The pfSense Documentation

Netgate

Jul 02, 2025

CONTENTS

Thoroughly detailed information and continually updated instructions on how to best operate pfSense® software.

CHAPTER

ONE

PREFACE

1.1 Acknowledgements

This documentation, and the pfSense® project itself, would not be possible without a great team of developers, contributors, customers, and a wonderful community. The project has received code contributions from several hundred individuals. Thousands more have done their part supporting the project by helping others on the forum, social media, and other platforms. And even more have contributed by purchasing hardware, support, and services. Our thanks go out to everyone who has done their part to make the project the great success it has become.

1.1.1 pfSense Developers

The current active pfSense software development team includes the following members (in alphabetical order by surname):

- Glen Barber
- Renato Botelho do Couto
- Leon Dang
- Brad Davis
- Peter Grehan
- Mateusz Guzik
- Reid Linnemann
- Christian McDonald
- Kris Molinari
- Jim Pingle
- Kristof Provost
- Luiz Otavio O Souza
- Steve Wheeler

We also want to give thanks to former project members, significant community contributors, and all FreeBSD developers who have assisted considerably with pfSense project development. Their time and effort throughout the last 15 years is meaningful and we appreciate their contributions.

1.2 Feedback

The publisher and authors encourage feedback for this documentation and the pfSense® software distribution. Please send suggestions, criticism and/or praise using the feedback forms at the bottom of each page.

For general feedback related to the pfSense project, please post to the forum. Links to these resources can be found at https://www.netgate.com/support/contact-support.

Welcome to *The pfSense Documentation*, written by the pfSense® project team and including contributions from community members.

This set of documents covers topics ranging from the installation process and basic configuration to advanced networking and firewalling using this popular open source firewall and router software distribution.

This is designed to be a friendly guide to common networking and security tasks along with a thorough reference for the capabilities of pfSense software. These documents cover the following topics (and more!):

- An introduction to pfSense software and its features.
- Firewall design and hardware planning.
- Installing and upgrading pfSense software.
- Using the web-based configuration interface.
- Backing up and restoring the firewall configuration.
- Firewalling fundamentals including defining and troubleshooting rules.
- Port forwarding and Network Address Translation (NAT).
- General networking and routing configuration.
- Virtual LANs (VLANs), Multi-WAN, and Bridging.
- Virtual Private Networks using IPsec and OpenVPN.
- Traffic shaping using ALTQ or Limiters.
- Wireless networking configuration.
- Captive Portal setup.
- High Availability using redundant firewalls.
- Various network-related services.
- Firewall monitoring, logging, traffic analysis, sniffing, packet capturing, and troubleshooting.
- Software package and third-party software installations.

There is also a *Menu Guide* with all standard menu choices available in the pfSense software GUI.

CHAPTER

TWO

INTRODUCTION

2.1 What does pfSense stand for/mean?

The early tag line for the pfSense open source project was "making sense of pf", referring to the packet filter technology at the core of the project.

PF in FreeBSD can perform many of the basic packet filtering and QoS firewall tasks that pfSense software provides, however, pfSense software makes it easier to manage, monitor, and maintain. It accomplishes this by layering an easy to use GUI and customized services on top of the operating system and relevant packages, resulting in a complete firewall/router/VPN solution that is capable of much more than the sum of the underlying components.

2.2 What is pfSense® Plus Software?

Netgate announced the creation of pfSense Plus software, and the renaming of the open-source project to pfSense Community Edition (CE), in January 2021. The rationale was simple: The existence of pfSense Plus software would allow Netgate to add advanced features required by business customers. In the time since that announcement, a number of premium capabilities have been added to pfSense Plus software that are not available in pfSense CE software.

2.2.1 Benefits of pfSense Plus Software

More Frequent Software Updates

One of the most significant differences is the release cadence.

Multiple Releases per Year

pfSense Plus software has major updates scheduled three times per year, and additional point releases when required. This allows Netgate to keep pfSense Plus software closely in sync with the many changes and updates that are made 'upstream,' including in FreeBSD.

See also:

Software Release Schedule

Cryptography and VPN Acceleration

pfSense Plus software incorporates a number of capabilities that improve the performance of VPN connectivity.

See also:

VPN Scaling

These exclusive capabilities include:

OpenVPN Data Channel Offload (DCO) support

This provides huge performance gains when processing encrypted OpenVPN data by reducing the amount of context switching that happens for each packet.

See also:

OpenVPN Data Channel Offload (DCO)

Intel IPsec Multi-Buffer (IIMB) support

This increases VPN performance on Intel, AMD and ARM platforms where extended instruction support is present by replacing some cryptographic functions provided by the kernel with accelerated functions that utilize those extended instructions.

See also:

IPsec-MB

Intel QuickAssist Technology (QAT) support

This is an Intel-specific hardware acceleration technology that significantly increases performance, using asynchronous processing, for many cryptographic operations.

See also:

Cryptographic Hardware

SafeXcel cryptographic accelerator support

This is an acceleration technology present on some ARM platforms, such as the Netgate 1100 and 2100 appliances.

See also:

Cryptographic Hardware

CESA support

This is an acceleration technology present on some ARM platforms such as the Netgate 3100 appliance.

See also:

Cryptographic Hardware

AWS VPC VPN Connection Wizard add-on package

This add-on package automatically creates a VPN tunnel and BGP configuration to communicate with an Amazon AWS VPC.

See also:

AWS VPC Wizard

IPsec Profile Wizard add-on package

This add-on package creates IPsec configuration profiles for Apple devices (iOS and macOS), and IPsec import script bundles for Windows devices.

See also:

IPsec Export Package

OpenVPN Client Import add-on package

This add-on package Imports a unified OpenVPN client configuration file as exported by an OpenVPN server.

See also:

OpenVPN Client Import Package

Additional Features

Additional premium features found in pfSense Plus software include:

ZFS Boot Environment (BE) Management in webConfigurator

This feature makes it easier to take snapshots of key file system areas, resulting in safer upgrades and major changes. If the user encounters problems with an upgrade or configuration change, the firewall can be 'rolled back' to an earlier known good state.

See also:

ZFS Boot Environments (Plus Only)

ZFS dashboard widget (to track status of disks using ZFS)

This feature allows easy monitoring of disks using the zfs file system.

See also:

ZFS Dashboard Widget

CARP mode (multicast or unicast)

This is an option to choose how CARP (High Availability) operates, either in multicast or unicast mode. Some environments (including virtualization) don't work well, or not at all, with multicast mode. pfSense CE software only supports multicast.

See also:

VIP Configuration Options

Ethernet (Layer 2) Filtering Rules support

This feature is experimental rule-based pass/block filtering of packets based on Ethernet (Layer 2) header attributes (e.g. MAC addresses). These rules are processed before other (L3) rules in the inbound direction, and after those rules outbound.

See also:

Ethernet (Layer 2) Rules

LDAP Client Certificate support

This feature supports a certificate sent to the LDAP server to identify this client when using an encrypted transport mode.

See also:

LDAP Authentication Servers

GUI Options for WAN 802.1X Authentication Bridging and VLAN 0 PCP Tagging

These options allow directly connecting to certain ISP networks which typically require specific devices at the edge, such as a modem with an authentication certificate.

See also:

WAN Connectivity with 802.1X Authentication Bridging and VLAN 0 PCP Tagging

Native Packet Flow Data Export for NetFlow/IPFIX

Starting with pfSense Plus software version 24.03 the firewall can directly export NetFlow v5 and IPFIX traffic flow data to one or more collectors using the `pflow(4)` feature in PF. The data is collected directly from firewall states and does not require a separate daemon, service, or add-on package.

See also:

Firewall Packet Flow Data

Capabilities For Netgate Hardware

There are also several capabilities in pfSense Plus software that are unique to the appliance hardware that Netgate sells and supports.

These include:

- ARM64 support (for Netgate's ARM-based appliances)
- The Firmware Update add-on package
- MMC Utilities package
- Support for specialized hardware such as status LEDs, reset buttons, switches, and hardware watchdog devices
- Default optimized configurations for Netgate hardware appliances

2.3 Why FreeBSD?

Numerous factors came under consideration when choosing a base operating system for the project. This section outlines the primary reasons for selecting FreeBSD.

2.3.1 Wireless Support

Wireless support is a key feature for some users. In 2004, wireless support in OpenBSD was very limited compared to FreeBSD. OpenBSD did not support drivers or security protocols and offered no plans for their implementation. To this day, FreeBSD surpasses the wireless capabilities of OpenBSD.

2.3.2 Network Performance

Network performance in FreeBSD is significantly better than that of OpenBSD. For small to mid-sized deployments, this generally does not matter; upper scalability is the primary issue in OpenBSD. One pfSense® developer managing several hundred OpenBSD firewalls using `pf` was forced to switch his high load systems to `pf` on FreeBSD to handle the high packets per second rate required by portions of his network. The network performance in OpenBSD has improved since 2004, but limitations still exist.

Multi-processor support for pf in FreeBSD allows for greater scalability and is utilized by pfSense software as seen in this network performance analysis: https://github.com/gvnn3/netperf/blob/master/Documentation/netperf.pdf.

2.3.3 Familiarity and ease of fork

The code for m0n0wall was based on FreeBSD, and pfSense software forked from m0n0wall. Changing the base operating system would require prohibitively large modifications and could have introduced limitations from other operating systems, requiring features to be removed or altered.

2.3.4 Alternative Operating System Support

There are no plans to support any other base operating systems at this time.

2.4 Common Deployments

pfSense® software can meet the needs of nearly any type and size of network environment, from a SOHO to datacenter environments. This section outlines the most common deployments.

2.4.1 Perimeter Firewall

The most common deployment of pfSense software is a perimeter firewall. pfSense software accommodates networks requiring multiple Internet connections, multiple LAN networks, and multiple DMZ networks. BGP (Border Gateway Protocol), connection redundancy, and load balancing capabilities are configurable as well.

See also:

These advanced features are further described in *Routing* and *Multiple WAN Connections*.

2.4.2 LAN or WAN Router

pfSense software configured as a LAN or WAN router and perimeter firewall is a common deployment in small networks. LAN and WAN routing are separate roles in larger networks.

LAN Router

pfSense software is a proven solution for connecting multiple internal network segments. This is most commonly deployed with VLANs configured with 802.1Q trunking, described more in *Virtual LANs (VLANs)*. Multiple Ethernet interfaces are also used in some environments. High-volume LAN traffic environments with fewer filtering requirements may need layer 3 switches or ASIC-based routers instead.

WAN Router

pfSense software is a great solution for Internet Service Providers. It offers all the functionality required by most networks at a much lower price point than other commercial offerings.

2.4.3 Special Purpose Appliances

pfSense software can be utilized for less common deployment scenarios as a stand-alone appliance. Examples include: VPN appliance, Sniffer appliance, and DHCP server appliance.

VPN Appliance

pfSense software installed as a separate Virtual Private Network appliance adds VPN capabilities without disrupting the existing firewall infrastructure, and includes multiple VPN protocols.

Sniffer Appliance

pfSense software offers a web interface for the `tcpdump` packet analyzer. The captured `.cap` files are downloaded and analyzed in Wireshark.

See also:

For more information on using the packet capture features, see *Packet Capturing*.

DHCP Server Appliance

pfSense software can be deployed strictly as a Dynamic Host Configuration Protocol server, however, there are limitations of the pfSense software GUI for advanced configuration of the ISC DHCP daemon.

See also:

For more information on configuring the DHCP service on pfSense, see *DHCP*.

2.5 Interface Naming Terminology

All interfaces on pfSense® software can be assigned any name desired, but they all start with default names: WAN, LAN, and OPT.

2.5.1 WAN

Short for *Wide Area Network*, WAN is the untrusted public network outside of the firewall. In other words, the WAN interface is the firewall's connection to the Internet or other upstream network. In a multi-WAN deployment, WAN is the first or primary Internet connection.

At a minimum, the firewall must have one interface, and that is WAN.

2.5.2 LAN

Short for *Local Area Network*, LAN is commonly the private side of a firewall. It typically utilizes a *private IP address* scheme for local clients. In small deployments, LAN is typically the only internal interface.

2.5.3 OPT

OPT or *Optional* interfaces refer to any additional interfaces other than WAN and LAN. OPT interfaces can be additional LAN segments, WAN connections, DMZ segments, interconnections to other private networks, and so on.

2.5.4 DMZ

Short for the military term *demilitarized zone*, DMZ refers to the buffer between a protected area and a war zone. In networking, it is an area where public servers are reachable from the Internet via the WAN but isolated from the LAN. The DMZ keeps the systems in other segments from being endangered if the network is compromised, while also protecting hosts in the DMZ from other local segments and the Internet in general.

Warning: Some companies misuse the term "DMZ" in their firewall products as a reference to 1:1 NAT on the WAN IP address which exposes a host on the LAN. For more information, see *1:1 NAT on the WAN IP, aka "DMZ" on Consumer Gateways*.

2.5.5 FreeBSD interface naming

The name of a FreeBSD interface starts with the name of its network driver. It is then followed by a number starting at `0` that increases incrementally by one for each additional interface sharing that driver. For example, a common driver used by Intel gigabit network interface cards is `igb`. The first such card in a firewall will be `igb0`, the second is `igb1`, and so on. Other common driver names include `cxl` (Chelsio 10G), `em` (Also Intel 1G), `ix` (Intel 10G), `bge` (various Broadcom chipsets), amongst numerous others. If a system mixes an Intel card and a Chelsio card, the interfaces will be `igb0` and `cxl0` respectively.

See also:

Interface assignments and naming are further covered in *Installing and Upgrading*.

2.6 Finding Information and Getting Help

This section offers guidance on finding information in this documentation, on pfSense® software in general, as well as providing further resources.

2.6.1 Finding Information

The search function on the documentation is the easiest way to find information on a specific topic. The most common features and deployments of pfSense software are covered in this documentation. When reading the HTML version of the documentation, the search function is in the upper left of the page. When reading an eBook style copy, consult the documentation for the book reader software for information on how to search.

There is a wealth of additional information and user experiences available on the various Netgate websites. The best way to search the sites is a Google search appending `site:netgate.com` to the query. This will search the website, forum, documentation, etc. which are all official sources of information.

2.6.2 Getting Help

A help icon is available on almost every page,  , and links to the associated page in documentation.

Netgate offers several other ways to get help with pfSense software, including the Netgate Forum and this documentation. There is also a pfSense subreddit where community members can assist each other. More information can be found on the Netgate website at Obtaining Support. Many of these links are reachable from the Help menu in the GUI.

2.7 Comparison to Commercial Alternatives

The question of security and support vs. commercial alternatives comes up from time to time. The history of this project since its inception in 2004 proves we're as secure as any, and better than many, commercial alternatives. The experiences of our customers proves not only can we match the service of any commercial firewall vendor, we exceed it. This page serves to debunk the common myths when comparing to commercial alternatives.

2.7.1 "Hardware" firewalls are better myth

Commercial firewall companies' marketing departments have done a fine job ingraining the myth of "hardware firewalls" into some people's minds. The reality is there is no such thing as a "hardware firewall." All firewalls are hardware that runs software. Most commercial firewalls are based on BSD (same as pfSense®) or Linux. Numerous commercial firewalls run many of the same underlying software programs that pfSense software uses. Many commercial alternatives run on x86 hardware that's no different from what people use for pfSense software. In fact many people have loaded pfSense software on hardware that used to run their commercial firewall, including Watchguard, Nortel, Barracuda and more.

2.7.2 Open source is insecure myth

Some people are of the mindset that because the source is open, it's insecure because everyone can see how it works. Anyone who has paid any attention to security over the past 20 years knows the absurdity of that statement. No software relies on the obscurity of source code for security. If there was any truth in that, Microsoft Windows would be the most secure OS ever created, when the reality is all of the open source operating systems (all the BSDs and Linux) have security track records that are worlds better than Windows'. History proves the same applies to any software. Internet Explorer is continually hit with major security holes that many times take weeks to patch while they're being exploited in the wild, while open source browsers Firefox, Chrome and others have had significantly better security track records.

The widespread UPnP vulnerabilities announced in 2013 affecting over 300 commercial products is another good example. The vendors of hundreds of commercial products made extremely basic security mistakes, shipping with absurdly insecure defaults, and shipping outdated software. That's never been an issue with pfSense software. That's only one example of where pfSense software has done a better job than many commercial vendors.

2.7.3 Commercial alternatives have better support myth

With some open source projects, it's true that a user is stuck if they need help. Netgate offers commercial support for pfSense software, Netgate TAC, that rivals anything other commercial vendor offers.

2.8 Can pfSense software meet regulatory requirements

Prospective pfSense® users commonly inquire about the ability to meet security requirements applicable to their specific environments. Some of those include PCI, SOX, GLBA, HIPAA, amongst numerous other similar regulations for publicly traded companies, financial institutions, healthcare institutions, and others.

There are numerous companies in many regulated industries using pfSense software that pass their audits with no problems, including all of the aforementioned regulations/standards amongst others. However it's important to keep in mind that a firewall is a small portion of the security infrastructure, and those regulations are more about policies, procedures, and configuration than the actual products being used.

So yes, pfSense software *can* meet regulatory requirements, but that is dependent on configuration, policies, procedures, amongst other things - there is no compliance silver bullet. There may be circumstances specific to one company that make another product a better fit for compliance (or other) reasons, but that's true of all commercial and open source solutions, there is no one product that is a perfect fit for everyone.

2.9 Can I sell pfSense software

Many consulting companies offer solutions based on pfSense® software to their customers. A business or individual can load pfSense software for themselves, friends, relatives, employers, and, yes, even customers, so long as the Trademark Guidelines and Apache 2.0 license requirements as detailed on the website are obeyed by all parties involved.

What can not be offered is a commercial redistribution of pfSense® software, for example the guidelines do not permit someone to offer "Installation of pfSense® software" as a service or to sell a device pre-loaded with pfSense® software to customers without the prior express written permission of ESF pursuant to the trademark policy.

Example 1
: A consultant may offer firewall services (e.g. "Fred's Firewalls"), without mentioning pfSense® software or using the logo in their advertising, marketing material, and so on. They can install pfSense® software and manage it for their customers.

Example 2
: Fred's Firewalls may make a customized distribution pfSense® software with their own name and logo used in place of the pfSense marks. They can use the pfSense marks to truthfully describe the origin of the software, such as "Fred's Firewall software is derived from the pfSense CE source code." Even though Fred's Firewall is based on pfSense® software, it **cannot** be referred to as "pfSense® software" since it has been modified.

Example 3
: Fred's Firewalls may sell their customized firewall distribution pre-loaded on systems to customers, so long as the relationship to pfSense software is clearly stated.

The Apache 2.0 license only applies to the software and **not** the pfSense name and logo, which are trademarks and may not be used without a license. Reading and understanding the trademark policy document is required before one considers selling pfSense software.

2.9.1 Contributing Back to the Project

We ask anyone profiting by using pfSense software to contribute to the project in some fashion. Ideally with the level of contributions from a business or individual corresponding to the amount of financial gain received from use of pfSense software. Many paths exist for resellers and consultants to contribute. For the long term success of the project this support is critically important.

- Purchase hardware and merchandise from the Netgate Store.
- Become a Netgate Partner to resell Netgate hardware pre-loaded with pfSense software.
- Development contributions - Dedicate a portion of internal developers' time to open source development.
- Help with support and documentation - Assisting users on the forum and mailing list, or contributing documentation changes, aides the overall project.
- Support subscription via Netgate TAC Having direct access to our team for any questions or deployment assistance helps ensure success.

2.9.2 Using the pfSense Name and Logo

The "pfSense" name and logo are trademarks of Electric Sheep Fencing, LLC.

The pfSense software source code is open source and covered by the Apache 2.0 license. That license only covers the source code and **not** our name and trademarks, which have restricted usage.

We think it is great that people want to promote and support the pfSense project. At the same time, we also need to verify that what is referred to as "pfSense" is a genuine instance of pfSense software and **not** modified in any way.

- The pfSense name and logo **MAY NOT** be used physically on a hardware device.
  - For example: A sticker, badge, etching, or similar rendering of the pfSense name or logo is NOT allowed.
- The pfSense logo **MAY NOT** be used on marketing materials or in other ways without a license, including references on websites.
- The pfSense name **MAY** be used to describe the case that a product is based on a pfSense distribution, but the designated product name may *not* include pfSense or a derivative. Basically stating facts regarding product origin is acceptable. Anything that implies that a product is endorsed by or made by ESF or the pfSense project is *not* allowed.

  Examples:
  - "Blahsoft Fireblah based on pfSense software" – Acceptable
  - "Blahsoft pfSense Firewall" – NOT Allowed
- **ONLY** an **UNMODIFIED** version of pfSense software can still be called "pfSense software".
  - If the source code has been changed, compiled/rebuilt separately, included extra file installations such as themes or add-on scripts, or any other customizations, it can **not** be called "pfSense software", it must be called something else.
  - Trademark protection aside, this requirement preserves the integrity and reputation of the pfSense project. It also prevents unverified changes that may be questionably implemented from being attributed to pfSense.
- If a pfSense distribution is modified, the resulting software **CANNOT** be called "pfSense" or anything *similar*. The new name must be distinct from pfSense. Trademark law does not allow use of names or trademarks that are confusingly similar to the pfSense Marks. This means, among other things, that law forbids using a variation of the pfSense Marks, their phonetic equivalents, mimicry, wordplay, or abbreviation with respect to similar or related projects, products, or services (for example, "pfSense Lifestyle," "PFsense Community," "pf-Sense Sensibility," "pfSensor", etc., **all** infringe on ESF's rights).

Examples:

- "pfSomething", or "somethingSense" – INFRINGING references
- "ExampleWall", "FireWidget" – NON-Infringing references

- The "pfSense" name **MAY NOT** be used in a company name or similar. A company **CANNOT** be named "pfSense Support, Ltd" or "pfSense Experts, LLC", or use it in a domain name or subdomain reference. However, the company can state support for pfSense software, offer training for pfSense software, etc.
- There **MUST** be a distinction between a company name and pfSense or Electric Sheep Fencing, LLC. No relationship or endorsement can be stated or implied between the two companies, unless we have explicitly licensed and agreed to such a statement.

2.10 Contact with Netgate Servers

For several essential and optional services, such as checking for updates, installing updates and packages, and the Auto Config Backup service, pfSense® software makes outgoing connections to servers owned and operated by Netgate.

This document identifies these connections with an explanation of why it makes contact, what is transmitted in both directions, and how administrators can control these operations.

Each of the services described also generates server logs which Netgate discards after **365 days** (1 year). Netgate uses these logs to monitor performance, detect problems, and gather usage statistics while also satisfying GDPR requirements.

2.10.1 Support contract information

Netgate offers a number of support options for both pfSense and TNSR software users. See https://www.netgate.com/support/ for details.

If administrators activate the **Netgate Service and Support** widget on the pfSense software GUI Dashboard, pfSense software will query Netgate servers to obtain the current support status, a list of web links, and other information to help administrators make the best use of their support options. This query occurs no more than once every 24 hours.

Note: This widget is active by default on installations of pfSense Plus software, but it can be removed at any time. It is not active by default on pfSense CE software.

Support contracts are tied to individual devices so Netgate must positively identify these devices when providing service. This is not easy to do: Serial numbers are not consistent across different hardware manufacturers and building a firewall running pfSense software from scratch on "white box" hardware is common. To overcome this problem and allow purchasers of Netgate support services to be sure that no one can "spoof" their support contract, Netgate uses a "Netgate Device ID" (NDI) which is displayed on the dashboard and in console/ssh menu banner.

The NDI is a hashed SHA256 value based on available information on the system. Netgate **cannot** reverse engineer from the NDI how it was generated, what information was gathered, or what values were used. Even if it were practical to reverse-hash SHA256 (it is not) only a string of meaningless characters would result. Netgate knows only that NDI "xyz" has been assigned to support contract "abc".

Information that is transmitted via the HTTPS connection to Netgate servers:

- Netgate ID

Server log information retained by Netgate for up to 1 year, then deleted:

- IP address

If administrators prefer not to have pfSense software transmit this information, remove or do not install the **Netgate Service and Support** Dashboard widget.

See also:

- *Managing Widgets*
- *Available Widgets*

2.10.2 Software Updates and Packages

To check for updates to pfSense software, navigate to **System > Update** or, if the **System Information** widget is active and configured to check for updates, visit the Dashboard. To install new packages or check for updates to installed packages, navigate to **System > Package Manager**.

These actions cause pfSense software to connect to Netgate servers and update its repository information and package metadata. The first connection is made to establish authorization level and request a list of any available updates.

To determine which updates are available for a given installation, pfSense software transmits the architecture (amd64, ARM64, etc) to the web service along with a list of the installed software components and their versions. The server can then respond with a list of any available updates (For example "stable", "development", etc) that are appropriate for the architecture type and authorized for the end-user installation (plus, community edition, etc).

Similar queries are made when installing new packages.

pfSense software will request updated repository information any time an administrator navigates to **System > Package Manager**, **System > Update** or when the **System Information** Dashboard widget is active and the option to **Disable the dashboard auto-update check** is *unchecked* under **System > Update** on the **Update Settings** tab (*Dashboard Check*). This option is *unchecked* by default.

Additionally, pfSense software automatically updates this metadata once per day. The timing is randomized and can be anywhere from 1:00 A.M. local time up to 24 hours later.

Information that is transmitted via the HTTPS connection to Netgate servers:

- Netgate ID
- Serial Number
- pfSense software and installed package versions
- Architecture
- Configured language (locale)
- Platform information (Netgate products, virtualization platform, cloud provider, etc.)

Server log information retained by Netgate for up to 1 year, then deleted:

- IP address
- Netgate ID
- Serial Number
- pfSense software and installed package versions
- Architecture
- Platform information (Netgate products, virtualization platform, cloud provider, etc.)

See also:

- *Dashboard Check*
- *Upgrade Guide*

- *Packages*
- *Installation Feedback*

2.10.3 Auto Config Backup (ACB)

Netgate offers an automatic configuration backup service, known as Auto Config Backup or ACB, which is free for anyone to use.

When pfSense software makes a backup via ACB, either automatically or manually, it encrypts the `config.xml` configuration file using AES-256 and a key provided by the administrator with options suitable for file encryption.

pfSense software then transmits this encrypted file to https://acb.netgate.com where it is stored for future retrieval.

pfSense software also transmits a unique and random "device key" to privately identify which backups belong to a given installation.

This device key must be unique to each firewall backing up its configuration. To do this the key is automatically generated by taking the SHA256 hash of the SSH service keys on the installation. This allows ACB to reliably and properly identify ownership of each backup in an anonymous way.

The encryption key never leaves the firewall in plain text. It exists within the `config.xml` data, but has already been encrypted. Netgate **cannot** decrypt any stored configuration file, nor link it to any particular firewall serial number or identifier.

The ACB service is not active by default. If administrators prefer not to have this information transmitted, disable or do not configure the Automatic Configuration Backup feature.

Information that is transmitted via the HTTPS connection to Netgate servers:

- Netgate ID
- Device key
- AES-256 encrypted configuration
- Timestamp
- Optional hint (in case the device key is lost)
- pfSense software version (in case the ACB data format changes in future versions)

Server log information retained by Netgate for up to 1 year, then deleted:

- IP address
- Netgate ID
- pfSense software version

See also:

- *Automatic Configuration Backup Service*

2.10.4 Bogon Network List Updates

Bogon networks are those which should never be seen on the Internet, including reserved and unassigned IP address space.

If any interfaces are configured to **Block Bogon Networks**, then shortly after initial installation and once per month after that, pfSense software will contact Netgate servers to obtain an updated list of Bogon Networks.

The update script runs at 3:00 A.M. local time, and sleeps a random amount of time up to 12 hours before performing the update.

The frequency of Bogon network updates can be adjusted using the **Update Frequency** option for bogons under **System > Advanced** on the **Firewall & NAT** tab. Updates may be performed on a Daily, Weekly, or Monthly basis.

Information that is transmitted via the HTTPS connection to Netgate servers:

- pfSense software version
- Netgate ID (optional)
- Release (plus/community)

Server log information retained by Netgate for up to 365 days, then deleted:

- IP address
- pfSense software version
- Netgate ID (optional)
- Release

The Bogon update can either send or omit the Netgate ID based on the **Netgate Device ID** option under **Installation Feedback** on **System > Advanced**, **Miscellaneous** tab. The default is to send the ID.

See also:

- *Block Bogon Networks*
- *Interface Configuration*
- *Installation Feedback*

2.10.5 Copyright

When an administrator receives a new Netgate device, installs a new version of pfSense software, or performs a factory reset, the GUI displays a copyright notice. Once an administrator dismisses the notice, the GUI does not display it again until it detects an updated notice.

This notice is a reminder of what may and may not be done with pfSense software.

Before the GUI displays the notice, its HTML contents are retrieved from Netgate servers in the currently configured language (locale). There are different versions of the notice for Netgate provided hardware and for the "Community Edition" of pfSense software.

Information that is transmitted via the HTTPS connection to Netgate servers:

- Netgate ID

The pfSense® Project is a free open source customized distribution of FreeBSD tailored for use as a firewall and router entirely managed by an easy-to-use web interface. This web interface is known as the web-based GUI configurator, or WebGUI for short. No FreeBSD knowledge is required to deploy and use pfSense software. In fact, the majority of users have never used FreeBSD outside of pfSense software. In addition to being a powerful, flexible firewalling and routing platform, pfSense software includes a long list of related features. The pfSense software package system allows further expandability without adding bloat and potential security vulnerabilities to the base distribution. pfSense software is a popular project with millions of downloads since its inception and hundreds of thousands of active installations. It has been proven successful in countless installations ranging from single computer protection in small home networks to thousands of network devices in large corporations, universities and other organizations.

To download the latest version, see previous versions, or to upgrade follow the guides located on the pfSense downloads page.

2.11 Project Inception

pfSense software was forked from the m0n0wall open source project in 2004. m0n0wall was focused specifically on providing a firewall/router for embedded devices and was sized for limited hardware resources. Initially pfSense software aimed at providing a firewall/router solution with an expanded set of capabilities on larger PC and server style hardware. pfSense software has continued to evolve over time, providing firewall, router, VPN, IDS/IPS, and more capabilities that work well on hardware from small home office size devices to large service provider size servers.

CHAPTER

THREE

RELEASES

This section contains information about past and present release of pfSense® software. This includes release notes and detailed version information.

3.1 25.07 New Features and Changes

This is a regularly scheduled software release including new features and bug fixes.

3.1.1 General

- Older devices with ISA-based serial console ports may not fully detect their console due to changes in how FreeBSD probes serial ports. pfSense plus software attempts to detect known affected models of hardware from Netgate. Other devices may require manual intervention.

  See *ISA Serial Console not Fully Functional* for details and a workaround.

- This version of pfSense Plus software includes a new kernel-based PPPoE backend, `if_pppoe`. This will replace the current MPD-based implementation. This new backend is more efficient and enables much faster speeds over PPPoE interfaces.

  This new PPPoE backend is not active by default in this version, but can be enabled with *the global option* under **System > Advanced** on the **Networking** tab. This backend will be enabled by default on future versions of pfSense Plus software.

  The `if_pppoe` backend does not support all advanced features of the MPD implementation. For example, it does not support MLPPP.

- This release includes support for DHCPv6 Prefix Delegation in the Kea DHCP daemon.

> **Warning:** Prefix Delegation settings in Kea use a different format than the ISC DHCPv6 daemon, so Kea **cannot** use existing settings for Prefix Delegation. Settings for Prefix Delegation must be re-created manually when switching from ISC DHCPv6 to Kea DHCPv6. For details, see *DHCPv6 Prefix Delegation*.

- Users of the Gandi Dynamic DNS service **must** change their current API token to a Personal Access Token (PAT) as Gandi now requires this authentication method for Dynamic DNS updates. For uninterrupted Dynamic DNS service, create a new PAT and save that PAT value in Gandi Dynamic DNS entries before upgrading to this release.

3.1.2 Security / Errata

This release fixes several security issues in pfSense Plus software, including:

- pfSense-SA-25_01.webgui Multiple problems in Dashboard widget key handling which could lead to XSS, denial of service, or configuration corruption.
- pfSense-SA-25_02.webgui OpenVPN management interface command injection from OpenVPN status and Dashboard widget.
- pfSense-SA-25_03.webgui Potential XSS in the AutoConfigBackup backup list.
- pfSense-SA-25_04.webgui Potential disclosure of AutoConfigBackup Device Key if SSH service is enabled and exposed to untrusted networks.
- pfSense-SA-25_05.webgui Stored XSS in Firewall Schedules.
- pfSense-SA-25_06.webgui Stored XSS in IPsec tunnel Phase 1 list.
- pfSense-SA-25_07.webgui Stored XSS in Wake on LAN pages and Dashboard widget.

Fixes for these security issues are available via the *Recommended System Patches* function of the *System Patches Package* for users running pfSense Plus software version 24.11.

3.1.3 pfSense Plus

Changes in this version of pfSense Plus software.

Aliases / Tables

- Added: System Aliases for various reserved networks #15776
- Changed: Exclude the WireGuard and Tailscale interface group system aliases from rules #15848

Auto Configuration Backup

- Fixed: Long configuration revision reasons can cause AutoConfigBackup upload to fail #12249
- Fixed: Potential XSS in AutoConfigBackup backup list on `services_acb.php` #15927
- Fixed: AutoConfigBackup scheduled backups always upload even when the configuration has not changed #16010
- Fixed: AutoConfigBackup remote revision timestamps may not be unique due to batch uploads #16011
- Fixed: "Reset" button on AutoConfigBackup Restore tab does not submit the form #16012

- Changed: AutoConfigBackup code cleanup and GUI refresh #16013
- Added: Download function for AutoConfigBackup entries #16014
- Added: Method to change the AutoConfigBackup device key #16015
- Changed: Change AutoConfigBackup default key generation format #16016
- Fixed: AutoConfigBackup entries show incorrect timestamps #16209

Backup / Restore

- Fixed: Reinstall Packages button reports another instance of `pfSense-upgrade` is running #15494
- Fixed: Backup configuration cache is not cleaned automatically #15994

Captive Portal

- Fixed: PHP error in Captive Portal with undefined zone interface list #15907
- Fixed: Captive Portal does not function with MAC filtering disabled #15926
- Fixed: Captive Portal service management via `pfSsh.php svc` fails when the zone name contains uppercase letters #16030
- Fixed: Creating a Captive Portal zone with uppercase letters overwrites existing zones of the same name #16032

Certificates

- Added: Certificate Authorities created in the GUI do not have the Basic Constraints extension marked critical #15818
- Changed: Additional error handling for invalid certificate configuration #15975

Configuration Backend

- Fixed: PHP error on save with very long configuration change descriptions #15911

DHCP (IPv4)

- Added: Kea DHCP Custom Configuration Support (IPv4 and IPv6) #15321
- Fixed: Kea fails to start if DHCP pool configuration contains default lease time or max lease time #15332
- Added: Kea Static ARP Support (IPv4 only) #15654
- Fixed: Kea can unintentionally attempt to spawn multiple processes and fail #16019
- Fixed: Static lease DNS records are incorrectly removed when backing lease expires #16022

DHCP (IPv6)

- Fixed: Old IPv6 addresses may continue to be used after DHCP or RA changes #12947
- Added: Kea DHCPv6 Prefix Delegation Support (IPv6 Only) #15652

DNS Forwarder

- Fixed: Unable to change DNS Forwarder domain overrides #15890

DNS Resolver

- Fixed: DNS Resolver option for Query Name Minimization cannot be disabled #15925

Dashboard

- Fixed: Clicking the picture widget image downloads the image with an invalid filename instead of showing it inline #15767
- Fixed: Dashboard `widgetkey` values are not validated on save or load, can lead to configuration corruption or other problems #15844
- Changed: Improve the system load impact from Dashboard widgets #15969

Diagnostics

- Fixed: Adding Wake-On-LAN entry from ARP table view can incorrectly include OEM text in MAC address field #15162
- Fixed: PHP error from invalid IPv6 address on `diagnostics_ping.php` #16005
- Fixed: The filtered states shown may include states for interfaces other than the selected interface #16043
- Fixed: Cannot kill states using the post-NAT address #16047

Dynamic DNS

- Added: Improve Dynamic DNS client IPv6 support #11177
- Added: Per-instance options to control Dynamic DNS client Check IP Service behavior #14067
- Fixed: Dynamic DNS uses the default gateway interface instead of the specified interface #14605
- Added: Support LuaDNS provider #15089
- Changed: Update Gandi LiveDNS service with API changes #15258
- Fixed: RFC 2136 Dynamic DNS cannot update AAAA records over IPv6 #16028
- Fixed: Dynamic DNS IP address may not be updated after changing the interface of a Dynamic DNS entry #16046

Gateway Monitoring

- Fixed: The monitoring IP address for dynamic gateways may be unexpectedly routed via a different gateway #16069
- Fixed: Improve gateway status detection with routed monitoring addresses #16180

Gateways

- Changed: Clarify descriptions for gateway recovery options #15429
- Fixed: Cannot set a new name when duplicating an existing gateway group #16036

IPsec

- Fixed: Input validation for duplicate remote gateways does not work when using the duplicate P1 button #15598
- Fixed: Firewall generates invalid rules for IPsec tunnels with descriptions containing special symbols #16095
- Fixed: Potential XSS in IPsec Phase 1 #16115
- Fixed: IPsec unnecessarily prompts to apply changes after input errors #16162

IPv6 Router Advertisements (radvd/rtsold)

- Fixed: Incorrect warning from `radvd` about `AdvRDNSSLifetime` value #12938
- Added: PREF64 support in Router Advertisements #15808
- Fixed: Routing Advertisements daemon fails to start when configured with more than 3 RDNSS entries in a prefix #15876

Interfaces

- Fixed: Config access error with null static routes #16104
- Fixed: Config access error after changing an interface from DHCP to Static #16105

L2TP

- Fixed: L2TP server settings are not saved correctly #15882

Logging

- Added: Enhanced firewall log action information display #15415
- Fixed: PHP error when saving System Log settings #15988

Multi-Instance Management

- Fixed: MIM GUI is unable to write IPv6 aliases #15959
- Fixed: Renaming an alias in MIM does not update firewall and NAT rules with the new alias name #15989

NTPD

- Fixed: PHP error after saving NTP settings with an interface selected #16063

OpenVPN

- Fixed: OpenVPN Status Page and Dashboard Widget use input values without validation #15856
- Fixed: Configuration upgrade from before revision 19.1 removes OpenVPN settings #15895

Operating System

- Fixed: `pftop` core dump with ICMP states #15595
- Fixed: Azure: User credentials entered during new VM deployments are not applied to the system #15871
- Fixed: Values obtained from `sysctl` are sometimes unexpectedly empty, leading to PHP and other math errors #14648
- Fixed: Errors on the console when starting/stopping services #15912
- Fixed: RAM disk configuration check fails at boot #16023
- Fixed: RAM Disk cron jobs are not saved correctly #16059
- Fixed: Panic accessing `sysctl` OID `net.inet.ip.nhdispatch` with an INVARIANTS kernel #16081
- Added: Reduce writes to disk when using ZFS #16210

PHP Interpreter

- Fixed: Cookie named `id` prevents some forms from being loaded or saved properly #11268

PPP Interfaces

- Fixed: PPPoE WAN loses IPv4 addresses on `IPV6CP LayerDown` events #16103
- Added: Support `if_pppoe` backend for PPPoE WAN interfaces #16134

Package System

- Fixed: Deleting one pre-installed package may delete other pre-installed packages #15643
- Fixed: The package `post-install` script does not run with a system upgrade on ZFS #16057
- Changed: `pkg` no longer supports setting `ALTABI` manually at run-time #16060

Rules / NAT

- Fixed: Separators for Ethernet rules span past the actions column #16079
- Added: NAT64 support #2358
- Fixed: SCTP states not purged causing subsequent SCTP INIT to be blocked #15924
- Fixed: Incorrect rule may be opened for editing after rule order has changed #15935
- Fixed: Tracking information for firewall rules is not shown when editing the rule #15936
- Fixed: Warning message in logs when changing firewall rules after setting Require Firewall Interface #15961
- Fixed: Deleting or adding a firewall rule may result in an unexpected rule order #16076
- Fixed: Potential XSS in Firewall Schedules #16114
- Fixed: Input validation prevents creating port forwards for the same port using a different address family #16130
- Fixed: Firewall rules using interface subnet aliases may prevent filter rules from loading after upgrades #16182

System Logs

- Added: Separate IDS/IPS and link-local firewall log entries from default block logging #16092

Traffic Shaper (ALTQ)

- Fixed: Error when viewing ALTQ Traffic Shaper queue status #15885

Traffic Shaper (Limiters)

- Fixed: Limiters saved while MIM is enabled disappear after reboot #16051
- Fixed: Input validation error when applying limiter changes #13158
- Fixed: Setting a limiter queue length greater than 100 prevents the limiter from loading #13662
- Fixed: Cannot add limiters named `new` #13687
- Fixed: PHP error when a queue is added with the same name as a limiter #15914

UPnP IGD & PCP

- Changed: Update UPnP IGD & PCP GUI text #15864
- Changed: Make the UPnP IGD & PCP STUN port optional #15865

Upgrade

- Fixed: Upgrade available LED not set before branch is selected. #15880
- Changed: Link to release information on the system update page #15953
- Fixed: Boot loader is not upgraded on UFS installs #16064

User Manager / Privileges

- Fixed: Users with Deny Config Write privilege can trigger some VLAN interface operations #15282
- Fixed: Users with Deny Config Write privilege can trigger some QinQ interface operations #15318
- Fixed: PHP error when a user is denied access to the dashboard #15873
- Fixed: Users with Deny Config Write privilege can trigger logging operations #15874
- Fixed: Users with Deny Config Write privilege can change their own password #15908

Wake on LAN

- Fixed: Potential XSS in Wake on LAN page and widget #16116

Web Interface

- Added: Custom message text for the login screen #9293
- Changed: Update nginx HTTP2 syntax #15863
- Fixed: Incorrect color in button text within disabled rows #15977

3.2 2.8.0 New Features and Changes

This pfSense® CE software release includes new features and bug fixes.

3.2.1 Upgrade Notes

> **Warning:** Due to major changes in PHP and base OS versions, there is a higher than usual chance that packages will interfere with the upgrade process.
>
> To give an upgrade the best possible chance of going smoothly, uninstall **all** packages before starting the upgrade.

Before upgrading, pay particular attention to the *Pre-Upgrade Tasks* section of the *Upgrade Guide*. The most crucial points are noted in this section, but the best practice is to follow all of the precautions noted in the Upgrade Guide.

Boot Loader

This version requires an updated boot loader, which is automatically handled by the upgrade process for nearly all cases. However, there may be some edge cases where the automatic update does not update the loader currently used by the device. For example, if there are multiple unmirrored disks and the BIOS/EFI Firmware is not booting from the disk containing the updated loader, but an older unrelated installation on a separate disk. One particular case where this can happen is when there is a previous installation to MMC which has been followed by an installation to an add-on SSD without clearing the MMC contents.

In these cases the best practice is to wipe the unused disk so it cannot interfere. See *Troubleshooting Multiple Disks* for details.

Legacy Serial Console

After upgrading, older devices with ISA-based serial console ports may not fully detect their console due to changes in how FreeBSD probes serial ports. Devices may require manual intervention.

Devices affected by this are primarily older non-EFI hardware running pfSense CE software. This includes devices such as the APU (1), RCC-DFF 2220, and RCC-VE models such as the 2440, 4860, and 8860.

See also:

See *ISA Serial Console not Fully Functional* for details and a workaround.

Note: Netgate devices running pfSense Plus software and which are known to be affected automatically handle this configuration and do not require manual changes.

Low Memory Hardware

Hardware with **1 GiB or less** available memory may have issues upgrading depending on which features, services, or packages are running.

Tip: For devices running ZFS, see *ZFS Tuning* for information on reducing ZFS memory usage.

For the best chance of success in these cases, temporarily disable any non-critical services before starting the upgrade. Rebooting before attempting the upgrade can also be beneficial.

3.2.2 General

- PHP has been upgraded from 8.2.x to 8.3.x
- The base operating system has been upgraded to FreeBSD 15-CURRENT
- This version of pfSense CE software includes a new kernel-based PPPoE backend, `if_pppoe`. This will replace the current MPD-based implementation. This new backend is more efficient and enables much faster speeds over PPPoE interfaces.

  This new PPPoE backend is not active by default in this version, but can be enabled with *the global option* under **System > Advanced** on the **Networking** tab. This backend will be enabled by default on future versions of pfSense Plus software.

  The `if_pppoe` backend does not support all advanced features of the MPD implementation. For example, it does not support MLPPP.

- The default State Policy has been changed from **Floating** to **Interface Bound** for increased security. However, **Interface Bound** states may have issues in certain cases with IPsec VTI, Multi-WAN policy routing (`route-to`), `reply-to`, as well as with High Availability state synchronization (pfsync) on non-identical hardware. Workarounds are in place to fall back to **Floating** states in certain cases, such as IPsec/VTI.

  The default policy can be toggled back to **Floating** using the **State Policy** option under **System > Advanced** on the **Firewall & NAT** tab.

  There is also an option to override this behavior on a per-rule basis in the advanced options when editing a firewall rule.

  See also:

  - *State Policy History*
  - *Firewall State Policy*
  - *State Policy*

- This release includes support for enhanced gateway recovery "fail back" by optionally clearing states from lower tier gateways when a more preferred gateway recovers.

  See also:

  - *State Killing on Gateway Recovery*
  - *Gateway Group Options*

- This release includes support for High Availability in the Kea DHCP daemon.

  This implementation has several advantages over the older ISC DHCP implementation, including:

  - Supports HA for DHCPv4 **and** DHCPv6.
  - Simplified HA setup, all in one place on each node for each type.
  - Works in hot standby mode, which is more reliable.
  - Can synchronize lease data over the SYNC interface for security and ease of use, and can optionally encrypt the sync data for added protection.

  See also:

  For in-depth information on this feature, see https://www.netgate.com/blog/improvements-to-kea-dhcp

- This release includes support for DNS Registration of DHCP client hostnames from the Kea DHCP daemon to the Unbound DNS Resolver
  - DNS records are updated dynamically on-the-fly, they do not require a resolver restart and are not disruptive.
  - Supports DNS Registration for DHCPv4 **and** DHCPv6
  - DNS Registration can be configured on a per-interface or global manner, with the ability to enable or disable specific interfaces as needed.
  - DNS records are not limited to the system domain name. DNS Registration honors the domain name on the DHCP settings for each interface **and** on static mappings.
  - DNS records are accurate/updated on both high availability peers
  - Static mappings can be registered when Kea starts (similar to ISC) or when a static mapping client obtains a lease.

- This release includes support for DHCPv6 Prefix Delegation in the Kea DHCP daemon.

> **Warning:** Prefix Delegation settings in Kea use a different format than the ISC DHCPv6 daemon, so Kea **cannot** use existing settings for Prefix Delegation. Settings for Prefix Delegation must be re-created manually when switching from ISC DHCPv6 to Kea DHCPv6. For details, see *DHCPv6 Prefix Delegation*.

See also:

For additional details on implementation of Kea DHCP features see https://redmine.pfsense.org/issues/15650

- Users of the Gandi Dynamic DNS service **must** change their current API token to a Personal Access Token (PAT) as Gandi now requires this authentication method for Dynamic DNS updates. For uninterrupted Dynamic DNS service, create a new PAT and save that PAT value in Gandi Dynamic DNS entries before upgrading to this release.

3.2.3 Security / Errata

This release fixes several security issues in pfSense CE software, including:

- pfSense-SA-25_01.webgui Multiple problems in Dashboard widget key handling which could lead to XSS, denial of service, or configuration corruption.
- pfSense-SA-25_02.webgui OpenVPN management interface command injection from OpenVPN status and Dashboard widget.
- pfSense-SA-25_03.webgui Potential XSS in the AutoConfigBackup backup list.
- pfSense-SA-25_04.webgui Potential disclosure of AutoConfigBackup Device Key if SSH service is enabled and exposed to untrusted networks.
- pfSense-SA-25_05.webgui Stored XSS in Firewall Schedules.
- pfSense-SA-25_06.webgui Stored XSS in IPsec tunnel Phase 1 list.
- pfSense-SA-25_07.webgui Stored XSS in Wake on LAN pages and Dashboard widget.

Fixes for these security issues are available via the *Recommended System Patches* function of the *System Patches Package* for users running pfSense CE software version 2.7.2.

3.2.4 pfSense CE

Changes in this version of pfSense CE software.

Aliases / Tables

- Added: Allow user-defined rules to utilize built-in system aliases #1979
- Fixed: Interface subnet aliases do not contain IPv6 VIPs #15096
- Added: System Aliases for various reserved networks #15776
- Changed: Exclude the WireGuard and Tailscale interface group system aliases from rules #15848

Authentication

- Fixed: PHP errors in LDAP server prevent it from falling back to Local Database #15122
- Fixed: GUI logout messages do not use the `auth` log facility #15719

Auto Configuration Backup

- Fixed: Long configuration revision reasons can cause AutoConfigBackup upload to fail #12249
- Fixed: `services_acb_settings.php` does not fully validate value of `frequency`, uses value without encoding #15224
- Fixed: Special characters in the ACB configuration change description can cause PHP errors #15711
- Fixed: AutoConfigBackup tries to upload backups before the system has finished booting #15718
- Fixed: Potential XSS in AutoConfigBackup backup list on `services_acb.php` #15927
- Fixed: AutoConfigBackup scheduled backups always upload even when the configuration has not changed #16010
- Fixed: AutoConfigBackup remote revision timestamps may not be unique due to batch uploads #16011
- Fixed: "Reset" button on AutoConfigBackup Restore tab does not submit the form #16012
- Changed: AutoConfigBackup code cleanup and GUI refresh #16013
- Added: Download function for AutoConfigBackup entries #16014
- Added: Method to change the AutoConfigBackup device key #16015
- Changed: Change AutoConfigBackup default key generation format #16016

Backup / Restore

- Added: Support for CD/DVD drives in the External Configuration Locator (ECL) #14728
- Fixed: DHCP leases may not be restored from older configuration backups #15076
- Fixed: PHP error when generating a notification after detecting a malformed configuration #15157
- Fixed: Skip Packages option for Configuration Backups fails with large configurations #15624

CARP

- Fixed: HA node with CARP VIP in backup state is unable to ping the active node using that CARP VIP address #14026

Captive Portal

- Fixed: Disconnecting a user from Captive Portal may allow previously established connections to continue #13226
- Added: Support using a mask to block MAC addresses in Captive Portal #15257
- Fixed: Old auto-added MAC addresses are not pruned for non-concurrent Captive Portal sessions #15299
- Fixed: Captive Portal logo fails to load after authenticated redirect #15404
- Fixed: Captive Portal zones can fail to start due to ID conflict #15772

- Fixed: PHP error in Captive Portal with undefined zone interface list #15907
- Fixed: Captive Portal service management via `pfSsh.php svc` fails when the zone name contains uppercase letters #16030
- Fixed: Creating a Captive Portal zone with uppercase letters overwrites existing zones of the same name #16032

Certificates

- Fixed: Certificate Manager GUI inconsistency in Revocation tab titles #15454
- Added: Certificate Authorities created in the GUI do not have the Basic Constraints extension marked critical #15818
- Changed: Additional error handling for invalid certificate configuration #15975

Configuration Backend

- Fixed: System proxy credentials with certain characters may fail to authenticate #15565

Console Menu

- Changed: Dynamically adjust the interface name maximum width in the login banner #13268
- Fixed: Declining to reset the admin account via the console menu still prompts to change the password #15751

DHCP (IPv4)

- Added: Settings tab for global Kea DHCP server options #5080
- Added: Better handling of duplicate IP addresses in static DHCP assignments #13256
- Changed: Reduce log spam when deleting a static DHCP entry #13263
- Added: Explicitly enable/disable DHCP Dynamic DNS updates in each scope #13894
- Fixed: Kea fails to restart due to race between process termination and startup #14977
- Fixed: Kea does not allow FQDNs for NTP servers but input validation does not prevent them from being added #14991
- Fixed: Kea DHCP PHP error from WINS server value #14996
- Fixed: Kea DHCP sends wrong bootloader file for UEFI #15032
- Fixed: Kea will not start with identical MAC address filters on multiple interfaces #15130
- Added: Kea DHCP Custom Configuration Support (IPv4 and IPv6) #15321
- Fixed: Changes in Kea DHCP interface pools may invalidate lease database content #15328
- Fixed: Kea fails to start if DHCP pool configuration contains default lease time or max lease time #15332
- Added: Kea High Availability Support (IPv4 and IPv6) #15575
- Added: Kea DNS Resolver (Unbound) Integration (IPv4 and IPv6) #15651
- Added: Kea Static ARP Support (IPv4 only) #15654
- Fixed: IPv4 DHCP client responses may be routed unexpectedly out unrelated WANs #15702
- Added: Kea DHCP lease database RAM disk support (IPv4 and IPv6) #15828

- Fixed: Kea can unintentionally attempt to spawn multiple processes and fail #16019

DHCP (IPv6)

- Fixed: Old IPv6 addresses may continue to be used after DHCP or RA changes #12947
- Fixed: Shortcut bar on DHCPv6 leases (`status_dhcpv6_leases.php`) navigates to DHCPv4 destinations, not DHCPv6 #15117
- Fixed: DHCPv6 settings page "DDNS Reverse" check box not showing current state #15118
- Added: Kea DHCPv6 Prefix Delegation Support (IPv6 Only) #15652

DNS Forwarder

- Added: Option to allow the DNS Forwarder to ignore system DNS servers #14165
- Fixed: DNS Forwarder ignores "Use remote DNS Servers, ignore local DNS" setting #15434
- Changed: Update dnsmasq to version 2.90 #15465

DNS Resolver

- Fixed: DNS Resolver host overrides ignore all aliases if first entry has a domain set but no hostname #14942
- Fixed: Applying interface changes may not update default ACLs for the DNS Resolver #15071
- Fixed: Potential local file include vulnerability via DNS Resolver Python Module Script include mechanism #15135
- Fixed: Local DNS resolution behavior does not add an IPv6 nameserver #15139
- Changed: Update Unbound to 1.22.0 #15483
- Fixed: Automatic EDNS value may be lower than expected #15704
- Fixed: Unbound configuration file contains Localhost address in forwarding mode with TLS enabled #15722
- Fixed: `unbound-checkconf` fails with python mode enabled #15723

Dashboard

- Fixed: Firewall Logs Dashboard Widget is slow and may fail to update #12673
- Added: Improve Thermal Sensors Dashboard widget readability #13520
- Fixed: Traffic Graph widget displays bandwidth usage values which are half the actual usage amount #14933
- Fixed: Firewall Logs Dashboard widget update interval does not behave as expected #15373
- Added: Show current boot method in System Information Dashboard widget #15422
- Fixed: Incorrect icon on collapsed dashboard widgets #15439
- Fixed: Dashboard widgets refresh at unintended intervals #15725
- Changed: Improve Thermal Sensors Dashboard widget refresh code #15728
- Fixed: Session cookie warnings #15729
- Fixed: Clicking the picture widget image downloads the image with an invalid filename instead of showing it inline #15767

- Fixed: Dashboard `widgetkey` values are not validated on save or load, can lead to configuration corruption or other problems #15844
- Changed: Improve the system load impact from Dashboard widgets #15969

Diagnostics

- Added: Add Kea information to `status.php` #14953
- Fixed: Adding Wake-On-LAN entry from ARP table view can incorrectly include OEM text in MAC address field #15162
- Fixed: `crash_reporter.php` displays PHP Error log without encoding #15264
- Added: Add EFI boot information to `status.php` #15297
- Added: Add `loader.conf.lua` contents to `status.php` #15298
- Fixed: Errors in `status.php` IPsec sections when IPsec is not configured #15310
- Fixed: Sanitize RFC 2136 Dynamic DNS update keys in `status.php` output #15490
- Fixed: File browser on `diag_edit.php` does not encode directory names before display #15525
- Fixed: State table entries printed on `diag_dump_states.php` may contain an unexpected interface #15657
- Fixed: PHP error from invalid IPv6 address on `diagnostics_ping.php` #16005
- Fixed: Cannot kill states using the post-NAT address #16047

Dynamic DNS

- Added: Enable `@` support for Azure in Dynamic DNS #10000
- Added: Improve Dynamic DNS client IPv6 support #11177
- Added: Per-instance options to control Dynamic DNS client Check IP Service behavior #14067
- Added: Enable `@` support for name.com in Dynamic DNS #14289
- Fixed: Dynamic DNS uses the default gateway interface instead of the specified interface #14605
- Added: Support LuaDNS provider #15089
- Changed: Update Gandi LiveDNS service with API changes #15258
- Changed: Update Dynamic DNS API URL for porkbun.com #15779
- Fixed: Dynamic DNS attempts to resolve entries with disabled interfaces #15802
- Fixed: RFC 2136 Dynamic DNS cannot update AAAA records over IPv6 #16028
- Fixed: Dynamic DNS IP address may not be updated after changing the interface of a Dynamic DNS entry #16046

FreeBSD

- Fixed: Kernel panic in HA nodes when under high load #15413

Gateway Monitoring

- Fixed: Gateway behavior differs when the gateway does not exist in the configuration #12920
- Fixed: Gateway monitoring includes disabled gateways #15635
- Fixed: The monitoring IP address for dynamic gateways may be unexpectedly routed via a different gateway #16069
- Fixed: Improve gateway status detection with routed monitoring addresses #16180

Gateways

- Fixed: Killing states on downed gateways breaks when `Skip rules when gateway is down` is enabled #15223
- Fixed: Killing states on downed gateways breaks for static interface configurations #15225
- Fixed: Removing a gateway group used as the default gateway results in no default route #15248
- Changed: Clarify descriptions for gateway recovery options #15429
- Fixed: Saving an IPv6 gateway overrides the IPv4 gateway #15589
- Fixed: No default route after boot #15791

Hardware / Drivers

- Fixed: Newer variant models within the PC Engines APU2 platform are not recognized, causing garbled early serial console output #13498
- Added: Recognize QAT 4xxx devices in System Information Widget #15233

High Availability

- Fixed: Removing a route from the High Availability primary node does not remove the entry from the routing table on the secondary node #15795

IGMP Proxy

- Fixed: IGMP proxy works intermittently #15043
- Fixed: Kernel Panic when IGMPProxy gets CIDR Removed #15831

IPsec

- Fixed: MSS clamping on VPN traffic does not work on IPsec IPv6 mobile VPNs #14312
- Fixed: Large number of IPsec tunnels causes long filter reload times #14893
- Fixed: IPsec VTI is not created correctly when using a Phase 2 remote type of `Network` #15124
- Fixed: Cannot configure dual stack IPsec tunnel to accept connections from any remote address on both address families #15147
- Fixed: Removing an IPsec Phase 1 entry can either remove the wrong Phase 2 entries or leave orphaned Phase 2 entries in the configuration #15171
- Fixed: Change Mobile IPsec RADIUS accounting to use `accounting_requires_vip` so accounting will not activate for non-mobile VPNs #15176
- Added: Show interface subnet details in a tooltip on the IPsec Phase 2 list #15245
- Fixed: Reordering IPsec Phase 2 entries may result in a malformed configuration #15384
- Fixed: Input validation for duplicate remote gateways does not work when using the duplicate P1 button #15598
- Fixed: Mobile IPsec does not automatically switch to failover gateway #15685
- Fixed: Mobile IPsec sends incorrect DNS attribute IDs #15755
- Fixed: Firewall generates invalid rules for IPsec tunnels with descriptions containing special symbols #16095
- Fixed: Potential XSS in IPsec Phase 1 #16115
- Fixed: IPsec allows deleting P1/P2 entries with an assigned VTI #16158
- Fixed: IPsec unnecessarily prompts to apply changes after input errors #16162

IPv6 Router Advertisements (radvd/rtsold)

- Fixed: Non Link-Local IPv6 CARP address does not get advertised to endpoints with RADVD #12581
- Fixed: Incorrect warning from `radvd` about `AdvRDNSSLifetime` value #12938
- Fixed: `radvd` service shows as stopped in services list when it should be disabled and hidden from that list #14936
- Fixed: Cannot disable Router Advertisements when the interface IPv6 configuration is set to `None` #14967
- Fixed: Router Advertisement daemon does not prioritize IPv6 GUA over ULA #15057
- Added: PREF64 support in Router Advertisements #15808
- Fixed: Routing Advertisements daemon fails to start when configured with more than 3 RDNSS entries in a prefix #15876

Installer

- Fixed: Clean installation using Auto (ZFS) + MBR (BIOS) does not boot #14930
- Fixed: Installing to ZFS mirror does not format or populate EFI partition on additional disks #15083

Interfaces

- Fixed: Adding MSS and MTU values on a LAGG VLAN interface breaks connectivity #14083
- Fixed: Sending IPv6 traffic on a disabled interface can trigger a kernel panic #14431
- Fixed: PHP error in `interfaces_qinq_edit.php` when creating a QinQ interface #15181
- Fixed: PHP error when applying interface settings if the `/tmp/.interfaces.apply` file is present but empty #15423
- Added: Use natural sorting when sorting interfaces #15437
- Fixed: OpenVPN QinQ interface creation fails #15692
- Fixed: Interface group members are not validated on load/save on `interfaces_groups_edit.php`, and are printed without encoding on `interfaces_groups.php` #15778
- Fixed: Config access error with null static routes #16104
- Fixed: Config access error after changing an interface from DHCP to Static #16105

LAGG Interfaces

- Fixed: Reconfiguring a parent LAGG interface breaks its VLANs #9453

Logging

- Fixed: Restarting the logging daemon during rotation also restarts `sshguard`, leading to frequent log messages #12747
- Changed: Remove `Time` column from OS Boot logs #15106
- Added: Enhanced firewall log action information display #15415
- Fixed: PHP error when saving System Log settings #15988

Multi-WAN

- Added: Ability to selectively kill states on gateway recovery #855

NTPD

- Added: NTP authentication support #8794

OpenVPN

- Added: More GUI options for OpenVPN Client-Specific Overrides #12522
- Added: OpenVPN NBDD server options #13085
- Fixed: OpenVPN WINS options may be visible even when NetBIOS is disabled #13087
- Fixed: Some OpenVPN NetBIOS settings are kept even when NetBIOS is disabled #13089
- Fixed: OpenVPN NetBIOS Node Type and Scope ID options are not pushed to clients #13090
- Fixed: `openvpn.auth-user.php` gets stuck at 100% CPU usage when RADIUS authentication times out #14386
- Fixed: OpenVPN forms invalid `route` statements for empty local networks #14919
- Fixed: PHP error with OpenVPN server certificate verification if the certificate has multiple `CN` attributes #15133
- Fixed: OpenVPN Wizard fails when a VIP is used #15148
- Changed: Remove deprecated OpenVPN hardware crypto engine option #15188
- Fixed: OpenVPN Status Page and Dashboard Widget use input values without validation #15856

Operating System

- Fixed: `/etc/rc.local` script content is executed at login instead of during boot sequence #10980
- Fixed: Values obtained from `sysctl` are sometimes unexpectedly empty, leading to PHP and other math errors #14648
- Fixed: Static ARP assignments lose `permanent` flag in ARP table #14970
- Fixed: Permissions on tmpfs RAM disk for `/var` are too lenient #15054
- Fixed: `pfctl` is unable to retrieve state creator list in certain circumstances #15108
- Fixed: `loader.conf` may be missing `loader_conf_files` so `loader.conf.lua` may not be parsed #15288
- Fixed: Proxy variables in `crontab` contents are improperly formatted #15502
- Fixed: `resizewin` occasionally gets fed a spurious line feed over certain serial console+client combinations #15777
- Fixed: Panic accessing `sysctl` OID `net.inet.ip.nhdispatch` with an INVARIANTS kernel #16081

PHP Interpreter

- Fixed: Cookie named `id` prevents some forms from being loaded or saved properly #11268
- Fixed: Extensions directory is not set in `rc.php_ini_setup` #14488
- Changed: Update PHP to 8.3.x #15053
- Fixed: `check_dnsavailable()` failing even when DNS is available #15127
- Fixed: PHP error display formatting issues #15263
- Fixed: Memory leak in pfSense module function `pfSense_get_ifaddrs()` #15471

PPP Interfaces

- Fixed: PPPoE WAN loses IPv4 addresses on `IPV6CP` `LayerDown` events #16103
- Added: Support `if_pppoe` backend for PPPoE WAN interfaces #16134

Package System

- Added: Allow overriding text scrolling during package install/uninstall #15022
- Fixed: Extra space in `pkg` configuration file `FreeBSD.conf` #15069
- Fixed: Updates fail against an authenticated upstream proxy #15094
- Fixed: Package navigation menus can be duplicated when reinstalling the package #15700
- Fixed: The package `post-install` script does not run with a system upgrade on ZFS #16057
- Changed: `pkg` no longer supports setting `ALTABI` manually at run-time #16060

Packet Capture

- Fixed: Unable to perform Packet Captures on a tailscale interface in GUI with default settings #15145
- Added: Allow filtering packet captures by system-defined protocols #15609

Routing

- Fixed: ICMPv6 Path MTU Discovery breaks with NPT #14290
- Fixed: IPsec VTI static routes may not be added after the system boots #15449
- Fixed: Routes with IPv6 Address as Next Hop for IPv4 Destination Causes Kernel Panic #15601

Rules / NAT

- Added: NAT64 support #2358
- Added: Kill states using the pre-NAT address #11556
- Changed: Add global option to set default PF State Policy (if-bound vs floating) #15173
- Added: Add per-rule option to set PF State Policy (if-bound vs floating) #15183
- Fixed: Outbound NAT rules using an alias without a matching address family create unexpected PF rules #15197
- Fixed: Advanced rule options tooltip does not show negated Tag option #15214
- Added: Show details of system aliases in tooltip on firewall and NAT rule lists #15234
- Fixed: Egress states remain when killing states for scheduled rules #15252
- Fixed: Interface-bound state policy does not handle IPsec VTI traffic as expected when filtering on `enc0` interface #15430
- Fixed: Per-rule byte counter values lost across a filter reload #15516
- Fixed: Separator positions are incorrect when copying interface group rules #15537
- Added: GUI options to change default SCTP state timeouts #15661
- Fixed: Setting the Port Forward interface to an interface group selects an invalid destination #15671
- Fixed: SCTP states not purged causing subsequent SCTP INIT to be blocked #15924
- Fixed: Incorrect rule may be opened for editing after rule order has changed #15935
- Fixed: Deleting or adding a firewall rule may result in an unexpected rule order #16076
- Fixed: Potential XSS in Firewall Schedules #16114
- Fixed: Input validation prevents creating port forwards for the same port using a different address family #16130
- Fixed: Firewall rules using interface subnet aliases may prevent filter rules from loading after upgrades #16182

S.M.A.R.T.

