Camel Case names ($myVeryLongVarName)
- When referencing variables inline in double quoted strings, use braces around the variable names:

```
$foo = "bar{$bar}bar";
```

- Avoid shell execution if at all possible. If it is unavoidable, ensure all variables passed to the shell are escaped using escapeshellarg() or similar
- Do not print user input back to the user without encoding it in some way (e.g. htmlspecialchars())
- Add comments in English whenever necessary or helpful
- Use // or /* */ style syntax for single line comments, do not use #
- Use /* */ style syntax for multi-line comments
- Use elseif and not else if when given a choice. The else if variant only works with braced syntax and not colon syntax (e.g. if: ... elseif: ... endif;).
- For testing the same variable against multiple strings or values directly, use a switch statement rather than a long chain of if/elseif/elseif/elseif/[...]/else statements.
- Add TODO: comments, when there is something to be done

- Add `FIXME:` comments, when something is broken
- add `NOTE:` comments, when there is something important other people should know beyond a traditional comment, for example a warning about not changing code in certain ways.
- Try to code in a readable way:

```
$header = "<head>{$foo}</head>";
$message = "SOME{$bar}TEXT";
```

  Is easier to read than:

```
$header="<head>".$foo."</head>";
$message = "SOME" . $bar . "TEXT";
```

- Try to simplify code for better readability:

```
if ($bool1)
   if ($bool2)
       if ($bool3)
           do_it();
whatever();
```

- Should be written as:

```
if ($bool1 && $bool2 && $bool3) {
   do_it();
}
whatever();
```

- Do not set unnecessary or single-use variables:

```
$is_set = isset($var);
if ($is_set) ...
```

- Loop variables are `$i`, `$j`, `$k`, ...
  - Do **NOT** use `$g` for a loop variable, as it conflicts with the global `$g` used by pfSense software
- All `switch` statements must have a `default`
- In classes, use `private`, `protected` and `public`, not `var` for attribute declaration
- Do not to use deprecated or obsolete syntax or functions
  - Keep an eye on future versions of PHP to avoid using functions that will be deprecated in the future as well
- If a PHP-internal function is an alias for another function, use the original (i.e. use `exit()` instead of `die()`)

Indent style

- Use K&R, BSD KNF variant style:

```
if ($x == $y) {
   something();
   ...
} else {
   somethingelse();
   ...
}
finalthing();
```

- When creating `if`, `for`, `foreach`, and other similar block style structures, even if there is only one statement inside, the use of braces is required.

  For example, good:

```
if ($foo) {
   something();
}
```

  Not good:

```
if($foo)
   something();
```

- If a conditional statement must span multiple lines, indent using four spaces to align with the start of the conditional above it:

```
   if ($foo1 && $foo2 && $foo3 && $foo4 && $foo5 && $foo6 &&
       $foo7 && $foo8 && $foo9) {
           something();
   }
```

- Do not put be a space between a function name and its argument list:

```
isset($myvar);
```

  - Conditional/control statements such as `if`, `foreach`, and `switch` are exceptions to this. Those must have a space before the parenthesis.

- … but **do** separate function arguments with a single space:

```
do_something($foo, 27, false);
```

- Use tabs for indentation – NOT spaces or a mixture of both
- … but spaces are OK in the middle of a line and for conditional alignment
- Use a tab stop of 8, rather than 4, in an editor.
- Ensure there is NO trailing whitespace at the end of a line, for example spaces or tabs when there is no more text afterward
- Ensure there is NO whitespace on empty lines. For example, a line must not contain only spaces or only tabs

Configuration Manipulation

- Boolean values which are false should be un-set:

```
$config['system']['enablesshd'] = "no";
```

  should be:

```
unset($config['system']['enablesshd']);
```

39.6.5 JavaScript Specific Rules

- pfSense software does not support outdated browsers, so do not take special measures to use code required by old/obsolete browsers or rendering engines
- pfSense software includes, among other JavaScript resources, Bootstrap and jQuery. While native JavaScript is best for simple tasks, if a developer can accomplish a goal easily using an included library, they can use it instead
- pfSense software does not currently utilize `transpiler` or similar utilities
- Take special care with user input or statements/variables that can be populated with user input to avoid creating a vulnerability vector such as XSS. User fields must be encoded or otherwise sanitized
  - For example, be extremely cautions of values inserted into JavaScript via PHP variables. `json_encode()` can help avoid a situation where a user-supplied string could include text such as quotes or semicolons that leads to execution of arbitrary JavaScript

39.6.6 Shell Script Specific Rules

- Use braces in **all** variable references for proper parameter expansion:

```
${SOMETHING}
```

39.6.7 Ports/Packages Specific Rules

When working with the pkg system and FreeBSD ports structure, adhere to the FreeBSD guidelines for code in these files.

Useful resources for working with pkg and ports include:

- The FreeBSD Porter's Handbook
- The FreeBSD Ports bsd.port.mk file
- Use portlint to check the syntax of the Makefile and other supporting files
  - Install portlint on a FreeBSD system and run the following command inside the root directory of the port:

```
portlint -CN
```

- Run the following command to make sure the contents of pkg-plist are correct:

```
make -DNO_DEPENDS check-plist
```

Other Guidelines:

- A port version or revision must increase for the port to be rebuilt, otherwise changes will not propagate to the pkg servers to be picked up by clients
  - For very minor changes, add or increase the `PORTREVISION` line immediately beneath `PORTVERSION` in the `Makefile`, starting at `1`, for example: A second revision would be `PORTREVISION=2`
  - For more significant changes, increase `PORTVERSION`
    - When increasing `PORTVERSION`, completely remove any `PORTREVISION` line, do not comment it out
  - Do not add or change `PORTEPOCH` except under direction of a committer

39.6.8 External Code

Code that has been imported from an external source does not need to be changed to fit these guidelines.

39.6.9 Editor Configuration

The pfSense software project uses a similar coding style to FreeBSD, which has editor configurations for Emacs and Vim. The FreeBSD man page style(9) contains additional relevant material.

CHAPTER

FORTY

LICENSING

pfSense® software uses a combination of Open Source software subject to several different licenses.

The following list shows each Open Source component along with its license.

Package Name	License

```
                    GNU GENERAL PUBLIC LICENSE
                       Version 2, June 1991

 Copyright (C) 1989, 1991 Free Software Foundation, Inc.,
 51 Franklin Street, Fifth Floor, Boston, MA 02110-1301 USA
 Everyone is permitted to copy and distribute verbatim copies
 of this license document, but changing it is not allowed.

                            Preamble

  The licenses for most software are designed to take away your
freedom to share and change it.  By contrast, the GNU General Public
License is intended to guarantee your freedom to share and change free
software--to make sure the software is free for all its users.  This
General Public License applies to most of the Free Software
Foundation's software and to any other program whose authors commit to
using it.  (Some other Free Software Foundation software is covered by
the GNU Lesser General Public License instead.)  You can apply it to
your programs, too.

  When we speak of free software, we are referring to freedom, not
price.  Our General Public Licenses are designed to make sure that you
have the freedom to distribute copies of free software (and charge for
this service if you wish), that you receive source code or can get it
```

(continues on next page)

(continued from previous page)

```
if you want it, that you can change the software or use pieces of it
in new free programs; and that you know you can do these things.

  To protect your rights, we need to make restrictions that forbid
anyone to deny you these rights or to ask you to surrender the rights.
These restrictions translate to certain responsibilities for you if you
distribute copies of the software, or if you modify it.

  For example, if you distribute copies of such a program, whether
gratis or for a fee, you must give the recipients all the rights that
you have.  You must make sure that they, too, receive or can get the
source code.  And you must show them these terms so they know their
rights.

  We protect your rights with two steps: (1) copyright the software, and
(2) offer you this license which gives you legal permission to copy,
distribute and/or modify the software.

  Also, for each author's protection and ours, we want to make certain
that everyone understands that there is no warranty for this free
software.  If the software is modified by someone else and passed on, we
want its recipients to know that what they have is not the original, so
that any problems introduced by others will not reflect on the original
authors' reputations.

  Finally, any free program is threatened constantly by software
patents.  We wish to avoid the danger that redistributors of a free
program will individually obtain patent licenses, in effect making the
program proprietary.  To prevent this, we have made it clear that any
patent must be licensed for everyone's free use or not licensed at all.

  The precise terms and conditions for copying, distribution and
modification follow.

                    GNU GENERAL PUBLIC LICENSE
   TERMS AND CONDITIONS FOR COPYING, DISTRIBUTION AND MODIFICATION

  0. This License applies to any program or other work which contains
a notice placed by the copyright holder saying it may be distributed
under the terms of this General Public License.  The "Program", below,
refers to any such program or work, and a "work based on the Program"
means either the Program or any derivative work under copyright law:
that is to say, a work containing the Program or a portion of it,
either verbatim or with modifications and/or translated into another
language.  (Hereinafter, translation is included without limitation in
the term "modification".)  Each licensee is addressed as "you".

Activities other than copying, distribution and modification are not
covered by this License; they are outside its scope.  The act of
running the Program is not restricted, and the output from the Program
is covered only if its contents constitute a work based on the
Program (independent of having been made by running the Program).
```

(continues on next page)

(continued from previous page)

```
Whether that is true depends on what the Program does.

  1. You may copy and distribute verbatim copies of the Program's
source code as you receive it, in any medium, provided that you
conspicuously and appropriately publish on each copy an appropriate
copyright notice and disclaimer of warranty; keep intact all the
notices that refer to this License and to the absence of any warranty;
and give any other recipients of the Program a copy of this License
along with the Program.

You may charge a fee for the physical act of transferring a copy, and
you may at your option offer warranty protection in exchange for a fee.

  2. You may modify your copy or copies of the Program or any portion
of it, thus forming a work based on the Program, and copy and
distribute such modifications or work under the terms of Section 1
above, provided that you also meet all of these conditions:

    a) You must cause the modified files to carry prominent notices
    stating that you changed the files and the date of any change.

    b) You must cause any work that you distribute or publish, that in
    whole or in part contains or is derived from the Program or any
    part thereof, to be licensed as a whole at no charge to all third
    parties under the terms of this License.

    c) If the modified program normally reads commands interactively
    when run, you must cause it, when started running for such
    interactive use in the most ordinary way, to print or display an
    announcement including an appropriate copyright notice and a
    notice that there is no warranty (or else, saying that you provide
    a warranty) and that users may redistribute the program under
    these conditions, and telling the user how to view a copy of this
    License.  (Exception: if the Program itself is interactive but
    does not normally print such an announcement, your work based on
    the Program is not required to print an announcement.)

These requirements apply to the modified work as a whole.  If
identifiable sections of that work are not derived from the Program,
and can be reasonably considered independent and separate works in
themselves, then this License, and its terms, do not apply to those
sections when you distribute them as separate works.  But when you
distribute the same sections as part of a whole which is a work based
on the Program, the distribution of the whole must be on the terms of
this License, whose permissions for other licensees extend to the
entire whole, and thus to each and every part regardless of who wrote it.

Thus, it is not the intent of this section to claim rights or contest
your rights to work written entirely by you; rather, the intent is to
exercise the right to control the distribution of derivative or
collective works based on the Program.
```

(continues on next page)

(continued from previous page)

```
In addition, mere aggregation of another work not based on the Program
with the Program (or with a work based on the Program) on a volume of
a storage or distribution medium does not bring the other work under
the scope of this License.

  3. You may copy and distribute the Program (or a work based on it,
under Section 2) in object code or executable form under the terms of
Sections 1 and 2 above provided that you also do one of the following:

    a) Accompany it with the complete corresponding machine-readable
    source code, which must be distributed under the terms of Sections
    1 and 2 above on a medium customarily used for software interchange; or,

    b) Accompany it with a written offer, valid for at least three
    years, to give any third party, for a charge no more than your
    cost of physically performing source distribution, a complete
    machine-readable copy of the corresponding source code, to be
    distributed under the terms of Sections 1 and 2 above on a medium
    customarily used for software interchange; or,

    c) Accompany it with the information you received as to the offer
    to distribute corresponding source code.  (This alternative is
    allowed only for noncommercial distribution and only if you
    received the program in object code or executable form with such
    an offer, in accord with Subsection b above.)

The source code for a work means the preferred form of the work for
making modifications to it.  For an executable work, complete source
code means all the source code for all modules it contains, plus any
associated interface definition files, plus the scripts used to
control compilation and installation of the executable.  However, as a
special exception, the source code distributed need not include
anything that is normally distributed (in either source or binary
form) with the major components (compiler, kernel, and so on) of the
operating system on which the executable runs, unless that component
itself accompanies the executable.

If distribution of executable or object code is made by offering
access to copy from a designated place, then offering equivalent
access to copy the source code from the same place counts as
distribution of the source code, even though third parties are not
compelled to copy the source along with the object code.

  4. You may not copy, modify, sublicense, or distribute the Program
except as expressly provided under this License.  Any attempt
otherwise to copy, modify, sublicense or distribute the Program is
void, and will automatically terminate your rights under this License.
However, parties who have received copies, or rights, from you under
this License will not have their licenses terminated so long as such
parties remain in full compliance.

  5. You are not required to accept this License, since you have not
```

(continues on next page)

(continued from previous page)

```
signed it.  However, nothing else grants you permission to modify or
distribute the Program or its derivative works.  These actions are
prohibited by law if you do not accept this License.  Therefore, by
modifying or distributing the Program (or any work based on the
Program), you indicate your acceptance of this License to do so, and
all its terms and conditions for copying, distributing or modifying
the Program or works based on it.

  6. Each time you redistribute the Program (or any work based on the
Program), the recipient automatically receives a license from the
original licensor to copy, distribute or modify the Program subject to
these terms and conditions.  You may not impose any further
restrictions on the recipients' exercise of the rights granted herein.
You are not responsible for enforcing compliance by third parties to
this License.

  7. If, as a consequence of a court judgment or allegation of patent
infringement or for any other reason (not limited to patent issues),
conditions are imposed on you (whether by court order, agreement or
otherwise) that contradict the conditions of this License, they do not
excuse you from the conditions of this License.  If you cannot
distribute so as to satisfy simultaneously your obligations under this
License and any other pertinent obligations, then as a consequence you
may not distribute the Program at all.  For example, if a patent
license would not permit royalty-free redistribution of the Program by
all those who receive copies directly or indirectly through you, then
the only way you could satisfy both it and this License would be to
refrain entirely from distribution of the Program.

If any portion of this section is held invalid or unenforceable under
any particular circumstance, the balance of the section is intended to
apply and the section as a whole is intended to apply in other
circumstances.

It is not the purpose of this section to induce you to infringe any
patents or other property right claims or to contest validity of any
such claims; this section has the sole purpose of protecting the
integrity of the free software distribution system, which is
implemented by public license practices.  Many people have made
generous contributions to the wide range of software distributed
through that system in reliance on consistent application of that
system; it is up to the author/donor to decide if he or she is willing
to distribute software through any other system and a licensee cannot
impose that choice.

This section is intended to make thoroughly clear what is believed to
be a consequence of the rest of this License.

  8. If the distribution and/or use of the Program is restricted in
certain countries either by patents or by copyrighted interfaces, the
original copyright holder who places the Program under this License
may add an explicit geographical distribution limitation excluding
```

(continues on next page)

(continued from previous page)

```
those countries, so that distribution is permitted only in or among
countries not thus excluded.  In such case, this License incorporates
the limitation as if written in the body of this License.

  9. The Free Software Foundation may publish revised and/or new versions
of the General Public License from time to time.  Such new versions will
be similar in spirit to the present version, but may differ in detail to
address new problems or concerns.

Each version is given a distinguishing version number.  If the Program
specifies a version number of this License which applies to it and "any
later version", you have the option of following the terms and conditions
either of that version or of any later version published by the Free
Software Foundation.  If the Program does not specify a version number of
this License, you may choose any version ever published by the Free Software
Foundation.

  10. If you wish to incorporate parts of the Program into other free
programs whose distribution conditions are different, write to the author
to ask for permission.  For software which is copyrighted by the Free
Software Foundation, write to the Free Software Foundation; we sometimes
make exceptions for this.  Our decision will be guided by the two goals
of preserving the free status of all derivatives of our free software and
of promoting the sharing and reuse of software generally.

                            NO WARRANTY

  11. BECAUSE THE PROGRAM IS LICENSED FREE OF CHARGE, THERE IS NO WARRANTY
FOR THE PROGRAM, TO THE EXTENT PERMITTED BY APPLICABLE LAW.  EXCEPT WHEN
OTHERWISE STATED IN WRITING THE COPYRIGHT HOLDERS AND/OR OTHER PARTIES
PROVIDE THE PROGRAM "AS IS" WITHOUT WARRANTY OF ANY KIND, EITHER EXPRESSED
OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE IMPLIED WARRANTIES OF
MERCHANTABILITY AND FITNESS FOR A PARTICULAR PURPOSE.  THE ENTIRE RISK AS
TO THE QUALITY AND PERFORMANCE OF THE PROGRAM IS WITH YOU.  SHOULD THE
PROGRAM PROVE DEFECTIVE, YOU ASSUME THE COST OF ALL NECESSARY SERVICING,
REPAIR OR CORRECTION.

  12. IN NO EVENT UNLESS REQUIRED BY APPLICABLE LAW OR AGREED TO IN WRITING
WILL ANY COPYRIGHT HOLDER, OR ANY OTHER PARTY WHO MAY MODIFY AND/OR
REDISTRIBUTE THE PROGRAM AS PERMITTED ABOVE, BE LIABLE TO YOU FOR DAMAGES,
INCLUDING ANY GENERAL, SPECIAL, INCIDENTAL OR CONSEQUENTIAL DAMAGES ARISING
OUT OF THE USE OR INABILITY TO USE THE PROGRAM (INCLUDING BUT NOT LIMITED
TO LOSS OF DATA OR DATA BEING RENDERED INACCURATE OR LOSSES SUSTAINED BY
YOU OR THIRD PARTIES OR A FAILURE OF THE PROGRAM TO OPERATE WITH ANY OTHER
PROGRAMS), EVEN IF SUCH HOLDER OR OTHER PARTY HAS BEEN ADVISED OF THE
POSSIBILITY OF SUCH DAMAGES.

                     END OF TERMS AND CONDITIONS

            How to Apply These Terms to Your New Programs

  If you develop a new program, and you want it to be of the greatest
```

(continues on next page)

(continued from previous page)

```
possible use to the public, the best way to achieve this is to make it
free software which everyone can redistribute and change under these terms.

  To do so, attach the following notices to the program.  It is safest
to attach them to the start of each source file to most effectively
convey the exclusion of warranty; and each file should have at least
the "copyright" line and a pointer to where the full notice is found.

    <one line to give the program's name and a brief idea of what it does.>
    Copyright (C) <year>  <name of author>

    This program is free software; you can redistribute it and/or modify
    it under the terms of the GNU General Public License as published by
    the Free Software Foundation; either version 2 of the License, or
    (at your option) any later version.

    This program is distributed in the hope that it will be useful,
    but WITHOUT ANY WARRANTY; without even the implied warranty of
    MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE.  See the
    GNU General Public License for more details.

    You should have received a copy of the GNU General Public License along
    with this program; if not, write to the Free Software Foundation, Inc.,
    51 Franklin Street, Fifth Floor, Boston, MA 02110-1301 USA.

Also add information on how to contact you by electronic and paper mail.

If the program is interactive, make it output a short notice like this
when it starts in an interactive mode:

    Gnomovision version 69, Copyright (C) year name of author
    Gnomovision comes with ABSOLUTELY NO WARRANTY; for details type `show w'.
    This is free software, and you are welcome to redistribute it
    under certain conditions; type `show c' for details.

The hypothetical commands `show w' and `show c' should show the appropriate
parts of the General Public License.  Of course, the commands you use may
be called something other than `show w' and `show c'; they could even be
mouse-clicks or menu items--whatever suits your program.

You should also get your employer (if you work as a programmer) or your
school, if any, to sign a "copyright disclaimer" for the program, if
necessary.  Here is a sample; alter the names:

  Yoyodyne, Inc., hereby disclaims all copyright interest in the program
  `Gnomovision' (which makes passes at compilers) written by James Hacker.

  <signature of Ty Coon>, 1 April 1989
  Ty Coon, President of Vice

This General Public License does not permit incorporating your program into
proprietary programs.  If your program is a subroutine library, you may
```

(continues on next page)

(continued from previous page)

```
consider it more useful to permit linking proprietary applications with the
library.  If this is what you want to do, use the GNU Lesser General
Public License instead of this License.
```

40.5 LGPL21+ License Text for multiple packages

The following license text applies to multiple packages:

Listing 5: Download: LGPL21+ for multiple packages

```
                  GNU LESSER GENERAL PUBLIC LICENSE
                       Version 2.1, February 1999

 Copyright (C) 1991, 1999 Free Software Foundation, Inc.
 51 Franklin Street, Fifth Floor, Boston, MA  02110-1301  USA
 Everyone is permitted to copy and distribute verbatim copies
 of this license document, but changing it is not allowed.

[This is the first released version of the Lesser GPL.  It also counts
 as the successor of the GNU Library Public License, version 2, hence
 the version number 2.1.]

                            Preamble

  The licenses for most software are designed to take away your
freedom to share and change it.  By contrast, the GNU General Public
Licenses are intended to guarantee your freedom to share and change
free software--to make sure the software is free for all its users.

  This license, the Lesser General Public License, applies to some
specially designated software packages--typically libraries--of the
Free Software Foundation and other authors who decide to use it.  You
can use it too, but we suggest you first think carefully about whether
this license or the ordinary General Public License is the better
strategy to use in any particular case, based on the explanations below.

  When we speak of free software, we are referring to freedom of use,
not price.  Our General Public Licenses are designed to make sure that
you have the freedom to distribute copies of free software (and charge
for this service if you wish); that you receive source code or can get
it if you want it; that you can change the software and use pieces of
it in new free programs; and that you are informed that you can do
these things.

  To protect your rights, we need to make restrictions that forbid
distributors to deny you these rights or to ask you to surrender these
rights.  These restrictions translate to certain responsibilities for
you if you distribute copies of the library or if you modify it.

  For example, if you distribute copies of the library, whether gratis
```

(continues on next page)