- Changed: Query for SMART data only on root disk devices #15586

SNMP

- Fixed: File descriptor leak in `bsnmpd` #15481

Services

- Fixed: NTP option “DNS Resolution” has no effect when using NTP pool hostnames #15552

Setup Wizard

- Changed: Error handling in the Setup Wizard is very user-unfriendly #15302

System Logs

- Added: Separate IDS/IPS and link-local firewall log entries from default block logging #16092

Traffic Shaper (Limiters)

- Fixed: Input validation error when applying limiter changes #13158
- Fixed: Setting a limiter queue length greater than 100 prevents the limiter from loading #13662
- Fixed: Cannot add limiters named `new` #13687
- Fixed: Packets are passed through dummynet twice when using `route-to` leading to half the expected bandwidth #14854
- Fixed: Fragmented packets delayed by limiters are lost #15156
- Fixed: Reply traffic on a secondary WAN may be dropped when passed through dummynet #15363
- Fixed: PHP error when a queue is added with the same name as a limiter #15914

UPnP IGD & PCP

- Fixed: Port forward rules created by `miniupnpd` do not expire #15470
- Changed: Update UPnP IGD & PCP GUI text #15864
- Changed: Make the UPnP IGD & PCP STUN port optional #15865

Upgrade

- Fixed: Upgrading an EFI system installed to ZFS mirror does not upgrade EFI loader on additional disks #15084
- Changed: Link to release information on the system update page #15953
- Fixed: Boot loader is not upgraded on UFS installs #16064

User Manager / Privileges

- Fixed: Users with Deny Config Write privilege can trigger some VLAN interface operations #15282
- Fixed: Users with Deny Config Write privilege can trigger some QinQ interface operations #15318
- Fixed: CLI password check exits with a write access error when checking is a read-only operation #15442
- Fixed: PHP error when a user is denied access to the dashboard #15873
- Fixed: Users with Deny Config Write privilege can trigger logging operations #15874
- Fixed: Users with Deny Config Write privilege can change their own password #15908

Virtual IP Addresses

- Fixed: `choparp` service is not stopped after deleting Proxy ARP type Virtual IP addresses #14929
- Fixed: Network and broadcast address input validation is incorrectly applied to IPv6 VIPs #15361

Wake on LAN

- Fixed: Potential XSS in Wake on LAN page and widget #16116

Web Interface

- Added: Overflow scrolling for top navigation drop-down menus in Fixed mode #7943
- Added: Custom message text for the login screen #9293
- Fixed: Some messages presented to users contain relative links to pages which may be invalid when triggered from certain packages #13413
- Changed: Update vendor files #13537
- Fixed: `status_interfaces.php` is missing several values for SFP modules #15112
- Changed: Remove `jquery-treegrid` unit testing files #15265
- Added: 50x and 404 error handling to GUI web server configuration #15322
- Changed: Remove deprecated HTTP/1.0 Pragma header #15781
- Changed: Use minified nvd3 vendor files #15782
- Changed: Update nginx HTTP2 syntax #15863
- Fixed: Incorrect color in button text within disabled rows #15977

XMLRPC

- Fixed: Secondary node attempts to delete the `admins` group when synchronizing accounts via XMLRPC #15067
- Fixed: Changes to the `admins` user group are not synced to the secondary node #15898

3.3 24.11 New Features and Changes

This is a regularly scheduled software release including new features and bug fixes.

3.3.1 General

- This release includes support for High Availability in the Kea DHCP daemon.

  This implementation has several advantages over the older ISC DHCP implementation, including:

  - Supports HA for DHCPv4 **and** DHCPv6.
  - Simplified HA setup, all in one place on each node for each type.
  - Works in hot standby mode, which is more reliable.

  - Can synchronize lease data over the SYNC interface for security and ease of use, and can optionally encrypt the sync data for added protection.

  See also:

  For in-depth information on this feature, see https://www.netgate.com/blog/improvements-to-kea-dhcp

- This release includes support for DNS Registration of DHCP client hostnames from the Kea DHCP daemon to the Unbound DNS Resolver
  - DNS records are updated dynamically on-the-fly, they do not require a resolver restart and are not disruptive.
  - Supports DNS Registration for DHCPv4 **and** DHCPv6
  - DNS Registration can be configured on a per-interface or global manner, with the ability to enable or disable specific interfaces as needed.
  - DNS records are not limited to the system domain name. DNS Registration honors the domain name on the DHCP settings for each interface **and** on static mappings.
  - DNS records are accurate/updated on both high availability peers
  - Static mappings can be registered when Kea starts (similar to ISC) or when a static mapping client obtains a lease.

See also:

For additional details on implementation of Kea DHCP features see https://redmine.pfsense.org/issues/15650

3.3.2 pfSense Plus

Changes in this version of pfSense Plus software.

Aliases / Tables

- Added: Allow user-defined rules to utilize built-in system aliases #1979

Authentication

- Fixed: `sshguard` is not properly detecting GUI login failures #15687
- Fixed: GUI logout messages do not use the `auth` log facility #15719

Auto Configuration Backup

- Fixed: Special characters in the ACB configuration change description can cause PHP errors #15711
- Fixed: AutoConfigBackup tries to upload backups before the system has finished booting #15718

Backup / Restore

- Fixed: Factory resetting the configuration removes WireGuard #15511
- Fixed: Skip Packages option for Configuration Backups fails with large configurations #15624

CARP

- Fixed: HA node with CARP VIP in backup state is unable to ping the active node using that CARP VIP address #14026

Captive Portal

- Fixed: Captive Portal logo fails to load after authenticated redirect #15404
- Fixed: Captive Portal zones can fail to start due to ID conflict #15772

Certificates

- Fixed: CA certificates are not added to the Trust Store #15440
- Fixed: Certificate Manager GUI inconsistency in Revocation tab titles #15454

Configuration Backend

- Fixed: System proxy credentials with certain characters may fail to authenticate #15565

Console Menu

- Fixed: Declining to reset the admin account via the console menu still prompts to change the password #15751

DHCP (IPv4)

- Added: Settings tab for global Kea DHCP server options #5080
- Fixed: Kea fails to restart due to race between process termination and startup #14977
- Fixed: Kea will not start with identical MAC address filters on multiple interfaces #15130
- Fixed: Changes in Kea DHCP interface pools may invalidate lease database content #15328
- Fixed: Kea does not send configured TFTP server name #15518
- Added: Kea High Availability Support (IPv4 and IPv6) #15575
- Added: Kea DNS Resolver (Unbound) Integration (IPv4 and IPv6) #15651
- Fixed: IPv4 DHCP client responses may be routed unexpectedly out unrelated WANs #15702
- Fixed: Hostnames for ISC DHCP leases are not removed from Unbound when switching to Kea #15750
- Added: Kea DHCP lease database RAM disk support (IPv4 and IPv6) #15828

DNS Forwarder

- Fixed: DNS Forwarder ignores "Use remote DNS Servers, ignore local DNS" setting #15434
- Changed: Update dnsmasq to version 2.90 #15465

DNS Resolver

- Fixed: Reduce disruptions when changing DNS records from DHCP leases in Unbound #5413
- Changed: Update Unbound to 1.22.0 #15483
- Fixed: Automatic EDNS value may be lower than expected #15704
- Fixed: Unbound configuration file contains Localhost address in forwarding mode with TLS enabled #15722
- Fixed: `unbound-checkconf` fails with python mode enabled #15723

Dashboard

- Added: Improve Thermal Sensors Dashboard widget readability #13520
- Fixed: Traffic Graph widget displays bandwidth usage values which are half the actual usage amount #14933
- Fixed: Firewall Logs Dashboard widget update interval does not behave as expected #15373
- Added: Show current boot method in System Information Dashboard widget #15422
- Fixed: Incorrect icon on collapsed dashboard widgets #15439
- Fixed: Dashboard widgets refresh at unintended intervals #15725
- Changed: Improve Thermal Sensors Dashboard widget refresh code #15728
- Fixed: Session cookie warnings #15729

Diagnostics

- Fixed: Sanitize RFC 2136 Dynamic DNS update keys in `status.php` output #15490
- Fixed: File browser on `diag_edit.php` does not encode directory names before display #15525
- Fixed: State table entries printed on `diag_dump_states.php` may contain an unexpected interface #15657

Dynamic DNS

- Added: Enable `@` support for Azure in Dynamic DNS #10000
- Added: Enable `@` support for name.com in Dynamic DNS #14289
- Changed: Update Dynamic DNS API URL for porkbun.com #15779
- Fixed: Dynamic DNS attempts to resolve entries with disabled interfaces #15802

FreeBSD

- Fixed: Kernel panic in HA nodes when under high load #15413

Gateway Monitoring

- Fixed: Gateway monitoring includes disabled gateways #15635

Gateways

- Fixed: No default route after boot #15791

High Availability

- Fixed: Removing a route from the High Availability primary node does not remove the entry from the routing table on the secondary node #15795

IGMP Proxy

- Fixed: Kernel Panic when IGMPProxy gets CIDR Removed #15831

IPsec

- Fixed: Mobile IPsec does not automatically switch to failover gateway #15685
- Fixed: Mobile IPsec sends incorrect DNS attribute IDs #15755

IPv6 Router Advertisements (radvd/rtsold)

- Fixed: Non Link-Local IPv6 CARP address does not get advertised to endpoints with RADVD #12581

Installer

- Fixed: Installing to ZFS mirror does not format or populate EFI partition on additional disks #15083

Interfaces

- Fixed: Adding MSS and MTU values on a LAGG VLAN interface breaks connectivity #14083
- Fixed: PHP error when applying interface settings if the `/tmp/.interfaces.apply` file is present but empty #15423
- Added: Use natural sorting when sorting interfaces #15437
- Fixed: OpenVPN QinQ interface creation fails #15692
- Fixed: Interface group members are not validated on load/save on `interfaces_groups_edit.php`, and are printed without encoding on `interfaces_groups.php` #15778

Logging

- Fixed: Restarting the logging daemon during rotation also restarts `sshguard`, leading to frequent log messages #12747

Multi-WAN

- Fixed: State Killing on Gateway Recovery fails for the default gateway group with the "Kill all" option selected #15694

NTPD

- Added: NTP authentication support #8794

OpenVPN

- Added: More GUI options for OpenVPN Client-Specific Overrides #12522
- Fixed: PHP error with OpenVPN server certificate verification if the certificate has multiple `CN` attributes #15133

Operating System

- Fixed: Kernel panic with pflow configured and active #15446
- Fixed: Proxy variables in `crontab` contents are improperly formatted #15502
- Fixed: `resizewin` occasionally gets fed a spurious line feed over certain serial console+client combinations #15777

PHP Interpreter

- Changed: Update PHP to 8.3.x #15053
- Fixed: Memory leak in pfSense module function `pfSense_get_ifaddrs()` #15471

Package System

- Fixed: Updates fail against an authenticated upstream proxy #15094
- Fixed: Package navigation menus can be duplicated when reinstalling the package #15700

Packet Capture

- Added: Allow filtering packet captures by system-defined protocols #15609

Routing

- Fixed: Interface-bound state policy does not handle IPsec VTI traffic as expected when filtering on `enc0` interface #15430
- Fixed: IPsec VTI static routes may not be added after the system boots #15449
- Fixed: Saving an IPv6 gateway overrides the IPv4 gateway #15589
- Fixed: Routes with IPv6 Address as Next Hop for IPv4 Destination Causes Kernel Panic #15601
- Fixed: Static routes using null gateways are not installed #15669

Rules / NAT

- Fixed: Per-rule byte counter values lost across a filter reload #15516
- Fixed: Separator positions are incorrect when copying interface group rules #15537
- Added: GUI options to change default SCTP state timeouts #15661
- Fixed: Setting the Port Forward interface to an interface group selects an invalid destination #15671

S.M.A.R.T.

- Changed: Query for SMART data only on root disk devices #15586

SNMP

- Fixed: File descriptor leak in `bsnmpd` #15481

Services

- Fixed: NTP option "DNS Resolution" has no effect when using NTP pool hostnames #15552

UPnP/NAT-PMP

- Fixed: Port forward rules created by `miniupnpd` do not expire #15470

Upgrade

- Fixed: Upgrading an EFI system installed to ZFS mirror does not upgrade EFI loader on additional disks #15084

User Manager / Privileges

- Fixed: CLI password check exits with a write access error when checking is a read-only operation #15442

Virtual IP Addresses

- Fixed: Network and broadcast address input validation is incorrectly applied to IPv6 VIPs #15361

Web Interface

- Changed: Remove deprecated HTTP/1.0 Pragma header #15781
- Changed: Use minified nvd3 vendor files #15782

3.4 24.03 New Features and Changes

This is a regularly scheduled software release including new features and bug fixes.

Tip: Consult the *Upgrade Guide* before proceeding with any upgrade.

3.4.1 Pre-Upgrade Cautions

Before upgrading, pay particular attention to the *Pre-Upgrade Tasks* section of the *Upgrade Guide*. The most crucial points are noted in this section, but the best practice is to follow all of the precautions noted in the Upgrade Guide.

ZFS Boot Environment Space Usage

Before attempting the upgrade, check the list of current ZFS Boot Environments (**System > Boot Environments**) and clean up any older entries to ensure they do not consume space which may be needed during the upgrade. See *Check and Clean Up ZFS Boot Environments* for details.

Low Memory Hardware and AWS/Azure Instances

Hardware with **1 GiB or less** available memory may have issues upgrading depending on which features, services, or packages are running. This includes some Netgate hardware such as the Netgate 1100 when running with ZFS and/or certain services/packages. For the best chance of success in these cases, temporarily disable any non-critical services before starting the upgrade.

pfSense Plus software can no longer run on AWS ".nano" size instances as they lack sufficient RAM to upgrade properly. Attempting to upgrade a ".nano" instance to pfSense Plus software version 24.03 will fail before the upgrade is performed. Migrate the instance to a ".micro" or larger size **before** attempting to upgrade, or redeploy instead.

Similar to the above, pfSense Plus software can no longer run on Azure A0 instances. Migrate to instances with more memory.

Netgate 3100 (32-Bit ARM) Limitations

Support for the EOL Netgate 3100 device architecture, `armv7`, is being phased out upstream in FreeBSD. While this release still contains base system functionality for the Netgate 3100, several packages are unavailable as they can no longer build for that architecture. The list of packages unavailable for the Netgate 3100 now also includes **Suricata**, **Squid**, and **squidGuard**.

Users who wish to continue using those packages on a Netgate 3100 **should not** upgrade to this release.

3.4.2 General

- pfSense Plus software version 24.03 makes sure the user changes the `admin` account password in the user manager away from the default value. It also ensures that the password is not set to the same value as the username. This validation happens during the setup wizard for new installations, on login and loading any GUI page for existing users, and at the console/shell menu.

  Most users will not notice any difference since they have likely changed their `admin` account password to a secure custom value in the past.

  Resetting the password via the console menu now prompts the user to set a custom password rather than using a default value.

  Note: These restrictions apply to all accounts. Users are also prevented from changing passwords to problematic values.

- The default State Policy has been changed from **Floating** to **Interface Bound** for increased security. However, **Interface Bound** states may have issues in certain cases with IPsec VTI, Multi-WAN policy routing (`route-to`), `reply-to`, as well as with High Availability state synchronization (pfsync) on non-identical hardware.

  The default policy can be toggled back to **Floating** using the **State Policy** option under **System > Advanced** on the **Firewall & NAT** tab.

  There is also an option to override this behavior on a per-rule basis in the advanced options when editing a firewall rule.

  See also:

  - *State Policy History*
  - *Firewall State Policy*
  - *State Policy*

- This release adds support for Packet Flow Data export via `pflow` in PF. This feature natively exports NetFlow/IPFIX flow data to an external collector.

  See also:

  - *Firewall Packet Flow Data*

- This release includes support for enhanced gateway recovery "fail back" by optionally clearing states from lower tier gateways when a more preferred gateway recovers.

  See also:

  - *State Killing on Gateway Recovery*
  - *Gateway Group Options*

- This version requires an updated boot loader, which is automatically handled by the upgrade process for nearly all cases. However, there may be some edge cases where the automatic update does not update the loader currently used by the device. For example, if there are multiple unmirrored disks and the BIOS/EFI Firmware is not booting from the disk containing the updated loader, but an older unrelated installation on a separate disk. One particular case where this can happen is when there is a previous installation to MMC which has been followed by an installation to an add-on SSD without clearing the MMC contents.

  In these cases the best practice is to wipe the unused disk so it cannot interfere. See *Troubleshooting Multiple Disks* for details.

3.4.3 Minor Revision

Devices running pfSense Plus software version 24.03 may be seeing a "24.03_1" update available which is a very minor revision made to address a missing dependency on 64-bit ARM devices (https://redmine.pfsense.org/issues/15433). The revision is kept the same on all platforms for consistency.

Upgrading to this version is safe, but not necessary at this time unless users are running on 64-bit ARM devices and want access to S.M.A.R.T. disk data (e.g. Netgate 2100 devices which have an add-on SSD).

Using the GUI or pfSense-upgrade from the console or shell to upgrade from 24.03 to 24.03_1, the device will want to reboot, but in this case that is unnecessary. However, doing so is harmless except for the minimal downtime involved in the reboot during that upgrade process.

Manually updating from the shell via `pkg update; pkg upgrade` will pull in the new revision and fixed dependency as needed. Run those commands from a shell prompt and confirm that the proposed changes are OK. No additional action is necessary.

Devices which have not yet upgraded to 24.03 or those installed fresh via the Netgate Installer will obtain the latest version automatically and do not require any additional action after upgrading.

3.4.4 pfSense Plus

Changes in this version of pfSense Plus software.

Aliases / Tables

- Fixed: Interface subnet aliases do not contain IPv6 VIPs #15096

Authentication

- Changed: Prevent usage of the default password in User Manager accounts #15266
- Fixed: PHP errors in LDAP server prevent it from falling back to Local Database #15122

Auto Configuration Backup

- Fixed: `services_acb_settings.php` does not fully validate value of `frequency`, uses value without encoding #15224

Backup / Restore

- Added: Support for CD/DVD drives in the External Configuration Locator (ECL) #14728
- Fixed: DHCP leases may not be restored from older configuration backups #15076
- Fixed: PHP error when generating a notification after detecting a malformed configuration #15157

Captive Portal

- Fixed: Disconnecting a user from Captive Portal may allow previously established connections to continue #13226
- Added: Support using a mask to block MAC addresses in Captive Portal #15257
- Fixed: Old auto-added MAC addresses are not pruned for non-concurrent Captive Portal sessions #15299

Console Menu

- Changed: Dynamically adjust the interface name maximum width in the login banner #13268

DHCP (IPv4)

- Added: Better handling of duplicate IP addresses in static DHCP assignments #13256
- Changed: Reduce log spam when deleting a static DHCP entry #13263
- Added: Explicitly enable/disable DHCP Dynamic DNS updates in each scope #13894
- Fixed: Stale Kea control socket lock file can prevent Kea from starting #14977
- Fixed: Kea does not allow FQDNs for NTP servers but input validation does not prevent them from being added #14991
- Fixed: Kea DHCP PHP error from WINS server value #14996
- Fixed: Kea DHCP sends wrong bootloader file for UEFI #15032

DHCP (IPv6)

- Fixed: DHCP6 client does not take any action if the interface IPv6 address changes during renewal #12947
- Fixed: Shortcut bar on DHCPv6 leases (`status_dhcpv6_leases.php`) navigates to DHCPv4 destinations, not DHCPv6 #15117
- Fixed: DHCPv6 settings page “DDNS Reverse” check box not showing current state #15118

DNS Forwarder

- Added: Option to allow the DNS Forwarder to ignore system DNS servers #14165

DNS Resolver

- Fixed: DNS Resolver host overrides ignore all aliases if first entry has a domain set but no hostname #14942
- Fixed: Applying interface changes may not update default ACLs for the DNS Resolver #15071
- Fixed: Potential local file include vulnerability via DNS Resolver Python Module Script include mechanism #15135
- Fixed: Local DNS resolution behavior does not add an IPv6 nameserver #15139
- Changed: Upgrade Unbound to >= 1.19.1 #15256

Dashboard

- Fixed: Firewall Logs Dashboard Widget is slow and may fail to update #12673

Diagnostics

- Changed: Add ZFS Boot Environment list to status output #15164
- Added: Add Kea information to `status.php` #14953
- Fixed: `crash_reporter.php` displays PHP Error log without encoding #15264
- Added: Add EFI boot information to `status.php` #15297
- Added: Add `loader.conf.lua` contents to `status.php` #15298
- Fixed: Errors in `status.php` IPsec sections when IPsec is not configured #15310

Gateway Monitoring

- Fixed: Gateway behavior differs when the gateway does not exist in the configuration #12920

Gateways

- Fixed: Killing states on downed gateways breaks when `Skip rules when gateway is down` is enabled #15223
- Fixed: Killing states on downed gateways breaks for static interface configurations #15225
- Fixed: Removing a gateway group used as the default gateway results in no default route #15248

Hardware / Drivers

- Fixed: Newer variant models within the PC Engines APU2 platform are not recognized, causing garbled early serial console output #13498
- Added: Recognize QAT 4xxx devices in System Information Widget #15233

IGMP Proxy

- Fixed: IGMP proxy works intermittently #15043

IPsec

- Added: Group-based Mobile IPsec Virtual Address Pool assignment via RADIUS #13227
- Fixed: MSS clamping on VPN traffic does not work on IPsec IPv6 mobile VPNs #14312
- Fixed: Large number of IPsec tunnels causes long filter reload times #14893
- Fixed: IPsec VTI is not created correctly when using a Phase 2 remote type of `Network` #15124
- Fixed: Cannot configure dual stack IPsec tunnel to accept connections from any remote address on both address families #15147
- Fixed: Removing an IPsec Phase 1 entry can either remove the wrong Phase 2 entries or leave orphaned Phase 2 entries in the configuration #15171
- Fixed: Change Mobile IPsec RADIUS accounting to use `accounting_requires_vip` so accounting will not activate for non-mobile VPNs #15176
- Added: Show interface subnet details in a tooltip on the IPsec Phase 2 list #15245
- Fixed: Reordering IPsec Phase 2 entries may result in a malformed configuration #15384

IPv6 Router Advertisements (radvd/rtsold)

- Fixed: `radvd` service shows as stopped in services list when it should be disabled and hidden from that list #14936
- Fixed: Cannot disable Router Advertisements when the interface IPv6 configuration is set to `None` #14967
- Fixed: Router Advertisement daemon does not prioritize IPv6 GUA over ULA #15057

Installer

- Fixed: Clean installation using Auto (ZFS) + MBR (BIOS) does not boot #14930

Interfaces

- Fixed: Sending IPv6 traffic on a disabled interface can trigger a kernel panic #14431
- Fixed: PHP error in `interfaces_qinq_edit.php` when creating a QinQ interface #15181

LAGG Interfaces

- Fixed: Reconfiguring a parent LAGG interface breaks its VLANs #9453

Logging

- Changed: Remove `Time` column from OS Boot logs #15106

Multi-WAN

- Added: Ability to selectively kill states on gateway recovery #855

OpenVPN

- Added: OpenVPN NBDD server options #13085
- Fixed: OpenVPN WINS options may be visible even when NetBIOS is disabled #13087
- Fixed: Some OpenVPN NetBIOS settings are kept even when NetBIOS is disabled #13089
- Fixed: OpenVPN NetBIOS Node Type and Scope ID options are not pushed to clients #13090
- Fixed: `openvpn.auth-user.php` gets stuck at 100% CPU usage when RADIUS authentication times out #14386
- Fixed: OpenVPN forms invalid `route` statements for empty local networks #14919
- Fixed: OpenVPN Wizard fails when a VIP is used #15148
- Changed: Remove deprecated OpenVPN hardware crypto engine option #15188

Operating System

- Added: Operating System support for PF `pflow` packet data flow export #15038
- Fixed: `/etc/rc.local` script content is executed at login instead of during boot sequence #10980
- Fixed: Static ARP assignments lose `permanent` flag in ARP table #14970
- Fixed: Permissions on tmpfs RAM disk for `/var` are too lenient #15054
- Fixed: `pfctl` is unable to retrieve state creator list in certain circumstances #15108
- Fixed: `loader.conf` may be missing `loader_conf_files` so `loader.conf.lua` may not be parsed #15288

PHP Interpreter

- Fixed: Extensions directory is not set in `rc.php_ini_setup` #14488
- Fixed: `check_dnsavailable()` failing even when DNS is available #15127
- Fixed: PHP error display formatting issues #15263

Package System

- Fixed: Extra space in `pkg` configuration file `FreeBSD.conf` #15069

Routing

- Fixed: ICMPv6 Path MTU Discovery breaks with NPT #14290

Rules / NAT

- Added: GUI to configure Packet Flow Data (`pflow`) export #15039
- Added: Kill states using the pre-NAT address #11556
- Changed: Add global option to set default PF State Policy (if-bound vs floating) #15173
- Added: Add per-rule option to set PF State Policy (if-bound vs floating) #15183
- Fixed: Outbound NAT rules using an alias without a matching address family create unexpected PF rules #15197
- Fixed: Advanced rule options tooltip does not show negated Tag option #15214
- Added: Show details of system aliases in tooltip on firewall and NAT rule lists #15234
- Fixed: Egress states remain when killing states for scheduled rules #15252

Setup Wizard

- Changed: Error handling in the Setup Wizard is very user-unfriendly #15302

Traffic Shaper (Limiters)

- Fixed: Packets are passed through dummynet twice when using `route-to` leading to half the expected bandwidth #14854
- Fixed: Fragmented packets delayed by limiters are lost #15156
- Fixed: Reply traffic on a secondary WAN may be dropped when passed through dummynet #15363

Upgrade

- Added: Boot Environments 2.0 #15280

Virtual IP Addresses

- Fixed: `choparp` service is not stopped after deleting Proxy ARP type Virtual IP addresses #14929

Web Interface

- Added: Overflow scrolling for top navigation drop-down menus in Fixed mode #7943
- Fixed: Some messages presented to users contain relative links to pages which may be invalid when triggered from certain packages #13413
- Changed: Update vendor files #13537
- Fixed: `status_interfaces.php` is missing several values for SFP modules #15112
- Changed: Remove `jquery-treegrid` unit testing files #15265
- Added: 50x and 404 error handling to GUI web server configuration #15322

XMLRPC

- Fixed: Secondary node attempts to delete the `admins` group when synchronizing accounts via XMLRPC #15067

3.5 23.09.1 New Features and Changes

This is a maintenance software release including new features and bug fixes.

Consult the *Upgrade Guide* before proceeding with any upgrade.

3.5.1 Security / Errata

FreeBSD Notices

This release includes corrections for several FreeBSD Errata Notices and Security Advisories, including:

- FreeBSD-SA-23:17.pf - TCP spoofing vulnerability in pf(4)
- FreeBSD-EN-23:16.openzfs - Potential ZFS Data Corruption

  For more information about ZFS data corruption, see *ZFS Data Corruption Details* later in this document.
- FreeBSD-EN-23:18.openzfs - High CPU usage by ZFS kernel threads
- FreeBSD-EN-23:17.ossl - ossl(4)'s AES-GCM implementation may give incorrect results
- FreeBSD-EN-23:20.vm - Incorrect results from the kernel physical memory allocator
- Performance issues in OpenSSL have also been identified and corrected, notably with acceleration such as AES-NI.

EFI Issue on Proxmox® VE

Some users of pfSense® software running under Proxmox VE 7.4 have had issues booting Virtual Machines via EFI. This may also affect other versions of Proxmox VE and pfSense software as well as FreeBSD.

Adding a serial port to the VM hardware appears to work around the issue for the time being. A fix for the root cause is under investigation and development for future versions.

At this time the best practice to avoid potential problems is to add a serial port to the VM, then shutdown the VM and start it back up **before** beginning the pfSense software upgrade process.

See also:

See *EFI Boot Issues* for additional recommendations.

ZFS Data Corruption Details

Two data corruption bugs were recently reported against ZFS, including the version of ZFS in recent releases of pfSense software. These bugs have been corrected upstream in FreeBSD and the fixes have been imported into this release.

One bug was in block cloning, which is disabled by default on pfSense software, and thus is unlikely to be a significant concern on this platform. The other bug has been present in ZFS for years and was difficult to trigger.

Given the history of data corruption problems due to hole reporting in files, the corrections for this issue include a preventive measure to disable hole reporting. The downside of disabling hole reporting is the possibly increased disk space usage.

Tip: Users on previous releases of pfSense software can reduce the likelihood of encountering the data corruption issue by creating a *System Tunable* for `vfs.zfs.dmu_offset_next_sync` with a value of `0`.

3.5.2 pfSense Plus

Changes in this version of pfSense Plus software.

Aliases / Tables

- Fixed: Rules using aliases of type `URL (IPs)` are not generated #14947

DHCP (IPv4)

- Fixed: ISC DHCP responds from a random port #15011

DHCP (IPv6)

- Fixed: PHP error on `services_dhcpv6.php` if the configuration contains an empty `dhcpv6` section #14978

DHCP Relay

- Fixed: Input validation prevents saving DHCPv6 Relay settings #14965

DNS Resolver

- Changed: Update Unbound to 1.18.0_1 to address looping UDP retries when ENOBUFS is returned #14980

IPsec

- Fixed: Mobile IPsec Group Authentication cannot be enabled #14963
- Fixed: Incorrect permissions on `ipsec.auth-user.php` #14974
- Fixed: IPsec log categories set to "Audit" do not function properly or save properly in the GUI #14990
- Changed: Update strongSwan to 5.9.11_3 #15050

Installer

- Added: Add an appropriately named file to install images to indicate what they are #14887

Interfaces

- Fixed: Mulicast traffic on a detached interface causes a panic #14917
- Fixed: PHP Error on `interfaces.php` when creating a PPP interface #14949
- Fixed: DHCP WAN with multiple (2+) IP Alias VIPs may show `0.0.0.0` as an interface address at boot #14966

OpenVPN

- Changed: Update OpenVPN to 2.6.8_1 #15049

Operating System

- Added: Method for users to customize shell initialization behavior #14746
- Fixed: Potential ZFS file corruption #15034

Rules / NAT

- Fixed: Invalid outbound NAT rules break the following rule #15024
- Fixed: Automatic outbound NAT rules show an empty NAT Address #15025

Traffic Graphs

- Fixed: Traffic graph filters apply incorrectly #14892

Upgrade

- Fixed: pfSense-boot does not update the EFI loader #15007

Web Interface

- Fixed: Firewall Maximum Table Entries "default size" is whatever is entered #11566

3.6 23.09 New Features and Changes

This is a regularly scheduled software release including new features and bug fixes.

Consult the *Upgrade Guide* before proceeding with any upgrade.

Warning: Before attempting the upgrade, check the list of current ZFS Boot Environments (**System > Boot Environments**) and clean up any older entries to ensure they do not consume space which may be needed during the upgrade. See *Check and Clean Up ZFS Boot Environments* for details.

3.6.1 General

- PHP has been upgraded to 8.2.11
- The base operating system has been upgraded to a more recent point on FreeBSD 14-CURRENT
- Support for SCTP has been improved in PF for firewall rules, NAT, and logging. Rules can now act on SCTP packets by port number, previously it was only possible to filter on source or destination address.
- OpenSSL in the base system has been upgraded from 1.1.1t to 3.0.12.

  For details, see *OpenSSL upgraded to 3.0.12*.
- Kea DHCP Server has been added as an opt-in feature preview for IPv4 and IPv6 DHCP service. Kea will eventually replace the ISC DHCPD daemon which is EOL.

  Warning: Kea is not yet feature complete. For details, see *Kea DHCP Server feature preview now available*.
- IPv6 Router Advertisement configuration has been relocated to **Services > Router Advertisement** as a part of the ongoing DHCP Server changes.
- Certain parts of the base system are being migrated to packages rather than grouping them all together in an archive in the "base" package. For the most part this should be entirely transparent to users.

  Specifically, the code from the main pfSense software repository is now a part of the "pfSense" package. This lets management of files be handled entirely by `pkg` rather than carrying them in an archive. This migration is ongoing, so future versions will include additional portions of the system being packaged differently.

- The default driver for NVMe storage devices changed from `nvd(4)` to `nda(4)`. For most users this will be a transparent change since the majority of installations are mounted by label and do not reference a storage device by name.

  Some swap configurations may reference the old device name in `/etc/fstab`. Editing that file and correcting device names from `nvd` to `nda`, followed by a reboot, should restore swap functionality.

  If the new driver is problematic in certain environments the default can be changed back to `nvd(4)` by adding a *loader tunable* for `hw.nvme.use_nvd=1`.

OpenSSL upgraded to 3.0.12

OpenSSL has been upgraded to 3.0.12 from 1.1.1 in FreeBSD.

This change was necessary as OpenSSL 1.1.1 reached its End of Life (EOL) on September 11, 2023. This means there will be no security patches for vulnerabilities affecting OpenSSL 1.1.1.

The OpenSSL team decided to make an explicit jump in numbering from 1.1.x to 3.x to highlight that this new version included major structural, and more importantly, application programming interface (API) and application binary interface (ABI) changes compared to previous OpenSSL versions.

In addition to the differences in the library they also deprecated numerous weak algorithms of various types.

Due to these differences, changing from OpenSSL 1.1 to OpenSSL 3.0 is not a simple upgrade. Netgate developers have handled most of these changes as automatically as possible, though some things may still require manual adjustments. See the warnings in the next section for details.

OpenSSL 3.0.x Upgrade Warnings

Weak Certificate Digests such as SHA1 are Deprecated

Warning: OpenSSL 3.0.x no longer supports certificates signed with SHA1 or other older/weaker hashes. The minimum recommended hash strength is SHA256.

The upgrade process detects usage of weak certificates for the GUI, Captive Portal, and OpenVPN:

- If the **GUI** or a **Captive Portal** zone utilizes a weak CA or server certificate, the upgrade process generates a new self-signed certificate as a stopgap measure to allow the processes to start and let the user in to make any necessary corrections.
- If an **OpenVPN** instance is using a weak certificate, the instance is disabled as there is no viable general automated recovery method.
- **OpenVPN peers** using SHA1 certificates will fail, but such issues must be corrected on the peers. This may mean renewing or reissuing certificates or re-exporting clients for peers if they are currently using weak certificates.
- Other consumers of certificates, such as add-on packages, may be similarly affected but cannot be automatically adjusted.

The best practice is to reconfigure all services utilizing certificates with stronger certificates and to test these functions before performing an upgrade to ensure a smoother transition.

Numerous Deprecated Encryption and Digest Algorithms Removed

Warning: OpenSSL 3.0.x removes a large number of deprecated encryption and digest algorithms. This primarily affects OpenVPN, as other areas had not supported the affected algorithms in some time.

Encryption algorithms removed from OpenVPN:

- ARIA
- Blowfish (e.g. BF-CBC), which was formerly an OpenVPN default
- CAST5
- DES
- DESX
- IDEA
- RC2
- RC5
- SEED
- SM4

Hash algorithms removed from OpenVPN:

- MD4
- MDC2
- SM3
- Whirlpool

On upgrade, tunnels using these deprecated algorithms will be adjusted so they use more secure default values when necessary.

The best practice is to reconfigure tunnels using modern secure encryption and hashing, and to test tunnels before performing an upgrade to ensure a smoother transition.

Other OpenSSL-Related Concerns

- The certificate manager in the GUI can still read and generate certificates using weak hashes, but warns against their use. Avoid creating any new entries using weak hashes. This support will eventually be removed.
- The certificate manager no longer supports importing PKCS#12 archive files which were encrypted with weak ciphers, such as RC2-40. Some operating systems still export using such weak ciphers by default, including macOS and Windows.
- IPsec does not require any adjustments, it still supports SHA1 certificates for the time being and no additional algorithms have been deprecated or removed.
- Unbound does not require any adjustments, it still supports SHA1 certificates for the time being.
- Though the legacy provider for OpenSSL 3.0.x is built and included it does not help to work around the issues mentioned above in any meaningful way.

Kea DHCP Server feature preview now available

The ISC DHCPD server has reached its End of Life (EOL) as of October 5, 2022. Though ISC has stated they may continue to publish security fixes if they are warranted.

Netgate developers have started the migration to Kea DHCP server from ISC as a replacement for ISC DHCPD for IPv4 and IPv6 DHCP service. Basic functionality is present, but not all features are supported at this time.

Warning: Currently the Kea implementation lacks the following DHCP server features:

- Local DNS Resolver/Forwarder Registration for static and dynamic DHCP clients
- Remote DNS server registration
- DHCPv6 Prefix Delegation
- High Availability Failover
- Lease statistics/graphs
- Custom DHCP options

Kea is available as an opt-in preview feature on this release. The UI and settings for Kea are shared with the existing DHCP server. Administrators can easily switch between ISC DHCPD and Kea by navigating to **System > Advanced**, **Networking** tab and changing the new **Server Backend** setting in the **DHCP Options** section.

After Kea integration is complete it will become the default DHCP server on a future release of pfSense software and eventually the deprecated ISC DHCP server will be removed. The exact timing of these changes has not been finalized.

Note: As a part of changes to the DHCP server, IPv6 Router Advertisement configuration has been separated from the DHCP server UI and relocated to **Services > Router Advertisement**.

3.6.2 Security

In addition to OpenSSL and other concerns in the base OS and packages, this release addresses the following vulnerabilities in pfSense software:

- pfSense-SA-23_08.webgui (XSS in `getserviceproviders.php`, #14547)
- pfSense-SA-23_09.webgui (XSS in `status_logs_filter_dynamic.php`, #14548)
- pfSense-SA-23_10.webgui (Authenticated Command Execution in `interfaces_gif_edit.php` and `interfaces_gre_edit.php`, #14549)
- pfSense-SA-23_11.webgui (Authenticated Command Execution in `packet_capture.php`, #14809)

Tip: Patches for these issues are also available in the latest version of the *System Patches Package* for users of pfSense Plus software version 23.05.1 and pfSense CE software version 2.7.0.

3.6.3 pfSense Plus

Changes in this version of pfSense Plus software.

Aliases / Tables

- Fixed: Firewall rules fail to load when a URL table alias file does not exist #13068
- Added: Type column on Alias lists #13245
- Fixed: Static ARP entries are not configured at boot #14374
- Fixed: Firewall rules are not displayed properly when they reference a URL table alias and its file does not exist #14574

Authentication

- Added: Option to invalidate GUI login session if the client address changes #14265

Backup / Restore

- Changed: Increase timeout for password entry when restoring an encrypted configuration via ECL #14769

CARP

- Added: Add unicast CARP indication and peer address to CARP status #14348
- Fixed: Adding an IP Alias VIP using a unicast CARP VIP as its parent changes the CARP VIP to multicast at the OS level #14586
- Added: Prevent CARP status/maintenance mode from being erroneously toggled #13804
- Fixed: IPsec restart in CARP event scripts does not check VIP properly and never runs #14738

Captive Portal

- Fixed: Captive Portal incorrectly allows leading zeroes on voucher roll numbers #14325
- Fixed: Link to view Captive Portal custom HTML page content does not work #14598

Certificates

- Fixed: Cannot validate Certificates against Certificate Revocation Lists for Intermediate Certificate Authorities #9889
- Added: Improve System menu behavior for Certificate Manager privileges #14347
- Fixed: CA and Certificate renewal page does not properly list some SHA1 certificates as being weak #14678

Configuration Upgrade

- Fixed: PHP Error in `upgrade216_ipsec_create_vtimap()` #14400

Console Menu

- Fixed: Serial console output fails to render properly in certain cases on 4100, 6100, and 8200. #13455
- Fixed: PHP shell script `pfanchordrill` shows duplicate anchor content #14637

DHCP (IPv4)

- Added: Introduce Kea DHCP as an alternative DHCP server for IPv4 and IPv6 #6960

DNS Resolver

- Fixed: DNS Resolver experiences intermittent resolution failures with SSL over TLS due to ASLR #14056
- Added: Unbound Advanced Settings entry for `sock-queue-timeout` #14731
- Changed: Update Unbound to 1.18.0 #14732

Dashboard

- Fixed: System Information widget does not properly form list of active hardware crypto algorithms #14417
- Fixed: Gateway widget tooltip incorrectly indicates some gateways as being default #14542

Diagnostics

- Fixed: `diag_edit.php` warning is not cleared after picking non-directory to load #7589
- Changed: Combining Interface and Rule ID state table filter fields returns no results #14399
- Fixed: Improve error handling in `status.php` #14513
- Added: Status output plugin hook for packages to include their own data #14777

Dynamic DNS

- Added: Include hostname being updated in Dynamic DNS notifications #9504
- Added: Dynamic DNS support for Porkbun #14402
- Fixed: PHP error with One.com Dynamic DNS provider #14649
- Fixed: List of Dynamic DNS types with split host+domain name is missing several providers #14783
- Fixed: Correct name of Gandi LiveDNS #14784
- Fixed: Multi-WAN Dynamic DNS does not fail over when preferred WAN loses link #14829

FreeBSD

- Fixed: Kernel textdumps are not recovered properly on systems with multiple swap partitions #14767

Gateways

- Fixed: Misleading error message when adding/editing static routes which use a gateway on a disabled interface #8846
- Fixed: Cannot select IP Alias VIP with CARP VIP parent in Virtual IP drop-down on Gateway Groups #14524
- Fixed: A default route can remain after setting the default gateway to None #14717

Hardware / Drivers

- Fixed: Unnecessary delay when querying `ixgbe(4)` interfaces with SFP ports #13911
- Added: Options to control Intel Speed Shift #14047
- Fixed: Cavium `qlnxe` / `if_qlnxe` driver is not present #14534
- Fixed: `bnxt(4)` driver errors #14569
- Added: QAT 200xx devices are not recognized as supported #14844

IGMP Proxy

- Fixed: Kernel panic when running IGMP Proxy: Sleeping thread owns a non-sleepable lock #12079
- Fixed: Input validation error when saving IGMP Proxy settings #14301
- Fixed: IGMP Proxy cannot start on VirtIO (`vtnet`) interfaces #14665

IPsec

- Changed: Clarify that the IPsec keep alive check option ignores Child SA Start Action #12762
- Fixed: PHP error in `status_ipsec.php` after removing active IPsec tunnel configuration #14525
- Fixed: Multi-WAN IPsec does not fail over when preferred WAN loses link #14626
- Added: Show IPsec phase 1 authentication type in Mode column of tunnel list #14726
- Fixed: IPsec rejects certificate without any SANs #14831

IPv6 Router Advertisements (radvd/rtsold)

- Fixed: IPv6 neighbor discovery protocol (NDP) fails in some cases #13423

Interfaces

- Fixed: GIF-based interface MTU is assigned to parent interface on boot when parent interface is a LAGG #13218
- Fixed: Cannot add a QinQ interface to a bridge #14377
- Fixed: `find_interface_ipv6_ll()` can return a VIP instead of the interface address #14392
- Fixed: Interface value is not properly validated when submitted on `interfaces_gif_edit.php` and `interfaces_gre_edit.php` #14549
- Fixed: Primary interface address is incorrectly set to the last address on the interface #14623
- Fixed: Link loss causes interfaces configured as Track Interface for IPv6 to lose their IPv4 addresses #14756
- Changed: Eliminate direct config access in `interfaces.php` #14790

Logging

- Fixed: Log rotation is not active if the configuration contains an empty <`syslog`> section or if that section is not present #14517
- Fixed: Per-log settings for file size and retention count are not honored #14545
- Added: Improve SCTP support in `filterlog` #14667

Notifications

- Added: Allow SMTP notifications from non-root processes #14337
- Fixed: PHP error when failing to write `config.cache` #14432

OpenVPN

- Fixed: DCO OpenVPN server bound to Localhost does not pass traffic as expected #14682
- Fixed: Rapidly clicking certain options on OpenVPN Client Overrides can cause hide/show field behavior to invert #13088
- Fixed: OpenVPN can select the wrong interface IP address when multiple addresses are present #14646
- Changed: Prevent weak SHA1 certificates from being used with OpenVPN clients and servers #14677
- Changed: Check for deprecated OpenVPN encryption and digest options on upgrade #14686

Operating System

- Fixed: Error when deleting ZFS Boot Environment created from duplicate of non-default entry #13348
- Fixed: Console and system log may contain unnecessary Netlink debug messages from IPsec #14370
- Added: Support receiving `EAPOL` frames on VLAN `0` in `wpa_supplicant` #14457
- Changed: Automatically configure PF states hash table size #14750
- Fixed: Panic when pfsync attempts to synchronize states between hosts with different rulesets #14804

PHP Interpreter

- Added: Option to configure a custom value for the PHP memory limit #13377
- Fixed: URL scheme is not properly validated in some cases #14356

PPP Interfaces

- Fixed: PPP interface default username/password are not being populated from provider data on `interfaces.php` and `interfaces_ppps_edit.php` #14544
- Fixed: `getserviceproviders.php` does not always validate value of `$connection`, displays without encoding #14547

PPPoE Server

- Fixed: PPPoE Server address input validation is incorrectly allowing IPv6 #13903

Packet Capture

- Added: Change default match modifier from "all of" to "any of" #14650
- Fixed: `packet_capture.php` uses `count` and `length` values in command execution without validation or encoding #14809

Rules / NAT

- Fixed: Ethernet rules using `(self)` as a source or destination make the ruleset fail to load #14478
- Fixed: Ethernet rule Action field hint text lists "reject" option which is not compatible with Ethernet rules #14515
- Fixed: Changes in Ethernet ruleset can lead to incorrect rule and separator order #14705
- Added: Support interface macros in Outbound NAT rules #3288
- Fixed: Negating `<interface> net` when a VIP exists on the interface results in unintended behavior #6799
- Added: Option to wait for interface selection before displaying firewall rules #13124
- Fixed: Default tab on `firewall_rules.php` is not selected if the configuration has no WAN interface #14345
- Added: Support interface groups in firewall rule source/destination fields #14448
- Fixed: "Convert interface definitions" option is not respected when bulk copying rules #14576
- Fixed: Rule separators are ordered incorrectly after removing rules in certain positions #14619
- Fixed: Rule separators are hidden when their index is greater than the number of rules #14621
- Added: Extend support for SCTP in firewall and NAT rules #14640
- Fixed: Separators get shifted when copying firewall rules between interfaces #14691
- Fixed: `ctype_digit()` returns unexpected result for values `<= 255` which can break some validation functions/usages #14702

System Logs

- Fixed: Firewall log parser does not handle SCTP log entries #13940
- Fixed: `status_logs_filter_dynamic.php` does not encode value of `interfacefilter` in raw mode #14548

Traffic Graphs

- Fixed: PHP Error when viewing Traffic Graphs in `iftop` mode #14500

Traffic Shaper (ALTQ)

- Added: Include `ixv` in ALTQ capable NIC list #14408
- Fixed: Kernel panic when using traffic shaping on a PPPoE interface #14497

Traffic Shaper (Limiters)

- Fixed: Limiters have no effect on upload traffic passed by policy routing rules #14039

Translations

- Fixed: Some functions fail if the Language does not exactly match an available Locale #13776
- Fixed: Polish translation contains an invalid `sprintf()` format in the text for `firewall_nat_out_edit.php` #13946

UPnP/NAT-PMP

- Changed: Update miniupnpd to 2.3.3 #14307
- Fixed: Remove broken `stun.sipgate.net` from UPnP STUN server list #14673

Upgrade

- Fixed: Update check in GUI does not always honor the configured proxy settings #14609

User Manager / Privileges

- Fixed: Copy function for User Manager Groups does not work for first group in list #14695

Web Interface

- Changed: GUI pages should use `POST` for AJAX calls, not `GET` #12431
- Fixed: Refactor IPsec code using config access functions #13704
- Fixed: PHP error in CSRF Magic from invalid time value #14394
- Fixed: Breadcrumb path missing on `system_register.php` #14462
- Changed: Prevent weak SHA1 certificates from being used with GUI and Captive Portal #14672
- Fixed: `status_carp.php` and `diag_dump_states.php` unresponsive with large state tables #14758
- Fixed: GUI TCP port is not updated in the configuration when saving with the field empty to remove an existing value #14820

Wireless

- Fixed: PHP error in `handle_wireless_post()` when toggling some wireless interface options #14579

3.7 2.7.2 New Features and Changes

This is a maintenance software release including new features and bug fixes.

Consult the *Upgrade Guide* before proceeding with any upgrade.

3.7.1 Security / Errata

FreeBSD Notices

This release includes corrections for several FreeBSD Errata Notices and Security Advisories, including:

- FreeBSD-SA-23:17.pf - TCP spoofing vulnerability in pf(4)
- FreeBSD-EN-23:16.openzfs - Potential ZFS Data Corruption

  For more information about ZFS data corruption, see *ZFS Data Corruption Details* later in this document.
- FreeBSD-EN-23:18.openzfs - High CPU usage by ZFS kernel threads
- FreeBSD-EN-23:17.ossl - ossl(4)'s AES-GCM implementation may give incorrect results
- FreeBSD-EN-23:20.vm - Incorrect results from the kernel physical memory allocator
- Performance issues in OpenSSL have also been identified and corrected, notably with acceleration such as AES-NI.

EFI Issue on Proxmox® VE

Some users of pfSense® software running under Proxmox VE 7.4 have had issues booting Virtual Machines via EFI. This may also affect other versions of Proxmox VE and pfSense software as well as FreeBSD.

Adding a serial port to the VM hardware appears to work around the issue for the time being. A fix for the root cause is under investigation and development for future versions.

At this time the best practice to avoid potential problems is to add a serial port to the VM, then shutdown the VM and start it back up **before** beginning the pfSense software upgrade process.

See also:

See *EFI Boot Issues* for additional recommendations.

ZFS Data Corruption Details

Two data corruption bugs were recently reported against ZFS, including the version of ZFS in recent releases of pfSense software. These bugs have been corrected upstream in FreeBSD and the fixes have been imported into this release.

One bug was in block cloning, which is disabled by default on pfSense software, and thus is unlikely to be a significant concern on this platform. The other bug has been present in ZFS for years and was difficult to trigger.

Given the history of data corruption problems due to hole reporting in files, the corrections for this issue include a preventive measure to disable hole reporting. The downside of disabling hole reporting is the possibly increased disk space usage.

Tip: Users on previous releases of pfSense software can reduce the likelihood of encountering the data corruption issue by creating a *System Tunable* for `vfs.zfs.dmu_offset_next_sync` with a value of `0`.

3.7.2 pfSense CE

Changes in this version of pfSense CE software.

DHCP (IPv4)

- Fixed: ISC DHCP responds from a random port #15011

DHCP (IPv6)

- Fixed: PHP error on `services_dhcpv6.php` if the configuration contains an empty `dhcpv6` section #14978

DHCP Relay

- Fixed: Input validation prevents saving DHCPv6 Relay settings #14965

IPsec

- Fixed: Mobile IPsec Group Authentication cannot be enabled #14963
- Fixed: Incorrect permissions on `ipsec.auth-user.php` #14974
- Fixed: IPsec log categories set to "Audit" do not function properly or save properly in the GUI #14990
- Changed: Update strongSwan to 5.9.11_3 #15050

Installer

- Added: Add an appropriately named file to install images to indicate what they are #14887

Interfaces

- Fixed: Mulicast traffic on a detached interface causes a panic #14917
- Fixed: PHP Error on `interfaces.php` when creating a PPP interface #14949

OpenVPN

- Changed: Update OpenVPN to 2.6.8_1 #15049

Operating System

- Fixed: Potential ZFS file corruption #15034

Rules / NAT

- Fixed: Invalid outbound NAT rules break the following rule #15024
- Fixed: Automatic outbound NAT rules show an empty NAT Address #15025

Upgrade

- Fixed: pfSense-boot does not update the EFI loader #15007

Web Interface

- Fixed: Firewall Maximum Table Entries "default size" is whatever is entered #11566

3.8 2.7.1 New Features and Changes

This is a maintenance software release including new features and bug fixes.

Consult the *Upgrade Guide* before proceeding with any upgrade.

3.8.1 General

- PHP has been upgraded to 8.2.11
- The base operating system has been upgraded to a more recent point on FreeBSD 14-CURRENT
- Support for SCTP has been improved in PF for firewall rules, NAT, and logging. Rules can now act on SCTP packets by port number, previously it was only possible to filter on source or destination address.
- OpenSSL in the base system has been upgraded from 1.1.1t to 3.0.12.

  For details, see *OpenSSL upgraded to 3.0.12*.
- Kea DHCP Server has been added as an opt-in feature preview for IPv4 and IPv6 DHCP service. Kea will eventually replace the ISC DHCPD daemon which is EOL.

  Warning: Kea is not yet feature complete. For details, see *Kea DHCP Server feature preview now available*.
- IPv6 Router Advertisement configuration has been relocated to **Services > Router Advertisement** as a part of the ongoing DHCP Server changes.
- Certain parts of the base system are being migrated to packages rather than grouping them all together in an archive in the "base" package. For the most part this should be entirely transparent to users.

  Specifically, the code from the main pfSense software repository is now a part of the "pfSense" package. This lets management of files be handled entirely by `pkg` rather than carrying them in an archive. This migration is ongoing, so future versions will include additional portions of the system being packaged differently.
- The default driver for NVMe storage devices changed from `nvd(4)` to `nda(4)`. For most users this will be a transparent change since the majority of installations are mounted by label and do not reference a storage device by name.

  Some swap configurations may reference the old device name in `/etc/fstab`. Editing that file and correcting device names from `nvd` to `nda`, followed by a reboot, should restore swap functionality.

  If the new driver is problematic in certain environments the default can be changed back to `nvd(4)` by adding a *loader tunable* for `hw.nvme.use_nvd=1`.

Troubleshooting

- Due to changes in `pkg`, the new version of `pkg` may not be able to properly locate and use the CA trust store when running on the previous version before upgrading.

  If the firewall is unable to load packages or check for updates after selecting the CE 2.7.1 upgrade branch, run `certctl rehash` from the console, a root shell prompt, or via **Diagnostics > Command Prompt**. This will allow `pkg` to utilize the system certificates until the next reboot.

OpenSSL upgraded to 3.0.12

OpenSSL has been upgraded to 3.0.12 from 1.1.1 in FreeBSD.

This change was necessary as OpenSSL 1.1.1 reached its End of Life (EOL) on September 11, 2023. This means there will be no security patches for vulnerabilities affecting OpenSSL 1.1.1.

The OpenSSL team decided to make an explicit jump in numbering from 1.1.x to 3.x to highlight that this new version included major structural, and more importantly, application programming interface (API) and application binary interface (ABI) changes compared to previous OpenSSL versions.

In addition to the differences in the library they also deprecated numerous weak algorithms of various types.

Due to these differences, changing from OpenSSL 1.1 to OpenSSL 3.0 is not a simple upgrade. Netgate developers have handled most of these changes as automatically as possible, though some things may still require manual adjustments. See the warnings in the next section for details.

OpenSSL 3.0.x Upgrade Warnings

Weak Certificate Digests such as SHA1 are Deprecated

Warning: OpenSSL 3.0.x no longer supports certificates signed with SHA1 or other older/weaker hashes. The minimum recommended hash strength is SHA256.

The upgrade process detects usage of weak certificates for the GUI, Captive Portal, and OpenVPN:

- If the **GUI** or a **Captive Portal** zone utilizes a weak CA or server certificate, the upgrade process generates a new self-signed certificate as a stopgap measure to allow the processes to start and let the user in to make any necessary corrections.
- If an **OpenVPN** instance is using a weak certificate, the instance is disabled as there is no viable general automated recovery method.
- **OpenVPN peers** using SHA1 certificates will fail, but such issues must be corrected on the peers. This may mean renewing or reissuing certificates or re-exporting clients for peers if they are currently using weak certificates.
- Other consumers of certificates, such as add-on packages, may be similarly affected but cannot be automatically adjusted.

The best practice is to reconfigure all services utilizing certificates with stronger certificates and to test these functions before performing an upgrade to ensure a smoother transition.

Numerous Deprecated Encryption and Digest Algorithms Removed

Warning: OpenSSL 3.0.x removes a large number of deprecated encryption and digest algorithms. This primarily affects OpenVPN, as other areas had not supported the affected algorithms in some time.

Encryption algorithms removed from OpenVPN:

- ARIA
- Blowfish (e.g. BF-CBC), which was formerly an OpenVPN default
- CAST5

- DES
- DESX
- IDEA
- RC2
- RC5
- SEED
- SM4

Hash algorithms removed from OpenVPN:

- MD4
- MDC2
- SM3
- Whirlpool

On upgrade, tunnels using these deprecated algorithms will be adjusted so they use more secure default values when necessary.

The best practice is to reconfigure tunnels using modern secure encryption and hashing, and to test tunnels before performing an upgrade to ensure a smoother transition.

Other OpenSSL-Related Concerns

- The certificate manager in the GUI can still read and generate certificates using weak hashes, but warns against their use. Avoid creating any new entries using weak hashes. This support will eventually be removed.
- The certificate manager no longer supports importing PKCS#12 archive files which were encrypted with weak ciphers, such as RC2-40. Some operating systems still export using such weak ciphers by default, including macOS and Windows.
- IPsec does not require any adjustments, it still supports SHA1 certificates for the time being and no additional algorithms have been deprecated or removed.
- Unbound does not require any adjustments, it still supports SHA1 certificates for the time being.
- Though the legacy provider for OpenSSL 3.0.x is built and included it does not help to work around the issues mentioned above in any meaningful way.

Kea DHCP Server feature preview now available

The ISC DHCPD server has reached its End of Life (EOL) as of October 5, 2022. Though ISC has stated they may continue to publish security fixes if they are warranted.

Netgate developers have started the migration to Kea DHCP server from ISC as a replacement for ISC DHCPD for IPv4 and IPv6 DHCP service. Basic functionality is present, but not all features are supported at this time.

Warning: Currently the Kea implementation lacks the following DHCP server features:

- Local DNS Resolver/Forwarder Registration for static and dynamic DHCP clients
- Remote DNS server registration

- DHCPv6 Prefix Delegation
- High Availability Failover
- Lease statistics/graphs
- Custom DHCP options

Kea is available as an opt-in preview feature on this release. The UI and settings for Kea are shared with the existing DHCP server. Administrators can easily switch between ISC DHCPD and Kea by navigating to **System > Advanced**, **Networking** tab and changing the new **Server Backend** setting in the **DHCP Options** section.

After Kea integration is complete it will become the default DHCP server on a future release of pfSense software and eventually the deprecated ISC DHCP server will be removed. The exact timing of these changes has not been finalized.

Note: As a part of changes to the DHCP server, IPv6 Router Advertisement configuration has been separated from the DHCP server UI and relocated to **Services > Router Advertisement**.

3.8.2 Security

In addition to OpenSSL and other concerns in the base OS and packages, this release addresses the following vulnerabilities in pfSense software:

- pfSense-SA-23_08.webgui (XSS in `getserviceproviders.php`, #14547)
- pfSense-SA-23_09.webgui (XSS in `status_logs_filter_dynamic.php`, #14548)
- pfSense-SA-23_10.webgui (Authenticated Command Execution in `interfaces_gif_edit.php` and `interfaces_gre_edit.php`, #14549)
- pfSense-SA-23_11.webgui (Authenticated Command Execution in `packet_capture.php`, #14809)

Tip: Patches for these issues are also available in the latest version of the *System Patches Package* for users of pfSense Plus software version 23.05.1 and pfSense CE software version 2.7.0.

3.8.3 pfSense CE

Changes in this version of pfSense CE software.

Aliases / Tables

- Fixed: Firewall rules fail to load when a URL table alias file does not exist #13068
- Added: Type column on Alias lists #13245
- Fixed: Static ARP entries are not configured at boot #14374
- Fixed: Firewall rules are not displayed properly when they reference a URL table alias and its file does not exist #14574

Authentication

- Added: Option to invalidate GUI login session if the client address changes #14265

Backup / Restore

- Changed: Increase timeout for password entry when restoring an encrypted configuration via ECL #14769

CARP

- Added: Prevent CARP status/maintenance mode from being erroneously toggled #13804
- Fixed: IPsec restart in CARP event scripts does not check VIP properly and never runs #14738

Captive Portal

- Fixed: Captive Portal incorrectly allows leading zeroes on voucher roll numbers #14325
- Fixed: Link to view Captive Portal custom HTML page content does not work #14598

Certificates

- Fixed: Cannot validate Certificates against Certificate Revocation Lists for Intermediate Certificate Authorities #9889
- Added: Improve System menu behavior for Certificate Manager privileges #14347
- Fixed: CA and Certificate renewal page does not properly list some SHA1 certificates as being weak #14678

Console Menu

- Fixed: PHP shell script `pfanchordrill` shows duplicate anchor content #14637

DHCP (IPv4)

- Added: Introduce Kea DHCP as an alternative DHCP server for IPv4 and IPv6 #6960

DNS Resolver

- Added: Unbound Advanced Settings entry for `sock-queue-timeout` #14731
- Changed: Update Unbound to 1.18.0_1 to address looping UDP retries when ENOBUFS is returned #14980

Dashboard

- Fixed: System Information widget does not properly form list of active hardware crypto algorithms #14417
- Fixed: Gateway widget tooltip incorrectly indicates some gateways as being default #14542

Diagnostics

- Fixed: `diag_edit.php` warning is not cleared after picking non-directory to load #7589
- Changed: Combining Interface and Rule ID state table filter fields returns no results #14399
- Fixed: Improve error handling in `status.php` #14513
- Added: Status output plugin hook for packages to include their own data #14777

Dynamic DNS

- Added: Include hostname being updated in Dynamic DNS notifications #9504
- Added: Dynamic DNS support for Porkbun #14402
- Fixed: PHP error with One.com Dynamic DNS provider #14649
- Fixed: List of Dynamic DNS types with split host+domain name is missing several providers #14783
- Fixed: Correct name of Gandi LiveDNS #14784
- Fixed: Multi-WAN Dynamic DNS does not fail over when preferred WAN loses link #14829

Gateways

- Fixed: Misleading error message when adding/editing static routes which use a gateway on a disabled interface #8846
- Fixed: Cannot select IP Alias VIP with CARP VIP parent in Virtual IP drop-down on Gateway Groups #14524
- Fixed: A default route can remain after setting the default gateway to None #14717

Hardware / Drivers

- Fixed: Unnecessary delay when querying `ixgbe(4)` interfaces with SFP ports #13911
- Added: Options to control Intel Speed Shift #14047
- Fixed: Cavium `qlnxe` / `if_qlnxe` driver is not present #14534
- Fixed: `bnxt(4)` driver errors #14569
- Added: QAT 200xx devices are not recognized as supported #14844

IGMP Proxy

- Fixed: Input validation error when saving IGMP Proxy settings #14301
- Fixed: IGMP Proxy cannot start on VirtIO (`vtnet`) interfaces #14665

IPsec

- Changed: Clarify that the IPsec keep alive check option ignores Child SA Start Action #12762
- Fixed: PHP error in `status_ipsec.php` after removing active IPsec tunnel configuration #14525
- Fixed: Multi-WAN IPsec does not fail over when preferred WAN loses link #14626
- Added: Show IPsec phase 1 authentication type in Mode column of tunnel list #14726
- Fixed: IPsec rejects certificate without any SANs #14831

IPv6 Router Advertisements (radvd/rtsold)

- Fixed: IPv6 neighbor discovery protocol (NDP) fails in some cases #13423

Interfaces

- Fixed: GIF-based interface MTU is assigned to parent interface on boot when parent interface is a LAGG #13218
- Fixed: Cannot add a QinQ interface to a bridge #14377
- Fixed: `find_interface_ipv6_ll()` can return a VIP instead of the interface address #14392
- Fixed: Interface value is not properly validated when submitted on `interfaces_gif_edit.php` and `interfaces_gre_edit.php` #14549
- Fixed: Primary interface address is incorrectly set to the last address on the interface #14623
- Fixed: Link loss causes interfaces configured as Track Interface for IPv6 to lose their IPv4 addresses #14756
- Changed: Eliminate direct config access in `interfaces.php` #14790

Logging

- Fixed: Log rotation is not active if the configuration contains an empty <`syslog`> section or if that section is not present #14517
- Fixed: Per-log settings for file size and retention count are not honored #14545
- Added: Improve SCTP support in `filterlog` #14667

Notifications

- Added: Allow SMTP notifications from non-root processes #14337
- Fixed: PHP error when failing to write `config.cache` #14432

OpenVPN

- Fixed: OpenVPN can select the wrong interface IP address when multiple addresses are present #14646
- Changed: Prevent weak SHA1 certificates from being used with OpenVPN clients and servers #14677
- Changed: Check for deprecated OpenVPN encryption and digest options on upgrade #14686
- Changed: Update OpenVPN to 2.6.7 #14985

Operating System

- Added: Method for users to customize shell initialization behavior #14746
- Changed: Automatically configure PF states hash table size #14750
- Fixed: Panic when pfsync attempts to synchronize states between hosts with different rulesets #14804

PHP Interpreter

- Added: Option to configure a custom value for the PHP memory limit #13377

PPP Interfaces

- Fixed: PPP interface default username/password are not being populated from provider data on `interfaces.php` and `interfaces_ppps_edit.php` #14544
- Fixed: `getserviceproviders.php` does not always validate value of `$connection`, displays without encoding #14547

PPPoE Server

- Fixed: PPPoE Server address input validation is incorrectly allowing IPv6 #13903

Packet Capture

- Added: Change default match modifier from "all of" to "any of" #14650
- Fixed: `packet_capture.php` uses `count` and `length` values in command execution without validation or encoding #14809

Rules / NAT

- Added: Support interface macros in Outbound NAT rules #3288
- Fixed: Negating `<interface> net` when a VIP exists on the interface results in unintended behavior #6799
- Added: Option to wait for interface selection before displaying firewall rules #13124
- Added: Support interface groups in firewall rule source/destination fields #14448
- Fixed: "Convert interface definitions" option is not respected when bulk copying rules #14576
- Fixed: Rule separators are ordered incorrectly after removing rules in certain positions #14619
- Fixed: Rule separators are hidden when their index is greater than the number of rules #14621
- Added: Extend support for SCTP in firewall and NAT rules #14640
- Fixed: Separators get shifted when copying firewall rules between interfaces #14691
- Fixed: `ctype_digit()` returns unexpected result for values `<= 255` which can break some validation functions/usages #14702

System Logs

- Fixed: `status_logs_filter_dynamic.php` does not encode value of `interfacefilter` in raw mode #14548

Traffic Graphs

- Fixed: PHP Error when viewing Traffic Graphs in `iftop` mode #14500
- Fixed: Traffic graph filters apply incorrectly #14892

Traffic Shaper (ALTQ)

- Fixed: Kernel panic when using traffic shaping on a PPPoE interface #14497

Translations

- Fixed: Some functions fail if the Language does not exactly match an available Locale #13776

UPnP/NAT-PMP

- Fixed: Remove broken `stun.sipgate.net` from UPnP STUN server list #14673

Upgrade

- Fixed: Update check in GUI does not always honor the configured proxy settings #14609

User Manager / Privileges

- Fixed: Copy function for User Manager Groups does not work for first group in list #14695

Web Interface

- Fixed: Refactor IPsec code using config access functions #13704
- Fixed: PHP error in CSRF Magic from invalid time value #14394
- Fixed: Breadcrumb path missing on `system_register.php` #14462
- Changed: Prevent weak SHA1 certificates from being used with GUI and Captive Portal #14672
- Fixed: `status_carp.php` and `diag_dump_states.php` unresponsive with large state tables #14758
- Fixed: Logo text is partially rendered when using Compact-RED theme on CE #14807
- Fixed: GUI TCP port is not updated in the configuration when saving with the field empty to remove an existing value #14820

Wireless

- Fixed: PHP error in `handle_wireless_post()` when toggling some wireless interface options #14579

3.9 23.05.1 New Features and Changes

This is a maintenance software release including bug fixes for issues in pfSense® Plus software version 23.05.

3.9.1 General

This release follows shortly after pfSense Plus software version 23.05. See the *23.05 Release Notes* for details on changes in that release.

Danger: This version includes newer ZFS features which may not be compatible with older boot loaders. These features **are not** enabled by default when upgrading to avoid potential problems with older boot loaders. Some ZFS commands run at the CLI, such as `zpool status`, may report that a pool can be upgraded, but doing so may also require manually updating the boot loader for the device to boot properly. Upgrading the ZFS pool **is not** necessary at this time. As such, the best practice is to leave it as-is. This will be handled automatically as needed in future updates.

Reinstalling the OS from current installation media will result in having the most recent boot loader and ZFS feature set.

3.9.2 pfSense Plus

Changes in this version of pfSense Plus software.

Aliases / Tables

- Fixed: PHP error when attempting to bulk import Alias content #14412

CARP

- Fixed: Unicast CARP VIPs do not communicate using IPv6 Link Local Addresses #14385
- Fixed: CARP VIPs can become master too early at boot time #2218

Captive Portal

- Fixed: System crashes or may become unresponsive with Captive Portal #14373
- Fixed: PHP error in Captive Portal `usedmacs` handling #14446

DNS Resolver

- Fixed: Setting system DNS servers can incorrectly modify routes for interface addresses #14288
- Fixed: Discrepancy in "TTL for Host Cache Entries" Description #14358

Dashboard

- Fixed: PHP error from empty <`plugins`> tag in `config.xml` #14474

IPsec

- Fixed: Reassembled packets received on a VTI are not forwarded #14396
- Fixed: PHP error in IPsec tunnels list #14458

Interfaces

- Fixed: Panic when changing the parent of a VLAN interface used by limiters #14433

Notifications

- Fixed: Notices incorrectly set system LEDs on hardware with less than three LEDs #14482

Rules / NAT

- Fixed: Outbound NAT rule input validation error when attempting to manually specify "Other Subnet" with a valid address #14354
- Fixed: Enable IPv6 over IPv4 tunneling option results in invalid PF rule #14415

Web Interface

- Fixed: "Max Processes" value is not stored properly when saving on `system_advanced_admin.php` #14425

3.10 23.05 New Features and Changes

This is a regularly scheduled software release including new features and bug fixes.

3.10.1 General

- This release includes support for cryptographic acceleration through the Multi-Buffer Crypto for IPsec Library (IPsec-MB, IIMB) which leverages special CPU instructions to accelerate several algorithms for multiple types of VPNs and other uses. See *Cryptographic Accelerator Support* for details.
- This release includes experimental support for Ethernet (Layer 2) rules. See *Ethernet (Layer 2) Rules* for details.
- As of this release, several new and recent features combined enable using the GUI alone to configure a setup compatible with the AT&T Residential Fiber Network. The same setup should work for any similar ISPs which require special handling such as Priority Code Point tagging on VLAN 0 and 802.1X authentication passthrough to a modem. Previous versions of pfSense Plus software required additional scripts (e.g. "pfatt") and/or manual changes outside the GUI.

  There is a new configuration recipe which covers using these features in the GUI to configure this use case: *WAN Connectivity with 802.1X Authentication Bridging and VLAN 0 PCP Tagging*.
- Unicast CARP support can be configured on a per-VIP basis for environments where multicast CARP cannot function. This is a step toward future enhancements in virtualization and cloud environments which are still under development, including high availability in AWS and Azure. See *VIP Configuration Options* for details.
- WireGuard is now installed by default on new installations. This **does not** affect upgrades or factory reset configurations, only fresh installations.
- Several improvements have been made to memory usage reporting and to reduce some reported cases of increased memory usage in the previous release. See *Memory Management* and *ZFS Tuning* for additional information on memory usage and tuning
- A bug in 23.01 caused some automatic dynamic gateway names to be in mixed case instead of all upper case, which may have led to loss of connectivity until the default gateway or gateway group membership was updated. This bug has been corrected, but anyone who worked around the problem by changing gateway entries will have to correct them again once they have upgraded to 23.05.

3.10.2 Security

- pfSense-SA-23_06.webgui A potential Authenticated Command Execution vulnerability from the `bridgeif` parameter on `interfaces_bridge_edit.php` in the GUI.

Note: Users of pfSense Plus software version 23.01, pfSense Plus software version 22.05.x, and pfSense CE software version 2.6.0 can obtain corrections for this issue from the Recommended Patches area of the *System Patches* package.

- pfSense-SA-23_07.kernel Denial of Service on pfSense Plus software version 23.01 due to a kernel panic from oversize IPv6 packets.

Warning: There is no patch for this issue as it is a problem in the kernel. Users must upgrade to pfSense Plus software version 23.05 or later to correct the problem.

This problem did not affect any version of pfSense Plus software prior to 23.01, nor does it affect any **released** version of pfSense CE software. Users of pfSense CE development snapshots must upgrade to a current snapshot to correct the problem.

3.10.3 Upgrade Paths

Devices running pfSense Plus software version 23.01 can upgrade directly to version 23.05.

Devices running pfSense Plus software version 22.05.1 and earlier must first upgrade to version 23.01, then they can upgrade to version 23.05.

Devices running pfSense CE software version 2.6.0 can also upgrade directly to pfSense Plus software version 23.05. Devices running pfSense CE software version 2.7.0 snapshots dated before the pfSense Plus software version 23.05 release can also upgrade directly. Snapshots after that time may still be able to upgrade, but check the forum for details.

3.10.4 pfSense Plus

Changes in this version of pfSense Plus software.

Aliases / Tables

- Fixed: Using PF reserved keywords for interface descriptions results in an invalid ruleset #14007
- Fixed: PHP error when attempting to bulk import Alias content #14013
- Fixed: Alias list is not sorted #14015

Authentication

- Added: Option to enable/disable console bell, enabled by default #14002

Auto Configuration Backup

- Fixed: PHP error if the configuration has an empty Auto Configuration Backup section #14076

Captive Portal

- Fixed: PHP error in Captive Portal if `usedmacs` list is empty #14172

Certificates

- Fixed: PHP errors when configuration lacks any certificates #14004
- Fixed: PHP error when exporting a CRL for an old CA #14022
- Fixed: Some blank SAN fields are not ignored when creating a certificate #14124
- Added: Ability to edit Certificate Revocation List properties #14185
- Changed: Add note to inform the user that the "Next Certificate Serial" value is ignored when the "Randomize Serial" option is enabled #14188

Console Menu

- Fixed: Console menu incorrectly shows option 99 on some ARMv7/ARM64 installations #14102
- Added: Print ZFS Boot Environment status in console menu banner #14323

Cryptographic Modules

- Added: Support for cryptographic acceleration using the Multi-Buffer Crypto for IPsec Library (IPsec-MB, IIMB) #14291

DHCP (IPv4)

- Fixed: DHCP Server generates an invalid configuration for static mappings when defining network booting and UEFI HTTPBoot URL #13573
- Fixed: Automatic DHCP failover firewall rules are not present in the ruleset when failover is active #13965
- Fixed: Multiple PHP errors in the DHCP Server when the configuration contains an empty section for an interface #13983
- Fixed: DHCP Server page does not properly select a default interface tab if neither WAN nor LAN are capable of being DHCP servers #14115

DHCP (IPv6)

- Fixed: Typo in `filter.inc` variable for DHCPv6 VLAN priority tag value #14010

DNS Forwarder

- Fixed: DNS Forwarder (`dnsmasq`) is using an invalid combination of options when "Query DNS servers sequentially" is enabled #13655

DNS Resolver

- Fixed: DNS Resolver does not generate automatic ACLs for IPv6 when Network Interfaces is set to "All" #13851

Dashboard

- Fixed: System Information Dashboard widget stops showing CPU details on aarch64 #14204
- Fixed: Changing the default IPsec widget tab removes all widgets #14053
- Fixed: Uptime displays plural seconds for multiple minutes in the System Information Dashboard widget #14176
- Added: Support for Intel PCH temperature values in thermal sensors #14255
- Fixed: PHP error in RSS widget after saving settings #14365

Diagnostics

- Added: Packet Capture GUI with granular control #13382
- Changed: Add more disk information to status output #14103

Dynamic DNS

- Changed: Improve DynDNS help text readability #14186

FreeBSD

- Fixed: Kernel panic accessing the GUI over IPsec in certain environments when using nginx `sendfile` with unmapped mbufs #13938
- Changed: Update Time Zone data to 2023c or later #14209

Gateways

- Fixed: Dynamic gateway names use mixed case instead of upper case, leading to configuration mismatches #14057
- Fixed: Gateway popup in firewall rule list does not indicate current gateway status #14327

Hardware / Drivers

- Fixed: Switch ports on 7100/1100/2100 do not have Auto MDI-X support enabled #13993
- Fixed: Undersized CESA TDMA descriptor pools can be exhausted, leading to errors #14235
- Fixed: Status LEDs on the Netgate 1100 do not function properly #14292
- Fixed: 2100/1100 PCIe bus devices are not recognized #14334
- Fixed: Intel e1000 driver (`em`, `igb`) cannot pass packets tagged with VLAN `0` #12821
- Fixed: Malicious Driver Detection event on `ixl(4)` driver #13003

IGMP Proxy

- Fixed: IGMP Proxy multicast group membership query packets have an invalid checksum #13929

IPsec

- Fixed: Deadlock in Charon VICI interface #13014
- Fixed: PHP error from upgraded IPsec tunnel containing only deprecated ciphers #14009
- Fixed: IPsec Phase 2 rekey failures with some PFS key groups #14217
- Fixed: PHP Error performing IPv6 `ip_in_subnet()` when passing a host addresses within prefix #14256

IPv6 Router Advertisements (radvd/rtsold)

- Fixed: No working IPv6 gateway if upstream RA does not contain M or O flags because rtsold does not execute script #14072

Interfaces

- Added: Priority Code Point (PCP) option on interface configuration #13511
- Fixed: SNMP logs "Device not configured" error message when queries involve built-in switch port interfaces #13976
- Fixed: PHP Error on `status_interfaces.php` with empty switch VLAN group configuration and assigned VLAN interfaces #13981
- Added: Promiscuous Mode option on interface configuration #14295
- Changed: Start `rtsold` immediately after `dhcp6c` sends a request #13492
- Fixed: DHCP client can fail permanently if an interface is down at boot #13671
- Changed: Trim blank characters from static IP address fields on the Interface configuration page #13959
- Fixed: PHP error in `gwlb.inc` when OpenVPN or IPsec instances referred to by assigned interface entries are missing #13973
- Fixed: PHP error when attempting to create a GIF interface on ARM #14035
- Fixed: Bridge interface is not properly validated when submitted on `interfaces_bridge_edit.php` #14052
- Fixed: IPv6 interface configuration race condition can lead to kernel panic #14164

Logging

- Added: Option to control log level of authentication messages in system logs (“Emergency” vs “Notice” level) #12464
- Fixed: Nothing is logged through `syslog` if the configuration contains an empty <`syslogd`> section or if that section is not present #14283

NTPD

- Fixed: PHP error in NTP widget and status with GPS data #13999
- Fixed: PHP error in NTP Server if the configuration contains a partial section of old `openntpd` settings #14033
- Fixed: PHP error when the `timeserver` section of the configuration is empty #14036

Notifications

- Fixed: Identical SMTP notifications repeat in an infinite loop under certain conditions #14031

OpenVPN

- Fixed: SSL/TLS OpenVPN Client fails with `ifconfig` error when the IPv4 Tunnel Network is defined #13350
- Fixed: OpenVPN crashes with Signal 8 with very low fragment size #13943
- Changed: Update OpenVPN Wizard to match current certificate and OpenVPN options #14183

Operating System

- Fixed: Early boot hangs on Hyper-V with Gen2 VMs #13895
- Fixed: OpenVPN and GIF interface create/destroy operations fail due to outdated `linker.hints` #13963
- Changed: Update memory graphs to account for changes in memory reporting #14011
- Fixed: FreeBSD default `cron` jobs are enabled when they should be disabled #14016
- Fixed: Kernel panic from incoming IPv6 connections #14077
- Fixed: Kernel panic when PF passes a large/fragmented ICMP6 packet #14092

PHP Interpreter

- Changed: Update PHP to 8.2.4 #14027
- Fixed: PHP error if a non-privileged shell user attempts an operation which needs to write `config.cache` #14061

PPP Interfaces

- Fixed: IPv6 does not work on secondary PPPoE WAN #13939
- Fixed: PPP interfaces do not request DNS servers when "DNS Server Override" is enabled #13962
- Fixed: PHP Error on `status_interfaces.php` from PPP interface uptime #14117

Package System

- Added: Package plugin hook for pf Ethernet rules #14293
- Added: Package plugin hook for web server configuration stanzas #13054

Rules / NAT

- Added: Support for Ethernet (L2) filtering rules #14308
- Fixed: PHP Error loading Floating rule tab with OpenVPN group rules when there are no OpenVPN instances in the configuration #13953
- Fixed: Custom default state timeouts are not respected in the ruleset #13992
- Fixed: PHP Error enabling ICMP6 using EasyRule #14037
- Fixed: The "Kill States" button does not work consistently #14091
- Changed: Match upstream changes in PF syntax to disable fragment disassembly #14098
- Fixed: PHP error when saving an ICMP firewall rule with no subtypes selected #14267
- Fixed: Associated firewall rule for NAT port forward does not inherit `nosync` property, gets synchronized #14335
- Fixed: PHP error from empty separator #14338

Services

- Fixed: Services Status page and Dashboard widget do not list the `radvd` service with certain static IPv6 configurations #14136

Setup Wizard

- Changed: Update firewall host and domain fields in the Setup Wizard to match the description and warning text from `system.php` #14250

System Logs

- Fixed: PHP error on `status_logs_settings.php` if the configuration contains an empty `syslog` section #13942
- Fixed: `syslogd` tries to bind interfaces with no IP address #14120

Traffic Graphs

- Fixed: PHP Error when viewing Traffic Graphs in `iftop` mode #14236

Traffic Shaper (Limiters)

- Fixed: Traffic shaped by limiters is dropped when routed to a GIF gateway #14055

Traffic Shaper Wizards

- Fixed: PHP errors when re-running Traffic Shaper Wizards with different settings #13915

Upgrade

- Fixed: pfSense Plus Upgrade repo data remains on the system after upgradng #14137
- Fixed: `pfSense-boot` can fail to copy the EFI bootloader #14045

User Manager / Privileges

- Fixed: "All" user group overwritten after assigning an existing user to a group #14363

Virtual IP Addresses

- Fixed: Firewall rules are not reloaded when removing a VIP, outdated rules/entries remain active #13908

Web Interface

- Changed: Replace direct config accesses for the rest of the paths in `system_advanced_admin.inc` #13701
- Changed: Replace direct config accesses in `system_advanced_sysctl` #13702
- Added: Support for `iwlwifi` wireless interfaces #14050

XMLRPC

- Fixed: PHP errors in `xmlrpc.php` during configuration synchronization if the target host has an empty XML tag for a given section #14034
- Fixed: PHP error when XMLRPC client attempts to synchronize without any synchronization settings in the configuration #14182
- Fixed: Filter/NAT rules configured with "No XMLRPC Sync" enabled are still synchronized #14316

3.11 23.01 New Features and Changes

This is a regularly scheduled software release including new features and bug fixes.

3.11.1 General

- PHP has been upgraded from 7.4 to 8.1
- The base operating system has been upgraded to FreeBSD 14-CURRENT

> **Warning:** As a part of the FreeBSD upgrade this version removes several deprecated IPsec algorithms:
>
> – 3DES Encryption
>
> – Blowfish Encryption
>
> – CAST 128 Encryption
>
> – MD5 HMAC Authentication
>
> The best practice is to reconfigure tunnels using better encryption and test them before performing an upgrade to ensure a smoother transition.
>
> On upgrade, IPsec tunnels will be adjusted to remove any deprecated algorithms from their configuration. The upgrade process will disable tunnels if they have no valid encryption or authentication options remaining. The upgrade process will notify the user of any changes it makes.
>
> This change only affects IPsec and not other uses of these algorithms. For example, BGP can still use TCP-MD5 authentication.

- A long-standing difficult-to-reproduce crash in Unbound during reloading has been addressed. Christian McDonald tracked down the source of the Unbound SIGHUP crashes to a reference counting bug within the MaxMindDB Python module. Both a patch to MaxMind and a port revision to FreeBSD ports were submitted and accepted, and the fix is included in the 23.01 release. It is now safe again to enable DHCP registration alongside Unbound Python mode in pfBlockerNG.
- In addition to the Unbound crash, Christian also identified a memory leak with DHCP registration and Unbound Python mode (#10624). This is largely mitigated by updates to Python and related libraries, but there is additional ongoing work to resolve it further for future release.
- Due to #13507, batch copying rules between interfaces on a previous release may have created multiple rules with the same internal tracker ID. This issue has been corrected, but any rules with duplicate IDs must be corrected manually (e.g. by deleting and re-copying or re-creating the rules).
- The pfBlockerNG package has been updated to match pfBlockerNG-devel. After upgrade it is safe to uninstall pfBlockerNG-devel (keeping settings) and install pfBlockerNG instead.

Note: On systems using ZFS, the first boot post-upgrade will appear to have higher than normal memory usage due to the large volume of filesystem activity that takes place during the upgrade process. This is harmless, however. This is due to ZFS ARC memory usage, which it will yield as needed if other processes require more memory. Rebooting the firewall after the upgrade completes will return the reported memory usage to a normal level.

See also:

ZFS Disk Activity Increases Memory Usage

If an installation continues to show higher than usual memory usage after rebooting, see potentially related issues #14016 and #14011.

3.11.2 Security

pfSense Plus 23.01-RELEASE includes fixes for multiple potential vulnerabilities:

- pfSense-SA-23_01.webgui: A potential XSS vulnerability in diag_edit.php from browsing directories containing specially crafted filenames on the filesystem.
- pfSense-SA-23_02.webgui: A potential XSS vulnerability in system_camanager.php and system_certmanager.php from specially crafted descriptions when editing entries.
- pfSense-SA-23_03.webgui: A potential authenticated arbitrary file creation vulnerability from the name parameter when creating or editing URL table aliases.
- pfSense-SA-23_04.webgui: A potential authenticated arbitrary command execution vulnerability in status.php from specially crafted filenames on the filesystem.
- pfSense-SA-23_05.sshguard: Anti-brute force protection bypass for GUI authentication requests containing certain proxy headers.

Note: Users of pfSense Plus 22.05.x and pfSense CE 2.6.0 can obtain corrections for these issues from the Recommended Patches area of the *System Patches* package.

3.11.3 Errata/Known Hardware Issues

- The **Netgate 1000** does not function on FreeBSD 14 and as a consequence it is unable to upgrade to this release. Attempting to check for updates on a **Netgate 1000** device will print a notification to this effect. No other models are impacted.
- Some older installations of pfSense Plus software on **Netgate 1100**, **Netgate 2100**, and **Netgate 2100 MAX** devices contain an EFI partition which does not have sufficient space to accommodate the new EFI loader for version 23.01 and later. This primarily affects UFS-based systems **initially** installed with version 21.02-p1 or before.

  Users with affected units **must** reinstall pfSense Plus software to run version 23.01 or later.

  Read *Troubleshooting Upgrades on Netgate 1100 and Netgate 2100 Devices* for details.
- The PCI bus in the **Netgate 1100** and **Netgate 2100** models does not currently function on 23.01. This was never an advertised feature, though some users have taken advantage of it in the past. If a device relies on the PCI bus, such as an add-on Wireless card, then consider the impact of upgrading to 23.01 where that will not be available (NG 9622).
- Devices based on "ADI" or "RCC" hardware, such as the **4860**, **8860**, and potentially other similar models, may have issues with the `ichsmb0` and/or `ehci0` devices encountering an interrupt loop, leading to higher than usual CPU usage (NG 8916).

  This can typically be worked around by disabling the affected device, with some caveats.

  To disable the `ichsmb0` device, which will disable the LED status indicators, add the following *Loader Tunable*:

```
hint.ichsmb.0.disabled=1
```

A similar method can be used to disable `ehci0` but doing so will also disable the internal MMC drive, so that should **only** be disabled when the device is booted and running from an add-on SSD.

This **does not** affect the **2220**, **2440** or **XG-2758**.

- There have been a small number of reports that pfSense Plus software version 23.01 installations using ZFS will not boot in Hyper-V, though it works OK for others (#13895). Test in a lab or non-production environment before attempting to deploy this version. In some cases removing the optical drive from the VM settings before upgrading has allowed it to boot successfully.
- Azure instances now use Gen2 and currently do not have a functional serial console, developers are working to address this in the next release.
- Devices using the i915 video driver require manual changes because FreeBSD moved the driver from the kernel to a package. In most cases this driver is not necessary, but it can be helpful on some platforms for HDMI hotplug support.

  To continue using the driver on 23.01, after the upgrade completes run `pkg install -y drm-510-kmod` from a shell. Then add the following *Loader Tunable*:

  ```
  kld_list="i915kms"
  ```

  Reboot the firewall after making the changes to activate the driver.
- There have been a small number of reports on non-Netgate hardware that accessing the GUI of a pfSense Plus software installation over IPsec can trigger a kernel panic. Developers have not yet been able to reproduce the crash, but there is a workaround for users encountering this problem: Create a *system tunable entry* to set `kern.ipc.mb_use_ext_pgs=0`. See #13938 for details and alternate workarounds.
- Some devices have an issue with the serial console display of password protected consoles and other aspects of the boot process, such as Boot Environment selection. The features may not render properly, but are still functional. This is not a regression in 23.01 as it also happened on 22.05.x. This has been reported on **Netgate 4100**, **Netgate 6100**, and **Netgate 8200** models. See #13455 for more information.
- The switch ports on the **Netgate 7100** do not have Auto-MDIX enabled on 23.01-RELEASE. If a straight-through Ethernet cable is connecting two **7100** units together (e.g. back-to-back for HA), it will not link on 23.01-RELEASE. This will be addressed in a future release. Replacing the cable with a crossover Ethernet cable will allow it to link in the meantime.
- On **Netgate 3100** units, OpenVPN, GIF, and other types of virtual interfaces may not function on 23.01 until the kernel linker hints are updated by running the following command from a shell prompt:

  ```
  kldxref /boot/kernel
  ```

  See #13963 for details.
- Dynamic interfaces (DHCP, PPP, etc) with mixed case descriptions may not have the same gateway name after upgrading, leading to a loss of connectivity due to the gateway name not matching the configuration. The simplest workaround is to change the interface name to all capital letters. For a patch, see #14057.

See also:

Numerous additional issues have been fixed since 23.01-RELEASE. Before reporting an error on the forum or elsewhere, first check the existing known issues on Redmine to see if the error already been reported and/or fixed.

3.11.4 pfSense Plus

Changes in this version of pfSense Plus software.

Aliases / Tables

- Fixed: Alias content is sometimes incomplete when an alias contains both FQDN and IP address entries #9296
- Fixed: Alias with non-resolving FQDN entry breaks underlying PF table #12708
- Fixed: Alias content is sometimes incomplete if the firewall cannot resolve an FQDN in the alias #13282
- Added: Specify CA trust store location when downloading and validating URL alias content #13367
- Fixed: Invalid alias name can still be used by code attempting to validate URL table content #13425
- Fixed: Deleting an alias marks the subsystem as unclean but also unconditionally reloads the filter configuration #13538
- Fixed: Missing descriptions for referrers to firewall aliases cause empty strings for references to be returned when deleting an in-use alias #13539

Authentication

- Fixed: Google LDAP connections fail due to lack of SNI for TLS 1.3 #11626
- Fixed: RADIUS authentication attempts no longer send RADIUS NAS IP attribute #13356
- Fixed: Unable to set web interface session timeout to `0` (i.e. never expire) #13561
- Fixed: Extra remote address information can confuse `sshguard` #13574
- Changed: Improve LDAP debugging #13718

Auto Configuration Backup

- Added: Option to list AutoConfigBackup entries in "reverse" order (newest at top) #11266
- Added: Support for international characters in the AutoConfigBackup Hint/Identifier field #13388

Backup / Restore

- Fixed: Multiple <`sshdata`> or <`rrddata`> sections in `config.xml` lead to an XML parsing error during restore #13132
- Fixed: Attempting to restore a 0 byte `config.xml` prints an error that the file cannot be read #13289
- Fixed: Configuration history restores revision no matter which option is clicked in confirmation dialog #13861
- Fixed: RRD restore process does not sanitize filenames from backup XML #13935

Build / Release

- Changed: Disable `pkg` compatibility flag which creates `txz` file extension symbolic links #12782

Captive Portal

- Fixed: Traffic passed by Captive Portal cannot use limiter queues on other rules #13148
- Fixed: Voucher CSV output has leading space before voucher code #13272
- Fixed: Error `dummynet: bad switch 21!` when using Captive Portal with Limiters #13290
- Fixed: Captive Portal breaks policy based routing for MAC address bypass clients #13323
- Fixed: Multiple Captive Portal interfaces do not properly form the list of portal IP addresses #13391
- Fixed: Custom logo or background image is created with two dots (`..`) before the file extension #13396
- Fixed: Captive Portal does not keep track of client data usage #13418
- Fixed: All Captive Portal users are given the same limiter pipe pair #13488
- Fixed: Captive Portal blocked MAC addresses are not blocked #13747
- Fixed: Rules for authenticated Captive Portal users are not removed when a zone is disabled #13756
- Fixed: Captive Portal RADIUS start/stop accounting does not reset counters at each accounting start #13838
- Fixed: Captive Portal does not apply RADIUS bandwidth limits to user pipes #13853

Certificates

- Fixed: CA path is not defined when using `curl` in the shell #12737
- Fixed: Exporting a PKCS#12 file from the certificate manager does not use the intended encryption algorithm #13257
- Fixed: Input validation is not rejecting invalid description characters when editing a CA or Certificate #13387
- Fixed: CRL expiration date with default lifetime is too long, goes past UTCTime limit #13424
- Fixed: ECDSA certificate renewal causes digest algorithm to be reset to SHA1 #13437

Configuration Backend

- Fixed: Input validation is checking RAM disk sizes when they are inactive #13479

Console Menu

- Fixed: Changing an interface IP address and gateway at the console does not save the new gateway if one already exists for the interface #12632
- Fixed: Hidden menu option `100` incorrectly handles HTTPS detection #13258

DHCP (IPv4)

- Added: Improve distinction between online and idle/offline entries in DHCP lease list #10345
- Changed: Clean up DHCP Server option language #13250
- Added: Input validation for numbered DHCP options in static mappings #13584
- Fixed: DHCP server "Disable Ping Check" option does not store value on save #13748

DHCP (IPv6)

- Fixed: `dhcp6c` is not restarted when applying settings when multiple WANs are configured for DHCP6 #13253
- Fixed: Advanced DHCP6 client settings only work for a single interface #13462
- Fixed: "Provide DNS servers to DHCPv6 clients" setting does not reflect a changed value until the page is reloaded #13594
- Fixed: DHCPv6 rules are not created for interfaces with static IPv6 #13633

DNS Forwarder

- Fixed: DNS Forwarder refuses valid retries from clients in certain cases #12901

DNS Resolver

- Fixed: Memory leak in Unbound with Python module and DHCP lease registration active #10624
- Fixed: Unbound crashes with signal 11 when reloading #11316
- Fixed: DNS Resolver is restarted during every `rc.newwanip` event even for interfaces not used in the resolver #12612
- Fixed: DNS resolver does not update its configuration or reload during link down events #13254
- Fixed: DNS Resolver responds with unexpected source address when the DNS over TLS server function is enabled #13393
- Fixed: Incorrect word in "Network Interfaces" help text on `services_unbound.php` #13453
- Changed: Update Unbound to use Python 3.11 instead of Python 3.9 #13867
- Changed: Update Unbound to 1.17.1 #13893

Dashboard

- Fixed: QAT detection on dashboard is incorrect if the driver does not attach #13674
- Fixed: APU1 hardware is not properly identified with current BIOS versions #13471

Diagnostics

- Fixed: File browser on `diag_edit.php` does not encode filenames before display #13262
- Fixed: Neighbor hostnames in the NDP Table on `diag_ndp.php` are always empty #13318
- Fixed: `status.php` uses <name> component of `/tmp/rules.packages.`<name> filenames in shell command without encoding #13426
- Changed: Add multicast group membership (`ifmcstat`) to `status.php` #13731

Dynamic DNS

- Fixed: Namecheap Dynamic DNS responses are not parsed properly #12816
- Fixed: DigitalOcean Dynamic DNS update fails with a "bad request" error #13167
- Fixed: Dynv6 Dynamic DNS client does not check the response code when updating #13298
- Fixed: DNSExit Dynamic DNS updates no longer work #13303

FilterDNS

- Fixed: Resolve interval for `filterdns` may not match the configured value #13067

FreeBSD

- Fixed: Cannot set EFI console as primary console when using both EFI and Serial #13080
- Fixed: CVE-2022-23093 / FreeBSD-SA-22:15.ping #13716

Gateway Monitoring

- Fixed: Marking a gateway as down does not affect IPsec entries using gateway groups #13076
- Fixed: Incorrect function parameters for `get_dpinger_status()` call in `gwlb.inc` #13295

Gateways

- Fixed: Recovering interface gateway may not be added back into gateway groups and rules when expected #13228

Hardware / Drivers

- Fixed: Software VLAN tagging does not work on `ixgbe(4)` interfaces #13381
- Fixed: Intel i226 network interfaces do not honor a manually selected link speed #13529
- Fixed: UDP checksum errors with `ixgbe` interfaces #13883

IPsec

- Fixed: `filterdns` does not monitor remote IPsec gateways for IPv6 address changes #12645
- Fixed: IPsec rejects certificates if any SAN is wildcard rather than rejecting when **all** SANs are wildcard #13373
- Changed: Information box on `status_ipsec.php` says "IPsec not enabled" even when a tunnel is established #13398
- Fixed: Incorrect quoting of Split DNS attribute value in `strongswan.conf` #13579
- Added: Support for ChaCha20-Poly1305 encryption with IPsec #13647
- Changed: Remove deprecated IPsec algorithms (3DES, Blowfish, and CAST 128 encryption; MD5 HMAC/Hashing) #13648

Interfaces

- Fixed: Primary interface address is not always used when VIPs are present #11545
- Added: Support for VLAN `0` #12070
- Fixed: Bridges with QinQ interfaces not properly set up at boot #13225
- Fixed: Several advanced DHCP6 client options do not inform the user when rejecting invalid input #13493
- Changed: Clean up obsolete code in `pfSense-dhclient-script` #13501
- Fixed: Assigned bridge interfaces are not configured at boot #13666
- Fixed: Code that sets IPv6 MTU can unintentionally act on IPv4 addresses #13675

OpenVPN

- Fixed: OpenVPN DCO panics with short UDP packets #13338
- Fixed: OpenVPN crashes after reaching the configured concurrent connection limit #13355
- Fixed: Traffic to OpenVPN DCO RA clients above the first available tunnel IP address is incorrectly routed #13358
- Added: Support for ChaCha20-Poly1305 and AES-128-GCM encryption with OpenVPN DCO #13649
- Fixed: GUI allows configuring OpenVPN DCO with incompatible options (TCP, compression, TAP, net30) #13664
- Fixed: OpenVPN status for multi-user VPN shows info icon to display RADIUS rules when there are none to display #13243

Operating System

- Fixed: Entries for `net.link.ifqmaxlen` duplicated in `/boot/loader.conf` #13280
- Fixed: `vmstat -m` value for `temp` is accounted for incorrectly, resulting in underflows #13316
- Fixed: Memory leak in PF when retrieving Ethernet rules #13525
- Changed: Update Python 3.9.15 to 3.9.16 in base system #13865
- Changed: Add Python 3.11.1 to base system #13866

PHP Interpreter

- Added: Upgrade PHP from 7.4 to 8.1 #13446
- Fixed: `fcgicli` fails to write packets with `nvpair` values that exceed `128` bytes #13638

PPP Interfaces

- Fixed: Services are not restarted when PPP interfaces connect #12811
- Fixed: PPP interface custom reset date/time Hour and Minute fields do not properly handle `0` value #13307

Routing

- Added: Enable `ROUTE_MPATH` multipath routing #9544

Rules / NAT

- Fixed: Rule separator positions change when deleting multiple rules #9887
- Fixed: User is forced to pick an NPt destination IPv6 prefix length even when choosing a drop-down entry which contains a defined prefix length #13240
- Fixed: The `negate_networks` table is duplicated in `rules.debug` #13308
- Fixed: Each line in the NPt destination IPv6 prefix list also contains the network of the previous line when multiple choices are present #13310
- Fixed: Using the copy (not clone) function on firewall rules unintentionally converts interface `address` to interface `net` #13364
- Fixed: PF can fail to load a new ruleset #13408
- Fixed: TCP traffic sourced from the firewall can only use the default gateway #13420
- Fixed: `easyrule` CLI script has multiple bugs and undesirable behaviors #13445
- Changed: Correct DHCP client rule descriptions in the generated firewall ruleset #13505
- Fixed: Copying multiple rules at the same time results in new rules with duplicate tracker IDs #13507
- Fixed: Toggling NAT rules using the button method does not enable/disable corresponding firewall rules #13545
- Fixed: Error creating port forward rule with port alias #13601

Traffic Shaper (ALTQ)

- Added: ALTQ GUI support for Broadcom Netextreme II (`bxe`) interfaces #13304

UPnP/NAT-PMP

- Fixed: UPnP/NAT-PMP status page does not display all port mappings #4500

User Manager / Privileges

- Fixed: RADIUS authentication not working over IPv6 #4154

Web Interface

- Fixed: Unnecessary link tag in login page #7996
- Fixed: "Dark" theme does not sufficiently distinguish between selected and deselected elements in option lists #11730
- Fixed: VGA install defaults to serial as primary console when loading/saving admin GUI settings without making changes #12960
- Changed: Spelling and typo corrections #13357
- Fixed: "Dark" theme uses the same colors for disabled and enabled input fields #13390
- Fixed: Input validation on `system_advanced_firewall.inc` uses incorrect variable references for some fields #13436
- Changed: Update external HTTPS/HTTP links #13440
- Fixed: Table row selection has poor contrast in Dark theme #13448
- Fixed: Changing the GUI port does not redirect the browser to the new port on save #13591

3.12 22.05/22.05.1 New Features and Changes

3.12.1 Version 22.05.1

pfSense Plus software version 22.05.1 is a special patch release which adds hardware support for the Netgate 8200 and newer hardware revsions of the 2100, as well as built-in dynamic repository support.

Important: The majority of pfSense Plus users will not need to run this version unless directed to do so by Netgate TAC. This limited patch release is not currently offered as an upgrade from 22.05.

3.12.2 Version 22.05

This is a regularly scheduled release of pfSense® Plus software including new features and bug fixes.

3.12.3 General

- Added: *OpenVPN Data Channel Offload (DCO)* support (Plus only)

Note: Some OpenVPN features and use cases are not compatible with DCO. See *Limitations* for a list of known DCO limitations.

- Added: *ZFS Boot Environment* (BE) snapshots support (Plus only)
- Changed: Captive Portal and Limiters now use only PF and not IPFW (Plus and CE)

3.12.4 Security

pfSense Plus 22.05-RELEASE includes a fix for the following potential vulnerability:

- pfSense-SA-22_05.webgui: A potential XSS vulnerability in firewall_aliases.php from URL table alias URLs.

Note: Users of pfSense CE 2.6.0 can obtain a correction for this issue from the Recommended Patches area of the *System Patches* package.

3.12.5 pfSense Plus

Changes in this version of pfSense Plus software.

Aliases / Tables

- Fixed: Renaming an alias does not update the alias names in static routes and OpenVPN instances #12727
- Added: Retain descriptions when exporting and importing aliases #12842

Authentication

- Added: GUI option to select the user password hashing algorithm #12855
- Fixed: LDAP setup does not display 'Global Root CA List' option unless another CA also exists #13185

Backup / Restore

- Changed: Comply with current iteration standards when encrypting and decrypting configuration files #12556
- Added: Support encrypted `config.xml` files when restoring via ECL #12685
- Added: Notify user if AutoConfigBackup is unable to successfully upload a backup #12724
- Added: Ability to sort AutoConfigBackup entries #12773
- Fixed: PHP error when upgrading from before configuration revision 21.6, `ipsec_create_vtimap()` is undefined #13097
- Added: Option to restore dashboard widget layout #13125
- Fixed: PHP error restoring DHCP lease data on fresh installation: #13157

CARP

- Changed: Reorganize CARP status page #12701
- Fixed: CARP event storm when leaving persistent CARP maintenance mode. #12961

Captive Portal

- Fixed: Allowed IP/Hostname "Direction" option is never used #12649
- Fixed: `nginx` logs an error that the port is already in use when restarting Captive Portal services #12651
- Fixed: Value of `net.inet.ip.dummynet.*` OIDs in `sysctl` are ignored #12733
- Fixed: Only TCP traffic is passed outbound though IPFW #12834
- Changed: Transition Captive Portal from IPFW to PF #13100

Certificates

- Added: Option to retain the existing serial number when renewing a CA or certificate #13010

Configuration Backend

- Added: Move command line history to a GUI option stored in `config.xml` rather than a manual flag file #12675
- Added: Eliminate duplicate shell commands from history file #12741

Configuration Upgrade

- Added: Playback script to perform a configuration upgrade on an arbitrary `config.xml` file #12973

Console Menu

- Added: Warn the user if they attempt to disable SSH from the menu while connected through SSH #13103

DHCP (IPv4)

- Fixed: Disabling DHCP Server RRD statistics does not work #12710
- Fixed: `HTTPClient` option not sent when using UEFI HTTP Boot #12892
- Fixed: `HTTPClient` option does not work for static mappings #12896
- Fixed: DHCP "Ignore denied clients" option with MAC Deny list set causes DHCP server to not start #12923
- Fixed: DHCP network boot filename can be incorrectly placed in DHCP Pool Options #12986
- Added: Relax DHCP maximum lease time input validation #13118
- Fixed: DHCP lease list displays wrong interface name in the "Leases in Use" summary if DHCP settings for a disabled interface remain in the configuration #13127

DHCP (IPv6)

- Fixed: Multiple DHCP6 WAN connections leads to multiple dhcp6c clients #6880
- Fixed: DHCPv6 server does not skip interfaces configured with invalid ranges #12527
- Fixed: RADVD can be started on both HA nodes when configured with an IPv6 link-local address #12582
- Fixed: Uninitialized array in `array_remove_duplicates()` #12749

DNS Forwarder

- Fixed: DNS Forwarder creates a loop when "Use local DNS, ignore remote DNS servers" is selected #12902
- Fixed: DNS Forwarder custom options may fail after save/restore when options are only separated by newline #13105

DNS Resolver

- Fixed: DNS Resolver does not restart during link up/down events on a static IP address interface #12613
- Added: Automatically create DNS Resolver ACLs for OpenVPN CSO entries #12636
- Fixed: DNS Resolver help text for **System Domain Local Zone Type** option refers users to `unbound.conf(5)` man page instead of pfSense docs #12781
- Fixed: DNS Resolver updates trust anchor at boot even with DNSSEC disabled which can lead to a startup delay of ~2 minutes if the firewall does not have Internet access #12985
- Fixed: DNS Resolver ACLs are not updated when OpenVPN networks change #12991
- Added: DNS Resolver option to keep probing when servers are down #13023

Dashboard

- Fixed: Firewall log widget action icon features stop working when new log entries are added dynamically #6253
- Added: Show `Inactive` for Hardware Crypto output instead of empty field on System Information dashboard widget when nothing can be accelerated #12714

Diagnostics

- Fixed: `diag_pftop.php` does not fully encode output #12915

Dynamic DNS

- Fixed: Dynamic DNS custom IPv6 service fails on 6rd tunnels #12590
- Fixed: GleSYS Dynamic DNS responses are not parsed properly #12672
- Added: IPv6 support for DNSimple Dynamic DNS #12744
- Fixed: Input validation prevents configuring wildcard Dynamic DNS records on GoDaddy #12750
- Added: Support wildcard Dynamic DNS records on DigitalOcean #12752
- Fixed: Google Domains Dynamic DNS responses are not parsed properly #12754

- Fixed: Input validation prevents configuring wildcard Dynamic DNS records on Google Domains #12761
- Fixed: Namecheap Dynamic DNS responses are not parsed properly #12816
- Fixed: Clicking Save & Force Update on a Dynamic DNS entry results in a GUI timeout #12870

Gateway Monitoring

- Fixed: Gateway monitoring should mark gateway as "offline" on PPPoE parent interface disconnect #12633
- Added: Option to disable auto-addition of static routes for `dpinger` #12687
- Changed: Update `dpinger` to 3.2 #12881

Gateways

- Fixed: `fixup_default_gateway()` should not remove a default gateway managed by a dynamic routing daemon #11692
- Fixed: IPv6 link local gateway default status not indicated in GUI #11764
- Fixed: IPv6 gateway group using link local addresses incorrectly logs a gateway change because it not including interface scope properly #12721
- Added: Retain knowledge of previous dynamic gateway IP address when interface is down #12931

Hardware / Drivers

- Added: Chelsio TOE support using the `t4_tom` module #9091
- Fixed: Hyper-V RSC support in `hn(4)` driver is enabled by default and results in very low throughput #12873

High Availability

- Added: Use consistent pf host ID and add GUI option to set a custom host ID in state synchronization settings #12702

IGMP Proxy

- Fixed: IGMP Proxy server is restarted during every `rc.newwanip` event #12609

IPsec

- Added: Option to choose default tab in IPsec status Dashboard widget #2456
- Fixed: IPsec VTI phase 2 traffic selectors default to address when defined as a network #11226
- Fixed: `filterdns` does not monitor remote IPsec gateways for IPv6 address changes #12645
- Fixed: Disallow remote gateway of `0.0.0.0` for VTI mode #12723
- Fixed: VTI gateway status stuck as "pending" after reboot #12763
- Changed: Update strongSwan #12934
- Fixed: ESP description in IPsec phase 2 proposal help text is ambiguous #12953

- Fixed: IKEv2 Mobile IPsec clients do not receive `INTERNAL_DNS_DOMAIN` (value `25`) attribute #12975
- Added: GUI option for IPsec `dns-interval` setting #13057
- Fixed: Delete function for IPsec SAD entries on `status_ipsec_sad.php` does not work #13071
- Fixed: Mobile IPsec clients cannot be manually disconnected from IPsec status screen #13131

Installer

- Fixed: Support encrypted `config.xml` files when restoring during install #12691
- Added: Recover existing SSH keys during installation #12809

Interfaces

- Added: Show SFP module details on `status_interfaces.php` #8861
- Added: Improved support for USB interfaces that may not always be present #9393
- Fixed: PPPoE WAN IP address different than expected when set static by ISP #11629
- Fixed: `devd` is not configured to act on USB interface attach/detach events #12606
- Changed: Restart services on interface changes #12619
- Fixed: Interface status "Total Interrupts" display is non-functional #12735
- Fixed: L2TP/PPTP interface assignment page loses some values after input validation error #12780
- Fixed: Link-Local IPv6 address on WAN with MAC spoofing changes if there is an IP Alias on WAN #12790
- Fixed: Link-local address does not reset after removing MAC address spoofing #12794
- Fixed: Disabled Captive Portal configuration prevents adding an interface to a bridge #12866
- Fixed: The ruleset is not regenerated after assigning an interface #12949

L2TP

- Fixed: L2TP MPD configuration is not updated when a dynamic WAN IP address changes #13066
- Fixed: L2TP stays bound to previous IP address after static IP address change #13082
- Fixed: Static routes to destinations at L2TP clients are not re-added after a client reconnects #13099

LAGG Interfaces

- Added: GUI option to configure layers for LACP hash #12819

Notifications

- Fixed: Slack notification options only allow `` -`` as a special character in channel names #13083

OpenVPN

- Fixed: OpenVPN IPv4 Tunnel Network incorrectly allows hostnames #11416
- Fixed: OpenVPN stays bound to previous IP address after interface changes #11864
- Added: OpenVPN option to limit concurrent connections per user #12267
- Fixed: OpenVPN does not clear old Cisco-AVPair anchor rules in some cases #12332
- Added: Use deferred client connections in OpenVPN #12407
- Fixed: OpenVPN re-synchronization also synchronizes override entries unnecessarily in some cases #12628
- Fixed: Automatic filter reload with OpenVPN client gateway uplink happens too soon or not at all #12771
- Fixed: PHP error when terminating OpenVPN sessions via the dashboard widget #12817
- Fixed: OpenVPN status display for TAP mode services shows peer-to-peer instead of client list in certain cases #12884
- Fixed: GUI does not reject an invalid OpenVPN tap mode configuration with an empty tunnel network "Bridge DHCP" disabled #12887
- Fixed: FQDN in network alias is omitted from OpenVPN networks list #12925
- Changed: Warn about OpenVPN shared key deprecation #12981
- Fixed: OpenVPN `remote_cert_tls` option does not behave correctly when enabled and later disabled #13056
- Fixed: Gateway events for IPv6 affect IPv4 OpenVPN instances and vice versa #13061
- Fixed: OpenVPN client `tls-client/client` configuration directive not handled properly #13116
- Changed: OpenVPN status page improvements #13129
- Fixed: OpenVPN `client-connect` file contains `topology` #13133
- Fixed: Per-user `route` files are not removed from `/tmp` when they are no longer needed #13145
- Fixed: OpenVPN override IPv4 tunnel network field changing value improperly #13274

Operating System

- Fixed: pf `hostid` value is handled inconsistently #12703
- Fixed: Some `sysctl` OIDs in `loader.conf.local` are silently removed #12862
- Fixed: Output from `pfctl -vvsr` does not include `ridentifier` value in the expected location #12868

PPP Interfaces

- Fixed: PPPoE WANs fail to reconnect after parameter negotiation failure #13092

PPPoE Server

- Fixed: PPPoE server panics with multiple client connections #13210

Package System

- Fixed: Packages are not automatically reinstalled when restoring configuration using the installer #12105
- Fixed: Packages with custom `internal_name` values do not reinstall properly when restoring a backup #12766
- Fixed: `write_rcfile()` does not create `rc_restart()` entry #13004

Packet Capture

- Added: Button to clear previous packet capture data #12968

Routing

- Fixed: Setting a default gateway of "None" does not remove the default gateway from the routing table #12536
- Fixed: Cannot remove IPv6 static routes #12728
- Fixed: Explicit PPPoE disconnect of a WAN Gateway Group member may not restore a default route. #13048

Rules / NAT

- Added: Toggle button to disable/enable multiple firewall rules #2505
- Added: Port forward NAT rules with "any" protocol #4259
- Added: Allow NPt to use dynamic IPv6 networks #4881
- Added: Button to copy rules from one interface to another #8365
- Fixed: Automatic Outbound NAT mode can create incorrect rules in some cases #11984
- Added: Utilize new `pfctl` abilities to kill states #12092
- Fixed: NAT reflection does not work for IPv6 port forwarding rules when configured for NAT+Proxy mode #12319
- Added: Allow the selection of "any" interface in floating rules #12392
- Fixed: Applying firewall rule changes does not clear dirty flag for aliases subsystem #12678
- Fixed: Automatic Outbound NAT rules do not include OpenVPN CSO entries #12792
- Fixed: Error loading ruleset due to illegal TOS value #12803
- Fixed: High latency and packet loss during a filter reload #12827
- Fixed: On startup "No routing address with matching address" might appear #12847
- Fixed: Some action buttons are always active for firewall rules, even if no rules are selected #12871

- Added: Toggle button to disable/enable multiple entries on NAT pages #12879
- Fixed: Delete button is always active for NAT rules, even if no rules are selected #12957
- Fixed: NAT Reflection generates duplicate rules when internal interface contains multiple VIPs in the same subnet #13012
- Fixed: NAT generates duplicate `no nat on` rules for port forwards with a destination of `Any` #13015
- Fixed: Input validation requires a gateway for floating `match out` rules #13027
- Fixed: Empty `negate_networks` table breaks policy routing rules #13049
- Fixed: The `negate_networks` table is not updated when an OpenVPN server is deleted #13055
- Added: Allow auto prefix with manual prefix-length in NPt #13070
- Fixed: Info icon on `firewall_nat_out.php` is incorrectly placed in manual outbound NAT mode #13164
- Fixed: Changing the redirect target for a Port Forward with an associated filter creates an incorrect firewall rule #13171
- Fixed: Incorrect usage of DSCP hex value #13178

SNMP

- Fixed: SNMP daemon is restarted during every `rc.newwanip` event #12611

Services

- Fixed: NTP service is not listed on `status_services.php` unless `config.xml` contains NTP configuration data #12775
- Fixed: Stale `sshdkeys.dirty` lock file prevents generating SSH server keys #13139

Traffic Shaper (ALTQ)

- Changed: Remove code references to unused `reset` parameter from traffic shaper pages #13042

Traffic Shaper (Limiters)

- Fixed: Incorrect ICMP reply when using limiters #9263
- Fixed: Pie and `fq_pie` are missing options and do not handle floating point number input correctly #12003
- Fixed: Utilize `dnctl(8)` to apply limiter changes without a filter reload #12579
- Fixed: Traffic routed through DUMMYNET by PF fails when IPFW is enabled #12954

Traffic Shaper Wizards

- Fixed: Traffic Shaper wizard can produce an invalid ruleset when configured with an IPv4 upstream SIP server #12937
- Fixed: Traffic shaper wizard rewrites Mbits to Kbits #13086

UPnP/NAT-PMP

- Added: uPnP fails to properly give out subsequent reservations when multiple gaming systems are playing the same game/using the same port. #7727
- Changed: Reorganize UPnP options #12624

Unknown

- Fixed: Many `exec()` functions do not use full path to executable files #11941

Upgrade

- Fixed: Upgrade does not work when using only IPv6 DNS servers #13162

User Manager / Privileges

- Fixed: Icon missing for user manager entries with a scope other than "user" #13174

Web Interface

- Fixed: Lack of DNS or Internet connectivity causes GUI to be slow #12141
- Fixed: Zero-value prefix IPv6 addresses are mishandled #12440
- Added: Option to filter state table contents by rule ID #12616
- Fixed: Changing RAM disk size does not prompt to reboot #12876
- Fixed: Input validation for IPv6 addresses allows invalid address compression in some cases #13069
- Added: Trim whitespace from MAC addresses in user input #13109

Wireless

- Fixed: Wireless interface WPA configuration fields are always visible #12998
- Fixed: Duplicate wireless interfaces are created at boot #12999

XMLRPC

- Fixed: Deleting a user on the primary node does not delete its home directory on secondary node during XMLRPC sync #12940

3.13 22.01/2.6.0 New Features and Changes

This is a regularly scheduled release of pfSense® CE and pfSense Plus software including new features, additional hardware support, and bug fixes.