(continued from previous page)

```
or for a fee, you must give the recipients all the rights that we gave
you.  You must make sure that they, too, receive or can get the source
code.  If you link other code with the library, you must provide
complete object files to the recipients, so that they can relink them
with the library after making changes to the library and recompiling
it.  And you must show them these terms so they know their rights.

  We protect your rights with a two-step method: (1) we copyright the
library, and (2) we offer you this license, which gives you legal
permission to copy, distribute and/or modify the library.

  To protect each distributor, we want to make it very clear that
there is no warranty for the free library.  Also, if the library is
modified by someone else and passed on, the recipients should know
that what they have is not the original version, so that the original
author's reputation will not be affected by problems that might be

introduced by others.

  Finally, software patents pose a constant threat to the existence of
any free program.  We wish to make sure that a company cannot
effectively restrict the users of a free program by obtaining a
restrictive license from a patent holder.  Therefore, we insist that
any patent license obtained for a version of the library must be
consistent with the full freedom of use specified in this license.

  Most GNU software, including some libraries, is covered by the
ordinary GNU General Public License.  This license, the GNU Lesser
General Public License, applies to certain designated libraries, and
is quite different from the ordinary General Public License.  We use
this license for certain libraries in order to permit linking those
libraries into non-free programs.

  When a program is linked with a library, whether statically or using
a shared library, the combination of the two is legally speaking a
combined work, a derivative of the original library.  The ordinary
General Public License therefore permits such linking only if the
entire combination fits its criteria of freedom.  The Lesser General
Public License permits more lax criteria for linking other code with
the library.

  We call this license the "Lesser" General Public License because it
does Less to protect the user's freedom than the ordinary General
Public License.  It also provides other free software developers Less
of an advantage over competing non-free programs.  These disadvantages
are the reason we use the ordinary General Public License for many
libraries.  However, the Lesser license provides advantages in certain
special circumstances.

  For example, on rare occasions, there may be a special need to
encourage the widest possible use of a certain library, so that it becomes
a de-facto standard.  To achieve this, non-free programs must be
```

(continues on next page)

(continued from previous page)

```
allowed to use the library.  A more frequent case is that a free
library does the same job as widely used non-free libraries.  In this
case, there is little to gain by limiting the free library to free
software only, so we use the Lesser General Public License.

  In other cases, permission to use a particular library in non-free
programs enables a greater number of people to use a large body of
free software.  For example, permission to use the GNU C Library in
non-free programs enables many more people to use the whole GNU
operating system, as well as its variant, the GNU/Linux operating
system.

  Although the Lesser General Public License is Less protective of the
users' freedom, it does ensure that the user of a program that is
linked with the Library has the freedom and the wherewithal to run
that program using a modified version of the Library.

  The precise terms and conditions for copying, distribution and
modification follow.  Pay close attention to the difference between a
"work based on the library" and a "work that uses the library".  The
former contains code derived from the library, whereas the latter must

be combined with the library in order to run.

                  GNU LESSER GENERAL PUBLIC LICENSE
   TERMS AND CONDITIONS FOR COPYING, DISTRIBUTION AND MODIFICATION

  0. This License Agreement applies to any software library or other
program which contains a notice placed by the copyright holder or
other authorized party saying it may be distributed under the terms of
this Lesser General Public License (also called "this License").
Each licensee is addressed as "you".

  A "library" means a collection of software functions and/or data
prepared so as to be conveniently linked with application programs
(which use some of those functions and data) to form executables.

  The "Library", below, refers to any such software library or work
which has been distributed under these terms.  A "work based on the
Library" means either the Library or any derivative work under
copyright law: that is to say, a work containing the Library or a
portion of it, either verbatim or with modifications and/or translated
straightforwardly into another language.  (Hereinafter, translation is
included without limitation in the term "modification".)

  "Source code" for a work means the preferred form of the work for
making modifications to it.  For a library, complete source code means
all the source code for all modules it contains, plus any associated
interface definition files, plus the scripts used to control compilation
and installation of the library.

  Activities other than copying, distribution and modification are not
```

(continues on next page)

(continued from previous page)

```
covered by this License; they are outside its scope.  The act of
running a program using the Library is not restricted, and output from
such a program is covered only if its contents constitute a work based
on the Library (independent of the use of the Library in a tool for
writing it).  Whether that is true depends on what the Library does
and what the program that uses the Library does.

  1. You may copy and distribute verbatim copies of the Library's
complete source code as you receive it, in any medium, provided that
you conspicuously and appropriately publish on each copy an
appropriate copyright notice and disclaimer of warranty; keep intact
all the notices that refer to this License and to the absence of any
warranty; and distribute a copy of this License along with the
Library.

  You may charge a fee for the physical act of transferring a copy,
and you may at your option offer warranty protection in exchange for a

fee.

  2. You may modify your copy or copies of the Library or any portion
of it, thus forming a work based on the Library, and copy and
distribute such modifications or work under the terms of Section 1
above, provided that you also meet all of these conditions:

    a) The modified work must itself be a software library.

    b) You must cause the files modified to carry prominent notices
    stating that you changed the files and the date of any change.

    c) You must cause the whole of the work to be licensed at no
    charge to all third parties under the terms of this License.

    d) If a facility in the modified Library refers to a function or a
    table of data to be supplied by an application program that uses
    the facility, other than as an argument passed when the facility
    is invoked, then you must make a good faith effort to ensure that,
    in the event an application does not supply such function or
    table, the facility still operates, and performs whatever part of
    its purpose remains meaningful.

    (For example, a function in a library to compute square roots has
    a purpose that is entirely well-defined independent of the
    application.  Therefore, Subsection 2d requires that any
    application-supplied function or table used by this function must
    be optional: if the application does not supply it, the square
    root function must still compute square roots.)

These requirements apply to the modified work as a whole.  If
identifiable sections of that work are not derived from the Library,
and can be reasonably considered independent and separate works in
themselves, then this License, and its terms, do not apply to those
```

(continues on next page)

(continued from previous page)

```
sections when you distribute them as separate works.  But when you
distribute the same sections as part of a whole which is a work based
on the Library, the distribution of the whole must be on the terms of
this License, whose permissions for other licensees extend to the
entire whole, and thus to each and every part regardless of who wrote
it.

Thus, it is not the intent of this section to claim rights or contest
your rights to work written entirely by you; rather, the intent is to
exercise the right to control the distribution of derivative or
collective works based on the Library.

In addition, mere aggregation of another work not based on the Library
with the Library (or with a work based on the Library) on a volume of
a storage or distribution medium does not bring the other work under
the scope of this License.

  3. You may opt to apply the terms of the ordinary GNU General Public
License instead of this License to a given copy of the Library.  To do
this, you must alter all the notices that refer to this License, so
that they refer to the ordinary GNU General Public License, version 2,
instead of to this License.  (If a newer version than version 2 of the
ordinary GNU General Public License has appeared, then you can specify
that version instead if you wish.)  Do not make any other change in

these notices.

  Once this change is made in a given copy, it is irreversible for
that copy, so the ordinary GNU General Public License applies to all
subsequent copies and derivative works made from that copy.

  This option is useful when you wish to copy part of the code of
the Library into a program that is not a library.

  4. You may copy and distribute the Library (or a portion or
derivative of it, under Section 2) in object code or executable form
under the terms of Sections 1 and 2 above provided that you accompany
it with the complete corresponding machine-readable source code, which
must be distributed under the terms of Sections 1 and 2 above on a
medium customarily used for software interchange.

  If distribution of object code is made by offering access to copy
from a designated place, then offering equivalent access to copy the
source code from the same place satisfies the requirement to
distribute the source code, even though third parties are not
compelled to copy the source along with the object code.

  5. A program that contains no derivative of any portion of the
Library, but is designed to work with the Library by being compiled or
linked with it, is called a "work that uses the Library".  Such a
work, in isolation, is not a derivative work of the Library, and
therefore falls outside the scope of this License.
```

(continues on next page)

(continued from previous page)

```
  However, linking a "work that uses the Library" with the Library
creates an executable that is a derivative of the Library (because it
contains portions of the Library), rather than a "work that uses the
library".  The executable is therefore covered by this License.
Section 6 states terms for distribution of such executables.

  When a "work that uses the Library" uses material from a header file
that is part of the Library, the object code for the work may be a
derivative work of the Library even though the source code is not.
Whether this is true is especially significant if the work can be
linked without the Library, or if the work is itself a library.  The
threshold for this to be true is not precisely defined by law.

  If such an object file uses only numerical parameters, data
structure layouts and accessors, and small macros and small inline
functions (ten lines or less in length), then the use of the object
file is unrestricted, regardless of whether it is legally a derivative
work.  (Executables containing this object code plus portions of the
Library will still fall under Section 6.)

  Otherwise, if the work is a derivative of the Library, you may
distribute the object code for the work under the terms of Section 6.
Any executables containing that work also fall under Section 6,

whether or not they are linked directly with the Library itself.

  6. As an exception to the Sections above, you may also combine or
link a "work that uses the Library" with the Library to produce a
work containing portions of the Library, and distribute that work
under terms of your choice, provided that the terms permit
modification of the work for the customer's own use and reverse
engineering for debugging such modifications.

  You must give prominent notice with each copy of the work that the
Library is used in it and that the Library and its use are covered by
this License.  You must supply a copy of this License.  If the work
during execution displays copyright notices, you must include the
copyright notice for the Library among them, as well as a reference
directing the user to the copy of this License.  Also, you must do one
of these things:

    a) Accompany the work with the complete corresponding
    machine-readable source code for the Library including whatever
    changes were used in the work (which must be distributed under
    Sections 1 and 2 above); and, if the work is an executable linked
    with the Library, with the complete machine-readable "work that
    uses the Library", as object code and/or source code, so that the
    user can modify the Library and then relink to produce a modified
    executable containing the modified Library.  (It is understood
    that the user who changes the contents of definitions files in the
    Library will not necessarily be able to recompile the application
```

(continues on next page)

(continued from previous page)

```
    to use the modified definitions.)

    b) Use a suitable shared library mechanism for linking with the
    Library.  A suitable mechanism is one that (1) uses at run time a
    copy of the library already present on the user's computer system,
    rather than copying library functions into the executable, and (2)
    will operate properly with a modified version of the library, if
    the user installs one, as long as the modified version is
    interface-compatible with the version that the work was made with.

    c) Accompany the work with a written offer, valid for at
    least three years, to give the same user the materials
    specified in Subsection 6a, above, for a charge no more
    than the cost of performing this distribution.

    d) If distribution of the work is made by offering access to copy
    from a designated place, offer equivalent access to copy the above
    specified materials from the same place.

    e) Verify that the user has already received a copy of these
    materials or that you have already sent this user a copy.

  For an executable, the required form of the "work that uses the
Library" must include any data and utility programs needed for
reproducing the executable from it.  However, as a special exception,
the materials to be distributed need not include anything that is
normally distributed (in either source or binary form) with the major
components (compiler, kernel, and so on) of the operating system on
which the executable runs, unless that component itself accompanies
the executable.

  It may happen that this requirement contradicts the license
restrictions of other proprietary libraries that do not normally
accompany the operating system.  Such a contradiction means you cannot
use both them and the Library together in an executable that you

distribute.

  7. You may place library facilities that are a work based on the
Library side-by-side in a single library together with other library
facilities not covered by this License, and distribute such a combined
library, provided that the separate distribution of the work based on
the Library and of the other library facilities is otherwise
permitted, and provided that you do these two things:

    a) Accompany the combined library with a copy of the same work
    based on the Library, uncombined with any other library
    facilities.  This must be distributed under the terms of the
    Sections above.

    b) Give prominent notice with the combined library of the fact
    that part of it is a work based on the Library, and explaining
```

(continues on next page)