Warning: When upgrading to pfSense Plus 22.01 and later versions, the `pfSense-upgrade` process will forcefully reinstall all operating system packages and add-on packages to ensure a consistent state and package set. This may increase the time the upgrade will take to download and install.

3.13.1 Security

This release includes corrections for the following vulnerabilities in pfSense software:

- pfSense-SA-22_01.webgui (File overwrite in `services_ntpd_gps.php`, #12191)
- pfSense-SA-22_02.webgui (Potential vulnerabilities with route collection on `diag_routes.php` , #12257)
- pfSense-SA-22_03.webgui (Potential vulnerabilities in OpenVPN form validation, #12677)
- pfSense-SA-22_04.webgui (XSS in `pkg.php`, #12725)

3.13.2 Errata

- There is a patch available to improve NAT behavior for UPnP and multiple game consoles or clients playing the same game but the fix was discovered too late for it to be included in 22.01/2.6.0.

  For additional details and instructions on how to apply the patch, see Redmine issue #7727 note #74 and #75, the Github commit, and the forum thread for testing feedback.

3.13.3 General

- This release contains several significant changes to IPsec for stability and performance. Read the IPsec section of this document carefully.

  Warning: IPsec VTI interface names have changed in this release. Configurations will be updated automatically where possible to use the new names.

  Check the interface names of assigned VTI instances under **Interfaces > Assignments** to ensure they are correct after the upgrade completes.

  If any third party software configurations or other manual changes referenced the old IPsec VTI interface names directly (e.g. `ipsecNNNN`) they must be updated to the new format.

- ZFS is now the default filesystem for new installations of pfSense Plus and pfSense CE software on all platforms which support booting from ZFS.

  - It is not possible to change from UFS to ZFS in place, a reinstallation of pfSense Plus or CE is required to migrate from UFS use ZFS.
  - The ZFS pool name and datasets have also been updated and optimized. Users who were already using ZFS may want to reinstall as well to ensure they have the most optimal disk layout.
  - pfSense Plus software has a new ZFS dashboard widget to track the status of disks using ZFS.
- **Log Compression** for rotation of System Logs is now disabled by default for new ZFS installations as ZFS performs its own compression.

Tip: The best practice is to disable **Log Compression** for rotation of System Logs manually for not only existing ZFS installations, but also for any system with slower CPUs. This setting can be changed under **Status > System Logs** on the **Settings** tab.

- The default password hash format in the User Manager has been changed from bcrypt to SHA-512. New users created in the User Manager will have their password stored as a SHA-512 hash. Existing user passwords will be changed to SHA-512 next time their password is changed.

Note: User Manager passwords are only stored as a hash, thus existing users cannot be automatically changed to the new format. To convert a user password from an older hash format, change the password for the user in the User Manager.

- The firewall now *bootstraps its clock* at boot in multiple ways, one of which utilizes multiple NTP servers with static IP addresses from Google Public NTP. This avoids a chicken-and-egg problem where the firewall cannot resolve NTP servers because DNSSEC, which is enabled by default, cannot function when the clock is inaccurate. The firewall performs this sync once per boot before it starts the NTP daemon.

Note: This behavior can easily be changed or disabled. See *Changing Clock Bootstrap Behavior*.

- Several areas of the documentation have been rewritten and updated for these releases. Notably, the IPsec and OpenVPN sections have been updated significantly including all of the related configuration recipes.

3.13.4 pfSense Plus

PHP Interpreter

- Fixed: PHP exits with signal 11 on SG-3100 when calling PCRE functions #11466

3.13.5 pfSense CE

Aliases / Tables

- Fixed: Error loading rules when URL Table Ports content is empty #4893
- Fixed: Mixed use of aliases in a port range produces unloadable ruleset #11818
- Fixed: Unable to create nested URL aliases #11863
- Fixed: Creating or editing aliases fails with multiple hosts separated by spaces #12124

- Fixed: When attempting to delete an in-use alias, input validation only prints the first item using the alias in the error message #12177

Authentication

- Changed: Use SHA-512 for user password hashes #10298
- Fixed: Deny SSH access for `admin` and `root` users when the `admin` GUI account is disabled #12346

Backup / Restore

- Fixed: Restoring from AutoConfigBackup presents reboot type selection option then reboots automatically #10662
- Added: Backup and restore SSH host key(s) #11118
- Fixed: Output from reboot process is printed on Backup & Restore page when restoring a configuration file #11909
- Fixed: Custom value for AutoConfigBackup schedule Hours is not shown when loading the settings page #11946
- Added: AutoConfigBackup performance improvements #12193
- Fixed: Viewing an AutoConfigBackup entry takes approximately 60 seconds to completely load #12247
- Changed: Explicitly state where AutoConfigBackup stores encrypted backup data #12296

Build / Release

- Changed: Remove deprecated `libzmq` code and references #12060

CARP

- Fixed: Cannot enter persistent CARP maintenance mode when CARP is disabled #11727
- Fixed: When a CARP VIP VHID change is synchronized to a secondary node, the CARP VIP is removed from the interface and the old VHIDs remain active #12202
- Fixed: Changing VHID on CARP VIP does not update VHID of related IP Alias VIPs #12227
- Fixed: `rc.carpmaster` only sends notifications via SMTP #12584

Captive Portal

- Fixed: Vouchers may expire too early when using RAM disks #11894
- Fixed: Incorrect variable substitution in captive portal error page #11902
- Fixed: Clicking “logout” on portal page does not function when logout popup is disabled #12138
- Fixed: Captive Portal database and `ipfw` rules are out of sync after unclean shutdown #12355
- Fixed: Captive Portal input validation for “After authentication Redirection URL” and “Blocked MAC address redirect URL” is swapped #12388
- Fixed: Captive Portal online user statistics data is not cleared on unclean shutdown #12455

Certificates

- Fixed: Certificate Revocation tab does not list active users of CRL entries #11831
- Fixed: Certificate manager reports CA as in use by an LDAP server when LDAP is not configured for TLS #11922
- Fixed: Certificate Manager performs redundant escaping of special characters in certificate DN fields #12034
- Added: Input validation to prevent unsupported UTF-8 characters from being used in certificate subject components #12035
- Fixed: Certificate Manager shows incorrect DN for imported entries with UTF-8 encoding #12041

Console Menu

- Fixed: Cannot configure WAN IP address with `/32` CIDR mask via console menu #11581
- Changed: Suppress kernel messages when loading `dummynet` and thermal sensor modules #12454

DHCP (IPv4)

- Added: DHCPv4 client does not support `supersede` statement for option 54 #7416
- Added: Support for UEFI HTTP Boot option in DHCPv4 Server #11659
- Fixed: DHCPv4 server configuration does not include ARM TFTP filenames #11905
- Fixed: ARM 32/64 network boot options are not parsed on Static DHCP Mapping page #12216

DHCP (IPv6)

- Fixed: DHCPv6 Server should not offer configuration options for unsupported PPPoE Server interfaces #12277

DHCP Relay

- Fixed: PHP error if no DHCPv6 Relay interfaces are selected #11969

DNS Resolver

- Fixed: Unbound crashes with signal 11 when reloading #11316
- Fixed: Unbound fails to start if its configuration references a python script which does not exist #12274
- Fixed: Unbound falls back to using all outgoing network interfaces if manually selected outgoing interface(s) are unavailable #12460

Dashboard

- Fixed: System Information widget unnecessarily polls data for hidden items #12241
- Fixed: IPsec widget generates errors if no tunnels are defined #12337
- Fixed: IPsec widget treats phase 1 in "connecting" state as connected #12347
- Added: Disks dashboard widget to replace Disk Usage section of System Information widget #12349
- Fixed: Thermal Sensors Dashboard widget filter for negative values refers to invalid variable #12470

Diagnostics

- Fixed: State table content on `diag_dump_states.php` does not sort properly #11852
- Changed: Hide "Reboot and run a filesystem check" for ZFS systems #11983
- Fixed: "GoTo line #" function does not work on `diag_edit.php` #12050
- Fixed: Sanitize WireGuard private and pre-shared keys in status output #12256
- Added: Include firewall rules from packages which failed to load in status output #12269
- Added: Include firewall rules generated from OpenVPN RADIUS ACL entries in status output #12316
- Fixed: ARP table interface column empty for entries on unassigned interfaces #12698

Dynamic DNS

- Added: Option to set interval of forced Dynamic DNS updates #9092
- Added: Support DNS Made Easy authentication without a username #9341
- Fixed: RFC 2136 Dynamic DNS client uses IPv6 alias VIP instead of Track IPv6 address for AAAA records #11816
- Added: New Dynamic DNS Provider: Strato #11978
- Fixed: Dynamic DNS cache expiration time check calculation method may cause update to happen on the wrong day #12007
- Fixed: NoIP.com incorrectly encodes Dynamic DNS update credentials #12021
- Added: New Dynamic DNS Provider: deSEC #12086
- Added: Support Check IP services which return bare IP address values #12194
- Fixed: Yandex Dynamic DNS client does not set the `PddToken` value #12331
- Added: Dynamic DNS client proxy support #12342
- Fixed: Update Dynamic DNS code for one.com to use their new login process #12352
- Fixed: Dynamic DNS updates do not respect certificate authority trust store #12589
- Fixed: Dynamic DNS client updates using a private IP address when it cannot determine the public IP address #12617
- Fixed: Dynamic DNS may not use the correct interface when updating during failover #12631

FreeBSD

- Fixed: Duplicate `comconsole_port` lines in `/boot/loader.conf` #11653
- Changed: Upgrade to `pkg` 1.17.x #12171

Gateways

- Added: Support DNS server gateway selection on `system.php` for multiple gateways not assigned to interfaces #12116
- Fixed: Default IPv4 gateway may be set to IPv6 gateway value in certain cases #12282

Hardware / Drivers

- Added: Support for network interfaces using the `qlnxe` driver #11750

High Availability

- Fixed: Incorrect RADVD log message on HA event #11966

IGMP Proxy

- Added: Support `0` CIDR mask for IGMP Proxy networks #7749

IPsec

- Fixed: Disconnected IPsec phase 2 entries are not shown in IPsec status #6275
- Fixed: UDP fragments received over IPsec tunnel are not properly reassembled and forwarded #7801
- Fixed: EAP-RADIUS Mobile IPsec clients with RADIUS-assigned addresses do not get additional configuration attributes #11447
- Fixed: Incorrect phase 2 entry removed when deleting multiple items consecutively #11552
- Fixed: strongSwan configuration contains incorrect structure for mobile pool DNS records #11891
- Fixed: IPsec status tunnel descriptions are incorrect #11910
- Changed: PC/SC Smart Card Daemon `pcscd` running on all devices at all times, should be optional #11933
- Fixed: IPsec status fails when many tunnels are connected #11951
- Fixed: Mobile IPsec advanced RADIUS parameters do not allow numeric values with a decimal point #11967
- Fixed: Mobile IPsec NAT/BINAT entries missing from firewall rules #12023
- Fixed: Applying IPsec settings for many tunnels is slow or times out #12026
- Fixed: Gateway alarm always triggers IPsec restart #12039
- Changed: Improve IPsec identifier settings #12044
- Fixed: IPsec status IKE disconnect button drops all connections for the IKE ID, not a specific IKE SA ID #12052
- Fixed: Tunnels with conflicting REQID values can lead to multiple identical Child SA entries #12155
- Added: IPsec keep alive option to initiate phase 2 without using ICMP #12169

- Added: Add connect/disconnect buttons to IPsec dashboard widget #12181
- Added: GUI options to configure IKE retransmission behavior #12184
- Fixed: IPsec status shows connect buttons while tunnel is connecting #12189
- Fixed: IPsec writes CRL files when tunnel does not use certificates #12195
- Fixed: IPsec settings fail to apply when a remote gateway is set to an FQDN and there are no DNS servers available #12196
- Fixed: Mobile IPsec phase 1 should not display "Gateway duplicates" option #12197
- Fixed: Disabling an IPsec phase 1 entry does not disable related phase 2 entries #12198
- Fixed: Disabled IPsec VTI interfaces are always created #12212
- Fixed: IPsec bypass rules display help text under each entry #12236
- Fixed: IPsec phase 1 entry with `0.0.0.0` as its remote gateway does not receive correct automatic firewall rules #12262
- Changed: Update "IPsec Filter Mode" option values and help text to reflect that VTI mode also helps transport mode (e.g. GRE) #12289
- Fixed: IPsec manual initiation and termination should use a timeout value or forced actions #12298
- Fixed: IPsec tunnels using a gateway group do not get reloaded in some cases #12315
- Fixed: IPsec Phase 2 entry incorrectly orders proposals in AH mode #12323
- Fixed: Hash algorithm GUI options are disabled after switching a phase 2 entry to AH mode #12324
- Fixed: IPsec VTI interface remote endpoint is not resolved the correct way #12328
- Fixed: Incorrect label for IPsec DH group 32 #12350
- Added: Distinguish between policy-based and route-based entries on IPsec status SPD tab #12397
- Fixed: Console boot output includes `Configuring IPsec VTI interfaces` when no VTI interfaces are configured #12419
- Changed: Add IPsec phase 2 BINAT subnet size input validation #12430
- Fixed: IPsec initiates on HA backup node when a tunnel interface is set to a gateway group #12566
- Fixed: IPsec Mobile Client RADIUS Advanced parameters are not reset to default values when disabled #12575

IPv6 Router Advertisements (RADVD)

- Fixed: `radvd` only responds to the first Router Solicitation received after each multicast Router Advertisement #10304
- Fixed: "Default preferred lifetime" router advertisement validation check uses incorrect variable #12159
- Fixed: IPv6 RA DNSSL lifetime is too short, not compliant with RFC 8106 #12173
- Fixed: Default IPv6 router advertisement intervals and lifetime are too low #12280
- Fixed: "Default preferred lifetime" field for IPv6 RA does not have input validation #12439
- Fixed: IPv6 interface prefix change not reflected in RADVD configuration #12604
- Fixed: Router Advertisement DNS search domain from one interface may unintentionally be used by other interfaces #12626

Installer

- Added: Restore RRD and extra data from configuration backups when restoring during installation #12518
- Fixed: Minnowboard Turbo cannot boot a clean install #12707

Interfaces

- Fixed: GRE and GIF tunnels on dynamic IPv6 interface are not brought up during boot #6507
- Fixed: Interface column empty in list of GIF tunnels when using IP Alias on CARP VIP as Interface #11337
- Fixed: QinQ using OpenVPN `ovpn` interface as a parent is not configured at boot time #11662
- Fixed: VLAN and QinQ edit pages allows selecting incompatible OpenVPN `tun` interfaces #11675
- Fixed: Advanced DHCP client configuration "Protocol timing" help text is in the wrong location #11926
- Added: VLAN list sorting #11968
- Fixed: Boot messages contain entries about configuring LAGG/VLAN/QinQ interfaces even when no entries of those types are configured #12002
- Fixed: Input validation incorrectly rejects a second IPv4-only GRE tunnel #12049
- Fixed: Interface assignment mismatch is not detected if VLAN-only parent interface is removed #12170
- Fixed: IPv6 DNS servers from dynamic sources are not listed on `status_interfaces.php` #12252
- Fixed: IPv6 gateway for an interface is not shown on `status_interfaces.php` if the interface does not also have an IPv4 gateway #12253
- Fixed: Remove subnet overlap check on LAN interfaces when using 6rd #12371
- Fixed: "6RD Prefix" field does not have input validation #12435
- Fixed: Trying to delete an assigned PPPoE interface fails without printing an error message #12514

L2TP

- Fixed: Kernel panic during L2TP retransmit #9058
- Fixed: FQDN L2TP server address is only resolved at boot #12072

Logging

- Fixed: Logging configuration added by a package is not removed on uninstall #11846
- Fixed: Remote log server input validation allows invalid values #12000
- Added: Disable log compression on new installations when `/var/log` is a ZFS dataset with compression enabled #12011
- Changed: Improve log settings help text for file size, compression, and retention count #12012
- Added: Create a log entry when a configuration change occurs #12118
- Fixed: Rotation settings for individual log files do not take effect after saving #12366

NTPD

- Added: Poll Interval For GPS and PPS #9439
- Added: Support for NTP Peer mode #11496
- Fixed: File overwrite in `services_ntpd_gps.php` via `gpsport` parameter #12191
- Added: Support SHA-256 hash NTP authentication #12213
- Fixed: ZFS installations without an RTC battery boot with clock at BIOS/EFI default value because they do not receive initial clock value from filesystem data #12769

Notifications

- Added: Option to suppress expiration notifications for revoked certificates #12109
- Added: Support for Slack notifications #12291
- Added: Send notification for halt, reboot, and reroot events #12441
- Fixed: `rc.notify_message` only sends notifications via SMTP #12585

OpenVPN

- Added: Support aliases in OpenVPN local/remote/tunnel network fields #2668
- Changed: Set `explicit-exit-notify` option by default for new OpenVPN server instances #11684
- Fixed: OpenVPN client certificate validation with OCSP always fails #11829
- Added: Option to validate OpenVPN peer TLS certificate key usage #11865
- Added: Log external IP address of OpenVPN clients on connect and disconnect #11935
- Fixed: DNS Resolver does not add PTR record for OpenVPN clients #11938
- Fixed: OpenVPN IPv6 tunnel network is not validated properly #11999
- Fixed: OpenVPN RADIUS-based firewall rules use incorrect port ranges #12020
- Fixed: Incorrect OpenVPN Client Export help link #12022
- Fixed: OpenVPN RADIUS-based firewall rules do not use expected value for RADIUS-assigned IP addresses #12076
- Fixed: Prevent using OpenVPN "Exit Notify" option with point-to-point modes #12102
- Fixed: OpenVPN Wizard configuration missing recently added default values #12172
- Fixed: OpenVPN does not clean up previous CA and CRL files #12192
- Changed: Move "Description" option on OpenVPN server and client pages to top of the page, show internal instance ID #12218
- Fixed: Prevent using OpenVPN "Inactive" option with point-to-point modes #12219
- Fixed: Configuration files are not deleted after disabling an OpenVPN instance #12223
- Fixed: OpenVPN page allows to delete/disable instance with an assigned interface #12224
- Fixed: OpenVPN status incorrect for TAP servers without a defined tunnel network #12232
- Fixed: OpenVPN client connect/disconnect scripts are not used in Remote Access (SSL/TLS) mode #12238

- Added: Pop-up window to view firewall rules generated from RADIUS ACL entries on the OpenVPN status page #12321
- Added: Support OpenVPN `client-kill` to terminate remote clients instead of clearing their session #12416
- Fixed: Set OpenVPN Gateway Creation value to "Both" by default for new instances #12448
- Fixed: OpenVPN form validation issues #12677

Operating System

- Changed: Ensure `/usr/local/sbin/` scripts use full path to executable files #11985
- Fixed: Update NGINX to address CVE-2021-23017 #12061
- Added: Suppress kernel messages for `lo0` configuration during boot #12094
- Changed: Convert RAM disks to `tmpfs` #12145
- Changed: Improve uses of `grep` which utilize user-supplied patterns #12265
- Fixed: Update mpd5 to address vulnerabilities in < 5.9_2 #12373
- Fixed: Update python to address vulnerabilities < 3.8.12 #12374
- Fixed: Multiple cURL Vulnerabilities #12434
- Changed: Add note in log settings that disabling logging also disables `sshguard` login protection #12511
- Fixed: Kernel panic in `nd6_dad_timer()` #12548

PHP Interpreter

- Fixed: `diag_dump_states.php` no longer filters by rule ID #12605

PPP Interfaces

- Fixed: PPP interfaces lose the description field in `ifconfig` output when restarted #11959

PPPoE Server

- Added: Option to select PPPoE Server authentication protocol #12438

Package System

- Fixed: Package <`plugins`> and <`tabs`> content missing from configuration in some cases #11290
- Added: Add `librdkafka` package to the pfSense package repository #12290
- Fixed: PHP error on `pkg_mgr_install.php` when multiple instances are running #12713
- Fixed: Potential XSS in `pkg.php` via `pkg_filter` #12725

RRD Graphs

- Added: Graph for hardware temperature readings #9297

Routing

- Fixed: Static routes using aliases are not automatically updated when alias content changes #7547
- Fixed: Input validation does not prevent removing a gateway used by a DNS server #8390
- Fixed: Kernel route table entries are removed if they match disabled static route entries #10706
- Fixed: Modifying static routes results in a logged error, changes are not reflected in routing table #11599
- Added: Require user to manually apply changes after altering static route entries #11895
- Fixed: Route data collection method on `diag_routes.php` has multiple issues #12257

Rules / NAT

- Added: IPv6 support in `easyrule` CLI script #11439
- Fixed: NAT rule overlap detection is inconsistent #11734
- Fixed: Input validation not working for 1:1 NAT entries using an alias as a destination #11923
- Fixed: `easyrule` script does not function properly #12151
- Fixed: IPv6 policy routing does not work if an IPsec tunnel phase 2 remote network is configured for `::/0` #12164
- Fixed: 1:1 NAT rule with internal IP address of "Any" results in an invalid firewall rule #12168
- Fixed: Firewall rule tabs load slowly when many rules on the tab utilize gateways #12174
- Fixed: VIP network addresses are not expanded on Port Forward rules #12233
- Fixed: Duplicating a Port Forward does not copy "Filter Rule Association" values of "None" or "Pass" #12272
- Added: Display default "Reflection Timeout" value on `system_advanced_firewall.php` #12318
- Fixed: NAT rule overlap detection does not check special networks #12361
- Fixed: Input validation prevents creating 1:1 NAT rules on OpenVPN #12408
- Fixed: 1:1 NAT edit page lists incorrect entries in the Destination field #12410
- Added: Icon for traffic direction on floating rules tab #12433
- Fixed: Port forward rules are not created for special networks (pppoe, openvpn) #12452
- Fixed: Automatic outbound NAT for reflection does not support IPv6 #12500
- Fixed: Interface group name starting with a digit creates invalid XML for rule separators #12529
- Added: Change Gateway/Group name in firewall rule list to clickable link to edit page for the entry #12555
- Fixed: Automatic rule tracker IDs incorrect after multiple filter reloads #12588
- Fixed: PHP error when clicking Delete on Outbound NAT with no rules selected #12694

SNMP

- Added: IPv6 support for base system SNMP service #12325

Services

- Fixed: System attempts to stop inactive services at shutdown #12001
- Fixed: System attempts to start inactive services at boot #12038

Traffic Shaper (ALTQ)

- Added: IPv6 support in the Traffic Shaper Wizard #4769
- Fixed: Panic when using CBQ traffic shaping #11470
- Added: Allow Chelsio T6 CXGBE (`cc`) drivers to be used for ALTQ traffic shaping #12499
- Changed: Traffic shaper wizard default bandwidth type should be Mbit/s #12501

Traffic Shaper (Limiters)

- Fixed: Unable to delete limiter referenced in filter rules #12503
- Fixed: Kernel panic when using `fq_pie` limiter scheduler #12622

UPnP/NAT-PMP

- Added: UPnP/NAT-PMP STUN configuration options #10587

Upgrade

- Changed: `pfSense-upgrade` should reinstall all packages on new version upgrades #12235

User Manager / Privileges

- Added: Copy button for group entries in the User Manager #12226

Virtual IP Addresses

- Fixed: Validation when deleting a VIP does not check if the VIP is used by IPsec phase 1 entries #12356
- Fixed: Validation when deleting a VIP does not prevent deleting a CARP VIP used as a parent for an IP Aliases VIP #12362

Wake on LAN

- Added: Wake on LAN button to wake all devices #12480

Web Interface

- Changed: Update font formats to WOFF2 #11507
- Fixed: DHCP Leases page and ARP table page fail to load if DNS is not available #11512
- Fixed: Notifications page cannot be saved without configuring or disabling SMTP #12107
- Changed: Convert help shortcut links to server-side redirects #12314
- Fixed: Help text for RAM disk settings does not mention Captive Portal data #12389
- Fixed: Input validation error can unintentionally result in removal of PPP type interface settings #12498

Wireless

- Fixed: `wpa_supplicant` uses 100% of a CPU core at boot #11453
- Fixed: Interfaces page does not show Wireless EAP client options #12239

XMLRPC

- Fixed: XMLRPC sync results in an error when a failover peer IP address is specified in DHCP server settings for an unconfigured interface #10955
- Added: XMLRPC synchronization for DHCP relay settings #11957
- Changed: XMLRPC client improvements #12051
- Fixed: Changes to an existing IPsec configuration are not applied on HA secondary after XMLRPC sync #12075

3.14 21.05.2 New Features and Changes

This is a maintenance release of pfSense® Plus software. pfSense Plus software version 21.05.2 corrects an issue with the pre-installed Netgate Firmware Upgrade package on Netgate 6100 hardware devices.

In certain circumstances the pre-installed Netgate Firmware Upgrade package could have incorrectly offered to downgrade the firmware when the hardware shipped from the factory with a newer firmware version than the copy contained within the 21.05.1 installation image.

The pfSense Plus software version number was increased for all models of Netgate hardware for consistency, but there are no functional changes for other hardware platforms. Upgrading a device in the field to 21.05.2 is not necessary at this time, but users may do so if they wish.

3.15 21.05.1 New Features and Changes

This is a maintenance release including bug fixes for issues affecting pfSense® Plus software version 21.05.

3.15.1 Security

This release includes corrections for the following vulnerabilities in pfSense software:

- Additional corrections for pfSense-SA-21_02.captiveportal (XSS in Captive Portal client login page, #11843)

3.15.2 General

3.15.3 pfSense Plus

FreeBSD

- Fixed: 32-bit ARM performance regression #12200

Operating System

- Changed: Native hardware package builds for 32-bit ARM #12201

PHP Interpreter

- Changed: Disable PCRE JIT to work around PHP PCRE crashes on multi-core 32-bit ARM systems #12004

Routing

- Fixed: Static routes may not be in routing table when expected #11986

3.16 21.05 New Features and Changes

This is a regularly scheduled software release of pfSense® Plus software including new features, additional hardware support, and bug fixes.

3.16.1 Security

This release includes corrections for the following vulnerabilities in pfSense software:

- pfSense-SA-21_02.captiveportal (XSS in Captive Portal client login page, #11843)

3.16.2 General

- Added: WireGuard add-on package
- Added: OpenVPN client import add-on package
- Fixed: `ix(4)` driver fails to attach if a broken or unsupported SFP module (e.g. incompatible media type) is present at boot time [NG 1586]
- Fixed: IP Address ranges do not work in aliases on 32-bit ARM [NG 5445]

3.16.3 pfSense Plus

Aliases / Tables

- Added: PHP shell playback script to modify Alias contents #11380

Authentication

- Added: Copy button for Authentication Server entries #11390

Backup / Restore

- Added: Randomize time of scheduled AutoConfigBackup runs #10811
- Fixed: Automated corruption recovery from cached `config.xml` backup files should check multiple backups #11748

Captive Portal

- Added: Redirect Captive Portal users to login page after they logout #11264
- Fixed: Captive Portal post-auth redirect is not properly respected #11842
- Fixed: Potential XSS vulnerability in Captive Portal `redirurl` handling #11843

Certificates

- Fixed: Certificate Manager does not report Unbound as using a certificate #11678
- Fixed: PHP error on certificate list due to unreadable private key #11859
- Fixed: Export P12 icon is missing if certificate is not locally renewable #11884

Configuration Upgrade

- Fixed: PHP error in `upgrade_212_to_213()` when upgrading certain IPsec tunnels #11801

Console Menu

- Changed: Allow reroot on ZFS from console and GUI reboot menu entries #11914

DHCP (IPv6)

- Fixed: `dhcp6withoutra_script.sh` does not get executed when advanced options are set #11883

DNS Forwarder

- Fixed: Disable DNSSEC option for dnsmasq #11781
- Fixed: Update dnsmasq to 2.85 to fix CVE-2021-3448 #11866

DNS Resolver

- Fixed: Unbound Python Integration repeatedly mounts `dev` without unmounting #11456
- Fixed: Stale hostname registration data for OpenVPN clients is not deleted from the DNS Resolver configuration at boot #11704
- Changed: Temporarily move back to Unbound 1.12.x due to instability on Unbound 1.13.x #11915

Dashboard

- Fixed: Thermal sensors widget no longer shows values from certain hardware #11787
- Fixed: IPsec Dashboard widget only displays first P2 subnet when using a single traffic selector #11893
- Fixed: Editing widgets on Dashboard causes a PHP Warning #11939

Diagnostics

- Fixed: ARP Table populates hostname values using expired DHCP lease data #11510
- Fixed: Sanitize OpenVPN Client Export certificate password in status output #11767
- Fixed: Sanitize Captive Portal RADIUS MAC secret in status output #11769
- Fixed: MAC address OEM information missing from ARP table #11819

Dynamic DNS

- Added: New Dynamic DNS Provider: Mythic-Beasts #7842
- Added: New Dynamic DNS Provider: one.com #11293
- Added: New Dynamic DNS Provider: Yandex PDD #11294
- Added: New Dynamic DNS Provider: NIC.RU #11358
- Added: New Dynamic DNS Provider: Gandi LiveDNS IPv6 #11420
- Fixed: Automatic 25-day forced Dynamic DNS update removes wildcard domain #11667
- Fixed: Digital Ocean Dynamic DNS help text is incorrect #11754
- Fixed: NoIP.com Dynamic DNS update failure is not detected properly #11815
- Fixed: Dynamic DNS edit page incorrectly hides username field when switching away from Digital Ocean #11840

Gateways

- Added: Input validation to prevent setting a load balancing gateway group as default #11164

Hardware / Drivers

- Changed: Deprecate old cryptographic accelerator hardware which is not viable on modern systems #11426
- Fixed: Using SHA1 or SHA256 with AES-NI may fail if AES-NI attempts to accelerate hashing #11524

IGMP Proxy

- Fixed: IGMP Proxy restarts unnecessarily after IPv6 gateway events #11904

IPsec

- Added: GUI option to set RADIUS Timeout for EAP-RADIUS #11211
- Added: Option to switch IPsec filtering modes to choose between `enc` and `if_ipsec` filtering #11395
- Changed: Move custom IPsec NAT-T port settings to Advanced Options #11518
- Fixed: strongSwan configuration always contains user EAP/PSK values #11564
- Added: IPsec GUI option to control Child SA `start_action` #11576
- Fixed: Error when adding both IPv4 and IPv6 P2 under an IPv4 or IPv6 only IKEv1 P1 #11651
- Fixed: Cannot disable IPsec P1 when related P2s are in VTI mode and enabled #11792
- Fixed: IPsec VTI interface names are not properly formed for more than 32 interfaces #11794
- Fixed: Applying IPsec settings for more than ~30 tunnels times out PHP #11795
- Fixed: `ipsec_vti()` does not skip disabled VTI entries #11832
- Fixed: IPsec GUI allows creating multiple identical Phase 1 entries when using FQDN for remote gateway #11912

IPv6 Router Advertisements (RADVD)

- Added: Use virtual link local IP address as RA source address for HA environments #11103
- Added: Shortcut buttons for service control and logs on RADVD configuration #11911
- Fixed: RADVD breaks on SIGHUP #11913

Interfaces

- Fixed: DHCP interfaces are always treated as having a gateway, even if one is not assigned by the upstream DHCP server #5135
- Fixed: Interfaces page displays MAC Address field for interfaces which do not support L2 #11387
- Fixed: CLI interface configuration without IPv6 leaves RA enabled #11609
- Fixed: Incomplete PPPoE custom reset values lead to invalid cron entry #11698
- Fixed: Error when changing MTU if the interface is used for both IPv4 and IPv6 default routes #11855

L2TP

- Fixed: Unused L2TP VPN files are not removed when the service is disabled #11299
- Added: GUI option to set MTU for L2TP VPN server #11406

NTPD

- Fixed: NTP widget displays incorrect status #11495
- Fixed: NTP authentication input validation rejects valid keys #11850

Notifications

- Fixed: Invalid HTML encoding in modal Notices window #11765

OpenVPN

- Added: Allow the firewall to use DNS servers provided to an OpenVPN client instance #11140
- Fixed: OpenVPN Wizard does not support gateway groups #11141
- Added: Set Explicit Exit Notify to 1 by default for new OpenVPN client instances #11521
- Added: Support for Cisco AVPair `{clientipv6}` template in firewall rules returns by RADIUS #11596
- Fixed: OpenVPN does not clean up parsed `Cisco-AVPair` rules on non-graceful disconnect #11699
- Fixed: OpenVPN does not kill IPv6 client states on disconnect #11700
- Fixed: OpenVPN client starts when CARP VIP is in BACKUP status when bound to Virtual IP aliased to CARP VIP #11793
- Fixed: Certificate validation with OCSP always fails in `openvpn.tls-verify.php` #11830
- Changed: Update OpenVPN to 2.5.2 #11844
- Fixed: OpenVPN client startup error if IPv6 Tunnel Network is defined in TAP mode #11869

Operating System

- Added: Kernel modules for alternate congestion control algorithms #7092
- Added: Kernel module for RTL8153 driver #11125
- Added: Xen console support #11402
- Fixed: Unquoted variable in `dot.tcshrc` can cause proxy password to be printed #11867

Routing

- Fixed: Static route targets may still reachable via default route when the gateway they should route through is down #11296
- Fixed: IPv4 link-local (`169.254.x.x`) gateway does not function #11806

Rules / NAT

- Added: Support for IPv6 firewall entries with dynamic delegated prefix and static host address #6626
- Fixed: Disabling all interfaces associated with a floating rule causes the firewall to generate an incorrect pf rule #11688
- Fixed: Input validation prevents creating 1:1 NAT rules on IPsec #11751
- Fixed: Invalid combinations of TCP flag matching options cause `pfctl` parser error #11762
- Fixed: Error loading rules in certain cases where an interface is temporarily without an address #11861

Traffic Shaper (ALTQ)

- Fixed: Harmless error when enabling traffic shaper #11229
- Fixed: Segmentation fault when loading ALTQ traffic shaping rules using FAIRQ #11550

Traffic Shaper (Limiters)

- Fixed: Unused Limiter entries with schedules create unnecessary cron jobs #11636
- Fixed: Error when setting queue limit on CODELQ limiter #11725

Upgrade

- Fixed: Language presented to user during upgrade is misleading #11897

Web Interface

- Added: Replace HTTP links with HTTPS in the GUI #11228
- Fixed: Ambiguous text in help and input validation error for system domain name #11658
- Fixed: PHP error if `PHP_error.log` file is too large #11685
- Fixed: RAM Disk Settings shows Kernel Memory at `0` Kb and does not allow the user to create RAM disks #11702
- Fixed: HTTP Referer error message text is incorrect #11873
- Fixed: Missing `/0` subnet when cloning repeatable CIDR mask controls #11880

WireGuard

- Fixed: Ignore WireGuard configurations under `<installedpackages></installedpackages>` #11808

Wireless

- Added: GUI options for WPA Enterprise with identity/password #2400

XMLRPC

- Fixed: XMLRPC synchronization restarts all OpenVPN instances on the secondary node when making any change on the primary node #11082
- Fixed: XMLRPC Client does not honor its default timeout value #11718

3.17 21.02.2/2.5.1 New Features and Changes

pfSense® Plus software version 21.02.2 and pfSense CE software version 2.5.1 are maintenance releases to address recently identified issues.

Warning: WireGuard was removed from the base system in releases after pfSense Plus 21.02-p1 and pfSense CE 2.5.0, when it was removed from FreeBSD.

If upgrading from a version that has WireGuard active, the upgrade will abort until all WireGuard tunnels are removed. For more details, see the *Release Notes*

WireGuard is available as an add-on package on pfSense Plus 21.05, pfSense CE 2.5.2, and later versions. The settings for the WireGuard add-on package are not compatible with the older base system configuration.

Note: The WireGuard package is still under active development. Follow the development progress on the developer's YouTube channel

Tip: To remove WireGuard tunnels, navigate to **VPN > WireGuard** and click the delete button for each tunnel. When the page displays **No WireGuard tunnels have been configured.**, the upgrade can proceed.

Note: This pfSense Plus software version contains all of the items noted below for pfSense CE as well.

Tip: For those who have not yet updated to 2.4.5-p1, consult the *previous release notes* and blog posts for those releases to read all important information and warnings before proceeding.

3.17.1 Known Issues / Errata

- There is an issue in this release with port forwarding on pfSense CE software installations with multiple WANs, see #11805 for details.
- There is an issue with AES-NI hash acceleration for SHA1 and SHA-256. If the AES-NI driver detects a system capable of accelerating SHA1 or SHA-256 and the firewall attempts to utilize one of those hashes, the affected operation may fail. This affects IPsec and OpenVPN, among other uses. pfSense Plus users can change to QAT acceleration on supported hardware instead. In cases where QAT is unavailable, change to AES-GCM, change to a different unaccelerated hash (e.g. SHA-512), or disable AES-NI. See #11524 for details.
- There is a similar issue which affects SafeXcel SHA1 and SHA2 hash acceleration on SG-1100 and SG-2100. On that hardware, change to an AEAD cipher such as AES-GCM or switch to an unaccelerated hash. This issue is being tracked internally on NG #6005
- The FRR package on pfSense Plus 21.02 and pfSense CE 2.5.0 and later no longer exchanges routes with BGP peers by default without being explicitly allowed to do so. This is more secure behavior but requires a manual change. To replicate the previous behavior, use **ONE** of the following workarounds:
  - Navigate to **Services > FRR BGP** on the **Advanced** tab and check *Disable eBGP Require Policy*, then **Save**.
  - Instead of disabling the policy check, create route maps which match and allow expected incoming and outgoing routes explicitly. This is the most secure method. See *Peer Filtering* and *BGP Example Configuration* for more information.
  - Manually create a route map to permit all routes (Name: `allow-all`, Action: *Permit*, Sequence: `100`), then set that route map on BGP neighbors for inbound and outbound peer filtering. This can be used as a placeholder for later migration to more secure route map filtering.

3.17.2 Security

This release includes corrections for the following vulnerabilities in pfSense software:

- pfSense-SA-21_01.webgui (XSS in Wake on LAN, #11616)

3.17.3 General

3.17.4 pfSense Plus

Certificates

- Fixed: CA and certificate validity end dates after 2038 are not handled properly on 32-bit ARM #11504

Interfaces

- Added: Interface Status page information for switch uplinks may be replaced by switch port data when media state monitoring is set #10804

Rules / NAT

- Fixed: State matching problem with reponses to packets arriving on non-default WANs #11436

Upgrade

- Fixed: LEDs do not indicate available upgrade status #11689

3.17.5 pfSense CE

Aliases / Tables

- Fixed: Alias name change is not reflected in firewall rules #11568

Authentication

- Fixed: Unreachable LDAP server for SSH auth causes boot process to stop at 'Synchronizing user settings' and no user can login over SSH #11644

Certificates

- Fixed: Invalid certificate data can cause a PHP error #11489
- Fixed: Renewing a self-signed CA or certificate does not update the serial number #11514
- Fixed: Unable to renew a certificate without a SAN #11652
- Fixed: Certificates with escaped x509 characters display the escaped version when renewing #11654
- Fixed: Creating a certificate while creating a user does not fully configure the certificate properly #11705
- Fixed: Renewing a certificate without a `type` value assumes a server certificate #11706

DNS Resolver

- Fixed: DNS Resolver does not add a `local-zone` type for `ip6.arpa` domain override #11403
- Fixed: DNS Resolver does not bind to an interface when it recovers from a down state #11547

Dashboard

- Fixed: CPU details are incorrect in the System Information widget after resetting log files #11428
- Fixed: Disabling 'State Table Size' in the System Information widget prevents other data from being displayed #11443

Gateway Monitoring

- Fixed: Automatic default gateway mode does not select expected entries #11729

Gateways

- Fixed: Gateways with "Use non-local gateway" set are not added to routing table #11433

IPsec

- Fixed: IPsec status incorrect for entries using expanded IKE connection numbers #11435
- Fixed: Distinguished Name (FQDN) IPsec peer identifier type is not formatted properly in `swanctl.conf` secrets #11442
- Fixed: Mobile IPsec DNS server input validation does not reject unsupported IPv4-mapped IPv6 addresses #11446
- Fixed: Broken help link on IPsec Advanced Settings tab #11474
- Fixed: Connect and disconnect buttons on the IPsec status page do not work for all tunnels #11486
- Fixed: IPsec tunnels using expanded IKE connection numbers do not have proper child SA names in `swanctl.conf` #11487
- Fixed: IPsec tunnel definitions have `pools =` entry in `swanctl.conf` with no value #11488
- Fixed: Mobile IPsec broken when using strict certificate revocation list checking #11526
- Fixed: IPsec VTI tunnel between IPv6 peers may not configure correctly #11537
- Fixed: IPsec peer ID of "Any" does not generate a proper remote definition or related secrets #11555
- Fixed: IPsec tunnel does not function when configured on a 6RD interface #11643

IPv6 Router Advertisements (RADVD)

- Fixed: IPv6 RA RDNSS lifetime is too short, not compliant with RFC 8106 #11105

Installer

- Fixed: Installer does not add required module to loader.conf when using ZFS #11483

Interfaces

- Fixed: IPv4 MSS value is incorrectly applied to IPv6 packets #11409
- Fixed: Gateway value for DHCP6 interfaces missing after RA events triggered script without gateway information #11454
- Fixed: Delayed packet transmission in cxgbe driver can lead to latency and reduced performance #11602
- Fixed: DHCP6 interfaces are reconfigured multiple times at boot when more than one interface is set to Track #11633

Logging

- Fixed: Entries from rotated log files may be displayed out of order when log display includes contents from multiple files #11639

Notifications

- Fixed: Telegram and Pushover notification API calls do not respect proxy configuration #11476

OpenVPN

- Fixed: OpenVPN authentication and certificate validation fail due to size of data passed through `fcgicli` #4521
- Added: Display negotiated data encryption algorithm in OpenVPN connection status #7077
- Fixed: OpenVPN does not start with several authentication sources selected #11104
- Fixed: OpenVPN client configuration page displays Shared Key option when set for SSL/TLS #11382
- Fixed: Incorrect order of `route-nopull` option in OpenVPN client-specific override configuration #11448
- Fixed: OpenVPN using the wrong OpenSSL command to list digest algorithms #11500
- Fixed: Selected Data Encryption Algorithms list items reset when an input validation error occurs #11554
- Fixed: OpenVPN does not start with a long list of Data Encryption Algorithms #11559
- Fixed: ACLs generated from RADIUS reply attributes do not parse `{clientip}` macro #11561
- Fixed: ACLs generated from RADIUS reply attributes have incorrect syntax #11569
- Fixed: OpenVPN binds to all interfaces when configured on a 6RD interface #11674

Operating System

- Fixed: Unexpected Operator error on console at boot with ZFS and RAM Disks #11617
- Changed: Upgrade OpenSSL to 1.1.1k #11755

Routing

- Fixed: Disabled static route entries trigger 'route delete' error at boot #3709
- Fixed: Route tables with many entries can lead to PHP errors and timeouts when looking up routes #11475
- Fixed: Error when removing automatic DNS server route #11578
- Fixed: IPv6 routes with a prefix length of 128 result in an invalid route table entry #11594
- Fixed: Error when deleting IPv6 link-local routes #11713

Rules / NAT

- Fixed: Saved state timeout values not loaded into GUI fields on system_advanced_firewall.php #11565
- Fixed: Firewall rule schedule cannot be changed #11747

Upgrade

- Fixed: pfSense Proxy Authentication not working #11383

Wake on LAN

- Fixed: Potential stored XSS vulnerability in services_wol.php #11616

Web Interface

- Fixed: Requests to `ews.netgate.com` do not honor proxy configuration #11464

XMLRPC

- Fixed: XMLRPC error with Captive Portal and CARP failover when GUI is on non-standard port #11425
- Fixed: Incorrect DHCP failover IP address configured on peer after XMLRPC sync #11519
- Fixed: PHP error in logs from XMLRPC if no sections are selected to sync #11638

3.18 2.7.0 New Features and Changes

This pfSense® CE software release includes new features and bug fixes.

3.18.1 Upgrade Notes

Warning: Due to major changes in PHP and base OS versions, there is a higher than usual chance that packages will interfere with the upgrade process.

To give an upgrade the best possible chance of going smoothly, uninstall **all** packages before starting the upgrade.

3.18.2 General

- PHP has been upgraded from 7.4.x to 8.2.6
- The base operating system has been upgraded to FreeBSD 14-CURRENT

Warning: As a part of the FreeBSD upgrade this version removes several deprecated IPsec algorithms:

- 3DES Encryption
- Blowfish Encryption
- CAST 128 Encryption
- MD5 HMAC Authentication

The best practice is to reconfigure tunnels using better encryption and test them before performing an upgrade to ensure a smoother transition.

On upgrade, IPsec tunnels will be adjusted to remove any deprecated algorithms from their configuration. The upgrade process will disable tunnels if they have no valid encryption or authentication options remaining. The upgrade process will notify the user of any changes it makes.

This change only affects IPsec and not other uses of these algorithms. For example, BGP can still use TCP-MD5 authentication.

- Added support for ChaCha20-Poly1305 encryption with IPsec
- Captive Portal has been migrated from IPFW to PF
- A long-standing difficult-to-reproduce crash in Unbound during reloading has been addressed. Christian McDonald tracked down the source of the Unbound SIGHUP crashes to a reference counting bug within the MaxMindDB Python module. Both a patch to MaxMind and a port revision to FreeBSD ports were submitted and accepted, and the fix is included in the 2.7.0 release. It is now safe again to enable DHCP registration alongside Unbound Python mode in pfBlockerNG.
- In addition to the Unbound crash, Christian also identified a memory leak with DHCP registration and Unbound Python mode (#10624). This is largely mitigated by updates to Python and related libraries, but there is additional ongoing work to resolve it further for future release.
- Fix for UPnP and multiple game systems
- New gateway state killing options for smoother failover
- Firewall/NAT rule usability improvements such as buttons to toggle multiple rules and copy rules to other interfaces
- OpenVPN upgraded to 2.6.4
- OpenVPN Shared Key Tunnels Deprecated – They still work, but will trigger warnings in the logs and GUI.
- New Packet Capture GUI

- UDP Broadcast Relay Package

Danger: This version includes newer ZFS features which may not be compatible with older boot loaders. These features **are not** enabled by default when upgrading to avoid potential problems with older boot loaders. Some ZFS commands run at the CLI, such as `zpool status`, may report that a pool can be upgraded, but doing so may also require manually updating the boot loader for the device to boot properly. Upgrading the ZFS pool **is not** necessary at this time. As such, the best practice is to leave it as-is. This will be handled automatically as needed in future updates.

Reinstalling the OS from current installation media will result in having the most recent boot loader and ZFS feature set.

3.18.3 Security

pfSense CE 2.7.0-RELEASE includes fixes for the following potential vulnerabilities:

- pfSense-SA-22_05.webgui: A potential XSS vulnerability in firewall_aliases.php from URL table alias URLs.
- pfSense-SA-23_01.webgui: A potential XSS vulnerability in diag_edit.php from browsing directories containing specially crafted filenames on the filesystem.
- pfSense-SA-23_02.webgui: A potential XSS vulnerability in system_camanager.php and system_certmanager.php from specially crafted descriptions when editing entries.
- pfSense-SA-23_03.webgui: A potential authenticated arbitrary file creation vulnerability from the name parameter when creating or editing URL table aliases.
- pfSense-SA-23_04.webgui: A potential authenticated arbitrary command execution vulnerability in status.php from specially crafted filenames on the filesystem.
- pfSense-SA-23_05.sshguard: Anti-brute force protection bypass for GUI authentication requests containing certain proxy headers.
- pfSense-SA-23_06.webgui A potential Authenticated Command Execution vulnerability from the `bridgeif` parameter on `interfaces_bridge_edit.php` in the GUI.

3.18.4 pfSense CE

Changes in this version of pfSense CE software.

Aliases / Tables

- Fixed: Alias content is sometimes incomplete when an alias contains both FQDN and IP address entries #9296
- Fixed: Alias with non-resolving FQDN entry breaks underlying PF table #12708
- Fixed: Renaming an alias does not update the alias names in static routes and OpenVPN instances #12727
- Added: Retain descriptions when exporting and importing aliases #12842
- Fixed: Potential XSS from URL and URL Table alias URLs #13060
- Fixed: Alias content is sometimes incomplete if the firewall cannot resolve an FQDN in the alias #13282
- Added: Specify CA trust store location when downloading and validating URL alias content #13367
- Fixed: Invalid alias name can still be used by code attempting to validate URL table content #13425

- Fixed: Deleting an alias marks the subsystem as unclean but also unconditionally reloads the filter configuration #13538
- Fixed: Missing descriptions for referrers to firewall aliases cause empty strings for references to be returned when deleting an in-use alias #13539
- Fixed: Using PF reserved keywords for interface descriptions results in an invalid ruleset #14007
- Fixed: Alias list is not sorted #14015

Authentication

- Fixed: User password hashes pseudo-random number generator may return insecure salt value #12801
- Added: GUI option to select the user password hashing algorithm #12855
- Fixed: LDAP setup does not display 'Global Root CA List' option unless another CA also exists #13185
- Fixed: Unable to set web interface session timeout to `0` (i.e. never expire) #13561
- Fixed: Extra remote address information can confuse `sshguard` #13574
- Changed: Improve LDAP debugging #13718
- Added: Option to enable/disable console bell, enabled by default #14002

Auto Configuration Backup

- Added: Option to list AutoConfigBackup entries in "reverse" order (newest at top) #11266
- Added: Support for international characters in the AutoConfigBackup Hint/Identifier field #13388
- Fixed: Auto Config Backup prints a confusing decryption error when using the wrong key #14060

Backup / Restore

- Changed: Comply with current iteration standards when encrypting and decrypting configuration files #12556
- Added: Support encrypted `config.xml` files when restoring via ECL #12685
- Added: Notify user if AutoConfigBackup is unable to successfully upload a backup #12724
- Added: Ability to sort AutoConfigBackup entries #12773
- Fixed: Sanitize SHA-512 user password hashes in `status.php` output #12810
- Added: Option to restore dashboard widget layout #13125
- Fixed: PHP error restoring DHCP lease data on fresh installation: #13157
- Fixed: Attempting to restore a 0 byte `config.xml` prints an error that the file cannot be read #13289
- Fixed: Configuration history restores revision no matter which option is clicked in confirmation dialog #13861
- Fixed: RRD restore process does not sanitize filenames from backup XML #13935

Build / Release

- Changed: Disable `pkg` compatibility flag which creates `txz` file extension symbolic links #12782

CARP

- Fixed: CARP VIPs can become master too early at boot time #2218
- Changed: Reorganize CARP status page #12701
- Fixed: CARP event storm when leaving persistent CARP maintenance mode #12961

Captive Portal

- Fixed: Allowed IP/Hostname "Direction" option is never used #12649
- Fixed: `nginx` logs an error that the port is already in use when restarting Captive Portal services #12651
- Fixed: Value of `net.inet.ip.dummynet.*` OIDs in `sysctl` are ignored #12733
- Fixed: Only TCP traffic is passed outbound through IPFW #12834
- Changed: Transition Captive Portal from IPFW to PF #13100
- Fixed: Voucher CSV output has leading space before voucher code #13272
- Fixed: Captive Portal breaks policy based routing for MAC address bypass clients #13323
- Fixed: Multiple Captive Portal interfaces do not properly form the list of portal IP addresses #13391
- Fixed: Custom logo or background image is created with two dots (`..`) before the file extension #13396
- Fixed: Captive Portal does not keep track of client data usage #13418
- Fixed: All Captive Portal users are given the same limiter pipe pair #13488
- Fixed: Captive Portal RADIUS start/stop accounting does not reset counters at each accounting start #13838
- Fixed: Captive Portal does not apply RADIUS bandwidth limits to user pipes #13853

Certificates

- Fixed: CA path is not defined when using `curl` in the shell #12737
- Added: Option to retain the existing serial number when renewing a CA or certificate #13010
- Fixed: Exporting a PKCS#12 file from the certificate manager does not use the intended encryption algorithm #13257
- Fixed: Input validation is not rejecting invalid description characters when editing a CA or Certificate #13387
- Fixed: CRL expiration date with default lifetime is too long, goes past UTCTime limit #13424
- Fixed: ECDSA certificate renewal causes digest algorithm to be reset to SHA1 #13437
- Fixed: Some blank SAN fields are not ignored when creating a certificate #14124
- Added: Ability to edit Certificate Revocation List properties #14185
- Changed: Add note to inform the user that the "Next Certificate Serial" value is ignored when the "Randomize Serial" option is enabled #14188

Configuration Backend

- Added: Move command line history to a GUI option stored in `config.xml` rather than a manual flag file #12675
- Added: Eliminate duplicate shell commands from history file #12741
- Fixed: Input validation is checking RAM disk sizes when they are inactive #13479

Configuration Upgrade

- Added: Playback script to perform a configuration upgrade on an arbitrary `config.xml` file #12973
- Fixed: PHP Error in `upgrade216_ipsec_create_vtimap()` #14400

Console Menu

- Fixed: Changing an interface IP address and gateway at the console does not save the new gateway if one already exists for the interface #12632
- Added: Warn the user if they attempt to disable SSH from the menu while connected through SSH #13103
- Fixed: Hidden menu option `100` incorrectly handles HTTPS detection #13258

DHCP (IPv4)

- Added: Improve distinction between online and idle/offline entries in DHCP lease list #10345
- Fixed: Disabling DHCP Server RRD statistics does not work #12710
- Fixed: `HTTPClient` option not sent when using UEFI HTTP Boot #12892
- Fixed: `HTTPClient` option does not work for static mappings #12896
- Fixed: DHCP "Ignore denied clients" option with MAC Deny list set causes DHCP server to not start #12923
- Added: Relax DHCP maximum lease time input validation #13118
- Fixed: DHCP lease list displays wrong interface name in the "Leases in Use" summary if DHCP settings for a disabled interface remain in the configuration #13127
- Changed: Clean up DHCP Server option language #13250
- Fixed: DHCP Server generates an invalid configuration for static mappings when defining network booting and UEFI HTTPBoot URL #13573
- Added: Input validation for numbered DHCP options in static mappings #13584
- Fixed: DHCP Server page does not properly select a default interface tab if neither WAN nor LAN are capable of being DHCP servers #14115

DHCP (IPv6)

- Fixed: Multiple DHCP6 WAN connections leads to multiple dhcp6c clients #6880
- Fixed: DHCPv6 server does not skip interfaces configured with invalid ranges #12527
- Fixed: RADVD can be started on both HA nodes when configured with an IPv6 link-local address #12582
- Fixed: Uninitialized array in `array_remove_duplicates()` #12749
- Fixed: Advanced DHCP6 client settings only work for a single interface #13462
- Fixed: "Provide DNS servers to DHCPv6 clients" setting does not reflect a changed value until the page is reloaded #13594
- Fixed: DHCPv6 rules are not created for interfaces with static IPv6 #13633

DNS Forwarder

- Fixed: DNS Forwarder refuses valid retries from clients in certain cases #12901
- Fixed: DNS Forwarder creates a loop when "Use local DNS, ignore remote DNS servers" is selected #12902
- Fixed: DNS Forwarder custom options may fail after save/restore when options are only separated by newline #13105
- Fixed: DNS Forwarder (`dnsmasq`) is using an invalid combination of options when "Query DNS servers sequentially" is enabled #13655

DNS Resolver

- Fixed: Memory leak in Unbound with Python module and DHCP lease registration active #10624
- Fixed: Unbound crashes with signal 11 when reloading #11316
- Fixed: DNS Resolver is restarted during every `rc.newwanip` event even for interfaces not used in the resolver #12612
- Fixed: DNS Resolver does not restart during link up/down events on a static IP address interface #12613
- Added: Automatically create DNS Resolver ACLs for OpenVPN CSO entries #12636
- Fixed: DNS Resolver help text for **System Domain Local Zone Type** option refers users to `unbound.conf(5)` man page instead of pfSense docs #12781
- Fixed: DNS Resolver updates trust anchor at boot even with DNSSEC disabled which can lead to a startup delay of ~2 minutes if the firewall does not have Internet access #12985
- Fixed: DNS Resolver ACLs are not updated when OpenVPN networks change #12991
- Added: DNS Resolver option to keep probing when servers are down #13023
- Fixed: DNS resolver does not update its configuration or reload during link down events #13254
- Fixed: DNS Resolver responds with unexpected source address when the DNS over TLS server function is enabled #13393
- Fixed: Incorrect word in "Network Interfaces" help text on `services_unbound.php` #13453
- Fixed: DNS Resolver does not generate automatic ACLs for IPv6 when Network Interfaces is set to "All" #13851
- Changed: Update Unbound to use Python 3.11 instead of Python 3.9 #13867
- Changed: Update Unbound to 1.17.1 #13893

- Fixed: DNS Resolver experiences intermittent resolution failures with SSL over TLS due to ASLR #14056
- Fixed: Setting system DNS servers can incorrectly modify routes for interface addresses #14288
- Fixed: Discrepancy in "TTL for Host Cache Entries" Description #14358

Dashboard

- Fixed: Firewall log widget action icon features stop working when new log entries are added dynamically #6253
- Added: Show `Inactive` for Hardware Crypto output instead of empty field on System Information dashboard widget when nothing can be accelerated #12714
- Fixed: Uptime displays plural seconds for multiple minutes in the System Information Dashboard widget #14176
- Added: Support for Intel PCH temperature values in thermal sensors #14255

Diagnostics

- Fixed: `diag_pftop.php` does not fully encode output #12915
- Fixed: File browser on `diag_edit.php` does not encode filenames before display #13262
- Fixed: Neighbor hostnames in the NDP Table on `diag_ndp.php` are always empty #13318
- Fixed: `status.php` uses <name> component of `/tmp/rules.packages.`<name> filenames in shell command without encoding #13426
- Changed: Add multicast group membership (`ifmcstat`) to `status.php` #13731
- Changed: Add more disk information to status output #14103

Dynamic DNS

- Fixed: Dynamic DNS custom IPv6 service fails on 6rd tunnels #12590
- Fixed: GleSYS Dynamic DNS responses are not parsed properly #12672
- Added: IPv6 support for DNSimple Dynamic DNS #12744
- Fixed: Input validation prevents configuring wildcard Dynamic DNS records on GoDaddy #12750
- Added: Support wildcard Dynamic DNS records on DigitalOcean #12752
- Fixed: Google Domains Dynamic DNS responses are not parsed properly #12754
- Fixed: Input validation prevents configuring wildcard Dynamic DNS records on Google Domains #12761
- Fixed: Namecheap Dynamic DNS responses are not parsed properly #12816
- Fixed: Clicking Save & Force Update on a Dynamic DNS entry results in a GUI timeout #12870
- Fixed: DigitalOcean Dynamic DNS update fails with a "bad request" error #13167
- Fixed: Dynv6 Dynamic DNS client does not check the response code when updating #13298
- Fixed: DNSExit Dynamic DNS updates no longer work #13303
- Changed: Improve DynDNS help text readability #14186

FilterDNS

- Fixed: Resolve interval for `filterdns` may not match the configured value #13067

FreeBSD

- Fixed: Cannot set EFI console as primary console when using both EFI and Serial #13080
- Fixed: CVE-2022-23093 / FreeBSD-SA-22:15.ping #13716
- Changed: Update Time Zone data to 2023c or later #14209

Gateway Monitoring

- Fixed: Gateway monitoring should mark gateway as "offline" on PPPoE parent interface disconnect #12633
- Added: Option to disable auto-addition of static routes for `dpinger` #12687
- Changed: Update `dpinger` to 3.2 #12881
- Fixed: Marking a gateway as down does not affect IPsec entries using gateway groups #13076
- Fixed: Incorrect function parameters for `get_dpinger_status()` call in `gwlb.inc` #13295

Gateways

- Fixed: `fixup_default_gateway()` should not remove a default gateway managed by a dynamic routing daemon #11692
- Fixed: IPv6 link local gateway default status not indicated in GUI #11764
- Fixed: IPv6 gateway group using link local addresses incorrectly logs a gateway change because it not including interface scope properly #12721
- Added: Retain knowledge of previous dynamic gateway IP address when interface is down #12931
- Fixed: Recovering interface gateway may not be added back into gateway groups and rules when expected #13228
- Fixed: Gateway popup in firewall rule list does not indicate current gateway status #14327

Hardware / Drivers

- Added: Chelsio TOE support using the `t4_tom` module #9091
- Fixed: Intel e1000 driver (`em`, `igb`) cannot pass packets tagged with VLAN `0` #12821
- Fixed: Hyper-V RSC support in `hn(4)` driver is enabled by default and results in very low throughput #12873
- Fixed: Malicious Driver Detection event on `ixl(4)` driver #13003
- Fixed: UDP checksum errors with `ixgbe` interfaces #13883

High Availability

- Added: Use consistent pf host ID and add GUI option to set a custom host ID in state synchronization settings #12702

IGMP Proxy

- Fixed: IGMP Proxy server is restarted during every `rc.newwanip` event #12609

IPsec

- Added: Option to choose default tab in IPsec status Dashboard widget #2456
- Fixed: IPsec VTI phase 2 traffic selectors default to address when defined as a network #11226
- Fixed: `filterdns` does not monitor remote IPsec gateways for IPv6 address changes #12645
- Fixed: Disallow remote gateway of `0.0.0.0` for VTI mode #12723
- Fixed: VTI gateway status stuck as "pending" after reboot #12763
- Fixed: ESP description in IPsec phase 2 proposal help text is ambiguous #12953
- Fixed: IKEv2 Mobile IPsec clients do not receive `INTERNAL_DNS_DOMAIN` (value `25`) attribute #12975
- Fixed: Deadlock in Charon VICI interface #13014
- Added: GUI option for IPsec `dns-interval` setting #13057
- Fixed: Delete function for IPsec SAD entries on `status_ipsec_sad.php` does not work #13071
- Fixed: Mobile IPsec clients cannot be manually disconnected from IPsec status screen #13131
- Fixed: IPsec rejects certificates if any SAN is wildcard rather than rejecting when **all** SANs are wildcard #13373
- Changed: Information box on `status_ipsec.php` says "IPsec not enabled" even when a tunnel is established #13398
- Fixed: Incorrect quoting of Split DNS attribute value in `strongswan.conf` #13579
- Added: Support for ChaCha20-Poly1305 encryption with IPsec #13647
- Changed: Remove deprecated IPsec algorithms (3DES, Blowfish, and CAST 128 encryption; MD5 HMAC/Hashing) #13648
- Fixed: Reassembled packets received on a VTI are not forwarded #14396

Installer

- Fixed: Support encrypted `config.xml` files when restoring during install #12691
- Added: Recover existing SSH keys during installation #12809

Interfaces

- Added: Show SFP module details on `status_interfaces.php` #8861
- Added: Improved support for USB interfaces that may not always be present #9393
- Fixed: Primary interface address is not always used when VIPs are present #11545
- Fixed: PPPoE WAN IP address different than expected when set static by ISP #11629
- Added: Support for VLAN `0` #12070
- Fixed: `devd` is not configured to act on USB interface attach/detach events #12606
- Changed: Restart services on interface changes #12619
- Fixed: Interface status "Total Interrupts" display is non-functional #12735
- Fixed: L2TP/PPTP interface assignment page loses some values after input validation error #12780
- Fixed: Link-Local IPv6 address on WAN with MAC spoofing changes if there is an IP Alias on WAN #12790
- Fixed: Link-local address does not reset after removing MAC address spoofing #12794
- Fixed: Disabled Captive Portal configuration prevents adding an interface to a bridge #12866
- Fixed: The ruleset is not regenerated after assigning an interface #12949
- Fixed: Bridges with QinQ interfaces not properly set up at boot #13225
- Changed: Start `rtsold` immediately after `dhcp6c` sends a request #13492
- Fixed: Several advanced DHCP6 client options do not inform the user when rejecting invalid input #13493
- Changed: Clean up obsolete code in `pfSense-dhclient-script` #13501
- Fixed: DHCP client can fail permanently if an interface is down at boot #13671
- Fixed: Code that sets IPv6 MTU can unintentionally act on IPv4 addresses #13675
- Changed: Trim blank characters from static IP address fields on the Interface configuration page #13959
- Fixed: Bridge interface is not properly validated when submitted on `interfaces_bridge_edit.php` #14052

L2TP

- Fixed: L2TP MPD configuration is not updated when a dynamic WAN IP address changes #13066
- Fixed: L2TP stays bound to previous IP address after static IP address change #13082
- Fixed: Static routes to destinations at L2TP clients are not re-added after a client reconnects #13099

LAGG Interfaces

- Added: GUI option to configure layers for LACP hash #12819

Logging

- Added: Option to control log level of authentication messages in system logs (“Emergency” vs “Notice” level) #12464

Notifications

- Fixed: Slack notification options only allow - as a special character in channel names #13083
- Fixed: Identical SMTP notifications repeat in an infinite loop under certain conditions #14031
- Fixed: Notices incorrectly set system LEDs on hardware with less than three LEDs #14482

OpenVPN

- Fixed: OpenVPN IPv4 Tunnel Network incorrectly allows hostnames #11416
- Fixed: OpenVPN stays bound to previous IP address after interface changes #11864
- Added: OpenVPN option to limit concurrent connections per user #12267
- Fixed: OpenVPN does not clear old Cisco-AVPair anchor rules in some cases #12332
- Added: Use deferred client connections in OpenVPN #12407
- Fixed: OpenVPN re-synchronization also synchronizes override entries unnecessarily in some cases #12628
- Fixed: Automatic filter reload with OpenVPN client gateway uplink happens too soon or not at all #12771
- Fixed: PHP error when terminating OpenVPN sessions via the dashboard widget #12817
- Fixed: OpenVPN status display for TAP mode services shows peer-to-peer instead of client list in certain cases #12884
- Fixed: GUI does not reject an invalid OpenVPN tap mode configuration with an empty tunnel network “Bridge DHCP” disabled #12887
- Fixed: FQDN in network alias is omitted from OpenVPN networks list #12925
- Changed: Warn about OpenVPN shared key deprecation #12981
- Fixed: OpenVPN `remote_cert_tls` option does not behave correctly when enabled and later disabled #13056
- Fixed: Gateway events for IPv6 affect IPv4 OpenVPN instances and vice versa #13061
- Fixed: OpenVPN Client Overrides: properly hide/show form fields #13088
- Fixed: OpenVPN client `tls-client/client` configuration directive not handled properly #13116
- Changed: OpenVPN status page improvements #13129
- Fixed: OpenVPN `client-connect` file contains `topology` #13133
- Fixed: Per-user `route` files are not removed from `/tmp` when they are no longer needed #13145
- Fixed: OpenVPN status for multi-user VPN shows info icon to display RADIUS rules when there are none to display #13243
- Fixed: OpenVPN override IPv4 tunnel network field changing value improperly #13274
- Changed: Update OpenVPN Wizard to match current certificate and OpenVPN options #14183
- Changed: Remove deprecated NCP enable/disable toggle from OpenVPN #14201

Operating System

- Fixed: pf `hostid` value is handled inconsistently #12703
- Fixed: Some `sysctl` OIDs in `loader.conf.local` are silently removed #12862
- Fixed: Output from `pfctl -vvsr` does not include `ridentifier` value in the expected location #12868
- Changed: Update memory graphs to account for changes in memory reporting #14011
- Fixed: Netlink debug messages from IPsec #14370
- Added: wpa_supplicant: add VLAN 0 support #14457

PHP Interpreter

- Added: Upgrade PHP from 7.4 to 8.1 #13446
- Fixed: `fcgicli` fails to write packets with `nvpair` values that exceed `128` bytes #13638
- Changed: Update PHP to 8.2.6 #14027

PPP Interfaces

- Fixed: Services are not restarted when PPP interfaces connect #12811
- Fixed: PPPoE WANs fail to reconnect after parameter negotiation failure #13092
- Fixed: PPP interface custom reset date/time Hour and Minute fields do not properly handle `0` value #13307
- Fixed: IPv6 does not work on secondary PPPoE WAN #13939

PPPoE Server

- Fixed: PPPoE server panics with multiple client connections #13210

Package System

- Fixed: Packages are not automatically reinstalled when restoring configuration using the installer #12105
- Fixed: Packages with custom `internal_name` values do not reinstall properly when restoring a backup #12766
- Fixed: `write_rcfile()` does not create `rc_restart()` entry #13004
- Added: Package plugin hook for web server configuration stanzas #13054

Packet Capture

- Added: Button to clear previous packet capture data #12968
- Added: Packet Capture GUI with granular control #13382

Routing

- Added: Enable `ROUTE_MPATH` multipath routing #9544
- Fixed: Setting a default gateway of "None" does not remove the default gateway from the routing table #12536
- Fixed: Cannot remove IPv6 static routes #12728
- Fixed: Explicit PPPoE disconnect of a WAN Gateway Group member may not restore a default route #13048

Rules / NAT

- Added: Toggle button to disable/enable multiple firewall rules #2505
- Added: Port forward NAT rules with "any" protocol #4259
- Added: Allow NPt to use dynamic IPv6 networks #4881
- Added: Button to copy rules from one interface to another #8365
- Fixed: Rule separator positions change when deleting multiple rules #9887
- Fixed: Automatic Outbound NAT mode can create incorrect rules in some cases #11984
- Added: Utilize new `pfctl` abilities to kill states #12092
- Fixed: NAT reflection does not work for IPv6 port forwarding rules when configured for NAT+Proxy mode #12319
- Added: Allow the selection of "any" interface in floating rules #12392
- Fixed: Applying firewall rule changes does not clear dirty flag for aliases subsystem #12678
- Fixed: Automatic Outbound NAT rules do not include OpenVPN CSO entries #12792
- Fixed: Error loading ruleset due to illegal TOS value #12803
- Fixed: High latency and packet loss during a filter reload #12827
- Fixed: On startup "No routing address with matching address" might appear #12847
- Added: Toggle button to disable/enable multiple entries on NAT pages #12879
- Fixed: Delete button is always active for NAT rules, even if no rules are selected #12957
- Fixed: NAT Reflection generates duplicate rules when internal interface contains multiple VIPs in the same subnet #13012
- Fixed: NAT generates duplicate `no nat on` rules for port forwards with a destination of `Any` #13015
- Fixed: Input validation requires a gateway for floating `match out` rules #13027
- Fixed: Empty `negate_networks` table breaks policy routing rules #13049
- Fixed: The `negate_networks` table is not updated when an OpenVPN server is deleted #13055
- Added: Allow auto prefix with manual prefix-length in NPt #13070
- Fixed: Info icon on `firewall_nat_out.php` is incorrectly placed in manual outbound NAT mode #13164
- Fixed: Changing the redirect target for a Port Forward with an associated filter creates an incorrect firewall rule #13171
- Fixed: Incorrect usage of DSCP hex value #13178
- Fixed: TCP traffic sourced from the firewall can only use the default gateway #13420
- Fixed: `easyrule` CLI script has multiple bugs and undesirable behaviors #13445

- Changed: Correct DHCP client rule descriptions in the generated firewall ruleset #13505
- Fixed: Toggling NAT rules using the button method does not enable/disable corresponding firewall rules #13545
- Fixed: The "Kill States" button does not work consistently #14091
- Changed: Match upstream changes in PF syntax to disable fragment disassembly #14098
- Fixed: Associated firewall rule for NAT port forward does not inherit `nosync` property, gets synchronized #14335
- Fixed: Default tab on `firewall_rules.php` is not selected if the configuration has no WAN interface #14345
- Fixed: Outbound NAT rule input validation error when attempting to manually specify "Other Subnet" with a valid address #14354
- Fixed: Enable IPv6 over IPv4 tunneling option results in invalid PF rule #14415

SNMP

- Fixed: SNMP daemon is restarted during every `rc.newwanip` event #12611

Services

- Fixed: NTP service is not listed on `status_services.php` unless `config.xml` contains NTP configuration data #12775

Setup Wizard

- Changed: Update firewall host and domain fields in the Setup Wizard to match the description and warning text from `system.php` #14250

System Logs

- Fixed: Firewall log parser does not handle SCTP log entries #13940

Traffic Shaper (ALTQ)

- Changed: Remove code references to unused `reset` parameter from traffic shaper pages #13042
- Added: ALTQ GUI support for Broadcom Netextreme II (`bxe`) interfaces #13304
- Added: Include `ixv` in ALTQ capable NIC list #14408

Traffic Shaper (Limiters)

- Fixed: Incorrect ICMP reply when using limiters #9263
- Fixed: Pie and `fq_pie` are missing options and do not handle floating point number input correctly #12003
- Fixed: Utilize `dnctl(8)` to apply limiter changes without a filter reload #12579
- Fixed: Traffic routed through DUMMYNET by PF fails when IPFW is enabled #12954
- Fixed: Traffic shaped by limiters is dropped when routed to a GIF gateway #14055

Traffic Shaper Wizards

- Fixed: Traffic Shaper wizard can produce an invalid ruleset when configured with an IPv4 upstream SIP server #12937

Translations

- Fixed: Polish translation contains an invalid `sprintf()` format in the text for `firewall_nat_out_edit.php` #13946

UPnP/NAT-PMP

- Fixed: UPnP/NAT-PMP status page does not display all port mappings #4500
- Added: uPnP fails to properly give out subsequent reservations when multiple gaming systems are playing the same game/using the same port #7727
- Changed: Reorganize UPnP options #12624
- Changed: Update miniupnpd to 2.3.3 #14307

Unknown

- Fixed: Many `exec()` functions do not use full path to executable files #11941
- Fixed: URL scheme is not properly validated in some cases #14356

Upgrade

- Fixed: Upgrade does not work when using only IPv6 DNS servers #13162
- Fixed: `pfSense-boot` can fail to copy the EFI bootloader #14045

User Manager / Privileges

- Added: Support for RADIUS authentication over IPv6 #4154
- Fixed: Icon missing for user manager entries with a scope other than "user" #13174

Virtual IP Addresses

- Fixed: Firewall rules are not reloaded when removing a VIP, outdated rules/entries remain active #13908

Web Interface

- Fixed: Unnecessary link tag in login page #7996
- Fixed: "Dark" theme does not sufficiently distinguish between selected and deselected elements in option lists #11730
- Fixed: Lack of DNS or Internet connectivity causes GUI to be slow #12141
- Changed: GUI pages should use `POST` for AJAX calls, not `GET` #12431
- Fixed: Zero-value prefix IPv6 addresses are mishandled #12440
- Added: Option to filter state table contents by rule ID #12616
- Fixed: Changing RAM disk size does not prompt to reboot #12876
- Fixed: VGA install defaults to serial as primary console when loading/saving admin GUI settings without making changes #12960
- Fixed: Input validation for IPv6 addresses allows invalid address compression in some cases #13069
- Added: Trim whitespace from MAC addresses in user input #13109
- Changed: Spelling and typo corrections #13357
- Fixed: "Dark" theme uses the same colors for disabled and enabled input fields #13390
- Fixed: Input validation on `system_advanced_firewall.inc` uses incorrect variable references for some fields #13436
- Changed: Update external HTTPS/HTTP links #13440
- Fixed: Table row selection has poor contrast in Dark theme #13448
- Added: Support for `iwlwifi` wireless interfaces #14050

Wireless

- Fixed: Wireless interface WPA configuration fields are always visible #12998
- Fixed: Duplicate wireless interfaces are created at boot #12999

XMLRPC

- Fixed: Deleting a user on the primary node does not delete its home directory on secondary node during XMLRPC sync #12940
- Fixed: Filter/NAT rules configured with "No XMLRPC Sync" enabled are still synchronized #14316

3.19 2.5.2 New Features and Changes

This is a regularly scheduled software release including new features and bug fixes.

3.19.1 Known Issues / Errata

- Dynamic DNS incorrectly encodes NoIP update credentials #12021

3.19.2 Security

This release includes corrections for the following vulnerabilities in pfSense® software:

- pfSense-SA-21_02.captiveportal (XSS in Captive Portal client login page, #11843)

3.19.3 General

- Added: WireGuard add-on package

3.19.4 pfSense CE

Aliases / Tables

- Added: PHP shell playback script to modify Alias contents #11380

Authentication

- Added: Copy button for Authentication Server entries #11390

Backup / Restore

- Added: Randomize time of scheduled AutoConfigBackup runs #10811
- Fixed: Automated corruption recovery from cached `config.xml` backup files should check multiple backups #11748
- Fixed: AutoConfigBackup schedule custom hour value lost on page load #11946

Captive Portal

- Added: Redirect Captive Portal users to login page after they logout #11264
- Fixed: Captive Portal post-auth redirect is not properly respected #11842
- Fixed: Potential XSS vulnerability in Captive Portal `redirurl` handling #11843

Certificates

- Fixed: Certificate Manager does not report Unbound as using a certificate #11678
- Fixed: PHP error on certificate list due to unreadable private key #11859
- Fixed: Export P12 icon is missing if certificate is not locally renewable #11884

Configuration Upgrade

- Fixed: PHP error in `upgrade_212_to_213()` when upgrading certain IPsec tunnels #11801

Console Menu

- Changed: Allow reroot on ZFS from console and GUI reboot menu entries #11914

DHCP (IPv6)

- Fixed: `dhcp6withoutra_script.sh` does not get executed when advanced options are set #11883

DNS Forwarder

- Fixed: Disable DNSSEC option for dnsmasq #11781
- Fixed: Update dnsmasq to 2.85 to fix CVE-2021-3448 #11866

DNS Resolver

- Fixed: Unbound Python Integration repeatedly mounts `dev` without unmounting #11456
- Fixed: Stale hostname registration data for OpenVPN clients is not deleted from the DNS Resolver configuration at boot #11704
- Changed: Temporarily move back to Unbound 1.12.x due to instability on Unbound 1.13.x #11915

Dashboard

- Fixed: Thermal sensors widget no longer shows values from certain hardware #11787
- Fixed: IPsec Dashboard widget only displays first P2 subnet when using a single traffic selector #11893
- Fixed: Editing widgets on Dashboard causes a PHP Warning #11939

Diagnostics

- Fixed: ARP Table populates hostname values using expired DHCP lease data #11510
- Fixed: Sanitize OpenVPN Client Export certificate password in status output #11767
- Fixed: Sanitize Captive Portal RADIUS MAC secret in status output #11769
- Fixed: MAC address OEM information missing from ARP table #11819
- Fixed: State table content on `diag_dump_states.php` does not sort properly #11852

Dynamic DNS

- Added: New Dynamic DNS Provider: Mythic-Beasts #7842
- Added: New Dynamic DNS Provider: one.com #11293
- Added: New Dynamic DNS Provider: Yandex PDD #11294
- Added: New Dynamic DNS Provider: NIC.RU #11358
- Added: New Dynamic DNS Provider: Gandi LiveDNS IPv6 #11420
- Fixed: Automatic 25-day forced Dynamic DNS update removes wildcard domain #11667
- Fixed: Digital Ocean Dynamic DNS help text is incorrect #11754
- Fixed: NoIP.com Dynamic DNS update failure is not detected properly #11815
- Fixed: Dynamic DNS edit page incorrectly hides username field when switching away from Digital Ocean #11840

Gateways

- Added: Input validation to prevent setting a load balancing gateway group as default #11164

Hardware / Drivers

- Changed: Deprecate old cryptographic accelerator hardware which is not viable on modern systems #11426
- Fixed: Using SHA1 or SHA256 with AES-NI may fail if AES-NI attempts to accelerate hashing #11524

High Availability

- Fixed: Incorrect RADVD log message on HA event #11966

IGMP Proxy

- Fixed: IGMP Proxy restarts unnecessarily after IPv6 gateway events #11904

IPsec

- Added: GUI option to set RADIUS Timeout for EAP-RADIUS #11211
- Added: Option to switch IPsec filtering modes to choose between `enc` and `if_ipsec` filtering #11395
- Changed: Move custom IPsec NAT-T port settings to Advanced Options #11518
- Fixed: strongSwan configuration always contains user EAP/PSK values #11564
- Added: IPsec GUI option to control Child SA `start_action` #11576
- Fixed: Error when adding both IPv4 and IPv6 P2 under an IPv4 or IPv6 only IKEv1 P1 #11651
- Fixed: Cannot disable IPsec P1 when related P2s are in VTI mode and enabled #11792
- Fixed: IPsec VTI interface names are not properly formed for more than 32 interfaces #11794
- Fixed: Applying IPsec settings for more than ~30 tunnels times out PHP #11795

- Fixed: `ipsec_vti()` does not skip disabled VTI entries #11832
- Fixed: IPsec GUI allows creating multiple identical Phase 1 entries when using FQDN for remote gateway #11912
- Fixed: Mobile IPsec advanced RADIUS parameters do not allow numeric values with a decimal point #11967

IPv6 Router Advertisements (RADVD)

- Added: Use virtual link local IP address as RA source address for HA environments #11103
- Added: Shortcut buttons for service control and logs on RADVD configuration #11911
- Fixed: RADVD breaks on SIGHUP #11913

Interfaces

- Fixed: DHCP interfaces are always treated as having a gateway, even if one is not assigned by the upstream DHCP server #5135
- Fixed: Interfaces page displays MAC Address field for interfaces which do not support L2 #11387
- Fixed: CLI interface configuration without IPv6 leaves RA enabled #11609
- Fixed: Incomplete PPPoE custom reset values lead to invalid cron entry #11698
- Fixed: Error when changing MTU if the interface is used for both IPv4 and IPv6 default routes #11855
- Added: VLAN list sorting #11968

L2TP

- Fixed: Unused L2TP VPN files are not removed when the service is disabled #11299
- Added: GUI option to set MTU for L2TP VPN server #11406

NTPD

- Fixed: NTP widget displays incorrect status #11495
- Fixed: NTP authentication input validation rejects valid keys #11850

Notifications

- Fixed: Invalid HTML encoding in modal Notices window #11765

OpenVPN

- Added: Allow the firewall to use DNS servers provided to an OpenVPN client instance #11140
- Fixed: OpenVPN Wizard does not support gateway groups #11141
- Added: Set Explicit Exit Notify to 1 by default for new OpenVPN client instances #11521
- Added: Support for Cisco AVPair `{clientipv6}` template in firewall rules returns by RADIUS #11596
- Changed: Set `explicit-exit-notify` option by default for new OpenVPN server instances #11684
- Fixed: OpenVPN does not clean up parsed `Cisco-AVPair` rules on non-graceful disconnect #11699
- Fixed: OpenVPN does not kill IPv6 client states on disconnect #11700
- Fixed: OpenVPN client starts when CARP VIP is in BACKUP status when bound to Virtual IP aliased to CARP VIP #11793
- Fixed: Certificate validation with OCSP always fails in `openvpn.tls-verify.php` #11830
- Changed: Update OpenVPN to 2.5.2 #11844
- Fixed: OpenVPN client startup error if IPv6 Tunnel Network is defined in TAP mode #11869

Operating System

- Added: Kernel modules for alternate congestion control algorithms #7092
- Added: Kernel module for RTL8153 driver #11125
- Added: Xen console support #11402
- Fixed: Unquoted variable in `dot.tcshrc` can cause proxy password to be printed #11867

Routing

- Fixed: IPv4 link-local (`169.254.x.x`) gateway does not function #11806

Rules / NAT

- Added: Support for IPv6 firewall entries with dynamic delegated prefix and static host address #6626
- Fixed: Disabling all interfaces associated with a floating rule causes the firewall to generate an incorrect pf rule #11688
- Fixed: Input validation prevents creating 1:1 NAT rules on IPsec #11751
- Fixed: Invalid combinations of TCP flag matching options cause `pfctl` parser error #11762
- Fixed: Port forward rules only function through the default gateway interface, `reply-to` does not work for Multi-WAN (CE Only) #11805
- Fixed: Error loading rules in certain cases where an interface is temporarily without an address #11861
- Fixed: NAT 1:1 fail to validate aliases #11923

Traffic Shaper (ALTQ)

- Fixed: Harmless error when enabling traffic shaper #11229
- Fixed: Segmentation fault when loading ALTQ traffic shaping rules using FAIRQ #11550

Traffic Shaper (Limiters)

- Fixed: Unused Limiter entries with schedules create unnecessary cron jobs #11636
- Fixed: Error when setting queue limit on CODELQ limiter #11725

Upgrade

- Fixed: Language presented to user during upgrade is misleading #11897

Web Interface

- Added: Replace HTTP links with HTTPS in the GUI #11228
- Fixed: Ambiguous text in help and input validation error for system domain name #11658
- Fixed: PHP error if `PHP_error.log` file is too large #11685
- Fixed: RAM Disk Settings shows Kernel Memory at `0` Kb and does not allow the user to create RAM disks #11702
- Fixed: HTTP Referer error message text is incorrect #11873
- Fixed: Missing `/0` subnet when cloning repeatable CIDR mask controls #11880
- Fixed: Update NGINX to address CVE-2021-23017 #12061

WireGuard

- Fixed: Ignore WireGuard configurations under `<installedpackages></installedpackages>` #11808

Wireless

- Added: GUI options for WPA Enterprise with identity/password #2400
- Fixed: `wpa_supplicant` uses 100% of a CPU core at boot #11453

XMLRPC

- Fixed: XMLRPC synchronization restarts all OpenVPN instances on the secondary node when making any change on the primary node #11082
- Fixed: XMLRPC Client does not honor its default timeout value #11718

3.20 21.02/21.02-p1/2.5.0 New Features and Changes

pfSense® Plus software version 21.02 and pfSense Community Edition (CE) software version 2.5.0 include a major OS version upgrade, a kernel WireGuard implementation, OpenSSL upgrades, VPN and related security improvements, plus numerous other bug fixes and new features.

Warning: The original plan was to include a RESTCONF API in pfSense® Plus software version 21.02 and pfSense software version 2.5.0, which for security reasons would have required hardware AES-NI or equivalent cryptographic accelerator support. Plans have since changed, and these versions do not contain the planned RESTCONF API, thus **pfSense® Plus software version 21.02 and pfSense Community Edition (CE) software version 2.5.0 DO NOT require AES-NI**.

Tip: For those who have not yet updated to 2.4.5-p1, consult the *previous release notes* and blog posts for those releases to read all important information and warnings before proceeding.

3.20.1 pfSense Plus

Version 21.02 is the first release of pfSense Plus software, formerly known as Factory Edition. For more details about the distinctions between pfSense Plus and pfSense CE, read the pfSense Plus Announcement. Customers running the Factory Edition of pfSense software version 2.4.5-p1 and older can upgrade in-place automatically to pfSense Plus software version 21.02 as with any other previous upgrade.

In this version, the changes in pfSense Plus software and pfSense CE software are roughly the same, with a few notable exceptions which are only available in pfSense Plus software:

- Support for Intel® QuickAssist Technology, also known as QAT.
  - QAT accelerates cryptographic and hashing operations on supported hardware, and can be used to accelerate IPsec, OpenVPN, and other OpenCrypto Framework-aware software.
  - Supported hardware includes many Intel-based systems sold by Netgate (e.g. XG-7100, SG-5100) and add-on cards.
  - From the FreeBSD man page:
    - The `qat` driver supports the QAT devices integrated with Atom C2000 and C3000 and Xeon C620 and D-1500 chipsets, and the Intel QAT Adapter 8950.
    - It can accelerate AES in CBC, CTR, XTS (except for the C2000) and GCM modes, and can perform authenticated encryption combining the CBC, CTR and XTS modes with SHA1-HMAC and SHA2-HMAC. The qat driver can also compute SHA1 and SHA2 digests.
- Improved SafeXcel cryptographic accelerator support for SG-2100 and SG-1100 which can improve IPsec performance.
  - From the FreeBSD man page:
    - The driver can accelerate the following AES modes: AES-CBC, AES-CTR, AES-XTS, AES-GCM, AES-CCM
    - The driver also implements SHA1 and SHA2 transforms, and can combine AES-CBC and AES-CTR with SHA1-HMAC and SHA2-HMAC for encrypt-then-authenticate operations.
- Updated *IPsec profile export*

  - Exports Apple profiles compatible with current iOS and macOS versions
  - New export function for Windows clients to configure tunnels using PowerShell

Version 21.02-p1

pfSense Plus software version 21.02-p1 is a special patch release to address a kernel problem affecting the SG-3100 which caused system instability (#11444). No additional fixes are present in the 21.02-p1 release.

See the detailed bug analysis blog post for more details.

3.20.2 Operating System / Architecture changes

- Base OS upgraded to FreeBSD **12.2-STABLE**
- OpenSSL upgraded to **1.1.1i-freebsd**
- PHP upgraded to **7.4** #9365 #10659
- Python upgraded to **3.7** #9360

3.20.3 Known Issues / Errata

- Deprecated the built-in relayd Load Balancer #9386
  - `relayd` does not function with OpenSSL 1.1.x
  - The `relayd` FreeBSD port has been changed to require libressl – There is no apparent sign of work to make it compatible with OpenSSL 1.1.x
  - The HAProxy package may be used in its place; It is a much more robust and more feature-complete load balancer and reverse proxy
  - For more information on implementing HAProxy, see *HAProxy package* and the Hangout
- There is an issue in this release with port forwarding on pfSense Plus software installations with multiple WANs, which has been resolved in the 21.02.2 patch release, see #11436 for details.
- There is an issue with AES-NI hash acceleration for SHA1 and SHA-256. If the AES-NI driver detects a system capable of accelerating SHA1 or SHA-256 and the firewall attempts to utilize one of those hashes, the affected operation may fail. This affects IPsec and OpenVPN, among other uses. pfSense Plus users can change to QAT acceleration on supported hardware instead. In cases where QAT is unavailable, change to AES-GCM, change to a different unaccelerated hash (e.g. SHA-512), or disable AES-NI. See #11524 for details.
- There is a similar issue which affects SafeXcel SHA1 and SHA2 hash acceleration on SG-1100 and SG-2100. On that hardware, change to an AEAD cipher such as AES-GCM or switch to an unaccelerated hash. This issue is being tracked internally on NG #6005
- The FRR package on pfSense Plus 21.02 and pfSense CE 2.5.0 and later no longer exchanges routes with BGP peers by default without being explicitly allowed to do so. This is more secure behavior but requires a manual change. To replicate the previous behavior, use **ONE** of the following workarounds:
  - Navigate to **Services > FRR BGP** on the **Advanced** tab and check *Disable eBGP Require Policy*, then **Save**.
  - Instead of disabling the policy check, create route maps which match and allow expected incoming and outgoing routes explicitly. This is the most secure method. See *Peer Filtering* and *BGP Example Configuration* for more information.

- Manually create a route map to permit all routes (Name: `allow-all`, Action: *Permit*, Sequence: `100`), then set that route map on BGP neighbors for inbound and outbound peer filtering. This can be used as a placeholder for later migration to more secure route map filtering.

Warning: See the FreeBSD 12.0 Release Notes for information on deprecated hardware drivers that may impact firewalls upgrading to pfSense software version 2.5.0. Some of these were renamed or folded into other drivers, others have been removed, and more are slated for removal in FreeBSD 13 in the future.

3.20.4 Aliases/Tables

- Fixed aliases to allow IPv6 prefix entries which end in IPv4 addresses (e.g. `x:x:x:x:x:x:d.d.d.d` from RFC 4291 section 2.2.2) #10694
- Fixed a PHP error processing aliases when the configuration contains no aliases section #9936
- Fixed URL-based Alias only storing last-most entry in the configuration #9074
- Fixed an issue with PF tables remaining active after they had been deleted #9790
- Added Internationalized domain names support for aliases #7255
- Added the ability to copy an existing alias when creating a new entry #6908
- Fixed handling of URL-based aliases containing multiple URLs #11256

3.20.5 Authentication

- Added RADIUS authentication for SSH users #10545
- Added LDAP authentication for SSH users #8698
- Added option to control behavior of unauthenticated LDAP binds #9909
- Converted LDAP TLS setup from environment variables to LDAP_OPT_X_TLS_* options #9417
- Set RADIUS NAS Identifier to include `webConfigurator` and the firewall hostname when logging in the GUI #9209
- Added LDAP extended query for groups in RFC2307 containers #9527
- Fixed errors when using RADIUS for GUI authentication while the WAN is down #11109

3.20.6 Backup/Restore

- Changed `crypt_data()` to use stronger key derivation #9421
- Updated `crypt_data()` syntax for OpenSSL 1.1.x #9420 #10178
- Disabled AutoConfigBackup manual backups when AutoConfigBackup is disabled #9785
- Improved error handling when attempting to restore encrypted and otherwise invalid configurations which result in errors (e.g. wrong encryption passphrase, malformed XML) #10179
- Added option to include the DHCP v4/v6 leases database in config.xml backups #10910
- Added option to include the Captive Portal database in config.xml backups #10868
- Added option to include the Captive Portal used MACs database in config.xml backups #10856

- Added option to prevent all extra data from being added to config.xml backups #10914
- Added password confirmation when encrypting a config.xml backup #10301
- Added support for GPT partitioned drives to the External Configuration Locator #9097
- Added support for Limiters to the Traffic Shaper backup and restore area option #4763
- Added option to backup Dynamic DNS area #3559
- Fixed restoration of active voucher data from backup #3128

3.20.7 Captive Portal

- Improved XMLRPC sync of Captive Portal database information #97
- Changed Captive Portal vouchers to use `phpseclib` so it can generate keys natively in PHP, and to work around OpenSSL deprecating key sizes needed for vouchers #9443
- Added `trim()` to the submitted username, so that spaces before/after in input do not cause authentication errors #9274
- Optimized Captive Portal authentication attempts when using multiple authentication servers #9255
- Fixed Captive Portal session timeout values for RADIUS users who do not have a timeout returned from the server #9208
- Changed Captive Portal so that users no longer get disconnected when changes are made to Captive Portal settings #8616
- Added an option so that Captive Portals may choose to remove or retain logins across reboot #5644
- Fixed deletion of related files when removing a Captive Portal zone #10891
- Fixed XMLRPC sync of Captive Portal used MACs database #10857
- Added validation of Captive Portal zone names to prevent using reserved words #10798
- Added support for IDN hostnames to Captive Portal Allowed Hostnames tab #10747
- Improved Captive Portal Allowed Hostnames so it supports multiple DNS records in responses #10724
- Fixed retention of automatic pass-through MAC entries when using Captive Portal Vouchers #9933
- Fixed Captive Portal Bandwidth per-user bandwidth limit values being applied when disabled #9437 #9311
- Changed handling of voucher logins with Concurrent Login option so that new logins are prevented rather than removing old sessions #9432 #2146
- Changed XMLRPC behavior to not remove zones from secondary node when disabling Captive Portal #9303
- Fixed XMLRPC sync failing to propagate voucher roll option changes to the secondary node #8809
- Fixed XMLRPC sync failing to create Captive Portal voucher files on secondary node #8807
- Fixed Captive Portal + Bridge interface validation #6528
- Added support for masking of Captive Portal pass-thru MACs #2424
- Added support for pre-filling voucher codes via URL parameters, so they can be used via QR code #1984

3.20.8 Certificates

- Fixed OCSP stapling detection for OpenSSL 1.1.x #9408
- Fixed GUI detection of revoked status for certificates issued and revoked by an intermediate CA #9924
- Removed PKCS#12 export links for entries which cannot be exported in that format (e.g. no private key) #10284
- Added an option to globally trust local CA manager entries #4068
- Added support for randomized certificate serial numbers when creating or signing certificates with local internal CAs #9883
- Added validation for CA/CRL serial numbers #9883 #9869
- Added support for importing ECDSA keys in certificates and when completing signing requests #9745
- Added support for creating and signing certificates using ECDSA keys #9843 #10658
- Added detailed certificate information block to the CA list, using code shared with the Certificate list #9856
- Added Certificate Lifetime to certificate information block #7332
- Added CA validity checks when attempting to pre-fill certificate fields from a CA #3956
- Added a daily certificate expiration check and notice, with settings to control its behavior and notifications (Default: 27 days) #7332
- Added functionality to import certificates without private keys (e.g. PKCS#11) #9834
- Added functionality to upload a PKCS#12 file to import a certificate #8645
- Added CA/Certificate renewal functionality #9842
  - This allows a CA or certificate to be renewed using its current settings (or a more secure profile), replacing the entry with a fresh one, and optionally retaining the existing key.
- **Added an "Edit" screen for Certificate entries**
  - This view allows editing the Certificate **Descriptive name** field #7861
  - This view also adds a (not stored) password field and buttons for exporting encrypted private keys and PKCS#12 archives #1192
- **Improved default GUI certificate strength and handling of weak values #9825**
  - Reduced the default GUI web server certificate lifetime to 398 days to prevent errors on Apple platforms #9825
  - Added notes on CA/Cert pages about using potentially insecure parameter choices
  - Added visible warnings on CA/Cert pages if parameters are known to be insecure or not recommended
- **Revamped CRL management to be easier to use and more capable**
  - Added the ability to revoke certificates by serial number #9869
  - Added the ability to revoke multiple entries at a time #3258
  - Decluttered the main CRL list screen
  - Moved to a single CRL create control to the bottom under the list rather than multiple buttons
- **Optimized CA/Cert/CRL code in various ways, including:**
  - Actions are now performed by `refid` rather than array index, which is more accurate and not as prone to being affected by parallel changes
  - Improved configuration change descriptions as shown in the GUI and configuration history/backups

  - Miscellaneous style and code re-use improvements
  - Changed CA/Cert date calculations to use a more accurate method, which ensures accuracy on ARM past the 2038 date barrier #9899

3.20.9 Configuration Backend

- Changed error handling on boot error 'XML configuration file not found' so the user is given an opportunity to fix the problem manually #10556

3.20.10 Configuration Upgrade

- Retired m0n0wall configuration upgrade support #10997

3.20.11 Console Menu

- Fixed `rc.initial` execution of `rc.local.running` #10978
- Fixed `rc.initial` handling of `-c` commands with arguments #10603
- Fixed console menu display of subnet masks for DHCP interfaces #10740

3.20.12 Dashboard

- Added PPP uptime to the Dashboard Interfaces Widget #9426
- Improved long description truncation behavior in the services status widget #10795
- Fixed Dashboard traffic graph widget display of bandwidth units (b/s vs. B/s) #9072
- Added adaptive state timeout indication to the state table usage meter #7016
- Fixed Thermal Sensors dashboard widget showing invalid sensors #10963
- Added default route indicator to Gateways widget #11057
- Added hardware interface name as a tooltip on Interfaces widget entries #11041

3.20.13 DHCP (IPv4)

- Fixed handling of spaces in DHCP lease hostnames by `dhcpleases` #9758
- Fixed DHCP leases hostname parsing problems which prevented some hostnames from being displayed in the GUI #3500
- Added OMAPI settings to the DHCP Server #7304
- Increased number of NTP servers sent via DHCP to 3 #9661
- Added an option to prevent known DHCP clients from obtaining addresses on any interface (e.g. known clients may only obtain an address from the interface where the entry is defined) #1605
- Added count of static mappings to list when editing DHCP settings for an interface #9282
- Fixed handling of client identifiers on static mappings containing double quotes #10295
- Added ARM32/64 network booting support to the DHCP Server #10374

- Increased the number of NTP servers for DHCP Static Mappings #10333
- Fix DHCP Dynamic DNS handling of per-host zone and key options from static mappings #10224
- Added per-host custom BOOTP/DHCP Options to static mappings #8990
- Added a button to clear all DHCP leases #7406
- Fixed ARPA zone declaration formatting in DHCP server configuration file #11224

3.20.14 DHCP (IPv6)

- Added options to disable pushing IPv6 DNS servers to clients via DHCP6 #9302
- Fixed DHCPv6 domain search list #10200
- Fixed validation to allow omission of DHCPv6 range for use with stateless DHCP #9596
- Fixed issues creating IPv6 Static Mappings #7443
- Fixed DHCPv6 merging an IPv6 prefix with the input submitted in DNS servers field when using Track Interface #7384
- Fixed prefix delegation not being requested if no interfaces were set to track6 #11005
- Fixed DHCPv6 Dynamic DNS domain key name validation #10844
- Fixed line formatting issues in the DHCPv6 configuration file #10675
- Fixed prefix not being included in the DNS entry registered by DHCPv6 #8156
- Fixed DHCPv6 static mapping changes requiring a restart of the DNS resolver to activate #10882
- Fixed issues running DHCPv6 on certain types of tracked interfaces (e.g. bridges, VLANs) #3965
- Fixed issues with WAN not renewing IPv6 address after an upstream failure #10966

3.20.15 DHCP Relay

- Fixed DHCP Relay validation to allow OpenVPN TAP interfaces #10711
- Fixed inconsistent validation behavior for DHCP relay and bridges #7778

3.20.16 Diagnostics

- Added Reroot and Reboot with Filesystem Check options to GUI Reboot page #9771
- Added option to control wait time between ICMP echo request (ping) packets `diag_ping.php` #9862
- Improved data sanitization in status.php #10946 #10944 Sanitize MaxMind GeoIP key #10797 #10569 #10794
- Added config history list to status.php #10696
- Added DNS Resolver configuration to status.php #10635
- Added L2TP VPN configuration to status.php #10583
- Changed pftop page to hide filtering controls for views which do not support filtering #10625
- Added support for IDN hostnames to DNS Lookup, Ping, and Traceroute #10538
- Fixed diag_dns.php link to Ping passing incorrect parameters #10537
- Added a button to clear the NDP cache #10975

- Added a button to clear the ARP cache #4038
- Fixed hostname being ignored when DNS Lookup calculates response time #11018
- Fixed **Kill States** button on `diag_dump_states.php` when used with CIDR-masked subnets #9270

3.20.17 DNS Forwarder

- Updated `dnsmasq` to 2.84 #11278

3.20.18 DNS Resolver

- Added IPv6 OpenVPN client addresses resolution to the DNS Resolver #8624
- Added DNS64 options to the DNS Resolver #10274
- Added support for multiple IP addresses in a DNS Resolver Host Override entry #10896
- Fixed DNS Resolver restart commands to work around potential environment issues #10781
- Fixed saving DNS Resolver ACL entries when using a non-English translation #10742
- Added support for IDN symbols in DNS Resolver ACL entries #10730
- Added Aggressive NSEC option to the DNS Resolver #10449
- Fixed DNS Resolver unintentionally retaining DHCP registration entries after disabling that feature #8981
- Fixed DNS Resolver restarting on every OpenVPN client connection when registering clients in DNS #11129
- Fixed issues with the DNS Resolver not starting when bound to disabled interfaces or interfaces without carrier #11087
- Fixed DNS Resolver custom TLS listen port being ignored #11051
- Improved formatting and ordering of items in the DNS Resolver access list configuration file #11309

3.20.19 Dynamic DNS

- Fixed Dynamic DNS Dashboard Widget address parsing for entries with split hostname/domain (e.g. Namecheap) #9564
- Added support for new CloudFlare Dynamic DNS API tokens #9639
- Added IPv6 support to No-IP Dynamic DNS #10256
- Fixed issues with Hover Dynamic DNS #10241
- Updated Cloudflare Dynamic DNS to query Zone ID with token #10992
- Added support for IPv6 to easyDNS Dynamic DNS #10972
- Added support for Domeneshop Dynamic DNS #10826
- Added Zone option to RFC 2136 Dynamic DNS #10684
- Updated FreeDNS Dynamic DNS to use their v2 API #10617
- Fixed DigitalOcean Dynamic DNS processing of zones with multiple pages of records #10592
- Improved Dynamic DNS Logging #10459
- Added support for dynv6.com Dynamic DNS #9642

- Fixed handling of Dynamic DNS AAAA records on 6rd tunnel interfaces bound to PPPoE interfaces #9641
- Added a button to duplicate Dynamic DNS entries #8952
- Fixed Dynamic DNS update for HE.net Tunnelbroker always setting IP address of the default WAN interface #11024
- Updated HE.net Tunnelbroker Dynamic DNS to use their current API #11037
- Added support for Wildcard A records for Gandi Dynamic DNS #11159
- Updated No-IP Dynamic DNS to use a newer API #6638
- Fixed Namecheap Dynamic DNS error code checking #5308
- Improved color blind accessibility of Dynamic DNS status #3229

3.20.20 Gateways

- Added support for obtaining a gateway via DHCP which is outside of the interface subnet #7380
- Added validation to prevent using descriptions on interfaces which would cause gateway names to exceeded the maximum allowed length #9401
- Added tooltip text to icons on the Gateways #10719
- Fixed issues with dpinger failing to update IPv6 gateway address on DHCPv6 WAN interfaces #8136

3.20.21 Hardware / Drivers

- Added `bnxt` driver for Broadcom NetXtreme interfaces #9155
- Added iOS/Android/Generic USB tethering driver #7467

3.20.22 IGMP Proxy

- Added input validation for IGMP Proxy settings #7163

3.20.23 Installer

- Created separate **Auto (UFS) UEFI** and **Auto (UFS) BIOS** installation options to avoid problems on hardware which boots differently on USB and non-USB disks #8638
- Fixed reinstalling with UFS on a ZFS formatted drive #10690
- Fixed platform detection for MBT-4220 and MBT-2220 on newer BIOS revisions #9242
- Fixed an issue with shutting down instead of rebooting after installing using ZFS #7307

3.20.24 Interfaces

- Added support for using IPv4 and IPv6 addresses on GRE interfaces at the same time #10392
- Added a check to disable Hardware Checksum Offloading in environments with interfaces which do not support it (e.g. `vtnet`, `ena`) #10723
- Changed the way interface VLAN support is detected so it does not rely on the VLANMTU flag #9548
- Added a PHP shell playback script `restartallwan` which restarts all WAN-type interfaces #9688
- Changed assignment of the `fe80::1:1` default IPv6 link-local LAN address so it does not remove existing entries, which could cause problems such as Unbound failing to start #9998
- Added automatic MTU adjustment for GRE interfaces using IPsec as a transport #10222
- Fixed SLAAC interface selection when using IPv6 on a link which also uses PPP #9324
- Added GUI interface descriptions to Operating System interfaces #1557
- Added the ability to assign virtual type interfaces (IPsec, OpenVPN, GIF, GRE, etc) during console interface assignment #10947
- Fixed TSO not being disabled in some cases #10836
- Fixed group name length input validation #10835
- Improved interface caching for environments with many interfaces #10680
- Fixed `fe80::1:1` being added to interfaces without track6 #10661
- Added a check to prevent stf (6RD/6to4) interfaces from being used as parent interfaces #10626
- Fixed redundant disabling of static ARP at boot before it could be enabled #10589
- Fixed initialization of bridges which include a GIF interface at boot #10524
- Fixed problems with post-install interface changes not being retained if the user did not complete the wizard #10383
- Fixed inefficiencies when applying settings to a VLAN parent interface #9154
- Fixed interface MTU setting not being applied to all IPv6 routes #6868
- Fixed handling of MTU setting for 6rd and 6to4 interfaces #6377
- Fixed IPv6 IP Alias preventing Track Interface from working with DHCPv6 and RA #5999
- Changed DHCP interface renewal behavior to not restart services if the IP address did not change #11142
- Fixed an error when changing bridge STP settings #11122
- Added a binary package with updated Realtek interface drivers #11079
- Improved link state visibility on Status > Interfaces #11045
- Removed VTI interfaces from Interface Group selection since they do not currently function in this manner #11134
- Fixed issues with IPv6 on top of IPv4 PPPoE placing default route on incorrect interface #9324

3.20.25 IPsec

- Added 25519 curve-based IPsec DH and PFS groups 31 and 32 #9531
- Enabled the strongSwan PKCS#11 plugin #6775
- Added support for ECDSA certificates to IPsec for IKE #4991
- Renamed IPsec "RSA" options to "Certificate" since both RSA and ECDSA certificates are now supported, and it is also easier for users to recognize #9903
- Converted IPsec configuration code from `ipsec.conf` `ipsec/stroke` style to `swanctl.conf` `swanctl/vici` style #9603
  - Split up much of the single large IPsec configuration function into multiple functions as appropriate.
  - Optimized code along the way, including reducing code duplication and finding ways to generalize functions to support future expansion.
  - For IKEv1 and IKEv2 with Split Connections enabled, P2 settings are properly respected for each individual P2, such as separate encryption algorithms #6263
    - **N.B.:** In rare cases this may expose a previous misconfiguration which allowed a Phase 2 SA to connect with improper settings, for example if a required encryption algorithm was enabled on one P2 but not another.
  - New GUI option under **VPN > IPsec**, **Mobile Clients** tab to enable RADIUS Accounting which was previously on by default. This is now disabled by default as RADIUS accounting data will be sent for every tunnel, not only mobile clients, and if the accounting data fails to reach the RADIUS server, tunnels may be disconnected.
  - Additional developer & advanced user notes:
    - For those who may have scripts which touched files in `/var/etc/ipsec`, note that the structure of this directory has changed to the new swanctl layout.
    - Any usage of `/usr/local/sbin/ipsec` or the stroke plugin must also be changed to `/usr/local/sbin/swanctl` and VICI. Note that some commands have no direct equivalents, but the same or better information is available in other ways.
    - IPsec start/stop/reload functions now use `/usr/local/sbin/strongswanrc`
    - IPsec-related functions were converged into `ipsec.inc`, removed from `vpn.inc`, and renamed from `vpn_ipsec_<name>` to `ipsec_<name>`
  - Reworked how reauthentication and rekey behavior functions, giving more control to the user compared to previous options #9983
- Reformatted `status_ipsec.php` to include more available information (rekey timer, encryption key size, IKE SPIs, ports) #9979
- Added support for PKCS#11 authentication (e.g. hardware tokens such as Yubikey) for IPsec #9878
- Fixed usage of Hash Algorithm on child ESP/AH proposals using AEAD ciphers #9726
- Added support for IPsec remote gateway entries using FQDNs which resolve to IPv6 addresses #9405
- Added manual selection of Pseudo-Random Function (PRF) for use with AEAD ciphers #9309
- Added support for using per-user addresses from RADIUS and falling back to a local pool otherwise #8160
- Added an option which allows multiple tunnels to use the same remote peer in certain situations (read warnings on the option before use) #10214
- Improved visible distinction of online/offline mobile IPsec users in the IPsec status and dashboard widget #10340

- Added options to change the IPsec NAT-T ports (local and remote) #10870
- Improved boot-time initialization of IPsec VTI interfaces #10842
- Added support for limiting IPsec VPN access by RADIUS user group #10748
- Changed IPsec to share the same RADIUS Cisco-AVPair parser code as OpenVPN for Xauth users #10469
- Fixed handling of IPsec VTI interfaces in environments with large numbers of IPsec tunnels #9592
- Added IPsec Advanced option to control maximum allowed Parallel P2 Rekey exchanges #9331
- Fixed issues with bringing up new Phase 2 entries on IPsec tunnels with "Split connections" enabled #8472
- Fixed issues where, in rare cases, IPsec tunnels would not reconnect until the firewall was rebooted #8015
- Improved the Remote Gateway field description for IPsec Phase 1 entries to indicate that `0.0.0.0` is allowed #7095
- Fixed issues with IKEv2 IPsec tunnels with multiple phase 2 entries combining traffic selectors in unexpected ways (set "Split Connections" to isolate them) #6324
- Added options to create IPsec bypass rules which prevent specific source and destination network pairs from entering policy-based IPsec tunnels #3329
- Documented settings which work around SA duplication issues experienced by users in certain cases #10176
- Improved IPsec GUI options for P1/P2 SA expiration and replacement to help prevent SA duplication #11219
- Fixed a PHP error in mobile IPsec input validation #11212
- Added validation to prevent unsupported wildcard certificates from being selected for use with IPsec #11297

3.20.26 IPv6 Router Advertisements (RADVD)

- Fixed Router Advertisement configuration missing information in Unmanaged mode #9710
- Fixed Router Advertisement lifetime input validation #10709

3.20.27 L2TP

- Fixed L2TP secret using an empty value after removing it from the GUI #10710
- Fixed L2TP input validation to allow leaving the remote address field blank when assigning addresses from RADIUS #7562
- Fixed inefficiencies in the initial L2TP reconfiguration process #7558
- Fixed L2TP Server and Client both using `l2tpX` for interface names #11006
- Fixed static routes on L2TP interfaces not being reapplied when reconnecting #10407
- Fixed L2TP server being restarted when making user account changes #11059

3.20.28 LAGG Interfaces

- Improved Interface Status and Widget information for LAGG #9187
- Fixed route for GIF/GRE peer when using VLAN on LAGG #10623
- Added option to toggle LACP PDU transmission fast timeout #10504
- Fixed LAGG member interface events causing filter reloads #10365
- Fixed issues with LAGG interface MTU being incorrectly applied to VLAN subinterfaces #8585
- Added option to control the master interface for LAGG in Failover mode #1019

3.20.29 Logging

- Changed system logging to use plain text logging and log rotation, the old binary clog format has been deprecated #8350
- Updated default log size (512k + rotated copies), default lines to display (500, was 50), and max line limits (200k, up from 2k) #9734
- Added log tabs for nginx, userlog, utx/lastlog, and some other previously hidden logs #9714
- Relocated Package Logs into a tab under System Logs and standardized display/filtering of package logs #9714
- Added GUI options to control log rotation #9711
- Added code for packages to set their own log rotation parameters #9712
- Removed the redundant `nginx-error.log` file #7198
- Fixed some instances where logs were mixed into the wrong log files/tabs (Captive Portal/DHCP/squid/php/others) #1375
- Reorganized/restructured several log tabs #9714
- Added a dedicated authentication log #9754
- Added an option for RFC 5424 format log messages which have RFC 3339 timestamps #9808
- Fixed an issue where a firewall log entry for loopback source/destination occasionally reported `127.0.0.1` as `127.0.01` #10776
- Fixed issues with `syslogd` using an old IP address after an interface IP address change #9660
- Added `watchfrr` to routing log #11207

3.20.30 Multi-WAN

- Fixed Gateways being removed from routing groups based on low alert thresholds #10546
- Fixed a possible race condition in gateway group fail-over causing unexpected behavior #9450
- Fixed a load balancing failure when one gateway had a weight of 1 and another gateway had a weight >1 #6025

3.20.31 NAT Reflection

- Fixed port forwards where the destination is a network alias creating invalid refection rules if multiple subnets are in that alias #7614

3.20.32 Notifications

- Deprecated & Removed Growl Notifications #8821
- Added a daily certificate expiration notification with settings to control its behavior #7332
- Fixed input validation of SMTP notification settings #8522
- Added support for sending notifications via Pushover API #10495
- Added support for sending notifications via Telegram #10354
- Fixed a PHP error when SMTP notifications fail #11063

3.20.33 NTPD

- Added GUI options for NTP sync/poll intervals #6787
- Added validation to prevent using `noselect` and `noserve` with pools #9830
- Added feature to automatically detect GPS baud rate #7284
- Fixed status and widget display of long hostnames and stratum #10307
- Fixed handling of the checkbox options on NTP servers #10276
- Updated GPS initialization commands for Garmin devices #10327
- Added an option to limit NTP pool server usage #10323
- Added option to force IPv4/IPv6 DNS resolution for NTP servers #10322
- Added support for NTP server authentication #8794
- Added an option to disable NTP #3567
- Added units to the NTP status page #2850

3.20.34 OpenVPN

- Updated OpenVPN to 2.5.0 #11020
  - The default compression behavior has changed for security reasons. Incoming packets will be decompressed, outgoing packets will not be compressed. There is a GUI control to alter this behavior.
  - Data cipher negotiation (Formerly known as Negotiable Cryptographic Parameters, or NCP) is now compulsory. Disabling negotiation has been deprecated. The option is still present in the GUI, but negotiation will be unilaterally enabled on upgrade. The upgrade process will attempt to use the expected data encryption algorithms before and after the upgrade completes, but in some cases more secure algorithms may be enabled as well. #10919

    We strongly encourage using AEAD ciphers such as AES-GCM, future versions of OpenVPN will require them and will not have configurable cipher lists.
- Added connection count to OpenVPN status and widget #9788