(continued from previous page)

```
    where to find the accompanying uncombined form of the same work.

  8. You may not copy, modify, sublicense, link with, or distribute
the Library except as expressly provided under this License.  Any
attempt otherwise to copy, modify, sublicense, link with, or
distribute the Library is void, and will automatically terminate your
rights under this License.  However, parties who have received copies,
or rights, from you under this License will not have their licenses
terminated so long as such parties remain in full compliance.

  9. You are not required to accept this License, since you have not
signed it.  However, nothing else grants you permission to modify or
distribute the Library or its derivative works.  These actions are
prohibited by law if you do not accept this License.  Therefore, by
modifying or distributing the Library (or any work based on the
Library), you indicate your acceptance of this License to do so, and
all its terms and conditions for copying, distributing or modifying
the Library or works based on it.

  10. Each time you redistribute the Library (or any work based on the
Library), the recipient automatically receives a license from the
original licensor to copy, distribute, link with or modify the Library
subject to these terms and conditions.  You may not impose any further
restrictions on the recipients' exercise of the rights granted herein.
You are not responsible for enforcing compliance by third parties with

this License.

  11. If, as a consequence of a court judgment or allegation of patent
infringement or for any other reason (not limited to patent issues),
conditions are imposed on you (whether by court order, agreement or
otherwise) that contradict the conditions of this License, they do not
excuse you from the conditions of this License.  If you cannot
distribute so as to satisfy simultaneously your obligations under this
License and any other pertinent obligations, then as a consequence you
may not distribute the Library at all.  For example, if a patent
license would not permit royalty-free redistribution of the Library by
all those who receive copies directly or indirectly through you, then
the only way you could satisfy both it and this License would be to
refrain entirely from distribution of the Library.

If any portion of this section is held invalid or unenforceable under any
particular circumstance, the balance of the section is intended to apply,
and the section as a whole is intended to apply in other circumstances.

It is not the purpose of this section to induce you to infringe any
patents or other property right claims or to contest validity of any
such claims; this section has the sole purpose of protecting the
integrity of the free software distribution system which is
implemented by public license practices.  Many people have made
generous contributions to the wide range of software distributed
through that system in reliance on consistent application of that
```

(continues on next page)

(continued from previous page)

```
system; it is up to the author/donor to decide if he or she is willing
to distribute software through any other system and a licensee cannot
impose that choice.

This section is intended to make thoroughly clear what is believed to
be a consequence of the rest of this License.

  12. If the distribution and/or use of the Library is restricted in
certain countries either by patents or by copyrighted interfaces, the
original copyright holder who places the Library under this License may add
an explicit geographical distribution limitation excluding those countries,
so that distribution is permitted only in or among countries not thus
excluded.  In such case, this License incorporates the limitation as if
written in the body of this License.

  13. The Free Software Foundation may publish revised and/or new
versions of the Lesser General Public License from time to time.
Such new versions will be similar in spirit to the present version,
but may differ in detail to address new problems or concerns.

Each version is given a distinguishing version number.  If the Library
specifies a version number of this License which applies to it and
"any later version", you have the option of following the terms and
conditions either of that version or of any later version published by
the Free Software Foundation.  If the Library does not specify a
license version number, you may choose any version ever published by

the Free Software Foundation.

  14. If you wish to incorporate parts of the Library into other free
programs whose distribution conditions are incompatible with these,
write to the author to ask for permission.  For software which is
copyrighted by the Free Software Foundation, write to the Free
Software Foundation; we sometimes make exceptions for this.  Our
decision will be guided by the two goals of preserving the free status
of all derivatives of our free software and of promoting the sharing
and reuse of software generally.

                            NO WARRANTY

  15. BECAUSE THE LIBRARY IS LICENSED FREE OF CHARGE, THERE IS NO
WARRANTY FOR THE LIBRARY, TO THE EXTENT PERMITTED BY APPLICABLE LAW.
EXCEPT WHEN OTHERWISE STATED IN WRITING THE COPYRIGHT HOLDERS AND/OR
OTHER PARTIES PROVIDE THE LIBRARY "AS IS" WITHOUT WARRANTY OF ANY
KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE
IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR
PURPOSE.  THE ENTIRE RISK AS TO THE QUALITY AND PERFORMANCE OF THE
LIBRARY IS WITH YOU.  SHOULD THE LIBRARY PROVE DEFECTIVE, YOU ASSUME
THE COST OF ALL NECESSARY SERVICING, REPAIR OR CORRECTION.

  16. IN NO EVENT UNLESS REQUIRED BY APPLICABLE LAW OR AGREED TO IN
WRITING WILL ANY COPYRIGHT HOLDER, OR ANY OTHER PARTY WHO MAY MODIFY
```

(continues on next page)

(continued from previous page)

```
AND/OR REDISTRIBUTE THE LIBRARY AS PERMITTED ABOVE, BE LIABLE TO YOU
FOR DAMAGES, INCLUDING ANY GENERAL, SPECIAL, INCIDENTAL OR
CONSEQUENTIAL DAMAGES ARISING OUT OF THE USE OR INABILITY TO USE THE
LIBRARY (INCLUDING BUT NOT LIMITED TO LOSS OF DATA OR DATA BEING
RENDERED INACCURATE OR LOSSES SUSTAINED BY YOU OR THIRD PARTIES OR A
FAILURE OF THE LIBRARY TO OPERATE WITH ANY OTHER SOFTWARE), EVEN IF
SUCH HOLDER OR OTHER PARTY HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH
DAMAGES.

                     END OF TERMS AND CONDITIONS

           How to Apply These Terms to Your New Libraries

  If you develop a new library, and you want it to be of the greatest
possible use to the public, we recommend making it free software that
everyone can redistribute and change.  You can do so by permitting
redistribution under these terms (or, alternatively, under the terms of the
ordinary General Public License).

  To apply these terms, attach the following notices to the library.  It is
safest to attach them to the start of each source file to most effectively
convey the exclusion of warranty; and each file should have at least the
"copyright" line and a pointer to where the full notice is found.

    <one line to give the library's name and a brief idea of what it does.>
    Copyright (C) <year>  <name of author>

    This library is free software; you can redistribute it and/or
    modify it under the terms of the GNU Lesser General Public
    License as published by the Free Software Foundation; either
    version 2.1 of the License, or (at your option) any later version.

    This library is distributed in the hope that it will be useful,
    but WITHOUT ANY WARRANTY; without even the implied warranty of
    MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE.  See the GNU
    Lesser General Public License for more details.

    You should have received a copy of the GNU Lesser General Public
    License along with this library; if not, write to the Free Software
    Foundation, Inc., 51 Franklin Street, Fifth Floor, Boston, MA  02110-1301  USA

Also add information on how to contact you by electronic and paper mail.

You should also get your employer (if you work as a programmer) or your
school, if any, to sign a "copyright disclaimer" for the library, if
necessary.  Here is a sample; alter the names:

  Yoyodyne, Inc., hereby disclaims all copyright interest in the
  library `Frob' (a library for tweaking knobs) written by James Random Hacker.

  <signature of Ty Coon>, 1 April 1990
```

A. HISTORY OF THE SOFTWARE
==========================

Python was created in the early 1990s by Guido van Rossum at Stichting
Mathematisch Centrum (CWI, see http://www.cwi.nl) in the Netherlands
as a successor of a language called ABC.  Guido remains Python's
principal author, although it includes many contributions from others.

In 1995, Guido continued his work on Python at the Corporation for
National Research Initiatives (CNRI, see http://www.cnri.reston.va.us)
in Reston, Virginia where he released several versions of the
software.

In May 2000, Guido and the Python core development team moved to
BeOpen.com to form the BeOpen PythonLabs team.  In October of the same
year, the PythonLabs team moved to Digital Creations, which became
Zope Corporation.  In 2001, the Python Software Foundation (PSF, see
https://www.python.org/psf/) was formed, a non-profit organization
created specifically to own Python-related Intellectual Property.
Zope Corporation was a sponsoring member of the PSF.

All Python releases are Open Source (see http://www.opensource.org for
the Open Source Definition).  Historically, most, but not all, Python
releases have also been GPL-compatible; the table below summarizes
the various releases.

    Release         Derived     Year        Owner       GPL-
                    from                                compatible? (1)

    0.9.0 thru 1.2              1991-1995   CWI         yes
    1.3 thru 1.5.2  1.2         1995-1999   CNRI        yes
    1.6             1.5.2       2000        CNRI        no
    2.0             1.6         2000        BeOpen.com  no
    1.6.1           1.6         2001        CNRI        yes (2)
    2.1             2.0+1.6.1   2001        PSF         no
```

(continues on next page)

(continued from previous page)

```
    2.0.1           2.0+1.6.1   2001        PSF         yes
    2.1.1           2.1+2.0.1   2001        PSF         yes
    2.1.2           2.1.1       2002        PSF         yes
    2.1.3           2.1.2       2002        PSF         yes
    2.2 and above   2.1.1       2001-now    PSF         yes

Footnotes:

(1) GPL-compatible doesn't mean that we're distributing Python under
    the GPL.  All Python licenses, unlike the GPL, let you distribute
    a modified version without making your changes open source.  The
    GPL-compatible licenses make it possible to combine Python with
    other software that is released under the GPL; the others don't.

(2) According to Richard Stallman, 1.6.1 is not GPL-compatible,
    because its license has a choice of law clause.  According to
    CNRI, however, Stallman's lawyer has told CNRI's lawyer that 1.6.1
    is "not incompatible" with the GPL.

Thanks to the many outside volunteers who have worked under Guido's
direction to make these releases possible.

B. TERMS AND CONDITIONS FOR ACCESSING OR OTHERWISE USING PYTHON
===============================================================

Python software and documentation are licensed under the
Python Software Foundation License Version 2.

Starting with Python 3.8.6, examples, recipes, and other code in
the documentation are dual licensed under the PSF License Version 2
and the Zero-Clause BSD license.

Some software incorporated into Python is under different licenses.
The licenses are listed with code falling under that license.

PYTHON SOFTWARE FOUNDATION LICENSE VERSION 2
--------------------------------------------

1. This LICENSE AGREEMENT is between the Python Software Foundation
("PSF"), and the Individual or Organization ("Licensee") accessing and
otherwise using this software ("Python") in source or binary form and
its associated documentation.

2. Subject to the terms and conditions of this License Agreement, PSF hereby
grants Licensee a nonexclusive, royalty-free, world-wide license to reproduce,
analyze, test, perform and/or display publicly, prepare derivative works,
distribute, and otherwise use Python alone or in any derivative version,
provided, however, that PSF's License Agreement and PSF's notice of copyright,
i.e., "Copyright (c) 2001, 2002, 2003, 2004, 2005, 2006, 2007, 2008, 2009, 2010,
2011, 2012, 2013, 2014, 2015, 2016, 2017, 2018, 2019, 2020, 2021, 2022 Python Software␣
```

(continues on next page)

(continued from previous page)

```
↪Foundation;
All Rights Reserved" are retained in Python alone or in any derivative version
prepared by Licensee.

3. In the event Licensee prepares a derivative work that is based on
or incorporates Python or any part thereof, and wants to make
the derivative work available to others as provided herein, then
Licensee hereby agrees to include in any such work a brief summary of
the changes made to Python.

4. PSF is making Python available to Licensee on an "AS IS"
basis.  PSF MAKES NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR
IMPLIED.  BY WAY OF EXAMPLE, BUT NOT LIMITATION, PSF MAKES NO AND
DISCLAIMS ANY REPRESENTATION OR WARRANTY OF MERCHANTABILITY OR FITNESS
FOR ANY PARTICULAR PURPOSE OR THAT THE USE OF PYTHON WILL NOT
INFRINGE ANY THIRD PARTY RIGHTS.