- Enabled the OpenVPN x509-alt-username build option #9884
- Restructured the OpenVPN settings directory layout
  - Changed from `/var/etc/openvpn[-csc]/<mode><id>.<file>` to `/var/etc/openvpn/<mode><id>/<x>`
    - This keeps all settings for each client and server in a clean structure
- Moved to `CApath` style CA structure for OpenVPN CA/CRL usage #9915
- Added support for OCSP verification of client certificates #7767
- Fixed a potential race condition in OpenVPN client ACLs obtained via RADIUS #9206
- Added support for more protocols (IP, ICMP), ports, and a template variable (`{clientip}`) in OpenVPN client ACLs obtained via RADIUS #9206
- Added the ability to register OpenVPN Remote Access (User Auth) clients in the DNS Resolver #10999
- Fixed an issue where duplicating an OpenVPN instance did not copy the password #10703
- Fixed issues with OpenVPN TCP clients failing to start #10650
- Added support for IPv6 OpenVPN ACLs obtained via RADIUS #10454
- Fixed validation to enforce OpenVPN client password usage when setting a username, to prevent a missing password from interrupting the boot process #10409
- Enabled asynchronous push in OpenVPN binary #10273
- Added OpenVPN client-specific override option to ignore routes pushed by the server ("push-reset") #9702
- Clarified behavior of OpenVPN server option for Duplicate Connections #10363

3.20.35 Operating System

- Fixed a network performance regression in the fast forwarding path with IP redirects enabled NG4965
- Fixed double ZFS entries in `loader.conf` #10375
- Added a method to enable persistent command history in the shell #11029
- Changed the default domain name of the firewall from `.localdomain` to `.home.arpa` #10533

3.20.36 Package System

- Disabled spell checking on package upgrade progress textarea #10637
- Fixed issues with package upgrade or reinstall hanging indefinitely #10610
- Fixed description used for buttons when editing packages #11208
- Deprecated the following packages: OpenBGPd, Quagga_OSPF, routed, blinkled, and gwled

3.20.37 PPP Interfaces

- Fixed issues with PPPoE over a VLAN failing to reconnect #9148
- Enabled selection of QinQ interfaces for use with PPP #9472
- Added option to set `Host-Uniq` value for PPPoE #10597
- Fixed incorrect interface assignment after switching from PPPoE #10240
- Fixed IPv6 not being disabled in mpd.conf when the IPv6 GUI option is set to 'disabled' #7386
- Fixed PPPoE interface errors due to MTU settings #11035

3.20.38 PPPoE Server

- Fixed PPPoE server ignoring secondary RADIUS Server #10926
- Fixed PPPoE server Accounting updates option #10869
- Removed unnecessary restarts of the PPPoE server when adding/modifying users #10318
- Added input validation to prevent enabling the PPPoE server on a PPPoE client interface #4510

3.20.39 Routing

- Fixed automatic static routes set for DNS gateway bindings not being removed when no longer necessary #8922
- Fixed missing tooltip text for icons on the Static Routes Page #10889

3.20.40 RRD Graphs

- Fixed RRD graph handling of NTP graph data with negative `freq` values #6503
- Fixed RRD graph creation for interfaces using CODELQ #6277

3.20.41 Rules / NAT

- Added the ability to configure negated tagging, to match packets which do not contain a given tag #10186
- Added support for IPv6 Port Forwards #10984
- Fixed handling of IPv6 NPt rules on 6rd WAN interfaces #10757
- Fixed 1:1 NAT issue when internal interface has VIPs #10752
- Fixed policy routing rules not being written correctly for a down gateway #10716
- Added EoIP to firewall rule Protocol list #10698
- Fixed separator bars on floating rules not covering the full table width #10667
- Fixed 1:1 NAT for IPv6 applying wrong subnet mask to "Single Host" #7742
- Added validation to prevent accidentally overlapping NPt networks and interface networks #7741
- Added support for dynamic interface addresses in 1:1 NAT rules #7705
- Added default values of TCP and UDP timeouts to the GUI #7362
- Fixed handling of IPv6 floating rules on 6rd interfaces #7142

- Fixed firewall rules for "PPPoE clients" only including the first PPPoE server instance #6598
- Fixed duplicated tracker IDs on block private networks rules #6030
- Fixed `reply-to` on rules for PPPoE WANs with IPv6 SLAAC #5258
- Added gateway/group IP addresses to mouseover on rules #885
- Fixed formatting of floating rules with large numbers interfaces #10892
- Fixed form rendering issues with Port Forward Address Fields in Safari #10674
- Fixed firewall ruleset failing to load at boot when new ruleset would be invalid #6028
- Fixed an issue adding or deleting separator bars when no rules are present #10827

3.20.42 S.M.A.R.T.

- Updated S.M.A.R.T. Page with new capabilities #9367

3.20.43 SNMP

- Fixed SNMP reporting incorrect speed for switch uplink interface on Netgate SG-3100 #10793
- Fixed SNMP input validation to require the Host Resources module when the PF module is also enabled #10471

3.20.44 Traffic Graphs

- Changed the Traffic Graph page from `rate` to `iftop` which brings IPv6 support and various other improvements #3334

3.20.45 Traffic Shaper (ALTQ)

- Changed default ALTQ queue bandwidth type to Mbit/s #10988
- Updated traffic shaper wizard settings for XBox and Wii ports #10837
- Added Broadcom NetXtreme to ALTQ-capable list #10762
- Added ALTQ support to the `ix(4)` driver #7378
- Fixed deletion of associated shaper queues when deleting an interface #3488
- Fixed ALTQ root queue bandwidth calculation #3381
- Fixed input validation for amount of queues supported by ALTQ schedulers #1353
- Added Google Stadia port range to the traffic shaper wizard #10743
- Fixed PHP errors in the traffic shaper wizard #10660
- Fixed ALTQ on `hn(4)` interfaces #8954

3.20.46 Traffic Shaper (Limiters)

- Fixed issues with `net.inet.ip.dummynet.*` tunables being ignored #10780
- Fixed issues with renaming limiters removing them from firewall rules #3924
- Fixed mask options not applying to sched limiter #10838
- Changed default Limiter queue bandwidth type to Mbit/s #10727

3.20.47 Translations

- Added Italian translation #9716

3.20.48 Upgrade

- Fixed issues with checking for updates from the GUI behind a proxy with authentication #9478
- Changed phrasing of message indicating the firewall is rebooting to upgrade #10387
- Fixed issues with the GUI incorrectly reporting "The system is on the latest version" #8870

3.20.49 UPnP

- Improved handling of UPnP with multiple gaming systems #7727

3.20.50 User Manager / Privileges

- Added menu entry for User Password Manager if the user does not have permission to reach the User Manager #9428
- Improved consistency of SSL/TLS references in LDAP authentication servers #10172
- Fixed irrelevant output being printed to users with `ssh_tunnel_shell` #9260
- Fixed theme not being applied to LDAP test results modal #7912
- Changed to more secure default values for certificates created through the user manager #11167
- Changed SSL/TLS LDAP authentication implementation to improve handling of multiple secure LDAP (SSL/TLS or STARTTLS) servers used at the same time #10704

3.20.51 Virtual IP Addresses

- Fixed a problem with PID file handling for the proxy ARP daemon #7379
- Fixed IP Alias VIPs on PPPoE interfaces #7132

3.20.52 Web Interface

- Updated JQuery to address multiple issues #10676
- Updated Bootstrap to 3.4.1 #9892
- Updated Font-Awesome to v5 #9052
- Increased the number of colors available for the login screen #9706
- Added TLS 1.3 to GUI and Captive Portal web server configuration, and removed older versions (TLS 1.0 removed from Captive Portal, TLS 1.1 removed from GUI) #9607
- Fixed empty lines in various forms throughout the GUI #9449
- Improved validation of FQDNs #9023
- Added `CHACHA20-POLY1305` to `nginx` cipher list #9896
- Fixed Setup Wizard input validation to allow Primary/Secondary DNS Server field to remain empty #10982
- Fixed Setup Wizard input validation for IPv6 DNS Servers #10720
- Added an option to omit DNS Servers from resolv.conf #10931
- Fixed the icon area within buttons not being clickable #10846
- Fixed visibility issues with multiple selection form control in the `pfsense-BETA-dark` theme #10705
- Updated documentation links in the GUI #10481
- Fixed netmask/prefix form control incorrectly resetting to `128/32` #10433
- Updated Help shortcut links #10135
- Improved handling of multiple login form submissions to avoid a potential CSRF error #9855
- Fixed reboot message when changing the Hardware Checksum Offloading setting #3031
- Added support for new site icons requested by current versions of Safari #11068
- Added descriptions to all `write_config()` calls #204

3.20.53 WireGuard

- Added kernel-based *WireGuard* VPN implementation #8786

3.20.54 Wireless

- Added support for the `athp(4)` wireless interface driver #9538 #9600
- Added support for the `ral(4)` wireless interface driver to arm64 #10934
- Added support for the `rtwn(4)` wireless interface driver #10639
- Added support for selecting 802.11n channel width (HT) #10678

3.20.55 Development

- Added a "periodic" style framework to allow for daily/weekly/monthly tasks from the base system or packages by way of plugin calls #7332
- Added a central file download function for internal use throughout the GUI
- Added TCP_RFC7413 in kernel, required for the BIND package #7293

3.20.56 XMLRPC

- Fixed XMLRPC synchronization of admin authorized keys for the admin user #9539
- Added option to synchronize changes for the account used for XMLRPC sync #9622
- Fixed XMLRPC synchronization for firewall rule descriptions with special characters #1478
- Fixed Incorrect synchronize IP address value causing XMLRPC errors #11017

3.21 2.4.5-p1 New Features and Changes

pfSense® software version 2.4.5-p1 addresses performance, security, and other miscellaneous issues found in *2.4.5*.

Warning: Proceed with caution when upgrading pfSense software while COVID-19 travel restrictions are in effect.

During this time of travel limitations, remote upgrades of pfSense software should be carefully considered, and avoided where possible. Travel restrictions may complicate any repair of any issue, including hardware-related issues that render the system unreachable. Should these issues require onsite physical access to remedy, repair of the issue may not be possible while travel restrictions related to COVID-19 are in effect.

Tip: For those who have not yet updated to 2.4.5-p1, consult the *previous release notes* and blog posts for those releases to read all important information and warnings before proceeding.

Note: Upgrading to pfSense software version 2.4.5-p1 requires `pfSense-upgrade` version 0.70 or later. Most installations will automatically pick up the new version and upgrade normally. If this does not happen automatically and the upgrade to version 2.4.5-p1 is not offered, use the following procedure:

- Navigate to **System > Updates**
- Set **Branch** to *Previous stable version*
- Wait a few moments for the upgrade check to complete
- Optional: Confirm that the latest version of *pfSense-upgrade* is present (version >= 0.70) using `pkg-static info -x pfSense-upgrade`.

  If the correct version is not present, wait a bit longer and check again as that package may be updating in the background.
- Set **Branch** to *Latest stable version*
- Wait a few moments for the upgrade check to complete

At this point, the upgrade check should see 2.4.5-p1 and the upgrade can proceed.

Note: pfSense software version 2.4.5-p1 includes `pkg` version 1.13.x which introduces a new metadata version. Most installations will automatically pick up the new version and upgrade normally. In certain cases, especially coming from much older versions, the `pkg` utility may require a manual update before it can correctly process the new metadata.

The `pkg` utility can be upgraded manually with the following command run from an ssh or console shell:

```
# pkg-static bootstrap -f
```

See *Repository Metadata Version Errors* for more details.

3.21.1 Security / Errata

- Addressed an issue with large `pf` tables causing system instability and high CPU usage during filter reload events #10414
- Fixed an issue with `sshguard` which could prevent it from protecting against brute force logins #10488
- Updated `unbound` to address CVE-2020-12662 and CVE-2020-12663 #10576
- Updated `json-c` to address CVE-2020-12762 #10609
- Addressed FreeBSD Security Advisories & Errata Notices including:
  - FreeBSD-SA-20:10.ipfw
  - FreeBSD-SA-20:12.libalias
  - FreeBSD-SA-20:13.libalias
  - FreeBSD-SA-20:15.cryptodev

3.21.2 Aliases / Tables

- Fixed handling of URL/URL table aliases with IDN hostnames #10321

3.21.3 Authentication

- Fixed handling of misconfigured groups which prevented the `admin` user from making configuration changes #10492
- Fixed a potential temporary privilege downgrade when deleting an account #9259

3.21.4 Backup / Restore

- Fixed handling of redundant/extraneous RRD tags when making configuration backups #10508

3.21.5 CARP

- Fixed handling of IPv6 CARP VIPs with non-significant zeros during XMLRPC sync #6579

3.21.6 Certificates

- Fixed a bug which prevented the user from removing a CA private key when editing #10509

3.21.7 Configuration Upgrade

- Fixed a PHP error during upgrade from <2.4.3 with empty tags in the IPsec configuration #10458

3.21.8 Console Menu

- Changed the naming convention of gateways created at the console to be the same as those created in the GUI #10264

3.21.9 DHCP (IPv6)

- Added default value placeholders to some DHCPv6 RA configuration options #10448
- Fixed DHCPv6 service Dynamic DNS errors #10346
- Fixed `rc.newwanipv6` being called for Request messages which `dhcp6c` should have discarded #9634
- Added dashed DUID support to DHCPv6 static mappings #2568

3.21.10 DHCP Relay

- Fixed DHCP Relay handling of scenarios where a target server may be on the same interface as some clients #10416
- Excluded unsupported interface types from DHCP Relay #10341

3.21.11 DHCP Server

- Fixed DHCPv6 static entries not being updated on external Dynamic DNS servers #10412
- Fixed DHCPv6 `domain-search` list not being sent to clients #10200
- Fixed DHCP Server not accepting IPv6 addresses for Dynamic DNS servers #6600

3.21.12 Diagnostics

- Several improvements and items added to status.php diagnostic output #10455 #10424 #10423 #10350 #10349 #10568
- Fixed Require State Filter setting on `diag_states.php` breaking filter rule link to associated states #10359

3.21.13 DNS Resolver

- Fixed IPsec and OpenVPN IPv6 tunnel network/pool prefixes not being added to automatic DNS Resolver ACLs #10460
- Fixed EDNS buffer size values to prepare for 2020 DNS flag day #10293
- Fixed DNS Resolver handling of entries from DHCP server which contain a trailing dot in domain names #8054

3.21.14 Dynamic DNS

- Fixed DigitalOcean Dynamic DNS client handling of IPv6 addresses #10390
- Fixed DNSExit update URL #9632

3.21.15 Hardware / Drivers

- Added support for `iwm` devices #7725

  Note: This device only supports Station mode. It does not support acting as an access point.

- Added `ng_etf` module to `armv6` and `aarch64` kernels #10463
- Added QLogic 10G driver (`qlxgb/qla80xx`) #9891
- Added `virtio_console` to the kernel #9985

3.21.16 IPsec

- Fixed selection of IPsec VTI Phase 2 local network address/mask values #10418
- Fixed saving IPsec connection breaking FRR BGP on VTI interfaces #10351
- Updated DH group warnings to say that group 5 is also weak #10221
- Fixed disabling IPsec Phase 1 with a VTI Phase 2 #10190
- Fixed disabled IPsec Phase 2 entries being unintentionally included in `vpn_networks` table #7622

3.21.17 L2TP

- Changed L2TP `mpd.secret` handling so that the server is not restarted after adding/modifying L2TP users #4866
- Fixed handling of L2TP usernames containing a realm separator (`@`) #9828
- Fixed Shared Secret handling in L2TP #10531 #10527

3.21.18 Limiters

- Fixed input validation of limiters with ECN #10211
- Fixed bogus extra warning dialog on when deleting limiters #9334

3.21.19 Notifications

- Fixed SMTP notification SSL validation to respect the user-selected behavior #10317

3.21.20 NTPD

- Added `localhost` to NTP Interface selection options #10348

3.21.21 OpenVPN

- Fixed OpenVPN `remote` statement protocol handling #10368
- Added option to configure OpenVPN username as common name behavior #8289

3.21.22 Operating System

- Fixed handling of RAM disk sizes not accounting for existing disk usage when calculating available kernel memory, which could prevent saving #10420
- Updated `pkg` to 1.13.x #10564
- Fixed problems preventing the Netgate Coreboot Package from updating Coreboot properly #10573

3.21.23 Packages

- Fixed handling of FreeRADIUS passwords containing non-XML-safe characters #4497
- Fixed handling of Squid LDAP search filters containing an accent #7654
- Fixed issues preventing FRR from working on certain platforms such as SG-1100 (arm64/aarch64) #10444
- Fixed issues preventing Suricata from working on certain platforms such as SG-1100 (arm64/aarch64) #10228

3.21.24 Rules / NAT

- Fixed Duplicate Outbound NAT entries from L2TP server addresses #10247
- Fixed Outbound NAT rules for mobile IPsec users with per-user addresses defined #9320
- Fixed IPv6 IP Alias VIPs not being added to Interface Network macros #8256
- Fixed Destination port range "Any" in Port Forward rules #7704
- Fixed display of interfaces on the Floating rules list #4629
- Fixed rule description validation to reject \ #10542
- Fixed setting NAT reflection timeout values #10591

3.21.25 Translations

- Fixed language selection for Chinese (Taiwan) / HK Translations #10525

3.21.26 Services

- Fixed `is_process_running()` handling of empty process, which could lead to an error when using the CLI to query the status of a service which does not exist #10540

3.21.27 Web Interface

- Fixed dark theme auto-complete popup field having dark text on dark background #10499
- Fixed using special characters in Schedule descriptions #10305
- Fixed WebGUI main page loading very slowly when there is no Internet connectivity #8987

3.22 2.4.5 New Features and Changes

pfSense® software version 2.4.5 contains a variety of bug fixes and maintenance updates.

Warning: Proceed with caution when upgrading pfSense software while COVID-19 travel restrictions are in effect.

During this time of travel limitations, remote upgrades of pfSense software should be carefully considered, and avoided where possible. Travel restrictions may complicate any repair of any issue, including hardware-related issues that render the system unreachable. Should these issues require onsite physical access to remedy, repair of the issue may not be possible while travel restrictions related to COVID-19 are in effect.

Tip: For those who have not yet updated to 2.4.5-p1, consult the *previous release notes* and blog posts for those releases to read all important information and warnings before proceeding.

3.22.1 Operating System / Architecture changes

- Base OS upgraded to FreeBSD 11.3-STABLE@r357046
- PHP upgraded to 7.2.29

3.22.2 Security / Errata

- Fixed dependency issues with `pfSense-upgrade` which may have caused it not to update itself properly #10303

> **Tip:** If the update check fails, or the update does not complete, run `pkg install -y pfSense-upgrade` to ensure that `pfSense-upgrade` is present.

- Added encoding to the hostname in `services_acb.php` #9584
- Added encoding to error output in `services_captiveportal_mac.php` #9609
- Improved Picture Widget input validation #9610 #9731 #9804
- Added a `fsck` run with `-z` for `UFS` filesystems on upgrade to address FreeBSD-SA-19:10.ufs #9612
- Fixed format of XMLRPC auth error to match GUI auth error #9782
- Added a custom CSRF Error page with warnings and confirmation prompts before resubmitting potentially harmful data #9799
- Fixed Status_Monitoring `rrd_fetch_json.php` error encoding #9601
- Fixed encoding of the user full name on `system_usermanager_addprivs.php` #10324
- Fixed input validation and output encoding of host on `diag_ping.php` #10355
- Addressed FreeBSD Security Advisories & Errata Notices
  - FreeBSD-SA-20:05.if_oce_ioctl
  - FreeBSD-SA-20:04.tcp
  - FreeBSD-SA-19:24.mqueuefs
  - FreeBSD-SA-19:23.midi
  - FreeBSD-SA-19:22.mbuf
  - FreeBSD-SA-19:21.bhyve
  - FreeBSD-SA-19:20.bsnmp
  - FreeBSD-SA-19:19.mldv2
  - FreeBSD-SA-19:18.bzip2
  - FreeBSD-SA-19:17.fd
  - FreeBSD-SA-19:16.bhyve
  - FreeBSD-SA-19:15.mqueuefs
  - FreeBSD-SA-19:14.freebsd32
  - FreeBSD-SA-19:13.pts
  - FreeBSD-SA-19:12.telnet
  - FreeBSD-SA-19:11.cd_ioctl

- FreeBSD-SA-19:10.ufs
- FreeBSD-SA-19:09.iconv
- FreeBSD-SA-19:08.rack
- FreeBSD-EN-20:06.ipv6
- FreeBSD-EN-20:04.pfctl
- FreeBSD-EN-19:18.tzdata
- FreeBSD-EN-19:17.ipfw
- FreeBSD-EN-19:16.bhyve
- FreeBSD-EN-19:15.libunwind
- FreeBSD-EN-19:14.epoch
- FreeBSD-EN-19:13.mds
- FreeBSD-EN-19:12.tzdata
- FreeBSD-EN-19:11.net

3.22.3 Aliases/Tables

- Fixed an issue when resolving FQDN entries in aliases where some entries could be missing #9296
- Improved URL Table aliases to support FQDNs which return muliple entries #8531
- Added a function to download the contents of an individual alias #9816

3.22.4 Authentication

- Added exception handling to authentication attempts #9150

3.22.5 Backup/Restore

- Added a special string (`NoReMoTeBaCkUp`) that when used in `write_config()` descriptions will prevent a remote backup #9693
- Removed legacy AutoConfigBackup options (there were no more active accounts using the retired legacy service) #9687 #9785
- Added CDATA protection to the `encryption_password` XML tag, which allows international characters to be used in that field #7186
- Added CDATA escape to more auth-related fields #9327
- Ensured that `kern.cam.boot_delay` is set for new installations and upgrades so that USB devices are properly initialized in time for configuration restore in the installer and ECL to function #9533

3.22.6 Captive Portal

- Fixed Captive Portal vouchers shortcut links #9722
- Changed Captive Portal redirect page selection order #9819
- Fixed a rare and intermittent issue where users could encounter an `nginx` error when restarting Captive Portal instances #10159

3.22.7 Certificates

- Added sorting and search/filtering to Certificate Authority & Certificate manager #9412
- Corrected wording of CA/Cert CN input validation #9234
- Fixed certificate Descriptive Name field behavior when adding a user certificate #9719
- Added `clientAuth` EKU to Server type certificates #9868
- Reduced the default GUI web server certificate lifetime to 398 days to prevent errors on Apple platforms #9825

3.22.8 Dashboard

- Added option to disable PTI display in System Information widget #9323

3.22.9 DHCP

- Fixed incorrect expansion of Dynamic DNS advanced options on the DHCPv6 Server page #9448
- Changed DHCP relay backend code to determine and specify separate upstream and downstream interface lists #9466
- Prevented OpenVPN interfaces from being used by DHCP relay, since that type of interface is not compatible #8443
- Added an option to disable ping check in dhcpd #9285
- Fixed **Show all configured leases** so it is persistent after deleting a DHCP lease #9133
- Added search/filter to DHCP/DHCPv6 leases #9791
- Improved DHCP client handling of timeout conditions and script failures #9267

3.22.10 Diagnostics

- Fixed a PHP warning in diag_dump_states.php #9780
- Fixed reverse lookup of IPv6 addresses on diag_dns.php #9543
- Fixed diag_system_activity.php to use batch mode for top so it displays process list w/o terminal, and increased amount of output displayed #9522
- Added search/filter ARP table and NDP status #9791

3.22.11 DNS

- Added `127.0.0.0/8` to the DNS Resolver `private-address` list for DNS rebinding protection #9708
- Fixed CIDR selection issues with /32 entries in DNS Resolver Access List entries #9586
- Fixed an issue saving DNS over TLS hostnames on systems with only one gateway #9898
- Fixed an issue where manually configured DNS servers may not have been active if "allow override" was disabled and they were also assigned dynamically #9963
- Added DNS Resolver (Unbound) Python Integration #9251

3.22.12 Dynamic DNS

- Fixed Dynamic DNS class constructor name #9779
- Fixed errors in DNSimple Dynamic DNS #9580
- Fixed handling of wildcard (*) hostname entries in Cloudflare Dynamic DNS #9361
- Added support for AAAA records to Digital Ocean Dynamic DNS #9280
- Fixed issues with Digital Ocean Dynamic DNS handling of empty hostnames #9602
- Cleaned up whitespace issues in Azure Dynamic DNS backend code #9271
- Added support for Linode Dynamic DNS #9268
- Fixed issues with IPv6 on Azure Dynamic DNS #9248
- Fixed handling of wildcards in Route53 Dynamic DNS #9053
- Fixed handling of wildcards in Loopia Dynamic DNS #8014
- Fixed CloudFlare Dynamic DNS processing when `proxied` is enabled #9362
- Fixed CloudFlare Dynamic DNS "Invalid TTL" error due to CloudFlare API update #10196
- Changed hostname to optional for DNS-O-Matic Dynamic DNS #7601
- Added support for Gandi LiveDNS Dynamic DNS #9452

3.22.13 Gateways

- Corrected PHP errors when marking gateways down in certain edge cases #9851

3.22.14 Interfaces

- Added more prefix delegation size entries to selection list on interfaces.php #9590
- Added initialization to the VLAN array in console setup #9582
- Fixed issues with Netgate & hardware model detection which caused problems with default interface mappings #8051
- Fixed issues with display of previously-entered IP address values on interfaces_ppps_edit.php #9741
- Added a confirmation prompt to disconnect/release actions on status_interfaces.php #9911
- Added drivers for Mellanox `mlx4` and `mlx5` network interface cards #7537

3.22.15 IPsec

- Fixed IPsec VTI interface creation logic #9781
- Added GUI option for IPsec P2/Child SA close action #9767
- Added IPsec DH and PFS groups 25, 26, and 27 #9757
- Added 25519 curve-based IPsec DH and PFS group 31 #9531
- Enabled NAT-T controls for IKEv2 #9695
- Improved handling of IPsec restarts breaking VTI routing #9668
- Fixed input validation that incorrectly prevented deleting IPsec P2 entries in some cases with VTI #9258
- Fixed IPsec `keyid` identifier handling #9243
- Fixed IPsec VTI MTU boot-time configuration #9111
- Escape Windows domain backslash in IPsec widget #9747
- Fixed VTI IPv6 address handling #9801
- Fixed Child SA button JS hide on status_ipsec.php, along with other cosmetic improvements #8847
- Added **Connect Children** button to status_ipsec.php to connect when IKE (Phase 1) is up but Child SAs (Phase 2 entries) are not #9954
- Fixed IPsec Phase 2 Remote Network field show/hide when changing between Phase 2 modes #9720
- Fixed IPsec configuration generation so that encryption options for every P2 on a given P1 are not duplicated on each P2 #6263
- Fixed a PHP error in IPsec package plugin hook processing #10217

3.22.16 Load Balancer

- Fixed a PHP when processing services when the configuration does not contain Load Balancer entries #10308

3.22.17 Logging

- Moved `igmpproxy` logs to `routing.log` #10139
- Moved `igmpproxy` verbose logging option to `services_igmpproxy.php` (formerly at `status_logs_settings.php`) #10139
- Updated `sshguard` and fixed a log processing regression #9971
- Fixed PHP errors in filter log processing when entries contain an invalid port #10255

3.22.18 Monitoring

- Fixed custom view titles being forced to lower case #9681
- Fixed packet graph scaling #9807
- Fixed a PHP error in RRD processing of ALTQ data #10248

3.22.19 Notifications

- Fixed SMTP notification password being unintentionally changed when testing SMTP settings #9684
- Reduced frequency of GEOM rebuild notifications #9256

3.22.20 NTPD

- Added validation to ensure NTP values are treated as numbers before use #9558
- Changed the default NTP pool server to `2.<domain>` so that it can use IPv6 #9931
- Improved handling of errors on the NTP status page to work/fail gracefully with custom ACLs for localhost in place #9829

3.22.21 OpenVPN

- Fixed JavaScript issue when selecting multiple OpenVPN NCP algorithms #9756
- Fixed OpenVPN wizard so it does not show DH parameter lengths that are not available #9748
- Fixed issues with OpenVPN resynchronizing when running on a gateway group #9595
- Added an option to set the OpenVPN TLS Key Direction #9030
- Added GUI options to configure OpenVPN keepalive parameters #3473
- Fixed instances of hidden invalid OpenVPN options affecting save operations #9674
- Added a copy action to OpenVPN pages #5851
- Improved sorting of bytes sent/receives on OpenVPN status page #7359
- Fixed visibility of the OpenVPN 'interface' option when multihome is selected #7840
- Reduced the OpenVPN server certificate lifetime to 398 days in the wizard to prevent errors on Apple platforms #9825
- Added input validation to prevent OpenVPN tunnel network reuse #3244
- Added Exit Notify to OpenVPN servers/client options #9078

3.22.22 Operating System

- Fixed serial console terminal size issues #9569
- Added the `strings` binary to base builds for troubleshooting #7791
- Changed UFS filesystem defaults to `noatime` on new installations #9483
- Fixed an issue where the IP header checksum was incorrect when reassembling packet fragments to a link with a different MTU #10189

3.22.23 Packet Capture

- Changed Packet Capture GUI to allow multiple TCP/UDP ports to be specified #9766
- Added start time to Packet Capture display #9831
- Added OSPF/OSPFv3 to Packet Capture protocols #9905
- Fixed Packet Capture to match both IPv4+IPv6 CARP when that protocol is selected #9867
- Fixed Packet Capture for the `pfsync` protocol #10183

3.22.24 Routing

- Fixed `(Default)` designation on routes to match the default route in the OS #9292
- Fixed static routes remaining in routing table after removal #9969

3.22.25 Rules / NAT

- Fixed state kill ordering in rc.newwanip #4674
- Added the ability to search firewall logs by tracking ID #8703
- Added GUI option to disable default blocking of APIPA networks #9966
- Added more common ports to the firewall rule drop-down list #10166
- Added input validation to prevent selecting `!*` (“not any”) in source or destination #10168
- Fixed invalid rules generated when using NAT reflection with a negated destination #10246

3.22.26 S.M.A.R.T.

- Updated the SMART page with new capabilities #9367

3.22.27 SNMP

- Fixed SNMP sysDescr contents to include hostname and patch version #9218

3.22.28 Traffic Shaping / Limiters

- Added input validation for Limiter delay values #9921
- Fixed the queue statistics parser to handle large values #9938

3.22.29 Translations

- Fixed an issue with international characters in configuration descriptions, which led to failures in certain cases, such as failing to set Manual Outbound NAT when the Language was set to pt_BR #6195
- Fixed a PHP error on `system_advanced_admin.php` when the language was set to French #10331

3.22.30 Upgrade / Installation

- Revised update check to provide a more consistent version string in JSON format #9778
- Disabled serial console on VGA memstick images #9488
- Fixed a PHP error when upgrading older configurations from revision 14.4 to 14.5 #9840

3.22.31 UPnP

- Fixed display of active UPnP sessions when configured with an alternate external address #9961

3.22.32 User Manager / Privileges

- Added input validation to prevent changing the authentication server name #9692
- Added privilege to manage integrated switches #9620
- Fixed privilege matching to handle JS anchor links #9550
- Removed wildcards incorrectly used in `isAllowedPage()` #9541
  - This issue could prevent a user in the admins group from reaching certain pages such as the User Manager.
- Improved Deny Config Write privilege handling in the User & Group Manager #9259
- Fixed input validation of group name sizes to allow longer remote groups #3792
- Fixed handling of L2TP and PPPoE user passwords containing invalid characters #10275

3.22.33 Web Interface

- Corrected input validation for firewall rule VLAN priority/set #9763
- Restricted Thoth tests to arm64 in status.php NG 2569
- Added kernel memory usage to status.php output #9705
- Redacted several additional fields in status.php output #9784 #9729 #9728 #9727 #9694 #9736 #9764
- Fixed a potential source of PHP errors when saving per-log settings #9540
- Added GUI components for MDS mitigation #9532
- Fixed integrated switch LAGG member editing on switch_ports.php #9447
- Fixed wizard.php selection option size attribute handling #8907
- Fixed platform detection for certain C2558/C2758 systems #6846
- Set `autocomplete=new-password` for forms containing authentication fields to help prevent browser auto-fill from completing irrelevant fields #9864
- Fixed processing of shortcuts for XML-based packages #9770
- Updated jQuery #9407
- Improved consistency of SSL/TLS references throughout the GUI #10172
- Updated various help references and links to use the pfSense book instead of external resources #10135 #10184

3.22.34 XMLRPC

- Fixed removal of the last ALTQ traffic shaping entry from the target system when performing an XMLRPC sync #9469
- Fixed removal of the last limiter entry from the target system when performing an XMLRPC sync #9468

3.23 2.4.4-p3 New Features and Changes

pfSense® software version 2.4.4-p3 addresses security and other issues found in *2.4.4-p2*.

Tip: For those who have not yet updated to 2.4.5-p1, consult the *previous release notes* and blog posts for those releases to read all important information and warnings before proceeding.

Warning: The upcoming pfSense release version 2.5.0 deprecates the built-in load balancer, and all related code has been removed as it is not compatible with FreeBSD 12. Plan migrations to alternate solutions such as the HAProxy package now.

See the *2.5.0 release notes* for more information.

3.23.1 Security / Errata

- Changed `sshguard` to block both ssh and the GUI using a single table, and removed the unnecessary manual scheduled table expiration pfSense-SA-19_02.sshguard #9223
- Fixed potential XSS vectors
  - pfSense-SA-19_01.webgui : Fixed potential XSS vectors in system_advanced_admin.php, interfaces_assign.php, firewall_rules_edit.php, firewall_shaper.php, services_igmpproxy_edit.php, services_ntpd_gps.php and diag_traceroute.php #9294
  - pfSense-SA-19_03.webgui : Fixed potential XSS vector in status_filter_reload.php #9499
  - pfSense-SA-19_04.webgui : Fixed potential XSS vector in the WOL widget #9507
  - pfSense-SA-19_05.webgui : Fixed potential XSS vector in services_acb.php #9508
- Fixed privilege issues
  - pfSense-SA-19_06.webgui : Restrict edit access to OpenVPN-related advanced settings, and added new privilege to delegate edit permissions #9511
  - pfSense-SA-19_07.webgui : Strengthen widget privilege matching to avoid a potential privilege bypass for users granted access to widgets #9512
  - pfSense-SA-19_08.webgui : Strengthen path privilege check to avoid a potential directory-traversal-like bypass method #9513
  - Added privileges for Auto Config Backup pages #9519
  - Updated privileges: Added misc missing pages, removed obsolete pages
- Addressed FreeBSD Security Advisories:
  - FreeBSD-SA-19:03.wpa
  - FreeBSD-SA-19:04.ntp
  - FreeBSD-SA-19:05.pf
  - FreeBSD-SA-19:06.pf
  - FreeBSD-SA-19:07.mds
  - FreeBSD-EN-19:08.tzdata
- Added DNS over TLS host verification #8602
  - Configure hostnames for DNS over TLS servers under **System > General**
- sqlite updates #9205

3.23.2 Backup / Restore

- Fixed issues with output buffering causing configuration backup download failures #9390
- Fixed automatic package reinstallation after restoring config.xml from the installer #9214
- Force <`enableserial`> when restoring a backup on a device with serial only console

3.23.3 Certificates

- Added missing countries from CA list on certificate pages #9308
- Fixed an error when adding a new user and choosing to generate a certificate #9317

3.23.4 DNS

- Fixed input validation on diag_dns.php to allow a trailing dot on hostnames #9276
- Removed non-functional tools links from diag_dns.php #9275
- Fixed rewriting of the DNS Resolver file `remotecontrol.conf` if it is present but empty #9470

3.23.5 Firewall Rules / NAT / Aliases

- Fixed intermittent pf errors when NAT reflection is enabled #9446
- Fixed reserved pf keyword matching when creating and editing aliases #9231
- Fixed duplicate entries showing on diag_tables.php from lockout tables #9359
- Fixed a PHP error deleting an imported NAT rule with no firewall rules present #9193
- Do not show scheduler icon when scheduler tag is empty

3.23.6 Gateways / Routing

- Fixed issues with the default IPv4 gateway set to a group failing after restart #9004

3.23.7 Interfaces

- Fixed PHP error from interface groups when editing QinQ entries

3.23.8 IPsec

- Fixed IPsec Phase 1 entries on upgrade to have their `protocol` field populated properly #9207

3.23.9 Operating System

- Fixed support for ZFS encrypted+mirrored swap #9281
- Fixed problems saving crash dumps when `/var` is a RAM disk #9409

3.23.10 Traffic Shaping

- Fixed a PHP error when loading a limiter that does not exist #9313
- Fixed limiter selection validation
- Fixed Queues menu items ending with ":" in certain languages #8970

3.23.11 WebGUI

- Numerous optimizations and improvements for status.php diagnostics output #9290
- Fixed a PHP error on system_advanced_network.php when disabling "IPv6 over IPv4 Tunneling" #9264
- Improved handling of large captures on diag_packet_capture.php and disabled viewing of captures larger than 50MiB. #9239
- Added hostname to login page title if the user has enabled **Show hostname on login banner** #9096
- Centralized the list of country codes used by multiple areas #9308
- Updated translation files

3.23.12 XMLRPC

- Clarified conditions for synchronizing certificates in HA Sync options #9283

3.24 2.4.4-p2 New Features and Changes

pfSense® software version 2.4.4-p2 adds support for new Netgate hardware and corrects issues found with *2.4.4-p1*.

Warning: For those who have not yet updated to 2.4.4-p1 or 2.4.4, consult the release notes and blog posts for those releases to read all important information and warnings before proceeding.

3.24.1 Miscellaneous

- Hardware support/improvements for Netgate products
- Fixed swap slice labeling in MBR mode and changed the way swap is located at boot time to detect and work around incorrect `fstab` swap labels created by the installer #9182
- Fixed handling of IPv6 name servers with nginx when using a certificate that requires OCSP stapling #9160
- Fixed handling of NPt rules using a /128 prefix #9163
- Fixed a PHP error in the Setup Wizard when dealing with static gateways #9170
- Updated Dynamic DNS to accommodate recent changes in the Digital Ocean API #9171
- Fixed OpenVPN RADIUS authentication use of `calling_station_id` #9178
- Fixed input validation that rejected certain valid hash algorithms when signing a CSR #9180
- Removed obsolete and unused OLSRD code #9117

3.25 2.4.4-p1 New Features and Changes

pfSense® software version 2.4.4-p1 corrects issues found with 2.4.4-RELEASE.

3.25.1 Security / Errata

- FreeBSD Errata Notice FreeBSD-EN-18:09.ip: IP fragment remediation causes IPv6 fragment reassembly failure #8934
- FreeBSD Errata Notice FreeBSD-EN-18:10.syscall NULL pointer dereference in freebsd4_getfsstat system call (CVE-2018-17154)
- FreeBSD Errata Notice FreeBSD-EN-18:11.listen Denial of service in listen syscall over IPv6 socket (CVE-2018-6925)
- FreeBSD Errata Notice FreeBSD-EN-18:12.mem Small kernel memory disclosures in two system calls (CVE-2018-17155)
- Fixed a potential authenticated command injection issue with PowerD settings pfSense-SA-18_09.webgui #9061
- Fixed handling of privileges on the **All** group that were previously ignored #9051

> **Warning:** Check the privileges on the **All** group before upgrading to avoid unintended privileges for accounts being respected that were not honored before

3.25.2 Certificates

- Fixed CRL lifetime errors due to 2038 rollover on 32-bit ARM platforms #9098
- Fixed date display of CA/Certificate validity ending dates after 2038 rollover on 32-bit ARM platforms #9100
- Fixed PHP errors when creating certificate entries #9099

3.25.3 DNS

- Updated Unbound to 1.8.1 to address issues with memory leaks, especially in DNS over TLS support #9059
- Fixed issues with the DNS search domain for the firewall being omitted from `resolv.conf` in certain cases #9056
- Fixed PHP errors in the DNS Forwarder #8967

3.25.4 Dynamic DNS

- Fixed an issue with FreeDNS Dynamic DNS sending an IP address with an update #8924
- Fixed issues with Custom (v6) Dynamic DNS logging a hostname error #8977

3.25.5 DHCP Server

- Fixed issues with DHCPv6 network boot settings #8949

3.25.6 Routing/Gateways

- Reduced the logging output of gateway change events #8914
- Fixed an issue with `dpinger` PID files causing it to get stuck in Pending status #8921
- Fixed display of a configured gateway monitor IP address when gateway monitoring is disabled #8953
- Fixed issues with double quotes in gateway descriptions causing a blank gateway drop-down on firewall rules #8962
- Fixed an issue where the default gateway was lost in certain cases with HA after a CARP VIP status transition #8465

3.25.7 IPsec

- Updated strongSwan to 5.7.1 #8898
- Added `0.0.0.0/0` to both sides of an IPsec VTI P2 to allow connections with third-party routed IPsec implementations that require its presence #8859
- Fixed boot-time handling of IPsec VTI static routes #9116
- Fixed IKEv2 EAP Identity/Client ID matching so that it is strictly performed, to avoid users getting incorrect per-user settings #9055
- Fixed handling of RADIUS server names containing a `.` in the IPsec configuration with strongSwan 5.7.1 #9106
- Updated AWS IPsec wizard to use EC2 instance profiles and security groups, and switched the wizard from OpenBGPD to FRR

3.25.8 Interfaces/VIPs

- Fixed issues with DHCP client MTU causing interface configure loops when advanced options are present #8507
- Fixed issues with the Hyper-V `hn(4)` driver and ALTQ #8954
- Fixed issues with Hyper-V `hn(4)` interfaces dropping UDP6 traffic when transmit checksums were enabled #9019
- Fixed an issue with IGMP proxy failing to start on PPPoE interfaces #8935
- Fixed an issue with IPv6 Transmit checksums not being disabled when hardware checksums were set to be disabled #8980
- Updated mpd to 5.8_8 to address issues with Orange MTU #8995
- Fixed PPPoE service name checks to allow `:` and other alphanumeric characters #9002
- Fixed PHP errors when creating QinQ entries #9109
- Fixed the MAC address shown when editing a LAGG entry to always show the hardware MAC for each NIC and not the currently active address, which is no longer accurate for LAGG members #8937
- Fixed a PHP error when setting an interface address to act as a DHCP server from the console, when no other DHCP servers are already configured #9144

- Fixed a situation where editing a VLAN interface caused all other VLAN interfaces with the same parent to be reconfigured, which led to several other issues #9115

> **Warning:** Editing a VLAN parent interface can still cause problems. If this becomes an issue on a firewall, consider moving from using the untagged parent to having that traffic be tagged so that the parent interface is not assigned or in use. #9154
>
> Known issues include:
>
> – PPPoE instances on VLANs will not reconnect after the interface is reconfigured #9148
>
> – VLAN interfaces that use IPv6 tracking may lose their addresses #9136

3.25.9 Hardware/Platform

- Fixed handling of EFI console when a device boots from UEFI, where `vidconsole` is not valid #8978
- Fixed PHP errors in switch configuration on platforms including integrated switches
- Added support for SG-5100 hardware watchdog

Note: Enable the Watchdog daemon under **System > Advanced** on the **Miscellaneous** tab, and then reboot and enable it in the BIOS with a timeout longer than the timeout configured in the GUI.

3.25.10 User Management / Authentication

- Fixed handling of privileges on the **All** group that were previously ignored #9051

> **Warning:** Check the privileges on the **All** group before upgrading to avoid unintended privileges for accounts being respected that were not honored before

- Added GUI options to control `sshguard` sensitivity and whitelisting to allow users to fine-tune the behavior of the brute force login protection #8864
- Added an option to enable SSH agent forwarding (disabled by default) #8590
- Fixed inconsistencies with ssh settings in the configuration #8974
- Fixed PHP errors with ssh settings #8606
- Added support for LDAP client certificates on authentication servers (Factory only) #9007
- Fixed an issue with **Local Database** authentication when using non-English languages in certain cases, such as with Captive Portal #9086

3.25.11 Captive Portal

- Fixed Captive Portal RADIUS NAS Identifier default values to include the zone name #8998
- Restored the ability to set a custom NAS Identifier on Captive Portal RADIUS settings #8998
- Fixed issues with Captive Portal logout popup #9010
- Fixed handling of the login page displayed when RADIUS MAC Authentication fails #9032
- Fixed username sent in RADIUS accounting with MAC-based authentication #9131
- Fixed an issue with the blocked MAC address redirect URL #9114

3.25.12 WebGUI / Dashboard

- Fixed `nginx` restart handling when toggling GUI web server options under **System > Advanced**, **Admin Access** tab
- Fixed empty crash reports after upgrade #8915
- Added CDATA protection to common name fields so they can safely contain international characters #9006

3.25.13 Firewall Rules / Aliases / NAT

- The `filterdns` daemon has been rewritten, solving a number of issues with the old implementation, including:
  - Fixes `filterdns` triggering every 16 seconds even when DNS records have not changed #7143
  - Fixes invalid FQDN entries in aliases causing an alias table to fail silently #8001
  - Fixes `filterdns` failing on a regular basis #8758
- Fixed `/etc/rc.kill_states` not correctly parsing `pfctl` output #8554
- Fixed formatting of alias names to still wrap but not replace underscores #8893
- Fixed PHP errors from `filter_rules_sort()` when a configuration contains no rules #8993
- Fixed PHP errors when creating schedules #9009
- Fixed PHP errors when creating entries on NAT pages #9080
- Fixed PHP errors from `easyrule` when no aliases are present #9119
- Fixed "Drag to reorder" description in rule list when rule drag-and-drop is disabled #9128

3.25.14 Traffic Shaping (ALTQ/Limiters)

- Fixed issues with Limiter queue display on upgraded configurations #8956
- Fixed the default limiter scheduler to match previous version (WF2Q+) #8973
- Added scheduler information to the limiter information page #8973

3.25.15 Packages

- Fixed issues with package installation causing problems when crossing major PHP versions #8938
- Fixed PHP errors when installing packages #9067

3.25.16 Backup/Restore

- Added schedule (cron) support to AutoConfigBackup #8947
- Fixed issues with AutoConfigBackup restoring a configuration from a different host #8901
- Fixed the AutoConfigBackup menu from the deprecated package still showing when the package is no longer present #8959
- Fixed an issue with **Reinstall Packages** hanging when run from **Diagnostics > Backup & Restore** #8933
- Fixed issues with multiple <rrddata> tags in `config.xml` #8994
- Fixed a race condition in package operations after a configuration restore that could lead to no packages being reinstalled #9045
- Fixed issues with the External Config Locator not finding a `config.xml` in `/config` #9066
- Fixed an issue where packages may not be reinstalled during a configuration restore performed immediately after a fresh install #9071
- Fixed a `stream_select()` error when restoring packages #9102

3.25.17 Wake on LAN

- Fixed issues with ordering of entries in Wake on LAN #8926
- Added top control buttons to Wake on LAN for **Add** and **Wake all Devices** when there are more than 25 entries #8943

3.25.18 NTP

- Fixed issues with NTP status when using `noquery` in the default permissions along with a specific ACL for localhost #7609

3.25.19 Logging / Notifications

- Fixed an issue with log file sizes >= `2^32/2` #9081
- Fixed PHP errors when saving log settings #9095
- Added a checkbox to disable TLS certificate verification for SMTP notifications #9001

3.25.20 Install/Upgrade

- Added a FAT partition to the installer memstick to make it easier to restore a `config.xml` file during the install process. Also includes a copy of the license and a README. #9104
- Fixed PHP errors in upgrade code for IPsec #9083

3.25.21 Miscellaneous

- Fixed HTTPS proxy authentication support for connections on the firewall itself #9029
- Clarified wording of **Kernel PTI** options on **System > Advanced**, **Miscellaneous** tab #9026
- Added a Save button to **Status > Traffic Graphs** to store default settings to use when loading the page #8976
- Added support for `nvme` controllers to the S.M.A.R.T. diagnostics page #9042

3.26 2.4.4 New Features and Changes

3.26.1 Significant Changes

OS Upgrade
Base Operating System upgraded to FreeBSD 11.2-RELEASE-p3. As a part of moving to FreeBSD 11.2, new hardware support is included for C3000-based hardware.

PHP 7.2
PHP upgraded to 7.2, which required numerous changes to syntax throughout the source code and packages.

Routed IPsec (VTI)
Routed IPsec is now possible using FreeBSD `if_ipsec(4)` Virtual Tunnel Interfaces (VTI). #8544 (See also: *Routed IPsec (VTI)*)

IPsec Speed Improvements
The new **Asynchronous Cryptography** option under the IPsec **Advanced Settings** tab can dramatically improve IPsec performance on multi-core hardware #8772

Default Gateway Group
The default gateway may now be configured using a Gateway Group setup for failover (each gateway on a different tier), which replaces Default Gateway Switching. #8187

Limiter AQM/Queue Schedulers
Limiters now include support for several Active Queue Management (AQM) methods and Queue Scheduler configurations such as FQ_CODEL. #6620 (See also: pfSense PR #3941)

Certificate Subject Requirements
The Certificate Manager and OpenVPN wizard now only require the **Common Name** to be set, and all other fields are optional. #8381

AutoConfigBackup is free!
AutoConfigBackup now integrated and free for all to use. (See also: *Automatic Configuration Backup Service*)

DNS over TLS
The DNS Resolver now includes support for DNS over TLS as both a client and a server, including for domain overrides. #8388 #8030 #8431

Captive Portal Authentication
Captive Portal authentication is now integrated with the User Manager system. Captive Portal instances may now use RADIUS, LDAP, or Local Authentication like other integrated services. The firewall will migrate existing Captive Portal RADIUS settings to the User Manager automatically on upgrade.

Captive Portal HTML Design and Usability
The default Captive Portal page has been redesigned. Controls have also been added which allow for the logo and background images and Terms of Service text to be customized without editing and uploading custom HTML code. #8793

Integrated Switch Improvements
Netgate devices with integrated switches such as the SG-3100 and XG-7100 can now configure per-port speed and duplex settings, discrete port configuration interfaces can now be tied to switch ports for up/down status, and LAGG support is also now available (Load Balance mode only)

3.26.2 Security

- FreeBSD SA for CVE-2018-6922: Resource exhaustion in TCP reassembly FreeBSD-SA-18:08.tcp
- FreeBSD SA for CVE-2018-3620, CVE-2018-3646: L1 Terminal Fault (L1TF) Kernel Information Disclosure FreeBSD-SA-18:09.l1tf
- FreeBSD SA for CVE-2018-6923: Resource exhaustion in IP fragment reassembly FreeBSD-SA-18:10.ip
- FreeBSD SA for CVE-2018-14526: Unauthenticated EAPOL-Key Decryption Vulnerability FreeBSD-SA-18:11.hostapd
- FreeBSD SA for CVE-2018-6924: Improper ELF header parsing FreeBSD-SA-18:12.elf
- FreeBSD errata notice for LazyFPU remediation causing potential data corruption FreeBSD-EN-18:08.lazyfpu
- Fixed a potential XSS vulnerability via GUI rule separators pfSense-SA-18_06.webgui #8654
- Fixed a potential XSS via custom GUI/dashboard settings pfSense-SA-18_07.webgui #8726
- Fixed a potential authenticated ACE vulnerability pfSense-SA-18_08.webgui #8843
- Upgraded strongSwan to 5.6.3 to address a buffer underflow leading to denial of service (CVE-2018-5388) #8746
- Updated default cryptographic settings for OpenVPN, IPsec, and Certificates #8594
- Changed the included DH groups to those defined in RFC 7919 #8582
- Added stronger IPsec Pre-Shared Key usage warnings, and a button to generate a secure PSK #8667
- Disabled OpenVPN compression by default on new instances for security reasons due to VORACLE – Users should strongly consider disabling compression on OpenVPN instances if they pass unencrypted data such as HTTP to arbitrary Internet sites #8788
- Patched OpenSSH for CVE-2018-15473, username enumeration/disclosure through malformed packets.
- Changed from `sshlockout_pf` to `sshguard` for monitoring failed logins and locking out offenders, this allows the lockout to work on IPv4 and IPv6 and also terminates states when adding offenders to the block list #7694 #7695

3.26.3 Errata

Warning: Third party packages from **alternate repositories** are causing problems for users with the upgrade process and also with post-upgrade behavior. These packages have never been supported, and had to be manually added by users outside of the GUI.

Due to the major changes required for FreeBSD 11.2 and PHP 7.2, third party packages from alternate repositories cannot be present during the upgrade. There is no way to predict if a third party package supports the new version or will cause the upgrade itself to fail.

The upgrade process will automatically remove `pfSense-pkg-*` packages installed from alternate repositories. After the upgrade completes, the user can reinstall these packages. Packages from **alternate repositories** will not appear in the **Installed Packages** list in the GUI, and must be entirely managed in the command line.

This change does not affect packages installed from the official pfSense® package repository.