5. PSF SHALL NOT BE LIABLE TO LICENSEE OR ANY OTHER USERS OF PYTHON
FOR ANY INCIDENTAL, SPECIAL, OR CONSEQUENTIAL DAMAGES OR LOSS AS
A RESULT OF MODIFYING, DISTRIBUTING, OR OTHERWISE USING PYTHON,
OR ANY DERIVATIVE THEREOF, EVEN IF ADVISED OF THE POSSIBILITY THEREOF.

6. This License Agreement will automatically terminate upon a material
breach of its terms and conditions.

7. Nothing in this License Agreement shall be deemed to create any
relationship of agency, partnership, or joint venture between PSF and
Licensee.  This License Agreement does not grant permission to use PSF
trademarks or trade name in a trademark sense to endorse or promote
products or services of Licensee, or any third party.

8. By copying, installing or otherwise using Python, Licensee
agrees to be bound by the terms and conditions of this License
Agreement.

BEOPEN.COM LICENSE AGREEMENT FOR PYTHON 2.0
-------------------------------------------

BEOPEN PYTHON OPEN SOURCE LICENSE AGREEMENT VERSION 1

1. This LICENSE AGREEMENT is between BeOpen.com ("BeOpen"), having an
office at 160 Saratoga Avenue, Santa Clara, CA 95051, and the
Individual or Organization ("Licensee") accessing and otherwise using
this software in source or binary form and its associated
documentation ("the Software").

2. Subject to the terms and conditions of this BeOpen Python License
Agreement, BeOpen hereby grants Licensee a non-exclusive,
royalty-free, world-wide license to reproduce, analyze, test, perform
and/or display publicly, prepare derivative works, distribute, and
otherwise use the Software alone or in any derivative version,
```

(continues on next page)

(continued from previous page)

```
provided, however, that the BeOpen Python License is retained in the
Software, alone or in any derivative version prepared by Licensee.

3. BeOpen is making the Software available to Licensee on an "AS IS"
basis.  BEOPEN MAKES NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR
IMPLIED.  BY WAY OF EXAMPLE, BUT NOT LIMITATION, BEOPEN MAKES NO AND
DISCLAIMS ANY REPRESENTATION OR WARRANTY OF MERCHANTABILITY OR FITNESS
FOR ANY PARTICULAR PURPOSE OR THAT THE USE OF THE SOFTWARE WILL NOT
INFRINGE ANY THIRD PARTY RIGHTS.

4. BEOPEN SHALL NOT BE LIABLE TO LICENSEE OR ANY OTHER USERS OF THE
SOFTWARE FOR ANY INCIDENTAL, SPECIAL, OR CONSEQUENTIAL DAMAGES OR LOSS
AS A RESULT OF USING, MODIFYING OR DISTRIBUTING THE SOFTWARE, OR ANY
DERIVATIVE THEREOF, EVEN IF ADVISED OF THE POSSIBILITY THEREOF.

5. This License Agreement will automatically terminate upon a material
breach of its terms and conditions.

6. This License Agreement shall be governed by and interpreted in all
respects by the law of the State of California, excluding conflict of
law provisions.  Nothing in this License Agreement shall be deemed to
create any relationship of agency, partnership, or joint venture
between BeOpen and Licensee.  This License Agreement does not grant
permission to use BeOpen trademarks or trade names in a trademark
sense to endorse or promote products or services of Licensee, or any
third party.  As an exception, the "BeOpen Python" logos available at
http://www.pythonlabs.com/logos.html may be used according to the
permissions granted on that web page.

7. By copying, installing or otherwise using the software, Licensee
agrees to be bound by the terms and conditions of this License
Agreement.

CNRI LICENSE AGREEMENT FOR PYTHON 1.6.1
---------------------------------------

1. This LICENSE AGREEMENT is between the Corporation for National
Research Initiatives, having an office at 1895 Preston White Drive,
Reston, VA 20191 ("CNRI"), and the Individual or Organization
("Licensee") accessing and otherwise using Python 1.6.1 software in
source or binary form and its associated documentation.

2. Subject to the terms and conditions of this License Agreement, CNRI
hereby grants Licensee a nonexclusive, royalty-free, world-wide
license to reproduce, analyze, test, perform and/or display publicly,
prepare derivative works, distribute, and otherwise use Python 1.6.1
alone or in any derivative version, provided, however, that CNRI's
License Agreement and CNRI's notice of copyright, i.e., "Copyright (c)
1995-2001 Corporation for National Research Initiatives; All Rights
Reserved" are retained in Python 1.6.1 alone or in any derivative
version prepared by Licensee.  Alternately, in lieu of CNRI's License
```

(continues on next page)

(continued from previous page)

```
Agreement, Licensee may substitute the following text (omitting the
quotes): "Python 1.6.1 is made available subject to the terms and
conditions in CNRI's License Agreement.  This Agreement together with
Python 1.6.1 may be located on the internet using the following
unique, persistent identifier (known as a handle): 1895.22/1013.  This
Agreement may also be obtained from a proxy server on the internet
using the following URL: http://hdl.handle.net/1895.22/1013".

3. In the event Licensee prepares a derivative work that is based on
or incorporates Python 1.6.1 or any part thereof, and wants to make
the derivative work available to others as provided herein, then
Licensee hereby agrees to include in any such work a brief summary of
the changes made to Python 1.6.1.

4. CNRI is making Python 1.6.1 available to Licensee on an "AS IS"
basis.  CNRI MAKES NO REPRESENTATIONS OR WARRANTIES, EXPRESS OR
IMPLIED.  BY WAY OF EXAMPLE, BUT NOT LIMITATION, CNRI MAKES NO AND
DISCLAIMS ANY REPRESENTATION OR WARRANTY OF MERCHANTABILITY OR FITNESS
FOR ANY PARTICULAR PURPOSE OR THAT THE USE OF PYTHON 1.6.1 WILL NOT
INFRINGE ANY THIRD PARTY RIGHTS.

5. CNRI SHALL NOT BE LIABLE TO LICENSEE OR ANY OTHER USERS OF PYTHON
1.6.1 FOR ANY INCIDENTAL, SPECIAL, OR CONSEQUENTIAL DAMAGES OR LOSS AS
A RESULT OF MODIFYING, DISTRIBUTING, OR OTHERWISE USING PYTHON 1.6.1,
OR ANY DERIVATIVE THEREOF, EVEN IF ADVISED OF THE POSSIBILITY THEREOF.

6. This License Agreement will automatically terminate upon a material
breach of its terms and conditions.

7. This License Agreement shall be governed by the federal
intellectual property law of the United States, including without
limitation the federal copyright law, and, to the extent such
U.S. federal law does not apply, by the law of the Commonwealth of
Virginia, excluding Virginia's conflict of law provisions.
Notwithstanding the foregoing, with regard to derivative works based
on Python 1.6.1 that incorporate non-separable material that was
previously distributed under the GNU General Public License (GPL), the
law of the Commonwealth of Virginia shall govern this License
Agreement only as to issues arising under or with respect to
Paragraphs 4, 5, and 7 of this License Agreement.  Nothing in this
License Agreement shall be deemed to create any relationship of
agency, partnership, or joint venture between CNRI and Licensee.  This
License Agreement does not grant permission to use CNRI trademarks or
trade name in a trademark sense to endorse or promote products or
services of Licensee, or any third party.

8. By clicking on the "ACCEPT" button where indicated, or by copying,
installing or otherwise using Python 1.6.1, Licensee agrees to be
bound by the terms and conditions of this License Agreement.

        ACCEPT
```

40.10 MPL20 License Text for ca_root_nss

The following license text applies to ca_root_nss:

Listing 10: Download: MPL20 for ca_root_nss

```
NSS is available under the Mozilla Public License, version 2, a copy of which
is below.

Note on GPL Compatibility
-------------------------

The MPL 2, section 3.3, permits you to combine NSS with code under the GNU
General Public License (GPL) version 2, or any later version of that
license, to make a Larger Work, and distribute the result under the GPL.
The only condition is that you must also make NSS, and any changes you
have made to it, available to recipients under the terms of the MPL 2 also.

Anyone who receives the combined code from you does not have to continue
to dual licence in this way, and may, if they wish, distribute under the
terms of either of the two licences - either the MPL alone or the GPL
alone. However, we discourage people from distributing copies of NSS under
the GPL alone, because it means that any improvements they make cannot be
reincorporated into the main version of NSS. There is never a need to do
this for license compatibility reasons.

Note on LGPL Compatibility
--------------------------

The above also applies to combining MPLed code in a single library with
code under the GNU Lesser General Public License (LGPL) version 2.1, or
any later version of that license. If the LGPLed code and the MPLed code
are not in the same library, then the copyleft coverage of the two
licences does not overlap, so no issues arise.

Mozilla Public License Version 2.0
==================================

1. Definitions
--------------

1.1. "Contributor"
    means each individual or legal entity that creates, contributes to
    the creation of, or owns Covered Software.

1.2. "Contributor Version"
    means the combination of the Contributions of others (if any) used
    by a Contributor and that particular Contributor's Contribution.

1.3. "Contribution"
    means Covered Software of a particular Contributor.
```

(continues on next page)

(continued from previous page)

```
1.4. "Covered Software"
    means Source Code Form to which the initial Contributor has attached
    the notice in Exhibit A, the Executable Form of such Source Code
    Form, and Modifications of such Source Code Form, in each case
    including portions thereof.

1.5. "Incompatible With Secondary Licenses"
    means

    (a) that the initial Contributor has attached the notice described
        in Exhibit B to the Covered Software; or

    (b) that the Covered Software was made available under the terms of
        version 1.1 or earlier of the License, but not also under the
        terms of a Secondary License.

1.6. "Executable Form"
    means any form of the work other than Source Code Form.

1.7. "Larger Work"
    means a work that combines Covered Software with other material, in
    a separate file or files, that is not Covered Software.

1.8. "License"
    means this document.

1.9. "Licensable"
    means having the right to grant, to the maximum extent possible,
    whether at the time of the initial grant or subsequently, any and
    all of the rights conveyed by this License.

1.10. "Modifications"
    means any of the following:

    (a) any file in Source Code Form that results from an addition to,
        deletion from, or modification of the contents of Covered
        Software; or

    (b) any new file in Source Code Form that contains any Covered
        Software.

1.11. "Patent Claims" of a Contributor
    means any patent claim(s), including without limitation, method,
    process, and apparatus claims, in any patent Licensable by such
    Contributor that would be infringed, but for the grant of the
    License, by the making, using, selling, offering for sale, having
    made, import, or transfer of either its Contributions or its
    Contributor Version.

1.12. "Secondary License"
    means either the GNU General Public License, Version 2.0, the GNU
    Lesser General Public License, Version 2.1, the GNU Affero General
```

(continues on next page)

(continued from previous page)

```
    Public License, Version 3.0, or any later versions of those
    licenses.

1.13. "Source Code Form"
    means the form of the work preferred for making modifications.

1.14. "You" (or "Your")
    means an individual or a legal entity exercising rights under this
    License. For legal entities, "You" includes any entity that
    controls, is controlled by, or is under common control with You. For
    purposes of this definition, "control" means (a) the power, direct
    or indirect, to cause the direction or management of such entity,
    whether by contract or otherwise, or (b) ownership of more than
    fifty percent (50%) of the outstanding shares or beneficial
    ownership of such entity.