- Removed options for the deprecated FEC LAGG Protocol #8734

3.26.4 Certificates

- Changed the Certificate Manager and OpenVPN wizard to only require the **Common Name** for the CA/Cert subject #8381
- Updated default cryptographic settings Certificates #8594
- Added support for OCSP Must-Staple certificates in the GUI (and ACME package) #8418
- Changed CRL support from using an abandoned PHP OpenSSL module patch to a pure PHP implementation compatible with PHP 7.2 #8762
- Fixed issues with several areas not properly parsing CA fields properly when they were not in the expected order #8801
- Changed the default CA and Certificate create action from "Import…" to "Create an internal…" #8851

3.26.5 DNS

- Added DNS over TLS for upstream forwarders to the DNS Resolver #8388
- Added DNS over TLS server support to the DNS Resolver #8030
- Added DNS over TLS options for DNS Resolver Domain Override #8431
- Fixed editing DNS Resolver ACLs in non-English languages #8539
- Added a DNS Resolver status page #8430
- Clarified that "Register DHCP leases in the DNS Resolver" only works for IPv4 addresses #8592
- Added IPv6 representation of IPv4 addresses in DNS Resolver DNS Rebinding checks #8750
- Fixed disabling the DHCP Server on interfaces when the DNS Resolver **DHCP Registration** option is enabled (Only one enabled interface is required) #8120
- Added advanced option for `qname-minimization` to the DNS Resolver #8028
- Fixed an issue with IDs when editing or deleting DNS Forwarder host override entries #8767

3.26.6 Dynamic DNS

- Added Dynamic DNS client for DigitalOcean DNS #8478
- Fixed Dynamic DNS clients usage of custom check IP services #8664
- Added Dynamic DNS client for Azure #7769
- Updated DNSimple Dynamic DNS client to use DNSimple API v2 #8071
- Fixed handling of username and password fields for custom Dynamic DNS entries #8782

3.26.7 Routing/Gateways

- Added the ability to set a Gateway Group as the default gateway. #3781 #8187
- Extended the maximum Gateway monitoring **Probe Interval** #8593
- Fixed handling of Gateway Group **Trigger Level** #8586
- Fixed inconsistency in display and usage of units for Gateway latency #8477
- Upgraded FRR to 5.0.1 for compatibility with FreeBSD 11.2 #8449
- Fixed FRR BGP MD5 support #8407
- Fixed handling of Router Advertisement preferences #6237

3.26.8 IPsec

- Added routed IPsec using FreeBSD `if_ipsec(4)` VTI #8544
- Added a GUI option to the IPsec **Advanced Settings** tab for Asynchronous Cryptography which can dramatically improve IPsec crypto operation performance on multi-core hardware #8772
- Added IPsec identifiers to **Status > IPsec** #8598
- Fixed a JavaScript variable issue in IPsec IKE Phase 1 causing the Key Length field to be blank in some browsers such as IE #8543
- Added IPsec mobile client options to configure different (virtual) IP addresses per user #8292
- Added IPsec mobile client options to configure different DNS servers per user #8644
- Updated default cryptographic settings for IPsec #8594
- Changed the default behavior of an IPsec Phase 1 to rekey as needed #8540
- Fixed handling of per-user IPsec rules from an authentication server #8765
- Added warnings and hints to IPsec encryption and hash choices about potentially insecure selections #8766
- Fixed an issue with handling IP Alias VIPs with CARP parent after an interface up/down event #8768

3.26.9 OpenVPN

- Disabled compression by default for new OpenVPN client and server instances for security reasons #8788
- Changed OpenVPN Authentication to use an asynchronous authentication plugin which avoids stalling server traffic during the authentication process, especially noticeable on down/broken authentication servers #7905
- Fixed display of **Bridge Route Gateway** options on OpenVPN tap bridge servers #8658
- Fixed handling of LDAP fields in the OpenVPN wizard and brought the options in line with current LDAP server options #8605
- Updated default cryptographic settings for OpenVPN #8594
- Added missing OpenVPN compression options (`stub-v2` and plain `compress`) #8788

3.26.10 DHCP Server

- Fixed validation of custom DHCP options #8534
- Fixed a situation where DHCPv6 was configured for LAN when the LAN interface was not assigned #8048
- Fixed an issue with XMLRPC synchronization of DHCP static mappings #8721

3.26.11 Interfaces / VIPs

- Removed IPv4 and IPv6 settings from the Interface configuration for assigned OpenVPN/GIF/GRE/Routed IPsec instances, since the IP addresses are managed by the parent config not interfaces.php #8687
- Fixed an HTTP_REFERER issue when changing the LAN IP address in the Setup Wizard #8524
- Fixed an HTTP_REFERER issue when changing an interface IP address while accessing the GUI from the same interface #8822
- Fixed handling of the FreeBSD 11.2-BETA dhclient MTU value #8507
- Added PPPoE multi-link over single link to allow users with a supported provider to have a larger MTU #8737
- Fixed a PPPoE MTU issue with ORANGE FR #8595
- Fixed QinQ interface assignment #8446
- Fixed radvd/IPv6 when using a LAN bridge #8429
- Fixed deleting IP Alias VIPs outside an interface subnet where a gateway exists in the same subnet #4438
- Fixed handling of IP Alias and CARP VIP subnet mask/prefix autodetection #8741
- Fixed a panic in IPv6 fragment logging #8499
- Fixed handling of DHCP option 77 in the DHCP client #7425
- Fixed deleting Interface Group members which are disabled #8800
- Fixed MAC address spoofing for bridge interfaces #8138
- Fixed an issue with string termination when creating interfaces through the pfSense PHP module #8683
- Fixed an issue where changing a LAGG could cause a VLAN using that LAGG as a parent interface to lose its association with the LAGG #8527

3.26.12 Integrated Switches

- Added GUI controls to configure LAGG on integrated switch ports (Load Balance mode only)
- Added GUI controls to configure Speed/Duplex for switch ports on integrated switches
- Added the ability to tie the status of an assigned VLAN interface to a switch port for integrated switches
- Added Switch Status to status.php for platforms with a switch #8525
- Fixed an issue switching between Port VLAN and 802.1q VLAN mode on integrated switches #8422
- Fixed an SNMP error on hardware with integrated switches #8600
- Added **Preserve Switch Configuration** option when restoring `config.xml` to keep the current active switch settings instead of those from the imported configuration to help with hardware transitions

3.26.13 Hardware/Platform

- Added support for the new SG-5100
- Fixed an issue with ARM hardware not completely halting when shut down (SG-3100 and SG-1000)
- Fixed HDMI hotplug issues on Minnowboard Turbot hardware (MBT-2220 and MBT-4220)
- Fixed SG-1000 autonegotiation for 10baseT speed and duplex #7532

3.26.14 User Management / Authentication

- Added a visible warning to the user when default password has not been changed #8596
- Fixed configuration descriptions user management operations and added logging #8548
- Fixed escaping of LDAP search parameters #8626
- Fixed an OS issue with adding a group to a user when creating the user #8553
- Fixed handling of LDAP bind credentials #8583
- Removed some legacy code from `auth.inc` #8742
- Fixed Group selections after an input error in the User Manager #8622
- Fixed inconsistent usage of `sshdkeyonly` in `system_advanced_admin.php` #8403
- Added SSH configuration option to require **both** Key **and** Username+Password authentication at the same time #8402
- Replaced `radius.inc` by pear-Auth_RADIUS #7024
- Fixed synchronization of User Manager group scope and operating system groups #7013
- Fixed logging and display of GUI user authentication source IP address when the user logs in through a proxy #8813
- Fixed logging and display of GUI user authentication sources to show what source authorized the login (e.g. LDAP, RADIUS, Local, Fallback) #8816

3.26.15 Captive Portal

- Integrated Captive Portal authentication into the User Manager to enable support for LDAP #5112
- Updated Captive Portal HTML/CSS to a modern design and added controls to customize images and ToS without uploading custom HTML #8793
- Fixed deleting **Allowed Hostnames** and **Allowed IP Addresses** entries in Captive Portal when a zone is disabled #8530
- Added support for setting Captive Portal traffic quotas #8202
- Added display of a custom username when Captive Portal is set to *None* for the authentication type #8361
- Changed handling of Called-Station-Id/Calling-Station ID to send a MAC address instead of IP address when using RADIUS authentication #4294
- Changed to a standardized NAS-Identifier when using RADIUS authentication #3686
- Corrected accounting updates not being sent when expected #8655
- Fixed an issue with XMLRPC synchronization of Captive Portal settings #8806

3.26.16 WebGUI / Dashboard

- Enabled HTTP2 for the Web GUI server #8552
- Updated the text and links in the HTML footer #8733
- Fixed display of available swap with multiple swap disks in the **System Information** Dashboard widget #8587
- Updated text in the Setup Wizard #8753
- Moved the simplepie RSS reader code to a FreeBSD port for easier updates #6998
- Fixed handling of the **Inverse** option in the Traffic Graphs Dashboard Widget #8367
- Fixed issues with the GUI following upgrade progress #8519
- Added a line to display the current GUI user viewing the Dashboard in the System Information Widget #8817

3.26.17 Firewall Rules / NAT / Shaping

- Added CoDel, FQ-CoDel, PIE and FQ-PIE AQMs to limiters #6620
- Fixed firewall ruleset errors related to VIPs and outbound rules #8518 #8408
- Added validation for IPv6 NPt input #8575
- Fixed a race condition in NAT reflection filter rules that could lead to a ruleset load failure #8604
- Fixed viewing the list of Port Forwards when a user only has the "WebCfg - Firewall: NAT: Port Forward" privilege #8563
- Fixed an issue with default field selection when editing Firewall Rules #8597
- Added code to prevent nested alias loops #8101
- Added interface groups support for NAT rules #1933
- Fixed a case where invalid IPv6 NAT rules could be generated #8437
- Fixed a case where IPv6 Neighbor Discovery and other similar valid messages sent from the unspecified address (`::`) were not allowed by default #8791

- Added **Select All** functionality to firewall and NAT rules #8812
- Fixed IPv6 address form field format tooltip #8834

3.26.18 Packages

- Fixed situation where the firewall would get stuck attempting to reinstall packages after restoring a configuration when there is no Internet connection #7604
- Added a new tag for package services, `<starts_on_sync/>`, to allow packages to declare that they start themselves during the sync process, which lets packages opt out of a (second) forced start at boot and during interface events #8850

  See also: #8620

3.26.19 Miscellaneous

- Fixed display of stored Load Balancer custom settings #8704
- Fixed handling of `loader.conf` and `loader.conf.local` so it will not remove customized options that override defaults #8571
- Fixed the restoration process for a `config.xml` from USB during install to remove RRD data so that the data does not indefinitely stay in `config.xml` #7634
- Fixed handling of special characters in L2TP user passwords #7623
- Fixed handling of sample bounds with custom timer periods on **Status > Monitoring** #6477
- Changed the crash reporter so that users can download the reports locally rather than submitting to a server #8764
- Added more redacted XML tags to status.php #8819
- Changed status.php to use `ifconfig -va` to show more detail, including attached SFP devices with certain network interface drivers #8860

3.27 2.4.3-p1 New Features and Changes

New features and changes for this release of pfSense® software:

3.27.1 Security / Errata

- FreeBSD SA for CVE-2018-8897 FreeBSD-SA-18:06.debugreg
- FreeBSD EN for CVE-2018-6920 and CVE-2018-6921 FreeBSD-EN-18:05.mem
- Fixed a potential LFI in pkg_mgr_install.php pfSense-SA-18_04.webgui #8485
- Fixed a potential XSS in pkg_mgr_install.php pfSense-SA-18_05.webgui #8486

3.27.2 Misc

- Added a check to avoid creating route-to rules for proxy ARP addresses
- Corrected alias name input validation text referring to well-known and registered ports #8409
- Corrected the list of pf reserved keywords to prevent aliases from using invalid custom names #8445
- Fixed an issue with Captive Portal access rules being left behind on disconnect #8441
- Fixed an issue with pressing Enter in the filter field of diag_pftop.php #8494
- Fixed an issue with invalid rules generated due to the presence of IPv6 Alias VIPs #8408
- Fixed an issue with IPsec mobile Pre-Shared Keys and iOS devices #8426
- Fixed an issue with selecting a gateway when switching a firewall rule away from IPv4+IPv6 mode #8447
- Fixed firewall rules generated by the OpenVPN wizard #8391
- Fixed handling of OpenVPN RADIUS attribute firewall rules #8480
- Fixed handling of XMLRPC user/group synchronization when that section is disabled on the primary #8450
- Fixed input validation to allow named services to be used in firewall rules rather than numbers alone #8410
- Fixed issues with IP alias VIPs on Localhost at boot time #8393
- Increased the default Firewall Maximum Table Entries value to 400000 to cope with the increased size of the IPv6 bogon address lists #8417
- Updated SimplePie RSS to 1.5.1 #8423
- Added more fields to the list that status.php uses to redact private information #8394

3.28 2.3.5-p2 New Features and Changes

New features and changes for this release of pfSense® software:

3.28.1 Security / Errata

- FreeBSD SA for CVE-2018-8897 FreeBSD-SA-18:06.debugreg
- FreeBSD EN for CVE-2018-6920 and CVE-2018-6921 FreeBSD-EN-18:05.mem
- Fixed a potential XSS vector in RRD error output encoding #8269 pfSense-SA-18_01.packages
- Fixed a potential XSS vector in diag_system_activity.php output encoding #8300 pfSense-SA-18_02.webgui
- Fixed a potential LFI in pkg_mgr_install.php #8485 pfSense-SA-18_04.webgui
- Fixed a potential XSS in pkg_mgr_install.php #8486 pfSense-SA-18_05.webgui
- Changed sshd to use delayed compression #8245
- Added encoding for firewall schedule range descriptions #8259

3.28.2 Misc

- Added an option to disable HSTS for the GUI web server #6650
- Added filtering to pfTop page
- Added ospf6d to the routing log
- Change get_interface_subnet() to use configured value if available
- Corrected sethelp call on firewall_rules_edit.php #8242
- Fixed an issue with selecting a gateway when switching a firewall rule away from IPv4+IPv6 mode #8447
- Fixed an issue with the address family selection for remote syslog servers using IPv6 #8323
- Fixed a problem when IPsec bypasslan was enabled while the LAN interface is disabled or doesn't have an IP address #8239
- Fixed config.xml corruption handling
- Fixed input validation for Certificate SAN values to disallow IP addresses for FQDN/Hostname entries`#8275 <https://redmine.pfsense.org/issues/8275>`__
- Fixed issues with OpenVPN when using a /31 IPv4 Tunnel Network #8261
- Fixed NTP Status server time for zones with minute offsets (fractions of an hour) #8129
- Fixed selection of IPv6 gateways when creating a new firewall rule #8053
- Fixed various pf "busy" errors when the ruleset is reloaded
- Improved handling of aliases that mix IP addresses and FQDNs #8290
- Improved update repository controls
- Increased the default Firewall Maximum Table Entries value to 400000 to cope with the increased size of the IPv6 bogon address lists #8417

3.29 2.4.3 New Features and Changes

New features and changes for this release of pfSense® software:

3.29.1 Security / Errata

- FreeBSD-SA-18:01.ipsec
- Kernel PTI mitigations for Meltdown (optional tunable) FreeBSD-SA-18:03.speculative_execution.asc
- IBRS mitigation for Spectre V2 (requires updated CPU microcode) FreeBSD-SA-18:03.speculative_execution.asc
- Added a CPU Microcode update mechanism (cpuctl module, sysutils/devcpu-data port)
- Imported a FreeBSD patch to fix boot issues when running as a hypervisor guest on AMD Family 15h processors (FreeBSD PR #213155)
- Added validation for RRD parameters to ensure passed filenames are valid #8269
- Fixed a potential XSS vector in RRD error output encoding #8269 pfSense-SA-18_01.packages Fixed a potential XSS vector in diag_system_activity.php output encoding #8300 pfSense-SA-18_02.webgui
- Fixed a potential XSS vector in traffic_graphs.widget.php settings #8302 pfSense-SA-18_03.webgui

- Fixed a potential CSRF issue in service control request processing #8296
- Enabled CSRF protection for all dashboard widgets #8301
- Added encoding for firewall schedule range descriptions #8259
- Changed sshd to use delayed compression #8245
- Increased PHP-FPM resources on systems with over 1GB RAM to improve performance #8125
- Imported a netstat fix for ARM platforms to improve performance and reduce CPU usage, especially on the Dashboard #8237
- Fixed a memory leak in the pfSense_getall_interface_addresses() function in the pfSense PHP module #8249
- Hardware support for the XG-7100, including:
  - C3000 NIC support (factory installations only)
  - C3000 SoC support (factory installations only)
  - Marvell 88E6190 switch support (factory installations only)

3.29.2 Traffic Shaping / Limiters

- Fixed hangs due to Limiters and pfsync in HA #4310
- Added the Chelsio *cxl* driver to the list of ALTQ capable interfaces #7607
- Fixed an issue with limiters that had fractional bandwidth values #8091
- Changed status_queues.php to provide 'realtime' statistics #8185

3.29.3 IPsec

- Changed IPsec Phase 1 to allow selecting both IPv4 and IPv6 so the local side can allow inbound connections to either address family #6886
- Changed IPsec Phase 1 to allow configuration of multiple IKE encryption algorithms, key lengths, hashes, and DH groups #8186
- Fixed a problem when IPsec bypasslan was enabled while the LAN interface is disabled or doesn't have an IP address #8239
- Added IPv6 LAN Network to the IPsec LAN bypass list #8321

3.29.4 OpenVPN

- Fixed an error message encountered by a few users when manually killing OpenVPN connections #8266
- Added an OpenVPN tap bridge configuration option to push the bridged interface address to clients as a route-gateway for routes/redirects #8267
- Added an option to the DNS Resolver which allows registering the CN of OpenVPN clients as hostnames #6847
- Added an option to OpenVPN clients and servers to suppress creation of IPv4 or IPv6 gateway addresses for an interface #6848
- Fixed issues with OpenVPN when using a /31 IPv4 Tunnel Network #8261
- Updated the OpenVPN wizard with the current UDP and TCP protocol selections #8298 Added the interface for a VPN to the OpenVPN client and server list screens

3.29.5 Notifications

- Changed SMTP notifications handling so they are batched, to avoid sending multiple e-mail messages in a short amount of time #4031
- Added a notification when the firewall boot sequence is complete #7643

3.29.6 Dashboard

- Fixed issues with the IPsec dashboard widget causes GUI failure #6318
- Changed the Dynamic DNS Widget so it shows the description of custom entries to identify them #7843
- Fixed a reference to deprecated updateGatewayDisplays() function in the Gateways dashboard widget #8303
- Added a setting to the temperature widget to display readings in Fahrenheit 8205
- Changed the picture widget so the picture is stored on the firewall filesystem and not in config.xml to reduce the size of backup data #8371
  - On upgrade, pictures will be moved out of config.xml, so backup this file separately if it is important

3.29.7 DHCP

- Added an option to the DHCP Server Dynamic DNS configuration to set the server key algorithm #6621
- Added DDNS Client Updates option to DHCPv4 #7131
- Fixed handling of the DHCPv6 DDNS reverse zone key #6319
- Fixed DHCPv4 static mappings so that multiple MAC for same DHCP address or hostname are allowed`#8220 <https://redmine.pfsense.org/issues/8220>`__
- Fixed a potential issue in detecting primary/secondary node in a failover configuration
- Improved DHCP relay destination interface discovery
- Fixed DHCPv6 lease display for entries that were not parsed properly from the lease database #7413

3.29.8 Dynamic DNS

- Added an option for RFC 2136 Dynamic DNS server key algorithm #8244
- Added an option for RFC 2136 source address used to send updates #8278
- Fixed issues with Dynamic DNS updates using a gateway group when the primary route is down #8333
- Added GoDaddy Dynamic DNS provider

3.29.9 Interfaces / VIPs

- Fixed issues on assign_interfaces.php with large numbers of interfaces #6400
- Fixed handling of CARP VIPs on disabled interfaces at boot time #6677
- Fixed issues with radvd being enabled on a disconnected interface #6974
- Fixed issues with rtsold on VLAN interfaces #7412
- Fixed issues with dhcp6c lock files after unclean shutdown when using "Do not wait for an RA" on IPv6 WAN interface #8106
- Added a feature to allow pppoe on a CARP VIP so it will only be active on whichever node is master #8184
- Fixed an error when editing PPP interfaces on a system with no VIPs #8322
- Added VLAN priority tagging for DHCPv6 client requests #8200
- Added support for configuring the DUID type for an IPv6 interfaces #8191
- Allow custom INIT string for PPP modem SIM Pin and APN settings
- Added an indicator for disabled interfaces on status_interfaces.php
- Fixed an issue with the PPP linkup and linkdown scripts and cellular modems
- Fixed an issue where the combination of CARP with bridging could lead to a deadlock #8056

3.29.10 Packages

- Fixed reinstall process for missing packages #8183

3.29.11 Captive Portal

- Fixed Pass-through MAC automatic additions so it does not add duplicate entries #8226
- Fixed a missing global definition in Captive Portal pass-through MAC removal #8238
- Fixed Captive Portal voucher sync errors when vouchers are expired or disconnected while the secondary node is master #8317
- Fixed Captive Portal voucher synchronization between HA nodes #7972

3.29.12 Certificates

- Fixed automatic SAN handling when the CN of a certificate contains a space #8252
- Fixed input validation for Certificate SAN values to disallow IP addresses for FQDN/Hostname entries #8275

3.29.13 Gateways/Routing

- Fixed handling of the Router Lifetime value on services_router_advertisements.php so it allows a value of *0* #7502
- Added ospf6d to the routing log
- Allow recursive aliases to be used with static routes

3.29.14 Rules/NAT

- Fixed various pf "busy" errors when the ruleset is reloaded
- Fixed issues with editing firewall rules in non-English languages that contain single quotes in translated strings #8219
- Added an option to disable drag-and-drop of firewall and NAT rules
- Added a check to prevent 1:1 NAT rules with missing information from being added to the ruleset
- Added firewall rule tracking ID to rule list (in counter tooltip) and firewall rule edit page #8348
- Fixed cases where automatic or scripted rules were not getting tracking IDs #8353
- Added a check to prevent automatic outbound firewall rules with missing information from being added to the ruleset #8360

3.29.15 Users/Authentication

- Fixed issues with XMLRPC user account synchronization causing GUI inaccessibility on secondary HA nodes #7469
- Fixed an issue where a user with no privileges could not logout #8297
- Increased maximum username length from 16 to 32 characters to catch up to the current allowed length in FreeBSD
- Fixed required field markings on LDAP authentication server configuration fields #8337
- Fixed display of the LDAP host when testing the GUI authentication source #8338

3.29.16 Misc

- Fixed NTP Status server time for zones with minute offsets (fractions of an hour) #8129
- Added support for custom shutdown scripts in /usr/local/etc/rc.d #8182
- Fixed a references to an undefined function while restoring a config.xml file from an older version #8231
- Added support to diag_packet_capture.php to capture traffic on the loopback interface #8257
- Fixed an issue with the RAM disk warning pop-up appearing when no changes were made #8268
- Fixed an issue with the address family selection for remote syslog servers using IPv6 #8323
- Silenced warnings from sysctl that otherwise went to stderr
- Added a disk size check to ZFS to prevent it from being used on disk which are too small to contain the OS and swap space #7308
- Added a check to prevent pfSense-upgrade from running as a non-root user #7762

- Added an option to disable the IGMP Proxy service #8356
- Fixed an issue with package handling when restoring a configuration that contains a branch configuration that is not valid for the target system version #8208

3.30 2.4.2-p1 New Features and Changes

New features and changes for this release of pfSense® software:

3.30.1 Security / Errata

- Updated OpenSSL to address CVE-2017-3737 and CVE-2017-3738 FreeBSD-SA-17:12.openssl
- Fixed a potential authenticated command execution issue in certificate data handling #8153 pfSense-SA-17_10.packages.asc
- Fixed a potential XSS issue in status_filter_reload.php #8143 pfSense-SA-17_11.packages.asc

3.30.2 Misc

- Fixed an issue with the subnet mask not being preserved properly when editing existing 1:1 NAT entries #8112
- Fixed an indexing issue when deleting Host Override entries from the DNS Forwarder #8159
- Fixed logging for L2TP and PPPoE server login/logout events #8164
- Removed ix from the ALTQ interface list since ALTQ support for the ix driver is not currently viable #7378
- Fixed a premature session timeout issue on pages which update exclusively using AJAX, such as status_graph.php #8116
- Fixed ping_hosts.sh so it does not unnecessarily run a CARP check when there are no IPsec hosts to ping #8172
- Fixed a missing global variable declaration in interface IP address detection
- Fixed issues with local authentication when using translated languages

3.31 2.4.2 New Features and Changes

New features and changes for this release of pfSense® software:

3.31.1 Security / Errata

- Updated to OpenSSL 1.0.2m to address CVE-2017-3736 and CVE-2017-3735
- FreeBSD-SA-17:10.kldstat
- FreeBSD-SA-17:08.ptrace
- Fixed a potential XSS vector in status_monitoring.php #8037 pfSense-SA-17_07.packages.asc
- Fixed a potential XSS vector in diag_dns.php #7999 pfSense-SA-17_08.webgui.asc
- Fixed a potential XSS vector on index.php via widget sequence parameters #8000 pfSense-SA-17_09.webgui.asc

- Fixed a potential XSS in the widgetkey parameter of multi-instance dashboard widgets #7998 pfSense-SA-17_09.webgui.asc
- Fixed a potential clickjacking issue in the CSRF error page

3.31.2 Interfaces

- Fixed PPP interfaces with a VLAN parent when using the new VLAN names #7981
- Fixed issues with QinQ interfaces failing to show as active #7942
- Fixed a panic/crash when disabling a LAGG interface #7940
- Fixed issues with LAGG interfaces losing their MAC address #7928
- Fixed a crash in radvd on SG-3100 (ARM) #8022
- Fixed an issue with UDP packet drops on SG-1000 #7426
- Added an interface to manage the built-in switch on the SG-3100 Trimmed more characters off the interface description to avoid console menu output line wrapping on a VGA console
- Fixed handling of the VIP uniqueid parameter when changing VIP types
- Fixed PPP link parameter field display when a VLAN parent interface was selected #8098

3.31.3 Operating System

- Fixed issues resulting from having a manually configured filesystem layout with a separate /usr slice #8065
- Fixed issues updating ZFS systems created ZFS using an MBR partition scheme (empty /boot due to bootpool not being imported) #8063
- Fixed issues with BGP sessions utilizing MD5 TCP signatures in routing daemon packages #7969
- Updated dpinger to 3.0
- Enhanced the update repository selection choices and methods
- Updated the system tunables that tell the OS not harvest data from interrupts, point-to-point interfaces and Ethernet devices to reflect the new name/format for FreeBSD 11
- Changed ruleset processing so that it retries if another process is in the middle of an update, rather than presenting an error to the user
- Fixed some UEFI boot issues on various platforms

3.31.4 Certificates

- Fixed invalid entries in /etc/ssl/openssl.cnf (only affected non-standard usage of openssl in the cli/shell) #8059
- Fixed LDAP authentication when the server uses a globally trusted root CA (new CA selection for "Global Root CA List") #8044
- Fixed issues creating a certificate with a wildcard CN/SAN #7994
- Added validation to the Certificate Manager to prevent importing a non-certificate authority certificate into the CA tab #7885

3.31.5 IPsec

- Fixed a problem using IPsec CA certificates when the subject contains multiple RDNs of the same type #7929
- Fixed an issue with enabling IPsec mobile client support in translated languages #8043
- Fixed issues with IPsec status display/output, including multiple entries (one disconnected, one connected) #8003
- Fixed display of multiple connected mobile IPsec clients #7856
- Fixed display of child SA entries #7856

3.31.6 OpenVPN

- Added an option for OpenVPN servers to utilize "redirect-gateway ipv6" to act as the default gateway for connecting VPN clients with IPv6, similar to "redirect-gateway def1" for IPv4. #8082
- Fixed the OpenVPN Client Certificate Revocation List option #8088

3.31.7 Traffic Shaping

- Fixed an error when configuring a limiter over 2Gb/s (new max is 4Gb/s) #7979
- Fixed issues with bridge network interfaces not supporting ALTQ #7936
- Fixed issues with vtnet network interfaces not supporting ALTQ #7594
- Fixed an issue with Status > Queues failing to display statistics for VLAN interfaces #8007
- Fixed an issue with traffic shaping queues not allowing the total of all child queues to be 100% #7786
- Fixed an issue with limiters given invalid fractional/non-integer values from limiter entries or passed to Captive Portal from RADIUS #8097

3.31.8 Rules/NAT

- Fixed selection of IPv6 gateways when creating a new firewall rule #8053
- Fixed errors on the Port Forward configuration page resulting from stale/non-pfSense cookie/query data #8039
- Fixed setting VLAN Priority via firewall rules #7973

3.31.9 XMLRPC

- Fixed a problem with XMLRPC synchronization when the synchronization user has a password containing spaces #8032
- Fixed XMLRPC Issues with Captive Portal vouchers #8079

3.31.10 WebGUI

- Added an option to disable HSTS for the GUI web server #6650
- Changed the GUI web service to block direct download of .inc files #8005
- Fixed sorting of Services on the dashboard widget and Services Status page #8069
- Fixed an input issue where static IPv6 entries allowed invalid input for address fields #8024
- Fixed a JavaScript syntax error in traffic graphs when invalid data is encountered (e.g. user was logged out or session cleared) #7990
- Fixed sampling errors in Traffic Graphs #7966
- Fixed a JavaScript error on Status > Monitoring #7961
- Fixed a display issue with empty tables on Internet Explorer 11 #7978
- Changed configuration processing to use an exception rather than die() when it detects a corrupted configuration
- Added filtering to the pfTop page
- Added a means for packages to display a modal to the user (e.g. reboot required before package can be used)

3.31.11 Dashboard

- Fixed display of available updates on the Installed Packages Dashboard widget #8035
- Fixed a font issue in the Support Dashboard widget #7980
- Fixed formatting of disk slices/partitions in the System Information Dashboard widget
- Fixed an issue with the Pictures widget when there is no valid picture saved #7896

3.31.12 Packages

- Fixed display of packages which have been removed from the repository in the Package Manager #7946
- Fixed an issue displaying locally installed packages when the remote package repository is unavailable #7917

3.31.13 Misc

- Fixed interface binding in ntpd so it does not erroneously listen on all interfaces #8046
- Fixed a problem where restarting the syslogd service would make sshlockout_pf process orphans #7984
- Added support for the ClouDNS dynamic DNS provider #7823
- Fixed an issue in the User and Group Manager pages when operating on entries immediately after deleting an entry #7733
- Changed the setup wizard so it skips interface configuration when run on an AWS EC2 Instance #6459
- Fixed an IGMP Proxy issue with All-multicast mode on SG-1000 #7710

3.32 2.4.1 New Features and Changes

3.32.1 Security / Errata

- Fixes for the set of WPA2 Key Reinstallation Attack issues commonly known as KRACK #7951
- Changed upgrade handling to use the pkg-static binary to prevent errors when moving to new major FreeBSD version Fixed a VT console race condition panic at boot on VMware platforms (especially ESXi 6.5.0U1) #7925
- Fixed a bsnmpd problem that causes it to use all available CPU and RAM with the hostres module in cases where disk drives are present without media inserted #6882
- Fixed an upgrade problem due to FreeBSD 11 removing legacy ada aliases, which caused some older installs to fail when mounting root post-upgrade #7937
- Changed the boot-time fsck process the ensure the disk is mounted read-only before running fsck in the preen mode.

3.32.2 Known Issues

- The VLAN changes mentioned in the **Interfaces** section may prevent PPP sessions from working on VLANs in some cases, see #7981

3.32.3 Interfaces

- Changed the VLAN interface names to use the 'dotted' format of FreeBSD, which is shorter and helps to keep the interface name smaller than the limit (16) This fixes the 4 digit VLAN issues when the NIC name is 6 bytes long.
- Improved the 'Assign Interfaces' console process to automatically stop when there are no more interfaces to assign
- Improved the 'Set interface IP address' console process to accept 'IP/mask' notation
- Fixed wireless client interfaces so they do not reconfigure wireless on a link up event, or else they can get stuck in a loop #7960
- Fixed setting VLAN Priority in VLAN interface configuration #7748

3.32.4 Dashboard

- Fixed a problem with the Picture Dashboard widget when it does not have a picture defined #7896
- Fixed time display for UTC in the NTP Dashboard Widget #7714
- Fixed an IPsec widget error when it would get back null data after a session ended #6318
- Improved error checking to prevent dashboard widget parsing errors

3.32.5 DNS

- Added an option for the DNS Resolver (Unbound) to serve expired records from the cache after their TTL expires which can improve speed in some cases #7814
- Fixed the DNS Resolver (Unbound) to allow snoop from localhost by default, otherwise "dig +trace" or "drill -T" queries from the firewall itself fail #7884

3.32.6 XMLRPC

- Fixed XMLRPC Sync to prevent a lock that would never be unlocked
- Fixed XMLRPC sync to ensure a proper empty array is returned instead of NULL, so that the last item of a section can be removed without error #7953

3.32.7 Misc

- Fixed Captive Portal voucher test and expire pages #7939
- Added UEFI 32 and UEFI 64 filenames defined inside a pool to dhcpd.conf #7949
- Fixed operation of the "Reset All States on WAN IP Change" GUI setting #7921
- Changed OpenVPN to retry client auth when it fails by default (auth-retry nointeract) #7506
- Changed the Cryptographic Accelerator module options to allow both the AES-NI and Crypto modules to be loaded at the same time #7810
- Added URL fingerprinting to the login page CSS
- Added the device serial/id to the console and SSH menu banner #7968
- Fixed "Unknown Step Values" in certain RRD graph cases #6860

3.33 2.4 New Features and Changes

3.33.1 Operating System / Architecture changes

Warning: **32-bit support has been deprecated and removed** – There are no images available for 32-bit (x86/i386) Intel architecture systems

Warning: **NanoBSD has been deprecated and removed** – There are no images available for NanoBSD, use a full install instead

- Upgrade of base OS to FreeBSD **11.1-RELEASE-p1**
- Added support for Netgate ARM-based systems such as the SG-1000
- Started using the FreeBSD installer instead of the old style installer (installation procedures have all changed)
  - The installer now supports UEFI #4044
  - If the new installer image will not boot on a specific piece of hardware, see *Troubleshooting Boot Issues*

  - The installer now supports ZFS
  - Added support to the new installer to copy an existing config.xml off an MS DOS formatted USB drive (formerly known as "PFI") #7689
  - Added support to the new installer to optionally recover config.xml off an existing installation drive (works with UFS and ZFS) #7708
- Fixed issues with major version base upgrades via pkg
- Changed cryptodev to load as a kernel module #5976

3.33.2 Security / Errata

- Converted various parts of the GUI to use POST instead of GET when performing actions that change the firewall state (e.g. delete or enable/disable an item) to avoid potential issues with cross-site request forgery and unintentional repeating of actions #4083
- FreeBSD 11.1 includes MAP_GUARD protection to protect against attacks such as Stack Clash
- pfSense-SA-17_07.packages
- A number of base system packages have been updated to address security issues, including dnsmasq, perl, cURL, and others.

3.33.3 Firmware Branch Behavior / Upgrading From Snapshots

- To control how a firewall obtains updates, visit **System > Update**, **Update Settings** tab

3.33.4 Known Issues

- Some systems may not be able to boot 2.4 installation images, for example, due to UEFI compatibility changes. These are primarily BIOS issues and not issues with the installer images. Upgrading from 2.3.x should still work on affected hardware.
- Users with ESXi or VMware Workstation may experience a boot-time crash during hardware detection, due to a race condition in the FreeBSD VT console code. This crash is infrequent and does not affect most users or most boot attempts, but since it is a race condition it can manifest randomly. To avoid the crash, configure the VM to use the `syscons` console rather than `vt` by editing `/boot/loader.conf.local` and adding this line:

```
kern.vty=sc
```

3.33.5 Cleanup

- Misc code cleanup, removal of patches that were no longer necessary or were inefficient
- Replaced multiple local copies of PHP PEAR libraries with updated copies using their official sources #3734
  - Notably, local static copies were replaced by their FreeBSD ports counterparts: pear, pear-XML_RPC2, pear-Net_IPv6, pear-Crypt_CHAP, pear-Mail, pear-Net_Growl
  - Code that relied on the old files was updated to use the current or replaced versions
- Removed all references to GLXSB (it was 32-bit only) #6755
- Removed all code in the builder and pfSense for handling the NanoBSD platform

- Removed all calls to conf_mount_rw / conf_mount_ro, since they were only required for NanoBSD
- Improved help text in various parts of the GUI

3.33.6 Wireless

- FreeBSD 11 contains an updated 802.11 stack with numerous improvements

> **Warning:** Wireless interfaces **must** be created on the **Wireless** tab under **Interfaces > Assignments** before they can be assigned! #6770

3.33.7 Firewall / Rules / NAT / Aliases

- Fixed issues with synproxy rules on a WAN/LAN style bridge #6769
- Fixed issues with limiters on rules that utilize NAT #4326
- Fixed issues with limiters used in conjunction with a transparent proxy or other local redirect rule #7050
- Fixed expansion of "Other" type VIP subnet entries in NAT destination drop-down selections #6094
- Fixed NAT rules so that when a port forward is disabled, its associated firewall rule is also disabled #6472
- Fixed handling of "URL Table (IPs)" and "URL (IPs)" when the file is hosted a server using HTTPS with a self-signed certificate #4766
- Show firewall rule descriptions in a column when viewing the log on new installs, upgrades retain their existing setting #7323
- Fixed firewall states showing a negative value for total bytes processed #7075
- Fixed handling of Port Forwards so they do not make up new destination information when a configured against a DHCP interface that does not currently have an address
- Fixed VLAN Priority pf syntax #7744
- Fixed a problem where pf scrub did not properly re-fragment unusual but valid IPv6 fragments, resulting in overlapping fragments #7485
- Fixed confirmation prompt handling when deleting a firewall state from diag_dump_states.php #7827
- Changed display of 1:1 NAT rules to match other firewall pages #7728

3.33.8 Traffic Shaping

- Added extra warnings to traffic shaping pages when the firewall has no interfaces capable of using ALTQ shaping #7032
- Fixed handling removal of shaping rules when deleting an interface #7231
- Added upgrade code to work around broken shaper rules from older wizard code #7434
- Fixed the Traffic Shaper so it shows interface names for disabled interfaces, rather than an 'empty' placeholder.
- Fixed handling of the priority field for different ALTQ shaper types

3.33.9 OpenVPN

- Upgraded OpenVPN to 2.4.x. #7054
  - This is a significant upgrade which includes support for a wide variety of new features, including AEAD ciphers such as AES-GCM.
  - AES-GCM can be accelerated by AES-NI, and is supported in SSL/TLS modes (not shared key) #7068
  - Added support for TLS Encryption as an optional TLS Key usage type. This encrypts the control channel, providing privacy and protocol obfuscation #7071
  - Added ECDH options to OpenVPN server and client options ("ECDH Only" choice for DH, ECDH Curve selection) #7063
  - Restructured the compression options to include LZ4 support and the new "compress" directive which replaces "comp-lzo" which has been deprecated. The old options remain for now, but are labeled "Legacy" #7064
  - Changed protocol selection for OpenVPN clients and servers because OpenVPN 2.4 treats "udp" and "tcp" as dual stack now #7062
    - Added "multihome" option in relevant protocol cases so OpenVPN will reply back using the address used to receive a packet #7062
  - Changed the DNS Server fields in the OpenVPN server options so they can define either IPv4 or IPv6 DNS servers to push to clients`#7061 <https://redmine.pfsense.org/issues/7061>`__
  - Added IPv6 support to status_openvpn.php and the OpenVPN widget #2766
  - Removed uses of the deprecated "tun-ipv6" OpenVPN directive, OpenVPN now always assumes IPv6 is enabled #7054
  - Replaced uses of the deprecated "client-cert-not-required" directive with its functional replacement "verify-client-cert none" #7073
  - Added support for Negotiable Crypto Parameters (NCP) to control automatic cipher selection between clients and servers #7072

Note: OpenVPN 2.4 handles CRL verification differently than previous versions, passing through validation to the library rather than handling it internally. This can cause some certificates to fail validation that may have passed previously. In particular, if a certificate is removed from a CRL, it may still fail validation until all copies of the CRL have been rewritten.

- Improved the help text on OpenVPN Client-Specific Overrides #7053
- Fixed issues with OpenVPN clients on dynamic or tunneled IPv6 interfaces (e.g. GIF) #6663
- Added locking to prevent issues with OpenVPN instance startup #6132
- Check OpenVPN server/client option visibility changes per mode #7331 #7451
- Added an OpenVPN GUI option for "fast-io" to clients and servers #7507
- Added an OpenVPN GUI Option for "sndbuf" and "rcvbuf", using the same value for both #7507
- Removed references to the defunct OpenVPN client manager port #7568
- Removed references to unused "Address Pool" setting in OpenVPN #7567
- Fixed OpenVPN server port validation to disallow "0", while still allowing it for a client port, which is the same meaning as blank/empty #7565

- Fixed OpenVPN help text for route_no_exec #7575
- Fixed description of the address assignment behavior for Tunnel Network fields in OpenVPN clients and servers #7573
- Remove the GUI option for "resolv-retry infinite" from OpenVPN, it is always enabled #7572
- Fixed the OpenVPN wizard so it better handles a user choosing a different type of authentication server than a previous run of the wizard #7569
- Fixed OpenVPN Auth Digest Algorithm selection so it does not use duplicate/alias names in the list, and added upgrade code to fix existing entries on upgrade so they use the actual digest name and not an alias #7685
- Fixed show/hide behavior of fields on vpn_openvpn_client.php in chrome #7451
- Changed OpenVPN wizard certificate input validation and encoding so it matches the standards of the current certificate manager #7854
- Fixed the OpenVPN wizard so it creates an OpenVPN server instance using current proper defaults #7864

3.33.10 IPsec

- Upgraded strongSwan to version 5.6.0
- Changed the default strongSwan logging levels such that IKE SA, IKE Child SA, and Configuration Backend all default to "Diag" #7007
- Added an option to set the Rekey Margin for IPsec tunnels in the Phase 1 settings
- Added RADIUS accounting support for mobile IPsec when accounting is enabled on the Authentication Server entry
- Added checks to prevent simultaneous/repeated calling of vpn_ipsec_configure() by /etc/rc.newipsecdns
- Added DH Groups 22, 23, 24 to IPsec Phase 2 selection for compatibility, but they should not normally be used for security reasons #6967

3.33.11 Certificate Management

- Added a check to ensure that the public key of the Certificate matches its private key when importing Certificate Authority and Certificate entries to prevent mismatching keys from being imported #6953
- Fixed error handling when creating a Certificate from the User Management section, failed actions will no longer fail silently #6953
- Fixed handling of Certificates generated from an imported CA when no starting serial number was set #6952
- Fixed handling of Certificate Authority deletion so that it does not remove associated certificates #6947
- Added "in-use" testing for Certificate Authority entries and disabled the delete action for CAs which are actively in use #6947
- Fixed choosing an existing user certificate when adding a certificate to an existing user #7297
- Added the ability for the certificate manager to sign a CSR using an internal CA #7383
- Added the ability to set the certificate type and SAN attributes in a Certificate Signing Request #7527
- Restructured how certificate types and SANs are handled in the cert manager when making a Cert/CSR/Signing, so each section can properly use the controls #7527 #7677

  It is now possible to add SANs and EKUs to certificates when signing using the certificate manager

Note: Attributes such as SANs and KU/EKU cannot be copied from a CSR when signing due to a deficiency in OpenSSL's x509 functions (they do not support "copy_extensions" at this time); These attributes must be specified manually when signing

- Fixed "server" certificate detection to key off of the EKU For "TLS Web Server Authentication" since nsCertType has been deprecated
- Added SAN, KU, and EKU information in an info block for each entry in the certificate list #7505
- Added the ability to use a wider range of characters in certificate fields as laid out by RFC 4514 #7540
- Added a useful error message when there is no private CA with which to create a new user certificate from within the user manager #7585
- Fixed the User Manager so it adds the username as the first SAN when making a user certificate at the same time a user is created #7666
- Added another possible Certificate Signing Request Armor string when validating on import #7383

3.33.12 Dynamic DNS

- Fixed response parsing for DNSimple Dynamic DNS #6874
- Fixed handling of password in Dynamic DNS entries to allow special characters #6688
- Changed CloudFlare and GratisDNS to use separate hostname and domain entry to handle TLDs with multiple components #6778
- Fixed the Save and Force Update button for RFC2136 Dynamic DNS #7291
- Fixed RFC2136 Dynamnic DNS updates at boot time #7295
- Added the 'local' directive to RFC2136 Dynamic DNS so updates are sourced correctly #7446
- Fixed options text and display for IPv4 DNS and Verify SSL on Dynamic DNS clients #7588
- Fixed issues with Dynamic DNS entries utilizing gateway groups for their interface #7719
- Added DreamHost Dynamic DNS support #7321

3.33.13 DHCP Server / Relay

- Fixed handling of DHCPv6 lease status when there are no leases #6717
- Fixed issues with DHCP Relay not working #6658
- Added input validation to prevent the DHCP server from being configured on interfaces that do not have enough addresses for clients (/31, /32) #6930
- Fixed issues with the DHCP Relay options display getting out of sync with checkbox settings #7155
- Fixed static DHCP lease edits updating BIND zones #3710
- Fixed checks for DHCP Relay when editing additional DHCP pools
- Fixed handling of forced Dynamic DNS hostnames for DHCPv6 static mappings #7324

3.33.14 ARP / NDP

- Fixed static ARP handling when creating or editing DHCP static mappings #6821
- Added error checking for static ARP entries to ensure both an IP address and MAC address are entered, and to ensure that both exist before an entry is applied #6969
- Improved the detail displayed on the ARP table view #6822
- Added an expiration field to the NDP list

3.33.15 Captive Portal

- Adapted Captive Portal to work without multi-instance ipfw patches #6606
- Fixed Captive Portal instances to select "No Authentication" for a zone by default, since it is the default behavior #7591
- Fixed links to the Captive Portal MAC management page so they include the zone name #7591

3.33.16 XMLRPC

- Switched to pear-XML_RPC2 and removed the outdated static client files
- Fixed handling of XMLRPC sync using a username other than "admin" #809

3.33.17 Routing/Gateways

- Removed "route change" patches and updated code that relied on the deprecated behavior #6828
- Fixed handling of default routes when a default gateway is removed or disabled #6659
- Fixed discovery of IPv6 gateway for assigned OpenVPN interfaces #6016
- Fixed issues with a missing default gateway/route on certain PPPoE links after reconnect or IP address change #6495
- Fixed some 'route: writing to routing socket: Invalid argument' warnings during boot time
- Added a log message for gateway events that shows that an alarm was raised/cleared
- Added a check to not run dpinger when an IPv6 address has the tentative flag even after the timeout
- Added a delay to allow dpinger time to properly initialize before using results

3.33.18 Interfaces / Virtual IP Addresses

- Removed Device Polling as it was no longer useful #7021
- Improved stability of the igb(4) driver #7149 #7166
- Fixed handling of rc.newwanipv6 when run from dhcp6c so it only runs when required and not for any change #7145
- Fixed handling of SIGTERM and SIGKILL in dhcp6c #7185
- Fixed dhcp6c not starting until an RA is received #5993
- Fixed a PPP service name error with certain providers, such as T-Mobile #6890

- Fixed 3G service status so it does not report misleading information #4287
- Added support for the IPv6 AUTO_LINKLOCAL flag on bridge interfaces
- Disabled DAD on stf interfaces to fix problems with dpinger
- Added an option to use static IPv6 over an IPv4 PPP parent (e.g. PPPoE) #7598
- Removed unused WINS code for L2TP #7559
- Improved L2TP Server DNS input validation #7560
- Added a test to disable internal L2TP users when activating RADIUS, to follow the behavior stated in the GUI #7561
- Fixed L2TP section log shortcut #7564
- Fixed upgrade handling of wireless interfaces #7809

3.33.19 NTP

- Added support for the ntpd "pool" directive to make better use of servers in NTP pools #5985
- Fixed time display on the NTP widget to show server time #7245
- Added support for NTP to process PGRMF NMEA sentences (Garmin-specific) #7193
- Added an absolute offset statistic to NTP monitoring graph display #7548

3.33.20 User Management / Authentication

- Fixed delays during bootup when LDAP is enabled for user authentication #6367
- Added privileges to control which users can view and/or clear notices #7051
- Added an authentication cache mechanism for GUI authentication from a remote server (e.g. LDAP, RADIUS) so the authentication is checked periodically (default: 30s) instead of on each page load #7097
- Added protocol selection (PAP, MD5-CHAP, MS-CHAPv1 and MS-CHAPv2) to RADIUS authentication server options #7111
- Added the username to the page to display when adding user privileges #7586
- Standardized privilege page and sorting between users and groups #7587
- Added a log message if a user tries to save the configuration but has the 'deny config write' permission
- Added "auth_check" type of simple test that a page can use to verify a user is logged in and has access, using less cpu, which is better for AJAX data polling
- Fixed certificate chain verification issues with LDAP authentication using intermediate CAs #7830
- Fixed PHP errors when STARTTLS fails for LDAP authentication

3.33.21 Packages

- Fixed issues with snort, squid/clamav, and squidGuard when /var is in a RAM disk #6878
- Fixed handling of custom_php_deinstall_command during post-deinstall of a package #7401
- Changed package related calls to get_pkg_info() to use the new pkg metadata mechanism

3.33.22 Console / Menu

- Added options to the console reboot menu selection to reboot into single user mode or run filesystem checks #6639

3.33.23 OS Upgrade

- Fixed issues when upgrading to 2.4 with a stale package .inc that caused a PHP error #6920
- Changed the upgrade script to use reroot instead of reboot for updates that do not include a new Kernel #6045

3.33.24 SNMP

- Added a workaround to prevent the hostres module from being used with bsnmpd on VMware Virtual Machines that have a cd0 device, which caused 100% CPU usage #6882

3.33.25 Services

- Converted all mpd-based features (e.g. PPPoE and L2TP server) to MPD5 if they used an older version #4706
- Removed unused and non-functional SMART service handling and e-mail configuration #6393
- Fixed IGMP Proxy failing to recognize an upstream interface #6099

3.33.26 WebGUI

- Added support for multiple languages, currently that list includes:
  - US English (Default), Bosnian, Chinese (Simplified, China), Chinese (Taiwan), Dutch, German, Norwegian Bokmal, Polish, Portuguese (Brazil), Russian, Spanish, Spanish (Argentina)
- Changed the design of the login page for the WebGUI to a more modern style, with several color choices available
- Added URL fingerprinting to JavaScript and CSS file references to improve client-side behavior when files change between versions #7251
- Updated Logo to the new logo and made it a vectorized SVG image for better scaling
- Updated favicon to the new logo and added multiple sizes for different platforms
- Completed work to mark required fields on GUI pages #7160
- Fixed long hostnames overlapping the “time” title in the monitoring graphs #6138
- Fixed CIDR/Prefix selector handling for IPv4/IPv6 #7625
- Removed the Gold menu
- Fixed handling of info block content inside tables #7504

- Improved handling of PHP errors for user-entered PHP code on diag_command.php
- Fixed alignment of the IPv6 over IPv4 input fields #7128
- Optimized retrieval of Traffic Graph data to reduce spikes in the graphs and load on the firewall
- Fixed a problem with the traffic graphs not respecting the theme colors #6746
- Revised setup wizard wording and links

3.33.27 Dashboard

- Rewrote Dashboard AJAX updating in a centralized and optimized way to reduce load, improve accuracy, and increase speed
- Added a new Customer Support dashboard widget, enabled by default and on upgrade
- Changed the way AJAX updates are handled on the Dashboard widgets to improve efficiency and fix issues with some widgets refreshing in a timely manner
- Added filters to more dashboard widgets #7122
- Added customization for dashboard widget names
- Fixed Interface Statistics dashboard widget issues with interfaces in a "down" state
- Fixed formatting issues with the Interface Statistics dashboard widget #7501
- Added the ability to place multiple copies of widgets on the dashboard, optional for each widget
- Added a line to display detected CPU cryptographic hardware, such as AES-NI, in the System Information dashboard widget even if the module isn't loaded #7529
- Fixed CPU package/core count displayed on the System Information dashboard widget
- Changed how pkg metadata is handled to reduce the load on the Dashboard and reduce unnecessary calls to the pkg server for the System Information dashboard widget update check, and for the Installed Packages dashboard widget
- Changed CPU usage calculation in the System Information dashboard widget to avoid sleep() in an AJAX call
- Fixed the IPsec widget tunnel status to handle newer strongSwan childid format #7499
- Fixed error when saving Wake on LAN dashboard widget without any WoL entries
- Fixed a problem where traffic could be counted twice in traffic graphs #7751
- Fixed a problem with the Installed Packages dashboard widget when no packages are installed #7811
- Changed date formats of some fields on the Dashboard to be more consistent #7805
- Added an option to the Interface Statistics dashboard widget to rotate the table (put interfaces in rows instead of columns) to improve the display on firewalls with numerous interfaces #7501

3.33.28 pftop

- Removed the "size" option from pftop as it had no effect, use the "bytes" option instead #7579
- Removed the 'peak' and 'rate' views for pftop since they only work in interactive mode with cached data, not batch mode which is used by the WebGUI #7580
- Fixed path to an old copy of the pftop WebGUI page in obsolete list #7581

3.33.29 DNS

- Changed /etc/hosts such that the FQDN is listed first, except for localhost, so that dnsmasq will properly reverse resolve hostnames #7771
- Fixed a problem where the DNS Search Domain List was not being populated into radvd.conf #7081
- Enabled Python support for Unbound #7549
- Added a control to disable automatically added host entries in Unbound
- Changed the way unbound is started at boot time on systems with DHCP6 WANs

3.33.30 Misc

- Added hardware support and detection for new Netgate models
- Changed the User Agent passed to outbound requests from pfSense to include more accurate host information
- Added the User Agent to the request data when updating the Bogons list
- Fixed growl and SMTP notifications so performing a test saves first, so the new settings are used as expected #7577
- Fixed loading issues with PHP extensions #6628
- Removed symbolic links for configuration files that redirected items from /etc/ to /var/etc/ #5538
- Added the ability to filter Packet Captures by MAC address #6743
- Updated status.php with new info and changed its output organization #7047
- Fixed a problem where a proxy defined for use by the firewall could not use HTTPS when using proxy authentication #6949
- Improved RAM disk backups and file management #7098
- Changed the way RAM disk contents are handled when enabled #5897
- Changed various support functions to better facilitate translation to additional languages
- Fixed interface name display on the Router Advertisement configuration page #7133
- Fixed various issues with handling of unusually formatted, but valid, IPv6 addresses #7147
- Improved error handling when a client is logged when it attempts to poll data via rrd_fetch_json.php #6748
- Fixed various issues when the configuration backup count was set to 0 (disabled) #7273
- Fixed handling of "0" for the number of backups to retain in the configuration history #7273
- Fixed an issue with long configuration change descriptions leading to wrapping issues in certain cases such as AutoConfigBackup #6363

- Fixed an issue with installing packages from a backup when restoring using the External Configuration Locater on the first boot post-install #7914

3.34 2.3.5-p1 New Features and Changes

New features and changes for this release of pfSense® software:

3.34.1 Security / Errata

- Updated OpenSSL to address CVE-2017-3737 and CVE-2017-3738 FreeBSD-SA-17:12.openssl
- Fixed a potential authenticated command execution issue in certificate data handling #8153 pfSense-SA-17_10.packages.asc
- Fixed a potential clickjacking issue in the CSRF error page
- Fixed a potential XSS issue in status_filter_reload.php #8143 pfSense-SA-17_11.packages.asc

3.34.2 Misc

- Fixed an issue in the User and Group Manager pages when operating on entries immediately after deleting an entry #7733
- Fixed sorting of Services on the dashboard widget and Services Status page #8069
- Fixed display of available updates on the Installed Packages Dashboard widget #8035
- Fixed display of packages which have been removed from the repository in the Package Manager #7946
- Fixed the OpenVPN Client Certificate Revocation List option #8088
- Fixed an issue with the Pictures widget when there is no valid picture saved #7896
- Fixed an indexing issue when deleting Host Override entries from the DNS Forwarder #8159
- Fixed a premature session timeout issue on pages which update exclusively using AJAX, such as status_graph.php #8116
- Fixed ping_hosts.sh so it does not unnecessarily run a CARP check when there are no IPsec hosts to ping #8172
- Fixed a missing global variable declaration in interface IP address detection

3.35 2.3.5 New Features and Changes

The pfSense® software version 2.3.x release is a Security and Errata maintenance release. 2.4.x is the primary stable supported branch. If the firewall hardware is capable of running 2.4.x, consider upgrading to that release instead.

Updating to 2.3.5 from 2.3.4 on an amd64 installation that could otherwise use 2.4.x requires configuring the firewall to stay on 2.3.x as follows:

- Navigate to **System > Update**, **Update Settings** tab
- Set **Branch** to **Security / Errata Only**
- Navigate back to the **Update** tab to see the latest 2.3.x update

If the update system offers an upgrade to 2.3.5 but the upgrade will not proceed, ensure the firewall has correct versions of the repository configuration and upgrade script for 2.3.x by running the following commands from the console or shell:

```
pkg install -fy pfSense-repo pfSense-upgrade
```

Firewalls running 32-bit (i386) installations of pfSense software do not need to take any special actions to remain on 2.3.x as they are unable to run later versions.

3.35.1 Operating System / Architecture changes

- Upgrade of base OS to FreeBSD **10.3-RELEASE-p20**
- Fixed issues with major version base upgrades via pkg

3.35.2 Security / Errata

- pfSense-SA-17_07.packages
- Fixes for the set of WPA2 Key Reinstallation Attack issues commonly known as KRACK in wpa_supplicant and hostapd (FreeBSD-SA-17:07.wpa)
- A number of base system packages have been updated to address security issues, including dnsmasq, perl, cURL, and others.

3.35.3 Interfaces

- Added support for the IPv6 AUTO_LINKLOCAL flag on bridge interfaces
- Added an option to use static IPv6 over an IPv4 PPP parent (e.g. PPPoE) #7598
- Added IPv6 Prefix Delegation interface selection
- Improved input validation for GIF interfaces #7789

3.35.4 Dashboard

- Rewrote Dashboard AJAX updating in a centralized and optimized way to reduce load, improve accuracy, and increase speed
- Added a new Customer Support dashboard widget, enabled by default and on upgrade
- Changed the way AJAX updates are handled on the Dashboard widgets to improve efficiency and fix issues with some widgets refreshing in a timely manner
- Changed how pkg metadata is handled to reduce the load on the Dashboard and reduce unnecessary calls to the pkg server for the System Information dashboard widget update check, and for the Installed Packages dashboard widget
- Improved error checking to prevent dashboard widget parsing errors
- Fixed a variable conflict in the NTP Status Dashboard widget #7795
- Fixed a problem with the Picture Dashboard widget when it does not have a picture defined #7896
- Changed IPsec Dashboard Widget tunnel status to handle newer strongSwan childid format #7499
- Fixed time display for UTC in the NTP Dashboard Widget #7714

3.35.5 WebGUI

- Changed the design of the login page for the WebGUI to a more modern style, with several color choices available
- Added URL fingerprinting to JavaScript and CSS file references to improve client-side behavior when files change between versions #7251
- Updated Logo to the new logo and made it a vectorized SVG image for better scaling
- Updated favicon to the new logo and added multiple sizes for different platforms
- Added an option for sorting the Interfaces menu by description
- Added "auth_check" type of simple test that a page can use to verify a user is logged in and has access, using less cpu, which is better for AJAX data polling
- Improved handling of PHP errors for user-entered PHP code on diag_command.php
- Changed Interfaces menu "(Assign)" to "Assignments" and added support for menu divider bars
- Fixed automatic selection of '128' as prefix/mask for IPv6 address fields #7625
- Replaced Math.trunc with Math.floor to make IE properly handle traffic graphs #7804
- Changed nginx configuration so it does not allow direct download of .inc files #8005
- Fixed hostname input handling on diag_dns.php

3.35.6 Gateways

- Added a delay to allow dpinger time to properly initialize before using results
- Added a log message when gateway alarms are raised/cleared to show the parameters that triggered the alarm
- Reset All States on WAN IP Change option #1629

3.35.7 Rules/NAT/Shaper

- Fixed handling of Port Forwards so they do not make up new destination information when a configured against a DHCP interface that does not currently have an address
- Fixed ALTQ Traffic Shaper PRIQ priority number validation

3.35.8 IPsec

- Added an option to set the Rekey Margin for IPsec tunnels in the Phase 1 settings
- Added RADIUS accounting support for mobile IPsec when accounting is enabled on the Authentication Server entry
- Added checks to prevent simultaneous/repeated calling of vpn_ipsec_configure() by /etc/rc.newipsecdns

3.35.9 Misc

- Fixed an issue with installing packages from a backup when restoring using the External Configuration Locater on the first boot post-install #7914
- Fixed handling of forced Dynamic DNS hostnames for DHCPv6 static mappings #7324
- Fixed several issues with cron job updating and removal
- Added the device serial/id to the console and SSH menu banner #7968
- Changed /etc/hosts such that the FQDN is listed first, except for localhost, so that dnsmasq will properly reverse resolve hostnames #7771

3.36 2.3.4-p1 New Features and Changes

The pfSense® software version 2.3.4-p1 errata release is a minor release after *2.3.4* and contains beneficial security and bug fixes.

3.36.1 Security / Errata

- pfSense Security Advisories
  - pfSense-SA-17_05.webgui:
    - Fixed a potential XSS issue in the diag_edit.php file browser #7650
    - Fixed a potential XSS in handling of the 'type' parameter on diag_table.php #7652
    - Fixed validation and a potential XSS in interface names on firewall_nat_edit.php #7651
  - pfSense-SA-17_06.webgui:
    - Added a warning screen to the GUI and prevent access if the client IP address is currently in the lockout table, and also remove the client's connection states #7693

3.36.2 Bug Fixes

Captive Portal

- Fixed Captive Portal RADIUS Authentication to only cache credentials when required to perform reauthentication #7528
- Restored the captive portal feature to view the captive portal page directly from the portal web server as an additional button #7646

Dynamic DNS

- Fixed issues with wildcard CNAME records disappearing from Loopia when doing a DNS update
- Fixed issues with CloudFlare Dynamic DNS
- Fixed Hover Dynamic DNS updates so they Verify the SSL Peer

Logging

- Added syslogd service definition to enable status display and control #4382
- Fixed issues with syslogd stopping when installing or uninstalling some packages #7256

Virtual IP Addresses

- Fixed issues with CARP status display overmatching some VIP numbers #7638
- Fixed pid file handling for choparp (Proxy ARP Daemon)
- Added the ability to sort the Virtual IP address list

DNS

- Fixed diag_dns.php so it will not create an empty alias if name does not resolve
- Fixed diag_dns.php to not show Add Alias if the user does not have privileges to add an alais
- Fixed diag_dns.php to change the update alias button text after adding an alias
- Fixed diag_dns.php to disable the Add Alias button when the host field is changed
- Fixed calls to unbound-control to have the full configuration path specified so they do not fail #7667
- Fixed handling of "redirect" zone entries in the DNS Resolver so they do not produce invalid zones #7690
- Changed the way the DNS Resolver code writes out host entries, so the zones are more well-formed #7690
- Changed the way the DNS Resolver process (unbound) is stopped, to allow it to exit cleanly. #7326

Interfaces

- Fixed DHCPv6 to request a prefix delegation even if no interfaces are set to track6 #4544
- Updated handling of original MAC address retention for interfaces with spoofed MACs
- Fixed an array handling problem when working with gateway entries on the Interface configuration page #7659
- Fixed handling of MSS clamping values for PPPoE/L2TP/PPTP WANs #7675

DHCP

- Fixed an issue where some DHCP Lease information was encoded twice with htmlentities/htmlspecialchars
- Fixed an issue where in some edge cases, a variable was not properly set in a loop, leading to a previous value being reused

Misc

- Removed "/usr/local/share/examples" from obsolete files list, some packages rely on the files being there
- Added a few more items to status.php for support purposes, such as a download button, socket buffer info, and the netgate ID
- Fixed status.php to redact BGP MD5 password/key in output #7642
- Fixed OpenVPN to use is_numeric() to make sure $prefix is not 0
- Changed the "Rule Information" section so it is consistent between firewall and NAT rule pages
- Fixed APU2 detection for devices running coreboot v4.x
- Fixed the tunable description for net.inet.ip.random_id #6087
- Fixed some outdated links for help and support
- Fixed some issues with empty config tags in packages #7624
- Fixed issues with entry IDs after deleting Authentication Server instances #7682

3.37 2.3.4 New Features and Changes

3.37.1 Security / Errata

- Updated base OS to FreeBSD 10.3-RELEASE-p19
- FreeBSD/ports Security Advisories
  - Updated ntpd to 4.2.8p10_2 FreeBSD-SA-17:03.ntp.asc
  - Updated cURL to 7.54.0 (CVE-2017-7407, CVE-2017-7468)
  - Updated libevent to 2.1.8 (CVE-2016-10197, CVE-2016-10196, CVE-2016-10195)
- pfSense® Software Advisories
  - Fixed encoding of displayed values from DHCP leases to prevent a badly formatted DHCP lease hostname from causing a potential XSS #7497 (pfSense-SA-17_04.webgui)
- See the Certificates section below for an important note about GUI certificate errors on Chrome 58 and later

3.37.2 Certificates

- Improved certificate generation to always include the CN as the first Subject Alternative Name (SAN), which fixes issues with Chrome 58+ #7496

  To work around an error with the firewall GUI certificate on Chrome 58+, take one of the following actions:

  - Generate and activate a new GUI certificate automatically, from the console/shell: pfSsh.php playback generateguicert
  - Utilize the *ACME package* to generate a trusted certificate for the GUI via Let's Encrypt
  - Create a own new CA/Server certificate and use that for the GUI
- Fixed linking of a certificates to its CA after submitting the signed version of a CSR #7512

3.37.3 Firewall Rules/NAT/Shaper

- Fixed restarting the Load Balancer (relayd) clearing system tables/aliases #7396
- Fixed ruleset generation to notify when an unresolvable alias is encountered by the parser #7421
- Fixed handling of a rule using an empty port alias #7428
- Fixed the traffic shaping wizard handling of SMB rules in Raise/Lower Other Protocols, it was producing an invalid rule #7434
- Fixed handling of alias renaming after input validation #7473
- Fixed handling of long rule descriptions #7294

3.37.4 Dashboard

- Improved formatting in the gateways widget by reducing the numeric precision of displayed values #6841
- Fixed the NTP widget to show the server time instead of client time #7245
- Added a "None" option to Widgets with filtering options #7318
- Added PPPoE uptime display on the Interfaces dashboard widget #6032
- Added filters to more dashboard widgets #7122
- Added BIOS information to the System Information widget
- Added Netgate Unique ID to the System Information widget

Note: This identifier for support services is only displayed on the Dashboard for information purposes and is **not** transmitted anywhere automatically by default. In the future, customers can use this identifier when requesting support information from Netgate staff or systems.