2. License Grants and Conditions
--------------------------------

2.1. Grants

Each Contributor hereby grants You a world-wide, royalty-free,
non-exclusive license:

(a) under intellectual property rights (other than patent or trademark)
    Licensable by such Contributor to use, reproduce, make available,
    modify, display, perform, distribute, and otherwise exploit its
    Contributions, either on an unmodified basis, with Modifications, or
    as part of a Larger Work; and

(b) under Patent Claims of such Contributor to make, use, sell, offer
    for sale, have made, import, and otherwise transfer either its
    Contributions or its Contributor Version.

2.2. Effective Date

The licenses granted in Section 2.1 with respect to any Contribution
become effective for each Contribution on the date the Contributor first
distributes such Contribution.

2.3. Limitations on Grant Scope

The licenses granted in this Section 2 are the only rights granted under
this License. No additional rights or licenses will be implied from the
distribution or licensing of Covered Software under this License.
Notwithstanding Section 2.1(b) above, no patent license is granted by a
Contributor:

(a) for any code that a Contributor has removed from Covered Software;
    or

(b) for infringements caused by: (i) Your and any other third party's
```

(continues on next page)

(continued from previous page)

```
    modifications of Covered Software, or (ii) the combination of its
    Contributions with other software (except as part of its Contributor
    Version); or

(c) under Patent Claims infringed by Covered Software in the absence of
    its Contributions.

This License does not grant any rights in the trademarks, service marks,
or logos of any Contributor (except as may be necessary to comply with
the notice requirements in Section 3.4).

2.4. Subsequent Licenses

No Contributor makes additional grants as a result of Your choice to
distribute the Covered Software under a subsequent version of this
License (see Section 10.2) or under the terms of a Secondary License (if
permitted under the terms of Section 3.3).

2.5. Representation

Each Contributor represents that the Contributor believes its
Contributions are its original creation(s) or it has sufficient rights
to grant the rights to its Contributions conveyed by this License.

2.6. Fair Use

This License is not intended to limit any rights You have under
applicable copyright doctrines of fair use, fair dealing, or other
equivalents.

2.7. Conditions

Sections 3.1, 3.2, 3.3, and 3.4 are conditions of the licenses granted
in Section 2.1.

3. Responsibilities
-------------------

3.1. Distribution of Source Form

All distribution of Covered Software in Source Code Form, including any
Modifications that You create or to which You contribute, must be under
the terms of this License. You must inform recipients that the Source
Code Form of the Covered Software is governed by the terms of this
License, and how they can obtain a copy of this License. You may not
attempt to alter or restrict the recipients' rights in the Source Code
Form.

3.2. Distribution of Executable Form

If You distribute Covered Software in Executable Form then:
```

(continues on next page)

(continued from previous page)

```
(a) such Covered Software must also be made available in Source Code
    Form, as described in Section 3.1, and You must inform recipients of
    the Executable Form how they can obtain a copy of such Source Code
    Form by reasonable means in a timely manner, at a charge no more
    than the cost of distribution to the recipient; and

(b) You may distribute such Executable Form under the terms of this
    License, or sublicense it under different terms, provided that the
    license for the Executable Form does not attempt to limit or alter
    the recipients' rights in the Source Code Form under this License.

3.3. Distribution of a Larger Work

You may create and distribute a Larger Work under terms of Your choice,
provided that You also comply with the requirements of this License for
the Covered Software. If the Larger Work is a combination of Covered
Software with a work governed by one or more Secondary Licenses, and the
Covered Software is not Incompatible With Secondary Licenses, this
License permits You to additionally distribute such Covered Software
under the terms of such Secondary License(s), so that the recipient of
the Larger Work may, at their option, further distribute the Covered
Software under the terms of either this License or such Secondary
License(s).

3.4. Notices

You may not remove or alter the substance of any license notices
(including copyright notices, patent notices, disclaimers of warranty,
or limitations of liability) contained within the Source Code Form of
the Covered Software, except that You may alter any license notices to
the extent required to remedy known factual inaccuracies.

3.5. Application of Additional Terms

You may choose to offer, and to charge a fee for, warranty, support,
indemnity or liability obligations to one or more recipients of Covered
Software. However, You may do so only on Your own behalf, and not on
behalf of any Contributor. You must make it absolutely clear that any
such warranty, support, indemnity, or liability obligation is offered by
You alone, and You hereby agree to indemnify every Contributor for any
liability incurred by such Contributor as a result of warranty, support,
indemnity or liability terms You offer. You may include additional
disclaimers of warranty and limitations of liability specific to any
jurisdiction.

4. Inability to Comply Due to Statute or Regulation
---------------------------------------------------

If it is impossible for You to comply with any of the terms of this
License with respect to some or all of the Covered Software due to
statute, judicial order, or regulation then You must: (a) comply with
the terms of this License to the maximum extent possible; and (b)
```

(continues on next page)

(continued from previous page)

```
describe the limitations and the code they affect. Such description must
be placed in a text file included with all distributions of the Covered
Software under this License. Except to the extent prohibited by statute
or regulation, such description must be sufficiently detailed for a
recipient of ordinary skill to be able to understand it.

5. Termination
--------------

5.1. The rights granted under this License will terminate automatically
if You fail to comply with any of its terms. However, if You become
compliant, then the rights granted under this License from a particular
Contributor are reinstated (a) provisionally, unless and until such
Contributor explicitly and finally terminates Your grants, and (b) on an
ongoing basis, if such Contributor fails to notify You of the
non-compliance by some reasonable means prior to 60 days after You have
come back into compliance. Moreover, Your grants from a particular
Contributor are reinstated on an ongoing basis if such Contributor
notifies You of the non-compliance by some reasonable means, this is the
first time You have received notice of non-compliance with this License
from such Contributor, and You become compliant prior to 30 days after
Your receipt of the notice.

5.2. If You initiate litigation against any entity by asserting a patent
infringement claim (excluding declaratory judgment actions,
counter-claims, and cross-claims) alleging that a Contributor Version
directly or indirectly infringes any patent, then the rights granted to
You by any and all Contributors for the Covered Software under Section
2.1 of this License shall terminate.

5.3. In the event of termination under Sections 5.1 or 5.2 above, all
end user license agreements (excluding distributors and resellers) which
have been validly granted by You or Your distributors under this License
prior to termination shall survive termination.

************************************************************************
*                                                                      *
*  6. Disclaimer of Warranty                                           *
*  -------------------------                                           *
*                                                                      *
*  Covered Software is provided under this License on an "as is"       *
*  basis, without warranty of any kind, either expressed, implied, or  *
*  statutory, including, without limitation, warranties that the       *
*  Covered Software is free of defects, merchantable, fit for a        *
*  particular purpose or non-infringing. The entire risk as to the     *
*  quality and performance of the Covered Software is with You.        *
*  Should any Covered Software prove defective in any respect, You     *
*  (not any Contributor) assume the cost of any necessary servicing,   *
*  repair, or correction. This disclaimer of warranty constitutes an   *
*  essential part of this License. No use of any Covered Software is   *
*  authorized under this License except under this disclaimer.         *
*                                                                      *
```

****************************************************************************

****************************************************************************
*                                                                          *
*  7. Limitation of Liability                                              *
*  --------------------------                                              *
*                                                                          *
*  Under no circumstances and under no legal theory, whether tort          *
*  (including negligence), contract, or otherwise, shall any               *
*  Contributor, or anyone who distributes Covered Software as              *
*  permitted above, be liable to You for any direct, indirect,             *
*  special, incidental, or consequential damages of any character          *
*  including, without limitation, damages for lost profits, loss of        *
*  goodwill, work stoppage, computer failure or malfunction, or any        *
*  and all other commercial damages or losses, even if such party          *
*  shall have been informed of the possibility of such damages. This       *
*  limitation of liability shall not apply to liability for death or       *
*  personal injury resulting from such party's negligence to the           *
*  extent applicable law prohibits such limitation. Some                   *
*  jurisdictions do not allow the exclusion or limitation of               *
*  incidental or consequential damages, so this exclusion and              *
*  limitation may not apply to You.                                        *
*                                                                          *
****************************************************************************

8. Litigation
-------------

Any litigation relating to this License may be brought only in the
courts of a jurisdiction where the defendant maintains its principal
place of business and such litigation shall be governed by laws of that
jurisdiction, without reference to its conflict-of-law provisions.
Nothing in this Section shall prevent a party's ability to bring
cross-claims or counter-claims.

9. Miscellaneous
----------------

This License represents the complete agreement concerning the subject
matter hereof. If any provision of this License is held to be
unenforceable, such provision shall be reformed only to the extent
necessary to make it enforceable. Any law or regulation which provides
that the language of a contract shall be construed against the drafter
shall not be used to construe this License against a Contributor.

10. Versions of the License
---------------------------

10.1. New Versions

Mozilla Foundation is the license steward. Except as provided in Section
10.3, no one other than the license steward has the right to modify or
```

(continues on next page)

(continued from previous page)

```
publish new versions of this License. Each version will be given a
distinguishing version number.

10.2. Effect of New Versions

You may distribute the Covered Software under the terms of the version
of the License under which You originally received the Covered Software,
or under the terms of any subsequent version published by the license
steward.

10.3. Modified Versions

If you create software not governed by this License, and you want to
create a new license for such software, you may create and use a
modified version of this License if you rename the license and remove
any references to the name of the license steward (except to note that
such modified license differs from this License).

10.4. Distributing Source Code Form that is Incompatible With Secondary
Licenses

If You choose to distribute Source Code Form that is Incompatible With
Secondary Licenses under the terms of this version of the License, the
notice described in Exhibit B of this License must be attached.

Exhibit A - Source Code Form License Notice
-------------------------------------------

  This Source Code Form is subject to the terms of the Mozilla Public
  License, v. 2.0. If a copy of the MPL was not distributed with this
  file, You can obtain one at http://mozilla.org/MPL/2.0/.

If it is not possible or desirable to put the notice in a particular
file, then You may include the notice in a location (such as a LICENSE
file in a relevant directory) where a recipient would be likely to look
for such a notice.

You may add additional accurate notices of copyright ownership.

Exhibit B - "Incompatible With Secondary Licenses" Notice
---------------------------------------------------------

  This Source Code Form is "Incompatible With Secondary Licenses", as
  defined by the Mozilla Public License, v. 2.0.

```
                  GNU LESSER GENERAL PUBLIC LICENSE
                       Version 2.1, February 1999

 Copyright (C) 1991, 1999 Free Software Foundation, Inc.
        51 Franklin St, Fifth Floor, Boston, MA  02110-1301  USA
 Everyone is permitted to copy and distribute verbatim copies
 of this license document, but changing it is not allowed.

[This is the first released version of the Lesser GPL.  It also counts
 as the successor of the GNU Library Public License, version 2, hence
 the version number 2.1.]

                            Preamble

  The licenses for most software are designed to take away your
freedom to share and change it.  By contrast, the GNU General Public
Licenses are intended to guarantee your freedom to share and change
free software--to make sure the software is free for all its users.

  This license, the Lesser General Public License, applies to some
specially designated software packages--typically libraries--of the
Free Software Foundation and other authors who decide to use it.  You
can use it too, but we suggest you first think carefully about whether
this license or the ordinary General Public License is the better
strategy to use in any particular case, based on the explanations
below.

  When we speak of free software, we are referring to freedom of use,
not price.  Our General Public Licenses are designed to make sure that
you have the freedom to distribute copies of free software (and charge
for this service if you wish); that you receive source code or can get
it if you want it; that you can change the software and use pieces of
it in new free programs; and that you are informed that you can do
these things.

  To protect your rights, we need to make restrictions that forbid
distributors to deny you these rights or to ask you to surrender these
rights.  These restrictions translate to certain responsibilities for
you if you distribute copies of the library or if you modify it.

  For example, if you distribute copies of the library, whether gratis
or for a fee, you must give the recipients all the rights that we gave
you.  You must make sure that they, too, receive or can get the source
code.  If you link other code with the library, you must provide
complete object files to the recipients, so that they can relink them
with the library after making changes to the library and recompiling
it.  And you must show them these terms so they know their rights.
```

(continues on next page)

(continued from previous page)

```
  We protect your rights with a two-step method: (1) we copyright the
library, and (2) we offer you this license, which gives you legal
permission to copy, distribute and/or modify the library.

  To protect each distributor, we want to make it very clear that
there is no warranty for the free library.  Also, if the library is
modified by someone else and passed on, the recipients should know
that what they have is not the original version, so that the original
author's reputation will not be affected by problems that might be

introduced by others.

  Finally, software patents pose a constant threat to the existence of
any free program.  We wish to make sure that a company cannot
effectively restrict the users of a free program by obtaining a
restrictive license from a patent holder.  Therefore, we insist that
any patent license obtained for a version of the library must be
consistent with the full freedom of use specified in this license.

  Most GNU software, including some libraries, is covered by the
ordinary GNU General Public License.  This license, the GNU Lesser
General Public License, applies to certain designated libraries, and
is quite different from the ordinary General Public License.  We use
this license for certain libraries in order to permit linking those
libraries into non-free programs.

  When a program is linked with a library, whether statically or using
a shared library, the combination of the two is legally speaking a
combined work, a derivative of the original library.  The ordinary
General Public License therefore permits such linking only if the
entire combination fits its criteria of freedom.  The Lesser General
Public License permits more lax criteria for linking other code with
the library.

  We call this license the "Lesser" General Public License because it
does Less to protect the user's freedom than the ordinary General
Public License.  It also provides other free software developers Less
of an advantage over competing non-free programs.  These disadvantages
are the reason we use the ordinary General Public License for many
libraries.  However, the Lesser license provides advantages in certain
special circumstances.

  For example, on rare occasions, there may be a special need to
encourage the widest possible use of a certain library, so that it
becomes a de-facto standard.  To achieve this, non-free programs must
be allowed to use the library.  A more frequent case is that a free
library does the same job as widely used non-free libraries.  In this
case, there is little to gain by limiting the free library to free
software only, so we use the Lesser General Public License.

  In other cases, permission to use a particular library in non-free
```

(continues on next page)

(continued from previous page)

```
programs enables a greater number of people to use a large body of
free software.  For example, permission to use the GNU C Library in
non-free programs enables many more people to use the whole GNU
operating system, as well as its variant, the GNU/Linux operating
system.

  Although the Lesser General Public License is Less protective of the
users' freedom, it does ensure that the user of a program that is
linked with the Library has the freedom and the wherewithal to run
that program using a modified version of the Library.

  The precise terms and conditions for copying, distribution and
modification follow.  Pay close attention to the difference between a
"work based on the library" and a "work that uses the library".  The
former contains code derived from the library, whereas the latter must

be combined with the library in order to run.

                  GNU LESSER GENERAL PUBLIC LICENSE
   TERMS AND CONDITIONS FOR COPYING, DISTRIBUTION AND MODIFICATION

  0. This License Agreement applies to any software library or other
program which contains a notice placed by the copyright holder or
other authorized party saying it may be distributed under the terms of
this Lesser General Public License (also called "this License").
Each licensee is addressed as "you".

  A "library" means a collection of software functions and/or data
prepared so as to be conveniently linked with application programs
(which use some of those functions and data) to form executables.

  The "Library", below, refers to any such software library or work
which has been distributed under these terms.  A "work based on the
Library" means either the Library or any derivative work under
copyright law: that is to say, a work containing the Library or a
portion of it, either verbatim or with modifications and/or translated
straightforwardly into another language.  (Hereinafter, translation is
included without limitation in the term "modification".)

  "Source code" for a work means the preferred form of the work for
making modifications to it.  For a library, complete source code means
all the source code for all modules it contains, plus any associated
interface definition files, plus the scripts used to control
compilation and installation of the library.

  Activities other than copying, distribution and modification are not
covered by this License; they are outside its scope.  The act of
running a program using the Library is not restricted, and output from
such a program is covered only if its contents constitute a work based
on the Library (independent of the use of the Library in a tool for
writing it).  Whether that is true depends on what the Library does
and what the program that uses the Library does.
```

(continues on next page)

(continued from previous page)

```
  1. You may copy and distribute verbatim copies of the Library's
complete source code as you receive it, in any medium, provided that
you conspicuously and appropriately publish on each copy an
appropriate copyright notice and disclaimer of warranty; keep intact
all the notices that refer to this License and to the absence of any
warranty; and distribute a copy of this License along with the
Library.

  You may charge a fee for the physical act of transferring a copy,
and you may at your option offer warranty protection in exchange for a

fee.

  2. You may modify your copy or copies of the Library or any portion
of it, thus forming a work based on the Library, and copy and
distribute such modifications or work under the terms of Section 1
above, provided that you also meet all of these conditions:

    a) The modified work must itself be a software library.

    b) You must cause the files modified to carry prominent notices
    stating that you changed the files and the date of any change.

    c) You must cause the whole of the work to be licensed at no
    charge to all third parties under the terms of this License.

    d) If a facility in the modified Library refers to a function or a
    table of data to be supplied by an application program that uses
    the facility, other than as an argument passed when the facility
    is invoked, then you must make a good faith effort to ensure that,
    in the event an application does not supply such function or
    table, the facility still operates, and performs whatever part of
    its purpose remains meaningful.

    (For example, a function in a library to compute square roots has
    a purpose that is entirely well-defined independent of the
    application.  Therefore, Subsection 2d requires that any
    application-supplied function or table used by this function must
    be optional: if the application does not supply it, the square
    root function must still compute square roots.)

These requirements apply to the modified work as a whole.  If
identifiable sections of that work are not derived from the Library,
and can be reasonably considered independent and separate works in
themselves, then this License, and its terms, do not apply to those
sections when you distribute them as separate works.  But when you
distribute the same sections as part of a whole which is a work based
on the Library, the distribution of the whole must be on the terms of
this License, whose permissions for other licensees extend to the
entire whole, and thus to each and every part regardless of who wrote
it.
```

(continues on next page)

(continued from previous page)

```
Thus, it is not the intent of this section to claim rights or contest
your rights to work written entirely by you; rather, the intent is to
exercise the right to control the distribution of derivative or
collective works based on the Library.

In addition, mere aggregation of another work not based on the Library
with the Library (or with a work based on the Library) on a volume of
a storage or distribution medium does not bring the other work under
the scope of this License.

  3. You may opt to apply the terms of the ordinary GNU General Public
License instead of this License to a given copy of the Library.  To do
this, you must alter all the notices that refer to this License, so
that they refer to the ordinary GNU General Public License, version 2,
instead of to this License.  (If a newer version than version 2 of the
ordinary GNU General Public License has appeared, then you can specify
that version instead if you wish.)  Do not make any other change in

these notices.

  Once this change is made in a given copy, it is irreversible for
that copy, so the ordinary GNU General Public License applies to all
subsequent copies and derivative works made from that copy.

  This option is useful when you wish to copy part of the code of
the Library into a program that is not a library.

  4. You may copy and distribute the Library (or a portion or
derivative of it, under Section 2) in object code or executable form
under the terms of Sections 1 and 2 above provided that you accompany
it with the complete corresponding machine-readable source code, which
must be distributed under the terms of Sections 1 and 2 above on a
medium customarily used for software interchange.

  If distribution of object code is made by offering access to copy
from a designated place, then offering equivalent access to copy the
source code from the same place satisfies the requirement to
distribute the source code, even though third parties are not
compelled to copy the source along with the object code.

  5. A program that contains no derivative of any portion of the
Library, but is designed to work with the Library by being compiled or
linked with it, is called a "work that uses the Library".  Such a
work, in isolation, is not a derivative work of the Library, and
therefore falls outside the scope of this License.

  However, linking a "work that uses the Library" with the Library
creates an executable that is a derivative of the Library (because it
contains portions of the Library), rather than a "work that uses the
library".  The executable is therefore covered by this License.
Section 6 states terms for distribution of such executables.
```

(continues on next page)

(continued from previous page)

```
  When a "work that uses the Library" uses material from a header file
that is part of the Library, the object code for the work may be a
derivative work of the Library even though the source code is not.
Whether this is true is especially significant if the work can be
linked without the Library, or if the work is itself a library.  The
threshold for this to be true is not precisely defined by law.

  If such an object file uses only numerical parameters, data
structure layouts and accessors, and small macros and small inline
functions (ten lines or less in length), then the use of the object
file is unrestricted, regardless of whether it is legally a derivative
work.  (Executables containing this object code plus portions of the
Library will still fall under Section 6.)

  Otherwise, if the work is a derivative of the Library, you may
distribute the object code for the work under the terms of Section 6.
Any executables containing that work also fall under Section 6,

whether or not they are linked directly with the Library itself.

  6. As an exception to the Sections above, you may also combine or
link a "work that uses the Library" with the Library to produce a
work containing portions of the Library, and distribute that work
under terms of your choice, provided that the terms permit
modification of the work for the customer's own use and reverse
engineering for debugging such modifications.

  You must give prominent notice with each copy of the work that the
Library is used in it and that the Library and its use are covered by
this License.  You must supply a copy of this License.  If the work
during execution displays copyright notices, you must include the
copyright notice for the Library among them, as well as a reference
directing the user to the copy of this License.  Also, you must do one
of these things:

    a) Accompany the work with the complete corresponding
    machine-readable source code for the Library including whatever
    changes were used in the work (which must be distributed under
    Sections 1 and 2 above); and, if the work is an executable linked
    with the Library, with the complete machine-readable "work that
    uses the Library", as object code and/or source code, so that the
    user can modify the Library and then relink to produce a modified
    executable containing the modified Library.  (It is understood
    that the user who changes the contents of definitions files in the
    Library will not necessarily be able to recompile the application
    to use the modified definitions.)

    b) Use a suitable shared library mechanism for linking with the
    Library.  A suitable mechanism is one that (1) uses at run time a
    copy of the library already present on the user's computer system,
    rather than copying library functions into the executable, and (2)
```

(continues on next page)

(continued from previous page)

```
    will operate properly with a modified version of the library, if
    the user installs one, as long as the modified version is
    interface-compatible with the version that the work was made with.

    c) Accompany the work with a written offer, valid for at least
    three years, to give the same user the materials specified in
    Subsection 6a, above, for a charge no more than the cost of
    performing this distribution.

    d) If distribution of the work is made by offering access to copy
    from a designated place, offer equivalent access to copy the above
    specified materials from the same place.

    e) Verify that the user has already received a copy of these
    materials or that you have already sent this user a copy.

  For an executable, the required form of the "work that uses the
Library" must include any data and utility programs needed for
reproducing the executable from it.  However, as a special exception,
the materials to be distributed need not include anything that is
normally distributed (in either source or binary form) with the major
components (compiler, kernel, and so on) of the operating system on
which the executable runs, unless that component itself accompanies
the executable.

  It may happen that this requirement contradicts the license
restrictions of other proprietary libraries that do not normally
accompany the operating system.  Such a contradiction means you cannot
use both them and the Library together in an executable that you

distribute.

  7. You may place library facilities that are a work based on the
Library side-by-side in a single library together with other library
facilities not covered by this License, and distribute such a combined
library, provided that the separate distribution of the work based on
the Library and of the other library facilities is otherwise
permitted, and provided that you do these two things:

    a) Accompany the combined library with a copy of the same work
    based on the Library, uncombined with any other library
    facilities.  This must be distributed under the terms of the
    Sections above.

    b) Give prominent notice with the combined library of the fact
    that part of it is a work based on the Library, and explaining
    where to find the accompanying uncombined form of the same work.

  8. You may not copy, modify, sublicense, link with, or distribute
the Library except as expressly provided under this License.  Any
attempt otherwise to copy, modify, sublicense, link with, or
distribute the Library is void, and will automatically terminate your
```

(continues on next page)

(continued from previous page)

```
rights under this License.  However, parties who have received copies,
or rights, from you under this License will not have their licenses
terminated so long as such parties remain in full compliance.

  9. You are not required to accept this License, since you have not
signed it.  However, nothing else grants you permission to modify or
distribute the Library or its derivative works.  These actions are
prohibited by law if you do not accept this License.  Therefore, by
modifying or distributing the Library (or any work based on the
Library), you indicate your acceptance of this License to do so, and
all its terms and conditions for copying, distributing or modifying
the Library or works based on it.

  10. Each time you redistribute the Library (or any work based on the
Library), the recipient automatically receives a license from the
original licensor to copy, distribute, link with or modify the Library
subject to these terms and conditions.  You may not impose any further
restrictions on the recipients' exercise of the rights granted herein.
You are not responsible for enforcing compliance by third parties with

this License.

  11. If, as a consequence of a court judgment or allegation of patent
infringement or for any other reason (not limited to patent issues),
conditions are imposed on you (whether by court order, agreement or
otherwise) that contradict the conditions of this License, they do not
excuse you from the conditions of this License.  If you cannot
distribute so as to satisfy simultaneously your obligations under this
License and any other pertinent obligations, then as a consequence you
may not distribute the Library at all.  For example, if a patent
license would not permit royalty-free redistribution of the Library by
all those who receive copies directly or indirectly through you, then
the only way you could satisfy both it and this License would be to
refrain entirely from distribution of the Library.

If any portion of this section is held invalid or unenforceable under
any particular circumstance, the balance of the section is intended to
apply, and the section as a whole is intended to apply in other
circumstances.

It is not the purpose of this section to induce you to infringe any
patents or other property right claims or to contest validity of any
such claims; this section has the sole purpose of protecting the
integrity of the free software distribution system which is
implemented by public license practices.  Many people have made
generous contributions to the wide range of software distributed
through that system in reliance on consistent application of that
system; it is up to the author/donor to decide if he or she is willing
to distribute software through any other system and a licensee cannot
impose that choice.

This section is intended to make thoroughly clear what is believed to
```

(continues on next page)

(continued from previous page)

```
be a consequence of the rest of this License.

  12. If the distribution and/or use of the Library is restricted in
certain countries either by patents or by copyrighted interfaces, the
original copyright holder who places the Library under this License
may add an explicit geographical distribution limitation excluding those
countries, so that distribution is permitted only in or among
countries not thus excluded.  In such case, this License incorporates
the limitation as if written in the body of this License.

  13. The Free Software Foundation may publish revised and/or new
versions of the Lesser General Public License from time to time.
Such new versions will be similar in spirit to the present version,
but may differ in detail to address new problems or concerns.

Each version is given a distinguishing version number.  If the Library
specifies a version number of this License which applies to it and
"any later version", you have the option of following the terms and
conditions either of that version or of any later version published by
the Free Software Foundation.  If the Library does not specify a
license version number, you may choose any version ever published by

the Free Software Foundation.

  14. If you wish to incorporate parts of the Library into other free
programs whose distribution conditions are incompatible with these,
write to the author to ask for permission.  For software which is
copyrighted by the Free Software Foundation, write to the Free
Software Foundation; we sometimes make exceptions for this.  Our
decision will be guided by the two goals of preserving the free status
of all derivatives of our free software and of promoting the sharing
and reuse of software generally.

                            NO WARRANTY

  15. BECAUSE THE LIBRARY IS LICENSED FREE OF CHARGE, THERE IS NO
WARRANTY FOR THE LIBRARY, TO THE EXTENT PERMITTED BY APPLICABLE LAW.
EXCEPT WHEN OTHERWISE STATED IN WRITING THE COPYRIGHT HOLDERS AND/OR
OTHER PARTIES PROVIDE THE LIBRARY "AS IS" WITHOUT WARRANTY OF ANY
KIND, EITHER EXPRESSED OR IMPLIED, INCLUDING, BUT NOT LIMITED TO, THE
IMPLIED WARRANTIES OF MERCHANTABILITY AND FITNESS FOR A PARTICULAR
PURPOSE.  THE ENTIRE RISK AS TO THE QUALITY AND PERFORMANCE OF THE
LIBRARY IS WITH YOU.  SHOULD THE LIBRARY PROVE DEFECTIVE, YOU ASSUME
THE COST OF ALL NECESSARY SERVICING, REPAIR OR CORRECTION.

  16. IN NO EVENT UNLESS REQUIRED BY APPLICABLE LAW OR AGREED TO IN
WRITING WILL ANY COPYRIGHT HOLDER, OR ANY OTHER PARTY WHO MAY MODIFY
AND/OR REDISTRIBUTE THE LIBRARY AS PERMITTED ABOVE, BE LIABLE TO YOU
FOR DAMAGES, INCLUDING ANY GENERAL, SPECIAL, INCIDENTAL OR
CONSEQUENTIAL DAMAGES ARISING OUT OF THE USE OR INABILITY TO USE THE
LIBRARY (INCLUDING BUT NOT LIMITED TO LOSS OF DATA OR DATA BEING
RENDERED INACCURATE OR LOSSES SUSTAINED BY YOU OR THIRD PARTIES OR A
```

(continues on next page)

(continued from previous page)

```
FAILURE OF THE LIBRARY TO OPERATE WITH ANY OTHER SOFTWARE), EVEN IF
SUCH HOLDER OR OTHER PARTY HAS BEEN ADVISED OF THE POSSIBILITY OF SUCH
DAMAGES.

                     END OF TERMS AND CONDITIONS

           How to Apply These Terms to Your New Libraries

  If you develop a new library, and you want it to be of the greatest
possible use to the public, we recommend making it free software that
everyone can redistribute and change.  You can do so by permitting
redistribution under these terms (or, alternatively, under the terms
of the ordinary General Public License).

  To apply these terms, attach the following notices to the library.
It is safest to attach them to the start of each source file to most
effectively convey the exclusion of warranty; and each file should
have at least the "copyright" line and a pointer to where the full
notice is found.

    <one line to give the library's name and a brief idea of what it does.>
    Copyright (C) <year>  <name of author>

    This library is free software; you can redistribute it and/or
    modify it under the terms of the GNU Lesser General Public
    License as published by the Free Software Foundation; either
    version 2.1 of the License, or (at your option) any later version.

    This library is distributed in the hope that it will be useful,
    but WITHOUT ANY WARRANTY; without even the implied warranty of
    MERCHANTABILITY or FITNESS FOR A PARTICULAR PURPOSE.  See the GNU
    Lesser General Public License for more details.

    You should have received a copy of the GNU Lesser General Public
    License along with this library; if not, write to the Free Software
    Foundation, Inc., 51 Franklin St, Fifth Floor, Boston, MA  02110-1301  USA

Also add information on how to contact you by electronic and paper mail.

You should also get your employer (if you work as a programmer) or
your school, if any, to sign a "copyright disclaimer" for the library,
if necessary.  Here is a sample; alter the names:

  Yoyodyne, Inc., hereby disclaims all copyright interest in the
  library `Frob' (a library for tweaking knobs) written by James
  Random Hacker.

  <signature of Ty Coon>, 1 April 1990
  Ty Coon, President of Vice

```
                    GNU GENERAL PUBLIC LICENSE
                       Version 2, June 1991

Copyright (C) 1989, 1991 Free Software Foundation, Inc.,
51 Franklin Street, Fifth Floor, Boston, MA 02110-1301 USA
Everyone is permitted to copy and distribute verbatim copies
of this license document, but changing it is not allowed.

                            Preamble
```

(continues on next page)

(continued from previous page)

```
  The licenses for most software are designed to take away your
freedom to share and change it.  By contrast, the GNU General Public
License is intended to guarantee your freedom to share and change free
software--to make sure the software is free for all its users.  This
General Public License applies to most of the Free Software
Foundation's software and to any other program whose authors commit to
using it.  (Some other Free Software Foundation software is covered by
the GNU Lesser General Public License instead.)  You can apply it to
your programs, too.

  When we speak of free software, we are referring to freedom, not
price.  Our General Public Licenses are designed to make sure that you
have the freedom to distribute copies of free software (and charge for
this service if you wish), that you receive source code or can get it
if you want it, that you can change the software or use pieces of it
in new free programs; and that you know you can do these things.

  To protect your rights, we need to make restrictions that forbid
anyone to deny you these rights or to ask you to surrender the rights.
These restrictions translate to certain responsibilities for you if you
distribute copies of the software, or if you modify it.

  For example, if you distribute copies of such a program, whether
gratis or for a fee, you must give the recipients all the rights that
you have.  You must make sure that they, too, receive or can get the
source code.  And you must show them these terms so they know their
rights.

  We protect your rights with two steps: (1) copyright the software, and
(2) offer you this license which gives you legal permission to copy,
distribute and/or modify the software.

  Also, for each author's protection and ours, we want to make certain
that everyone understands that there is no warranty for this free
software.  If the software is modified by someone else and passed on, we
want its recipients to know that what they have is not the original, so
that any problems introduced by others will not reflect on the original
authors' reputations.

  Finally, any free program is threatened constantly by software
patents.  We wish to avoid the danger that redistributors of a free
program will individually obtain patent licenses, in effect making the
program proprietary.  To prevent this, we have made it clear that any
patent must be licensed for everyone's free use or not licensed at all.

  The precise terms and conditions for copying, distribution and
modification follow.

                    GNU GENERAL PUBLIC LICENSE
   TERMS AND CONDITIONS FOR COPYING, DISTRIBUTION AND MODIFICATION

  0. This License applies to any program or other work which contains
```

(continues on next page)

(continued from previous page)

```
a notice placed by the copyright holder saying it may be distributed
under the terms of this General Public License.  The "Program", below,
refers to any such program or work, and a "work based on the Program"
means either the Program or any derivative work under copyright law:
that is to say, a work containing the Program or a portion of it,
either verbatim or with modifications and/or translated into another
language.  (Hereinafter, translation is included without limitation in
the term "modification".)  Each licensee is addressed as "you".

Activities other than copying, distribution and modification are not
covered by this License; they are outside its scope.  The act of
running the Program is not restricted, and the output from the Program
is covered only if its contents constitute a work based on the
Program (independent of having been made by running the Program).
Whether that is true depends on what the Program does.

  1. You may copy and distribute verbatim copies of the Program's