3.37.5 Configuration

- Fixed issues restoring a configuration containing packages when the firewall does not have Internet connectivity #6594
- Fixed factory reset when Captive Portal has Vouchers enabled #7508
- Cleaned up unused code in diag_backup.php

3.37.6 Interfaces

- Changed interface handling so it retains the original vendor MAC address at power up when spoofing, so it can be restored without a reboot #7011
- Fixed interface assignment of QinQ interfaces #4669
- Fixed errors in PPP service provider selection when a country without providers is selected #7399
- Fixed input handling when editing static IP address fields on interfaces #7493
- Added the ability for DHCP Client WANs to specify a list of IP addresses from which to reject leases #7510

3.37.7 User Manager / Authentication

- Added a warning to system_authservers.php to warn that RADIUS does not work with IPv6 #4154
- Added a status icon to the User Manager to show if a user is enabled or disabled #7517

3.37.8 General GUI

- Added navigation links to breadcrumbs #7099
- Improved service name support and error handling in pfSenseHelpers.js #7445

3.37.9 DHCP

- Changed dhcpleases so it does not start when DHCP Relay is enabled #6750
- Fixed checks for DHCP Relay being enabled/disabled so they are skipped when editing an additional pool

3.37.10 ARP / NDP

- Added the ability to delete NDP entries #7513
- Added expiration field to NDP listing #7514

3.37.11 Misc

- Fixed DNS issues when upgrading NanoBSD #7345
- Fixed the Reset Demotion Status for CARP to function when the demotion value is negative #7424
- Fixed editing of Host Overrides in the DNS Resolver/Forwarder pages #7435
- Fixed service handling (start/stop/restart) for Captive Portal #7444
- Fixed display of the ALTQ "queue" view in pfTop due to recent changes in the pfTop port #7461
- Added support for the Dynamic DNS Client Hover #7511
- Fixed UTF-8 handling in Base64 decoding on diag_edit.php
- Fixed handling of traffic graph data irregularities #7515
- Added visual separation to the legend on the installed packages list #7203
- Changed SMTP and Growl notification test to use the new, unsaved settings #7516

3.38 2.3.3-p1 New Features and Changes

The pfSense® software version 2.3.3-p1 errata release is a minor release after *2.3.3* and contains beneficial security and bug fixes.

3.38.1 Security / Errata

- Updated to FreeBSD 10.3-RELEASE-p17
  - FreeBSD-SA-17:02.openssl (CVE-2016-7055, CVE-2017-3731, CVE-2017-3732)
- Upgraded cURL to 7.53.0 (CVE-2017-2629)

3.38.2 Bug Fixes

- Fixed issues with the upgrade check seeing the version of pfSense-upgrade instead of pfSense in some circumstances. #7343
- Fixed handling of domain-only (@ record) updates for CloudFlare Dynamic DNS #7357
- Fixed a problem with the Dynamic DNS Widget where RFC2136 entries showed an incorrect status #7290
- Fixed Dynamic DNS status widget formatting for medium with browser window #7301
- Fixed a problem with HTML tags showing in certificate description drop-down lists in the Certificate Manager #7296
- Fixed an error loading some older rules with ICMP types #7299
- Fixed display of selected ICMP types for old rules without an ipprotocol option set #7300
- Fixed Log widget filter interface selection with custom interface descriptions #7306
- Fixed the widget Filter All button so it does not affect all widgets #7317
- Fixed the password reset script so it resets the expiration date for the admin account when run, to avoid the user still being locked out #7354

- Fixed the password reset script so it properly handles the case when the admin account has been removed from config.xml #7354
- Fixed input validation of TCP State Timeout on firewall rules so it is not arbitrarily limited to a maximum of 3600 seconds #7356
- Fixed console settings for XG-1540/XG-1541 to use the correct default console #7358
- Fixed initial setup handling of VLAN interfaces when they were assigned at the console before running the Setup Wizard #7364
- Fixed display of OpenSSL and input errors when working in the Certificate Manager #7370
- Fixed Captive Portal "disconnect all" button
- Fixed pkg handling timeouts #6594
- Updated blog URL in the RSS widget
- Removed whirlpool from the list of CA/certificate digest algorithms since it does not work #7370

3.39 2.3.3 New Features and Changes

3.39.1 Security / Errata

- Updated to FreeBSD 10.3-RELEASE-p16
  - FreeBSD Security Advisories
    - FreeBSD-SA-16:29.bspatch
    - FreeBSD-SA-16:31.libarchive
    - FreeBSD-SA-16:33.openssh
    - FreeBSD-SA-16:35.openssl
    - FreeBSD-SA-16:37.libc
    - FreeBSD-SA-16:38.bhyve
    - FreeBSD-SA-16:39.ntp
    - FreeBSD-SA-17:01.openssh
  - FreeBSD Errata Notices
    - FreeBSD-EN-16:17.vm
    - FreeBSD-EN-16:18.loader
- pfSense® Software Advisories
  - pfSense-SA-17_01.webgui
    - Fixed validation and encoding on Captive Portal status pages #7019
  - pfSense-SA-17_02.webgui
    - Fixed update_config_field() in wizard.php so it does not pass user input through eval() #7230
  - pfSense-SA-17_03.webgui
    - Added encoding for 'from' and 'to' before output on pkg_mgr_install.php #7225
    - Added encoding for the contents of pkg_filter before output #7227

    * Converted easyrule.php to use a confirmation landing page so that the parameters can be submitted via POST #7228

- Updated numerous third-party libraries and supporting programs
- Changed behavior of fsck during bootup to improve filesystem stability #6340
- Added protection to /etc/ttys to prevent corruption or missing lines

3.39.2 Known Issues

- The Captive Portal **Disconnect All Users** button does not fully disconnect all users PR#3565
- RFC 2136 Dynamic DNS Entries will show red on the Dashboard widget even when correctly updated #7290
- Firewall rules without an IP protocol set in the configuration which also have an ICMP type set may not load or display correctly. #7299 #7300

3.39.3 General Info

- Added Packages: tinc, cellular, LCDproc, TFTP Server
- Fixed numerous typos and wording issues
- Added marking for required fields on various pages #7083
- Input validation fixes on various pages
- Cleaned up some unneeded files/pages/functions
- Fixed broken/outdated links

3.39.4 OpenVPN

- Changed OpenVPN RADIUS authentication to send proper NAS-Port-Type, NAS-Port, and NAS-Identifier values #6609
- Added compression option to handle connecting to OpenVPN peers which do not have LZO compiled into their OpenVPN executable #6739
- Added a workaround to block outside DNS on Windows 10 OpenVPN clients to prevent DNS leaks #6719
- Improved OpenVPN server handling when using CARP VIPs in Gateway Groups
- Improved handling of chained/intermediate CAs in OpenVPN #2800
- Changed OpenVPN widget so it updates dynamically #6723
- Adapted the encryption cipher list to the new output format in OpenVPN 2.3.12, also now displays key and block lengths #6849
- Changed OpenVPN server list to display more information
- Improved error message to explicitly state allowable characters for certificate fields in the OpenVPN wizard #6432
- Fixed handling of OpenVPN authentication when the backend server name contains special characters (e.g. '&') #7002
- Fixed saving an OpenVPN instance on a DHCP interface that does not currently have an IP address #7031
- Added an IPv6 Tunnel Network field to OpenVPN Client-Specific Overrides #7053

- Fixed changing between tun and tap mode for OpenVPN Clients
- Changed OpenVPN startup to avoid overwriting its configuration, and to wait for its PID file to be written
- Fixed OpenVPN binding to an IP Alias VIP #7136
- Fixed display of disabled OpenVPN clients #7180
- Fixed handling of "redirect-gateway" in Client-Specific Overrides #6633

3.39.5 IPsec

- Clarified IPsec Key Exchange Version drop-down to specify IKEv1/IKEv2 #6898
- Fixed handling of static routes for IPsec peers on tunnels bound to IP Aliases VIPs with CARP parents
- Fixed MSS clamping for mobile IPsec clients #7005
- Added IPsec to the State Table interface list

3.39.6 Interfaces

- Fixed handling of LAGG MTU when child QinQ interfaces are present #6227
- Improved behavior when using DHCP before RA #5993
- Added the ability to send a DHCP Release from Status > Interfaces, rather than only stopping dhclient
- Fixed issues adding/editing QinQ entries
- Fixed input validation of QinQ entries
- Fixed validation to prevent an interface, interface group, and alias from using the same name #6976
- Updated interface group name validation rules to match limits of the operating system
- Prevented interface group names, interface names, and aliases from starting with `pkg_` to reserve it for packages use (e.g. tinc) #7173
- Added validation to prevent Interface Group Names from containing a dash #7173
- Added validation to prevent Interface Groups from being renamed to an existing name #7183
- Fixed issues with Interface Statistics widget display #7134
- Fixes for interfaces_ppps_edit.php to fix MTU validation, interface friendly names, advanced options expansion
- Changed linkup event handling to ignore events for interfaces that are member of bridges which have no IP address configured
- Fixed input validation for L2TP and PPTP WAN type interfaces #6732
- Added validation to prevent adding duplicate gateways from the Interface configuration page
- Fixed handling of IPv6 checksum options for "Disable hardware checksum offload" #5321
- Fixed handling of the confirmation dialog when deleting a VLAN #6916
- Fixed handling of wireless MAC address spoofing
- Fixed wireless channel changing #6833
- Improved labels and help text for IPv6 tunneling options
- Added the ability for an L2TP or PPTP WAN to use a hostname for the remote gateway #6899

3.39.7 Certificate Management

- Added missing recommended key lengths and digests to certificate manager
- Fixed CRL editing so that certificates already contained the CRL are not displayed

3.39.8 Users / Authentication / Privileges

- Fixed SSH Keyboard-Interactive authentication #6963
- Added STARTTLS to LDAP Authentication Server Configuration
- Improved WebGUI usability when a remote LDAP server is not available
- Fixed issues with local_sync_accounts failing during boot when using an LDAP server on a non-local network or hostname #6857
- Fixed port build options for scponly #7012
- Fixed notifications so that the Mark All as Read button is not shown to users who do not have sufficient privileges to use it #3454
- Added privileges to control display of notices #7051
- Standardized privilege name capitalization
- Fixed issues with low-privilege users accessing Help pages #7139 #7140
- Added a privilege for UPnP & NAT-PMP configuration #7141
- Simplified tcsh prompt and changed the prompt so it respects default terminal colors

3.39.9 Firewall / Rules / NAT / Aliases / States

- Fixed restoring rule type selection after input errors while saving firewall rules
- Fixed a copy/paste error in variable test when validating firewall rule ports.
- Corrected the descriptions and behavior of the Adaptive Start and Adaptive End settings for firewall state handling
- Fixed display of the number of states in the Firewall Rules page
- Moved “Any” to top of protocol list in firewall rules
- Fixed issues with hidden fields on firewall_rules_edit.php #7057
- Fixed issues with moving rules that required scrolling while dragging #6895
- Enhanced ICMP type handling in rules
- Fixed issues when hovering the mouse pointer over aliases on disabled rules making the hint difficult to read #6448
- Fixed handling of firewall rule separators when a NAT associated rule is deleted #6676
- Added field to specify source-hash key for outbound NAT rules
- Fixed issues with **Firewall > NAT > Edit** forgetting destination type selection when input errors occur #6224
- Removed “self” as a destination from NAT 1:1 rules
- Fixed NAT rules so that when a port forward is disabled, its associated firewall rule is also disabled #6472
- Fixed 1:1 NAT address family validation #6927

- Fixed problems with nested aliases containing FQDNs #6982
- Changed the Status > Filter Reload page so it shows the entire filter reload progress, rather than only the last state #6931
- Fixed labels on diag_states_summary.php #6711
- Fixed initial state of confirmation checkboxes on diag_resetstate.php
- Changed Diag > States so it can optionally require a filter before displaying states, to improve handling with large state tables #7069

3.39.10 Traffic Shaping

- Added Chelsio network cards (cxl) to the list of drivers that are capable of using ALTQ #6830
- Fixed the traffic shaper wizard so it uses whole numbers instead of decimals #6779

3.39.11 HA / CARP

- Fixed issues when XMLRPC synchronizes IP Alias type Virtual IP addresses bound to Localhost #7010
- Fixed a bug where the CARP VIP status was incorrect when the interface has more than one CARP VIP

3.39.12 DHCP/DHCPv6 Server / Router Advertisements

- Updated the ISC DHCP Daemon to fix issues with missing hostnames in leases, and removed workarounds that are no longer needed #6840
- Fixed reversed behavior of "Change DHCPv6 display lease time from UTC to local time" #6640
- Fixed incorrect index for edit action on DHCP Leases #7233
- Added an option to force a Dynamic DNS hostname in DHCP/DHCP6 Server settings
- Changed DHCP lease times to always display in 24-hour clock format
- Added an option to allow BOOTP to be specifically disabled in the DHCP Server settings #4351
- Fixed validation to allow URLs for TFTP Server in DHCP Server settings #6634
- Improve dhcpd and dhcpleases reload handling
- Fixed DHCP NTP Server form validation to allow hyphens #6806
- Fixed restore of DHCP6 leases on full install when using MFS /var
- Fixed a problem with the DHCP range being reset if the Setup Wizard was re-run when a custom DHCP range already exists #4820
- Fixed issues with DHCP traffic being blocked with DHCP Relay enabled #6996
- Changed the DHCP/DHCPv6 server GUI so it can be configured (but not run) while DHCP Relay is enabled #6997
- Added Client ID to DHCP Leases display, if present
- Added Client ID to DHCP Mapping list, if present
- Disabled DHCP server on interfaces with subnet >= 31 #6930
- Changed DHCP6 client to allow a prefix size of /59

- Changed DHCP6 server to allow a prefix size of /59 and /61
- Added new “Ignore client identifiers” option to DHCP Server
- Fixed handling of DNS entries for IPv6 static mappings when using delegated prefixes #6768
- Improved the help text for Router Advertisement configuration #6889

3.39.13 DNS / Resolver / Forwarder

- Allow a variable number of DNS servers #5549
- Changed interface boxes in the DNS Resolver so they can be resized
- Fixed sorting of DNS Forwarder hosts and domains in config.xml #6903
- Fixed DNS Resolver (unbound) logging after clearing logs #6915
- Added support for “deny_non_local” and “refuse_non_local” ACLs in the DNS Resolver #6914
- Fixed DNS Server Gateway validation
- Changed behavior of DNS Resolver overrides to only add FQDN entries, not short hostnames #6064
- Fixed issues with DNS Resolver Host Overrides not being updated properly #6712

3.39.14 NTP / GPS

- Fixed display of Prefer/No Select checkboxes invisible when adding entries in NTP Server settings #6788
- Fixed handling of NTP IPv6 restrict clauses
- Fixed setting default NTP access restrictions when there are no custom restrictions #6454
- Fixed NTP status widget IPv6 address handling so addresses are not truncated #4815
- Fixed the NTP Orphan Mode stratum field #7034
- Fixed issues with NTP GPS status
- Fixed a case that could result in an empty ‘restrict’ line in the NTP configuration #7110
- Added a limit for NTP time source fields so they cannot exceed the maximum number saved to configuration #7164
- Fixed display and behavior issues with NTP ACLs #6984
- Improved parsing of GPS initialization and output, and add support for more GPS output formats and extended status
- Added an autocorrect tool for checksums on GPS initialization commands #7159

3.39.15 Captive Portal

- Changed Captive Portal MACs page to be sortable #6786
- Fixed handling of Captive Portal user bandwidth set to 0 #6872
- Changed Captive portal to send "Admin Reset" as termination cause when disconnecting a user from the WebGUI
- Added option to Captive Portal to include idle time in total session time
- Fix bandwidth limitation settings in Captive Portal MAC passthrough
- Fixed links to view current Captive Portal page for all interfaces #6391
- Converted Captive Portal active sessions to a sortable table
- Added code to hide the client MAC address column in Captive Portal status when MAC filtering is disabled, rather than displaying an empty column
- Added popup with session details to the Captive Portal active sessions list on the status page
- Added button to disconnect all Captive Portal users
- Worked around race condition between captiveportal_disconnect_all() and captiveportal_prune_old()
- Added locking to avoid race conditions between rc.prunecaptiveportal and captiveportal_disconnect_all()
- Reworked logging and RADIUS accounting when disabling a Captive Portal zone or rebooting
- Increased speed of captiveportal_disconnect_all()

3.39.16 Dynamic DNS

- Added the ability to change the URL queried by Dynamic DNS entries to check the external IP address (Services > Dynamic DNS, Check IP Services tab) #6591
- Added support for All-Inkl Dynamic DNS provider
- Added support for duiadns.net Dynamic DNS provider
- Added support for CloudFlare Proxy to Dynamic DNS
- Added Cloudflare Dynamic DNS IPv6 support #6623
- Fixed status checking on Dynamic DNS (RFC2136), updates were always considered successful even on failure #6357
- Fixed handling of multiple RFC2136 entries #6153
- Fixed links in RFC2136 entries in the Dynamic DNS widget #7126
- Fixed HTTP header processing for Dynamic DNS updates
- Fixed handling of custom IPv6 Dynamic DNS in the widget #6922
- Changed Cloudflare and Gratis plus Dynamic DNS to store passwords in base64
- Updated Route 53 Dynamic DNS to fix several reported issues #3973 #6751 #5054
- Fixed handling of ZoneEdit Dynamic DNS when used with a CARP VIP #6992
- Removed excess loops from the Dynamic DNS Widget

3.39.17 Gateways / Routing

- Added the ability to disable gateway monitoring actions without disabling gateway monitoring #3151
- Changed gateway notifications to notify by email and syslog when a gateway goes up or down
- Improved gateway notification mechanisms
- Fixed handling of deleting or disabling static default gateways so they are properly removed from the routing table #6659
- Fixed L2TP WAN dynamic gateway naming #6980
- Fixed status display for unmonitored gateways
- Fixed static blackhole route handling
- Fixed handling of long hostnames on Diagnostics > Routes #6869
- Corrected behavior of disabled static routes #3560
- Created a PHP Shell playback script to view the gateway status from the shell and status output #7046

3.39.18 Notifications

- Fixed SMTP settings test so it properly displays results
- Fixed validation of secure SMTP Connection Modes (SSL/TLS and STARTTLS are mutually exclusive)
- Removed validation of password mismatches when SMTP or Growl notifications are disabled #7129
- Changed format of file_notice() alerts in webgui for easier reading

3.39.19 Graphs / Monitoring

- Changed traffic graphs to use d3.js (Dashboard and Status > Traffic Graphs)
- Moved export button to heading for Status > Monitoring page
- Moved graph labels so long hostnames do not overlap as easily #6138
- Improved error checking in case JSON isn't returned when building graphs #6748
- Added a missing RRD step value to lookup table #6860
- Added support for multiple views in Status > Monitoring graphs (Adds tab shortcuts to different graph views)
- Added a per-view "Refresh Interval" option to Status > Monitoring graphs
- Fixed fix null acronyms and axis label for queues/queuedrops graph in Status > Monitoring
- Enabled Area and Bar graph types for Status > Monitoring graphs

3.39.20 WebGUI

- Added an option to allow display of the firewall hostname on the login page
- Added filtering to widgets where appropriate
- Standardized PHP memory limit configuration
- Fixed formatting issues with the Installed Packages widget #6601
- Improved Compact-RED theme
- Changed service running/stopped icons
- Fixed issues with JavaScript confirmation prompts missing words (e.g. “Are you sure you wish to?”) #6972
- Fixed issues with packages that toggle visibility of advanced options areas #7100
- Removed the crash reporter link from the dashboard when a user does not have crash_reporter page access #7043
- Fixed display of Package installation message #7226
- Fixed “” tag processing in package XML handling
- Fixed inconsistent handling of empty/null configuration settings in config.xml #6893

3.39.21 Logging

- Increased filtering tail limit for logging to ensure enough entries will be displayed #6652
- Added a means for packages to request a syslogd socket inside a chroot environment #4898
- Added BIND logging to proper facility #5524
- Improved handling of the TFTP Proxy/xinetd process when it is disabled, to reduce log messages #6308

3.39.22 Misc

- Updated simplepie (RSS Parsing library) to 1.4.3
- Fixed storing of IPv6 addresses so they are always saved in lower case #6864
- Fixed bsnmpd “printcap” log errors #6838
- Fixed a foreach error when restoring a configuration without packages
- Fixed handling of signal traps in the console menu #6741
- Fixed “Goto line #” action on diag_edit.php so pressing the enter key also activates the function
- Changed the PHP Execute feature of Diagnostics > Command so that it does not generate a crash report from a syntax error #6702
- Added enable link to Status > UPnP & NAT-PMP error message if disabled #6689
- Changed the time zone help text to clarify and warn against the use of the Etc time zones that use POSIX style signs, which are the opposite of what most users expect #7089
- Added validation to prevent duplicate Wake on LAN entries
- Fixed permissions on /var/tmp when /var is a RAM disk #7120
- Added a fallback for get_pkg_info() to use pkg info if there is no local copy of the repository catalog

- Removed spurious output from the PHP Shell executable when running a playback script from a command prompt #7045
- Updated status.php with new info and changed its output organization #7246

3.40 2.3.2-p1 New Features and Changes

3.40.1 2.3.2 Update 1

- FreeBSD-SA-16:26.openssl - Multiple vulnerabilities in OpenSSL. The only significant impact on pfSense® software is OCSP for HAproxy and FreeRADIUS.
- Several HyperV-related Errata in FreeBSD 10.3, FreeBSD-EN-16:10 through 16:16. See https://www.freebsd.org/relnotes/10-STABLE/errata/errata.html for details.
- Several built-in packages and libraries have been updated, including:
  - PHP to 5.6.26
  - libidn to 1.33
  - curl to 7.50.3
  - libxml2 to 2.9.4
- The hardware serial number is now displayed in the system information widget, or a host UUID if a serial number is not found. This is for display purposes and facilitates users seeking support in identifying their hardware.
- Added encoding to the 'zone' parameter on Captive Portal pages.
- Added output encoding to diag_dns.php for results returned from DNS. #6737
- Worked around a Chrome bug with regular expression parsing of escaped characters within character sets. Fixes "Please match the requested format" on recent Chrome versions. #6762
- Fixed DHCPv6 server time format option #6640
- Fixed /usr/bin/install missing from new installations. #6643
- Increased filtering tail limit for logging so searching will locate sufficient entries. #6652
- Cleaned up Installed Packages widget and HTML. #6601
- Fixed widget settings corruption when creating new settings. #6669
- Fixed various typos and wording errors.
- Removed defunct links to the devwiki site. Everything is on https://www.netgate.com/docs/pfsense/ now.
- Added a field to CA/Cert pages for OU, which is required by some external CAs and users. #6672
- Fixed a redundant HTTP "User-Agent" string in DynDNS updates.
- Fixed the font for sortable tables.
- Added a check to verify if an interface is active in a gateway group before updating dynamic DNS.
- Fixed wording of the "Reject leases from" option for a DHCP interface (it can only take addresses, not subnets.) #6646
- Fixed error reporting for SMTP settings test.
- Fixed saving of country, provider, and plan values for PPP interfaces
- Fixed checking of invalid "Go To Line" numbers on diag_edit.php. #6704

- Fixed off-by-one error with “Rows to Display” on diag_routes.php. #6705
- Fixed description of the filter box on diag_routes.php to reflect that all fields are searchable. #6706
- Fixed description of the box for the file to edit on diag_edit.php. #6703
- Fixed description of the main panel on diag_resetstate.php. #6709
- Fixed warning dialog when a box is unchecked on diag_resetstate.php. #6710
- Fixed log shortcut for DHCP6 areas. #6700
- Fixed the network delete button showing when only one row was present on services_unbound_acls.php #6716
- Fixed disappearing help text on repeatable rows when the last row is deleted. #6716
- Fixed dynamic DNS domain for static map DHCP entries
- Added control to set dashboard widget refresh period
- Added “-C /dev/null” to the dnsmasq command line parameters to avoid it picking up an incorrect default configuration which would override our options. #6730
- Added “-l” to traceroute6 to show both IP Addresses and Hostnames when resolving hops on diag_traceroute.php. #6715
- Added note about max ttl/hop limit in source comment on diag_traceroute.php.
- Clarified language on diag_tables.php. #6713
- Cleaned up the text on diag_sockets.php. #6708
- Fixed display of VLAN interface names during console assignment. #6724
- Fixed domain-name-servers option showing twice in pools when set manually.
- Fixed handling of DHCP options in pools other than the main range. #6720
- Fixed missing hostnames in some cases with dhcpdv6. #6589
- Improved pidfile handling for dhcpleases.
- Added checks to prevent accessing an undefined offset in IPv6.inc.
- Fixed the display of the alias popup and edit options on source and destination for both the address and port on outbound NAT.
- Fixed handling of backup config count. #6771
- Removed some dangling PPTP references that are no longer relevant.
- Fixed up/caught up remote syslog areas. Added “routing”, “ntpd”, “ppp”, “resolver”, fixed “vpn” to include all VPN areas (IPsec, OpenVPN, L2TP, PPPoE Server). #6780
- Fixed missing checkboxes in some cases when adding rows on services_ntpd.php. #6788
- Revised service running/stopped icons.
- Added a check to CRL management to remove certificates from the drop-down list that are already contained in the CRL being edited.
- Fixed rule separators moving when multiple firewall rules are deleted at the same time. #6801

3.41 2.3.2 New Features and Changes

3.41.1 SSH Daemon

Note: The ssh host keys were made more secure, and if a client remembers an older, weaker key, the ssh client may refuse to connect. Remove the older key and then make the ssh client learn the new key.

- Changed sshd to use stronger Key Exchange algorithms and disabled some older, weaker algorithms. Clients may need to be updated to handle the new Key Exchange methods.

  Currently allowed Key Exchange Algorithms: `curve25519-sha256@libssh.org`, `diffie-hellman-group-exchange-sha256`
- Removed the ECDSA host key from the sshd configuration
- Added ED25519 host key to the sshd configuration
- Changed the list of available ciphers.

  Current allowed ciphers: `chacha20-poly1305@openssh.com,aes256-gcm@openssh.com, aes128-gcm@openssh.com,aes256-ctr,aes192-ctr,aes128-ctr`
- Changed the list of available Message Authentication Code methods,

  Current MAC list: `hmac-sha2-512-etm@openssh.com,hmac-sha2-256-etm@openssh.com, hmac-ripemd160-etm@openssh.com,umac-128-etm@openssh.com,hmac-sha2-512,hmac-sha2-256, hmac-ripemd160,umac-128@openssh.com`

3.41.2 Backup/Restore

- Don't allow applying changes on interface mismatch post-config restore until the reassignment is saved. #6613

3.41.3 Dashboard

- Dashboard now has per-user configuration options, documented in *User Manager*. #6388

3.41.4 DHCP Server

- Disabled dhcp-cache-threshold to avoid bug in ISC dhcpd 4.3.x omitting client-hostname from leases file, which makes dynamic hostname registration fail in some edge cases. #6589
- Note that DDNS key must be HMAC-MD5. #6622

3.41.5 DHCP Relay

- Imported fix for dhcrelay relaying requests on the interface where the target DHCP server resides. #6355

3.41.6 Dynamic DNS

- Allow * for hostname with Namecheap. #6260

3.41.7 Interfaces

- Fix "can't assign requested address" during boot with track6 interfaces. #6317
- Remove deprecated link options from GRE and gif. #6586, #6587
- Obey "Reject leases from" when DHCP "Advanced options" is checked. #6595
- Protect enclosed delimiters in DHCP client advanced configuration, so commas can be used there. #6548
- Fix default route on PPPoE interfaces missing in some edge cases. #6495

3.41.8 IPsec

- strongSwan upgraded to 5.5.0.
- Include aggressive in ipsec.conf where IKE mode auto is selected. #6513

3.41.9 Gateway Monitoring

- Fixed "socket name too large" making gateway monitoring fail on long interface names and IPv6 addresses. #6505

3.41.10 Limiters

- Set pipe_slot_limit automatically to maximum configured qlimit value. #6553

3.41.11 Monitoring

- Fixed no data periods being reported as 0, skewing averages. #6334
- Fix tooltip showing as "none" for some values. #6044
- Fix saving of some default configuration options. #6402
- Fix X axis ticks not responding to resolution for custom time periods. #6464

3.41.12 OpenVPN

- Re-sync client specific configurations after save of OpenVPN server instances to ensure their settings reflect the current server configuration. #6139

3.41.13 Operating System

- Fixed pf fragment states not being purged, triggering "PF frag entries limit reached". #6499
- Set core file location so they can't end up in /var/run and exhaust its available space. #6510
- Fixed "runtime went backwards" log spam in Hyper-V. #6446
- Fixed traceroute6 hang with non-responding hop in path. #3069
- Added symlink /var/run/dmesg.boot for vm-bhyve. #6573
- Set net.isr.dispatch=direct on 32 bit systems with IPsec enabled to prevent crash when accessing services on the host itself via VPN. #4754

3.41.14 Router Advertisements

- Added configuration fields for minimum and maximum router advertisement intervals and router lifetime. #6533

3.41.15 Routing

- Fixed static routes with IPv6 link local target router to include interface scope. #6506

3.41.16 Rules / NAT

- Fixed "PPPoE Clients" placeholder in rules and NAT, and ruleset error when using floating rules specifying PPPoE server. #6597
- Fixed failure to load ruleset with URL Table aliases where empty file specified. #6181
- Fixed TFTP proxy with xinetd. #6315

3.41.17 Upgrade

- Fixed nanobsd upgrade failures where DNS Forwarder/Resolver not bound to localhost. #6557

3.41.18 Virtual IPs

- Fixed performance problems with large numbers of virtual IPs. #6515
- Fixed PHP memory exhaustion on CARP status page with large state tables. #6364

3.41.19 Web Interface

- Added sorting to DHCP static mappings table. #6504
- Fixed file upload of NTP leap seconds. #6590
- Added IPv6 support to diag_dns.php. #6561
- Added IPv6 support to filter logs reverse lookup. #6585
- Package system - retain field data on input error. #6577
- Fixed multiple IPv6 input validation issues allowing invalid IPv6 IPs. #6551, #6552
- Fixed some DHCPv6 leases missing from GUI leases display. #6543
- Fixed state killing for 'in' direction and states with translated destination. #6530, #6531
- Restore input validation of captive portal zone names to prevent invalid XML. #6514
- Replaced calendar date picker in the user manager with one that works in browsers other than Chrome and Opera. #6516
- Restored proxy port field to OpenVPN client. #6372
- Clarify description of ports aliases. #6523
- Fixed translation output where gettext passed an empty string. #6394
- Fixed speed selection for 9600 in NTP GPS configuration. #6416
- Only allow IPv6 IPs on NPT screen. #6498
- Add alias import support for networks and ports. #6582
- Fixed sortable table header wrap oddities. #6074
- Clean up Network Booting section of DHCP Server screen. #6050
- Fix "UNKNOWN" links in package manager. #6617
- Fix missing bandwidth field for traffic shaper CBQ queues. #6437

3.41.20 UPnP

- UPnP presentation URL and model number now configurable. #6002

3.41.21 User Manager

- Prohibit admins from deleting their own accounts in the user manager. #6450

3.41.22 Other

- Added PHP shell sessions to enable and disable persistent CARP maintenance mode. "playback enablecarpmaint" and "playback disablecarpmaint". #6560
- Exposed serial console configuration for nanobsd VGA. #6291

3.42 2.3.1 New Features and Changes

3.42.1 Security/Errata

- FreeBSD Security Advisories
  - FreeBSD-SA-16:17 OpenSSL
  - FreeBSD-SA-16:18 atkbd
  - FreeBSD-SA-16:19 sendmsg
- **OpenVPN upgraded from 2.3.10 to 2.3.11. Fixes two potential security** issues.
  - OpenVPN 2.3.11 Change Log
- pfSense® Software Advisories
  - pfSense-SA-16_03.webgui
  - pfSense-SA-16_04.filterlog
  - 2.3.1 update 1 patches pfSense-SA-16_05.webgui.

3.42.2 Config Upgrade

- Fixed config upgrade for CARP VIPs on gateway groups, GRE and gif for uniqid format. #6222
- Fixed config upgrade for IP aliases with CARP IP parent. #6164
- Correct OpenVPN topology config upgrade to retain 2.2.x and prior net30 topology. #6140
- Correct and adjust apinger parameters to dpinger parameters automatically on upgrade. #6142

3.42.3 Gateways

- Fix static route for IPv6 monitor IP with link-local gateway. #6353
- Fix default gateway switching with IPv6 and link-local gateways. #6258

3.42.4 OS / Backend

- NanoBSD is now permanent read-write, to avoid issues with slow rw->ro mount times and systems getting stuck read-only mounted. #6184
- Systems using a RAM disk for /var/ have their alias tables backed up and restored during bootup. #6189
- Set console settings (serial configuration, password protection, etc.) post-upgrade. #6120
- Ensure package repo is updated with latest metadata when checking for latest version. #6115
- Display consistent firmware version on dashboard and in update checker. #6320
- Correct description of update branch options. #6136
- Prevent update checking failures from killing webGUI. #6177
- Make pkg use configured proxy server settings where they exist. #6149

3.42.5 Web GUI

- Fix row delete button on unsaved aliases, NTP, UPnP and other screens. #6101
- Captive portal MAC passthrough credits waiting period box restored. #6290
- Outbound NAT edit screen destination field alias auto-completion restored. #6287
- Captive portal allowed IPs direction selection on edit fixed. #6267
- Restored input validation on port forwards to prohibit IPv6. #6265
- Restored input validation on firewall rules to prohibit IPv6 IPs in IPv4 rules and vice versa. #6211
- Fixed PHP error on edit of PPP interfaces. #6264
- Fixed radio button placement on gateways dashboard widget settings. #6259
- Fixed display post-refresh of system information dashboard widget. #6251
- Restored in/out bytes counters on Status>Interfaces. #6244
- Correctly show and hide OpenVPN topology field as applicable. #6236 #6214
- Correct voucher character set input validation. #6231
- Disable background update checking on dashboard update check is disabled. #6212
- Restore input validation of IP address family and rule type, verifying IPv6 IPs with IPv6 rules, and IPv4 for IPv4 rules. #6218
- Add validation of address family and protocol combinations on packet capture page. #6219
- Add validation of IP aliases with CARP parent interfaces to ensure matching address family. #6218
- Restore GET parameters on status_graph.php. #6192
- Fixed PHP error on input validation failure with floating rules in some cases. #6175
- Use CDATA for firewall rule separator descriptions so non-English characters work. #6174
- Fix port forward edit destination field filling when virtual IPs configured. #6173
- Fix load balancer monitor edit. #6171
- Restore “none” in load balancer fall-back pool. #6170
- Restore use of aliases in load balancer. #6169
- Fix duplicate for load balancer pools and virtual servers. #6168
- Restore description field on lagg edit page. #6163
- Fix saving of bogons update frequency. #6162
- Restore description field on captive portal IP passthrough. #6161
- Fix saving of sticky connections timeout field. #6146
- Show all restore areas in backup/restore screen. #6144
- Fix moving of rule separator before saving. #6128
- Use consistent up and down arrow formats on dashboard widgets. #6123
- Fix typo on OpenVPN server description. #6102
- Fix missing string on notification “mark as read” button. #6104
- Fix firewall rule separator positioning with easy rule addition. #6105

- Prevent closing of info box on monitoring page. #6106
- Add custom date range option to monitoring page. Use infoblock on IPsec PSK screen. #6107
- Fixed loss of "Do not NAT" enable on edit on outbound NAT. #6112
- Correct label of 1:1 NAT edit screen. #6114
- Add AJAX updates to NTP status page. #6117
- Fix button spacing on Edit File and Command pages. #5995
- Fix specification of port in DNS Resolver domain overrides. #6091
- Fix moving of multiple items to bottom of list on firewall, NAT and IPsec screens. #6092
- Fix setup wizard with only WAN assigned and using static IP. #6093
- Remove logo from wizard since it's now redundant. #6095
- Fix gateway widget cut-off with 3 column dashboard. #6096
- Fixed force update on RFC 2136 DDNS. https://redmine.pfsense.org/issues/6359
- Fix reboot prompt when changing RAM disk setting and encountering an input error. #6349
- Fix highlighted tab when editing IPsec mobile P1. #6341
- Fix selection of configured speed and duplex on interface page. #6331
- Fix division by zero in status_queues.php. #6329
- Fix alignment issues in forms. #6327
- Fix entry of CIDR range in host aliases for conversion to IPs. #6322
- Allow use of # and ! again in DNS Forwarder domain overrides. #6310
- Restored hostname infobox in menu bar. #6306
- Fixed editing and deleting of additional DHCP pools. #6303
- Fixed requests to diag_system_activity.php piling up on slow systems. #6166

3.42.6 Interfaces

- Unset LAN DHCPv6/RA configuration if LAN interface is removed. #6152

3.42.7 IPsec

- Fix starting of strongswan twice. #6160

3.42.8 DNS Resolver

- Switched domain overrides from stub-zone to forward-zone so domain overrides don't require the target server provide recursion. #6065
- Allow adding 0.0.0.0/0 to access lists. #6073
- Added 100,000 and 200,000 options for Unbound cache limit. #6230
- Fix Unbound startup where both DNS Forwarder and Resolver are enabled. #6354

3.42.9 DHCP Server

- Hostnames now allowed for NTP servers. #6239

3.42.10 IPsec

- Fixed LAN interfaces stopping functioning when IPsec is in use. #6296
- Mobile PSK matching issue with multiple PSKs fixed. #6286
- leftsendcert=always specified for all RSA types. #6082
- rc.newipsecdns fixed to check correct enabled status. #6351

3.42.11 Notifications

- Fixed growl notifications to unresolvable hostname generating crash report. #6187
- Fixed growl notification test with no password. #6221

3.42.12 Captive Portal

- Fixed error handling captive portal username with single quote. #6203
- Fixed issues with mixed-case zone names. #6278

3.42.13 OpenVPN

- Prevent leading space in tunnel network configuration causing invalid configuration. #6198

3.42.14 User Manager

- Fix RADIUS login with attribute class (25) when the server returns multiple attribute entries with different data. #6086
- Honor deny config write for RADIUS users. #6088

3.42.15 Package System

- Uninstall all packages pre-upgrade from <= 2.2.x to 2.3 to avoid problems from old packages. Reinstall them post-upgrade. #6137
- Fix reinstall of renamed packages post-upgrade to 2.3. #6118
- Fix package reinstallation getting stuck in loop when there is no Internet connectivity post-upgrade. #6180

3.42.16 Other

- Removed lua support from nginx to not deprecate old CPUs lacking CMOV support. #6185
- Added validation to console menu interface assignment to prevent creating duplicate VLANs. #6183
- Blacklisted S.M.A.R.T. options with Hyper-V to prevent crash. #6147
- Silence SSH host key log spam. #6143
- Fix order of gateway and gateway group name in gateway down log message. #6134
- Allow use of @ in hostname field for Namecheap DDNS. #6122
- Fix console error where $nat_if_list isn't an array. #6307
- Include patch number in version display. #6309
- Fix pw groupdel error in log during boot. #6352
- Fixed stale xmlrpc.lock preventing config sync from functioning. #6328
- Fixed failed chown on startup with /var as a RAM disk. #6131
- Crash reporter now ignores warnings in release versions. #6178
- Fixed crash reporter to show full PHP warnings in development versions. #6097

3.42.17 Update 1

2.3.1 update 1 (2.3.1_1) was released on May 25, 2016 with the following fixes/changes since 2.3.1-RELEASE.

- Security issue pfSense-SA-16_05.webgui patched.
- Lowered default LDAP timeout from 25 seconds to 5 seconds. #6367
- Fixed handling of IPsec negotiation mode with IKE version set to auto. #6360
- Increase PHP's memory limit to 512 MB on 64 bit versions to better accommodate systems with a large number of active states. #6364
- Set request_terminate_timeout the same as max_execution_time to prevent many possible circumstances of "504 gateway error" from occurring. #6396
- Fix use of URL IP type aliases in firewall rules. #6403
- Fix show/hide fields Javascript in Chrome on macOS. #6401
- Fixed save of "IPv6 over IPv4 Tunneling" address on System>Advanced, Networking. #6381

3.42.18 Update 2 through 4

These were internal-only versions that weren't publicly-released.

3.42.19 Update 5

2.3.1 update 5 (2.3.1_5) was released on June 16, 2016 with the following fixes/changes since 2.3.1_1.

- Fixed command injection vulnerability in auth.inc via User Manager. #6475
- Fixed command injection vulnerability in pkg_mgr_install.php id parameter. #6474
- Upgraded PHP to 5.6.22
- Fixed Captive Portal redirect hangs caused by longer keepalive_timeout in nginx. #6421
- Fixed DDNS PTR zone in dhcpd.conf with third octet of 0. #6413
- Fixed save and reset buttons on load balancer status page. #6254
- Fixed schedule editing on firewall rules page. #6428
- Allow "-" character in TFTP server field on DHCP Server page. #6433
- Allow "-" and "_" characters in system tunables. #6438
- Fixed changing of link type on PPPs edit screen. #6439
- Fixed setting of "RADIUS issued IPs" on L2TP page. #6440
- Restored apply changes button for interface mismatch post-config restore. #6460
- Fixed display of Outbound NAT port aliases. #6463
- Fixed schedule edit allowing invalid time range. #6468

3.43 2.3 New Features and Changes

3.43.1 Security/Errata

- FreeBSD Security Advisories:
  - FreeBSD-SA-16:01.sctp
  - FreeBSD-SA-16:02.ntp
  - FreeBSD-SA-16:05.tcp
  - FreeBSD-SA-16:07.openssh
  - FreeBSD-SA-16:09.ntp
  - FreeBSD-SA-16:11.openssl
  - FreeBSD-SA-16:12.openssl
  - FreeBSD-SA-16:15.sysarch
- pfSense® Security Advisories:
  - pfSense-SA-16_01.webgui
  - pfSense-SA-16_02.webgui

Several obsolete items were removed from this release. The items are noted again in the sections below, but worth emphasizing:

- The PPTP **VPN Server** has been completely removed. The protocol has been broken for over three years.

  The PPTP WAN client remains for use with ISPs still using PPTP.

- Layer 7 classification support has been removed from the traffic shaper.

  It was rarely used, had been broken for all of 2.2.x, had absurdly high CPU usage, and snort filters better/faster

- WEP support has been removed from Wireless interfaces. #5123

  No reason to still be using this in this day and age. If it is still needed, use external AP.

- Single DES support has been removed from IPsec (3DES remains).

  It should not be used, it is not secure.

- 1GB NanoBSD images have been removed, as they were not large enough to proper accommodate the system and upgrade data. The supported sizes for NanoBSD images are now 2GB and 4GB.
- The default system password hash has been changed to bcrypt. Current passwords will continue to work. Existing users need to reset their password to convert to the new hash. More info below under "Authentication". #4120
- The LiveCD platform has been removed. The ISO is a bootable installer, as always, but it cannot run a live system.
  - The installer ISO image is now named "pfSense–RELEASE-.iso", with the .iso extension signifying the type of image it is (optical media installer).
  - For the very few people who were still using LiveCD, if the hardware can boot from USB, install to a USB thumb drive and run from it instead. If the options to keep /var and /tmp in RAM are active, and no packages are installed, the net result should be similar but ultimately more functional.

3.43.2 Dashboard/Widgets/GUI

- Converted GUI to the Bootstrap framework, completely new look
- Changed the GUI and Captive Portal web server to nginx; removed lighttpd. #5719
- Cleaned up a lot of GUI code, option text, etc
- TLS v1.0 disabled for the GUI. #5984
- Removed old style themes, introduced new CSS-based themes
- Refactored JavaScript and CSS, moved included items to more convenient locations
- Added more AJAX updating in widgets and other places
- Changed to more intuitive and modern icons and action buttons rather than the old confusing icon set (now using font-awesome icons)
- Changed log display to be more consistent (single page for most logs, common filtering options)
- Removed obsolete fifolog support. It was never used or fully implemented, and had no GUI option.
- Improved notices in the GUI
- Made breadcrumbs and page title handling more consistent
- Added an option to have the top menu follows the user when scrolling
- Renamed several GUI file names to match menu structure. #5628
- Fixed AES-NI hardware display in the system information widget. #4911
- Added widescreen support to the Dashboard. #5195
- Improved password field handling security. Stored passwords are not presented back to the user in HTML. A masked value is returned instead. All password fields have also been changed to require confirmation.
- Many pages have been reworked for improved internationalization

- Changed info box functions, removed print_info_box_np, now print_info_box and print_apply_box are used to print appropriate boxes without problematic automatic detection
- Moved RRD graphs to **Status > Monitoring** #5498
- Changed RRD GUI interface to D3 rather than using the RRD graph command, so that a newer rrdtool base could be used with minimal added dependencies. #5498
- Monitor IP added to gateways widget. #4782
- Increased max_input_vars from 1000 to 5000 to accommodate larger aliases. #4780
- Fixed NTP RRD graphs to accommodate negative values. #4423

3.43.3 OS/Backend

- Moved to a FreeBSD 10.3-RELEASE base
- Added tryforward() support to get (nearly all of) the performance of fastforward with IPsec enabled
- Overhauled the build system
  - Eliminated the -tools repository
  - Removed Patches, changes are now applied a vendor branch of FreeBSD
  - Rewrote/changed the build scripts significantly
  - Moved the new build scripts to the main pfSense repository
- PHP Upgraded to 5.6
- Replaced pecl-APC with opcache. #4744
- Added support for -c parameters to /etc/rc.initial. #4422
- Added optional package for kernel debug symbols. #5330
- Rewrote system_set_harddisk_standby() for the current CAM-based ATA stack. #4569
- Fixed a Panic/Crash with "sbflush_internal: cc 4294967166 || mb 0 || mbcnt 0". #4689
- Fixed a kernel panic with AES-NI. #4702
- Updated AES-GCM/AES-NI bits from FreeBSD -HEAD. #4841
- Removed zoneinfo.tgz file for Time Zones, move to the same format as FreeBSD. #4726
- Fixed tcpdump with zerocopy enabled (net.bpf.zerocopy_enable=1). #5257
- Added ability to disable PV disks and NICs on Xen. #5452
- Removed the built-in but unused MySQL PHP modules and added them to the pkg server instead. They may be added as package dependencies or manually installed as needed.
- Followed FreeBSD (r294560) in ceasing generation of rsa1 and dsa ssh server host keys by default
- Removed support for nanobsd images < 2GB #5836
- Overhauled IP address handling code in various parts of the system
- scponly package is included by default. #5190
- Shortened F1 boot prompt delay on nanobsd. #3426

3.43.4 Packages

Note: The list of available packages in pfSense 2.3 has been significantly trimmed. Netgate has removed packages that have been deprecated upstream, no longer have an active maintainer, or were never stable.

- Removed use of PBI-based packages, moved to pkg(ng)
- Fixed installation and handling of packages to use pkg, now works identically in the GUI and shell/console
- Changed packages to use the FreeBSD ports format/layout to work with pkg
- XMLRPC calls for package information and installation have been removed, replaced with native pkg functions. #4575
- Added support for packages to be (re)built automatically by Poudriere
- Added search capability to Available Packages list to filter packages by keywords. #5324
- Fixed the version comparison code in the Package manager. #4924
- Added support for tags in listtopic fields for use by packages
- Factory reset now completely uninstalls packages. #5829
- Improved handling of package install post-upgrade. #3597

3.43.5 System Updates

- Major changes to update management
- Removed "full update" or "full slice" upgrade for systems on 2.3 to later versions

  These files will remain available for use by older versions updating to 2.3.
- The "Full Backup" feature has been deprecated.
- Changed system updates to be handled via pkg
- Changed Base, kernel, and standard pre-installed binares to packages
- Removed "Firmware" nomenclature, now only referred to as "Update"
- Fixed updating of base to work the same from the console or the GUI
- Added preliminary support for restarting system services without rebooting in cases when the base is updated but the kernel is the same.

3.43.6 Gateways/Routing

- Replaced apinger with dpinger(!). #5624
  - This fixes many gateway monitoring related issues, including incorrect latency and loss in various edge cases.
  - Eliminates status file race conditions that caused update failures on services bound to gateway groups in some edge cases. #5180 and #3818 among others.
  - Fixed gateway monitoring startup at boot time with assigned OpenVPN interfaces. #4587
  - Check gateway monitor settings after upgrade, dpinger has different options than apinger.
- Added code to allow gateways outside of an interface subnet. #972

- Corrected "State Killing on Gateway Failure" description. #4709
- Fixed disabling of a static route set to use a disabled gateway. #4813
- Added standard deviation to gateway status and widget
- Fixed dynamic gateway logic to prevent GIF/GRE from making dummy/unusable gateways that show up for monitoring/routing/etc #5766
- Changed static routes handling for DNS servers so they are removed when a gateway is disabled #4921
- Increased gateway weight limit from 5 to 30. #5843
- Fixed issues with PPP type WANs and the Default Gateway Switching option. #1837
- Fixed dynamic gateway handling for OpenVPN tap clients. #5981
- Fixed display of full interface name in Diagnostics>Routes. #5484

3.43.7 Rules/NAT/pf

- Added drag-and-drop rule reordering for firewall and NAT rules.
- Fixed a situation where pf drops IPv6 packets with fragment header followed by a last fragment only. #2762
- Fixed "LAN network" in v6 rules not working when a link-local address is assigned to LAN. #3656
- Added reordering for 1:1 NAT rules. #3888
- Improved handling of firewall rule tracker IDs for port forward associated rules
- Added support for a separator bar in firewall and NAT rules for use as a visual reference. #5373
- Standardized the NPt options in the GUI so their options and appearance are more similar to 1:1 NAT
- Added a "no binat" checkbox to 1:1 NAT screen for exclusions. #3887
- Limited pfsync syncpeer to IPv4 since it does not support IPv6 #4648
- Changed the default CARP pass rules to use "no state" to avoid issues with broken L2 gear that duplicates packets #5800
- Added sorting to Alias lists #4195
- Added a hit counter to the firewall rule display with states and bandwidth consumed by packets matching rules.
- Fixed issues with the DNS Forwarder and DNS Resolver being enabled concurrently (on different ports) in an HA environment #5882
- Added a visual indication in the rule list for floating rules with the "quick" property set #5860
- Improved state display on **Diagnostics > States**, now shows packets and bytes for each state
- Fixed aliases containing both FQDNs and IPv6 subnets. #5872
- Fixed removal of downloaded URL table alias contents when alias is deleted. #5856
- Significantly improved validation of downloaded data for URL Table aliases. #5848
- Fixed possibilities for creating an invalid ruleset with missing URL Table Ports aliases. #5845
- Fixed filterdns issues with significant system clock time jumps. #4166
- Added firewall rules hit counter. #3504

3.43.8 Interfaces/VIPs

- Fixed pfSense_getall_interface_addresses truncating IPv6 link local IP addresses. #4062
- Add GUI setting for VLANs PCP. #4133
- Fixed GRE interfaces failing to have a RUNNING state after reboot. #4191
- Fixed setting non-default MTUs in some edge cases. #4397
- Added input validation on bridges to prevent adding the same interface to multiple bridges. #4595
- Fixed CARP not working under bhyve. #4623
- Improved input validation for 6RD, GRE and gif interfaces, helping prevent invalid configurations.
- Changed input validation to allow /31 to be used for CARP VIPs since that is now supported and works in FreeBSD. #5533
- Added debug logging option for DHCP6 client. #4534
- Fixed cases where DHCP6 client (dhcp6c) was being launched multiple times in some circumstances. #5621
- Upgraded dhcp6c. #5734
- Upgraded DHCP client to ISC dhcpd 4.3.3P1.
- Fixed applying of non-default MTU on gif interfaces post-boot with dynamic IP WANs. #5842
- Added support for PPPoE with MTU/MRU > 1492, RFC 4638. #4542
- Fixed issues with link cycling on some Intel 10G ix NICs #5913
- Corrected ALTQ test to show that ix/ixgbe NICs are capable of traffic shaping. #5923
- Improved handling of default interface assignment for some hardware. #4535
- Corrected input validation for invalid IPv6 IPs with leading or trailing colon. #6024
- Fixed orphaning of VLANs on lagg interfaces after editing the lagg. #6014
- Fixed loss of some dhcpleases and dhcpleases6 logs. #5968
- Fixed adding of routes immediately post-reboot for delegated IPv6 prefixes to sub-routers. #5957
- Fixes to DHCPv6 leases status page and prefixes.php. #5944 #4206
- Fixed loss of IPv6 IP on track6 interfaces when saving and applying changes on that interface. #5945
- Fixed incorrect interface mismatch prompt post-config restore when using VLANs on lagg. #5892
- Added support for multiple span interfaces on bridges. #5871
- Prevent naming conflicts between interfaces and interface groups. #5795
- Prevent naming conflicts between interfaces and aliases. #5778
- Fixed use of IP aliases with GRE tunnels. #4450
- Fixed application of bridge advanced options after interface added to bridge. #4312
- Set MTU back to default after clearing the field. #3926
- Fixed IPv6 IP aliases on CARP IPs. #3716
- Fixed IP alias on CARP IPs where IP alias above CARP parent in list. #3257
- Fixed modifying unassigned VLAN interfaces changing assigned VLAN. #3209

3.43.9 Authentication

- Fixed the WebGUI becoming slow or unusable when an LDAP server used for GUI auth is unreachable. #3383
- Fixed a problem with using 'local' as the name of an authentication server 'Descriptive Name'. #4469
- Fixed default Auth Server selection on system_usermanager_settings.php. #5440
- Added support for bcrypt as a passwd hash and enabled it as the system default #4120
- Replaced the default passwd hash for root/admin using bcrypt (blowfish).
  - Existing user passwords will continue to work in their existing format until the user's password is changed.
  - User passwords cannot be automatically converted as they are not stored plain text. To convert the password hash of an existing user to bcrypt, edit the user and change their password.
- Added the ability to filter privileges when adding them to a user or group, to make finding them easier.
- Fixed updating of group file for renamed groups. #6013
- Fixed handling of groups with spaces in their names. Local group names can no longer contain spaces. New group scope option "Remote" added for LDAP and RADIUS use where spaces in group names are valid. #6012
- Added support for RFC2307 style LDAP groups. #4923

3.43.10 Services

- Fixed handling of the SNMP Bind Interface. #3883
- Fixed ntpd crashes on 32 bit with dynamic WAN reconnections and OpenVPN client configured. #4155
- Fixed a kernel panic with APU and SNMP with mibII. #4403
- Updated igmpproxy to the latest version. #4672

  The old version had some custom patches, so be wary of behavior changes
- Added encoding for DHCP/DHCPv6 server additional BOOTP text options to preserve data when stored in XML #5623
- Fixed duplication action for Load Balancer Monitor entries #4441
- Upgraded DHCP Server and Relay to ISC dhcpd 4.3.3P1
- Added statistics gathering for DHCP Server leases. #5387
- Fixed DDNS key issues with DHCP and DHCPv6 Server enabled on multiple interfaces. #5603
- Added custom ACLs for NTP (restrictions by network) #4463
- Prevent starting of radvd in circumstances where it shouldn't. #5812
- Added description column to DHCP leases status screen. #5729
- inetd replaced with xinetd (used for proxy mode NAT reflection and TFTP proxy). #5707
- DHCP lease counters added to Status>DHCP Leases. #5186
- Allow configuration of RAs when DHCPv6 Relay is enabled. #6063
- Fixed DHCPv6 Server's DDNS. #4675
- DHCP Server menu item now defaults to the first interface with an enabled DHCP Server instance. #4647
- Allow configuring DHCPv6 and RAs on track6 interfaces. #3029

- Fixed RADIUS NAS IP in PPPoE server. #185
- Deprecated ntpdate_sync_once.sh, replacing with ntpd -g. #6053

3.43.11 DNS

- Fixed Unbound IPv6 link local handling. #4021
- Added validation for advanced configuration directives in Unbound. #4411
- Upgraded dnsmasq to 2.76.0test8 to fix crashes in 2.75. #5341
- Fixed Unbound binding to IP alias virtual IPs. #5464
- Changed Namecheap dynamic DNS to use separate hostname and domain name fields #4366
- Added Multi-WAN support to RFC 2136 Dynamic DNS.
- Added RFC 2136 support to the Dynamic DNS widget
- Added input validation to prevent the same DNS server from being added multiple times on **System > General** #5915
- Fixed CloudFlare dynamic DNS to not configure 'proxiable' and 'proxied' parameters. #6005
- Fixed dnsmasq host overrides when both DNS Forwarder and Resolver are enabled. #5883
- Added RFC 2136 dynamic DNS to dashboard widget. #5862
- Added multi-WAN support to RFC 2136 dynamic DNS client. #5862
- Don't specify 127.0.0.0/8 IPs as forward-addr in Unbound configuration. #5750
- Added input validation to require configured DNS servers before enabling Resolver's forwarding mode. #4747
- Added Google Domains DDNS support. #4322
- Added DNS Made Easy DDNS support. #1258
- Allow @ in Dynamic DNS hostnames. #3900
- Improve IPv6 link local handling in DNS Resolver and Forwarder so it works across configuration restores and with HA config sync. #3802

3.43.12 IPsec

- Upgraded to strongSwan 5.4.0.
- Fixed multiple possibilities for IPsec status hangs. #5520
- Revised handling of IPsec reloading when strongswan.conf is changed. #4353
- Fixed problems with the search domain in IPsec mobile clients. #4418
- Added support for elliptic curve for IPsec on webconfigurator. #4683
- Added input validation for authentication backend when using EAP-RADIUS with IKEv2 Mobile IPsec. #5219
- Fixed unit display on IPsec status pages for time and data to be more human-friendly. #5364
- Removed support for single DES from IPsec #5543 (3DES Remains)
- Removed global IPsec disable flag as it is no longer necessary. On upgrade, if the IPsec enable box was unchecked, all Phase 1 entries are disabled individually instead.
- Changed IPsec 'up' commands to start in the backgound so they are non-blocking #5882

- Disabled the strongSwan unity plugin by default, and improved the method used to disable the plugin #4178
- Removed unnecessary and troublesome 'pass out' rules for mobile IPsec #5819
- Fixed "no valid leases object found" log spam with IPsec dashboard widget. #5855
- Fixed automatically added WAN rules (UDP 500, 4500, ESP) when using IPsec with IP aliases. #5500
- Fixed IKEv2 to Cisco ASA resulting in traffic selector mismatch when initiated by traffic. #4719
- Added "split connections" option to phase 1 for IKEv2 for interoperability with third party devices that do not support multiple traffic selectors on one child SA (Cisco ASA, others). #4704
- Added dynamic AJAX update to status_ipsec.php. #6049

3.43.13 OpenVPN

- Changed the default behavior of the OpenVPN server to use topology subnet, not net30. #5526
- Changed Client-Specific Overrides so they can be set to apply to specific servers rather than being globally set. #5526
- Fixed OpenVPN Server validation of self-signed certificates with a depth of 2. #4329
- Fixed overwriting of custom `/etc/dh-parameters.*` on upgrade. #4816
- Fixed invalid rules generated with some AVPair-defined ACLs. #5451
- Improved display of server certificates on OpenVPN servers to help avoid users incorrectly picking user certificates for servers. #5602
- Fixed OpenVPN client specification of auth-user-pass in shared key modes where it's not valid. #5941
- Fixed problems with OpenVPN and some use of special characters in the username or password. #4605

3.43.14 MPD/PPP VPN/Services

- Removed PPTP Server. #4226
- Add MS-CHAPv2 option to L2TP Configuration. #4732
- Fixed editing of multiple PPPoE connections with dial on demand enabled changing the port assignment. #4378
- Added a user login count option to the PPPoE server

3.43.15 UPnP/NAT-PMP

- Enabled port-in-use checking in miniupnpd. #4320
- Enabled IPv6 for miniupnpd. #4321
- Set secure_mode=yes in miniupnpd configuration #5627

3.43.16 Wireless

- Removed WEP. #5123
- Improved default settings for Wireless interfaces

3.43.17 Captive Portal

- Fixed Captive Portal to support more than 120 VLAN interfaces. #4150
- Added an option in Captive Portal for FreeRADIUS-friendly stop/start RADIUS accounting updates that solves problems with user session time limits. #2164
- Fixed selection of RADIUS NAS IP with VIPs when editing Captive Portal zone. #5656

3.43.18 Traffic Shaping

- Fixed CODELQ scheduler defaults. #4692
- Removed Layer 7 classification support from the traffic shaper #5508
- Relaxed the shaper wizard interface validation when there are no interfaces with gateways selected #4524
- Fixed traffic shaper failure with "bandwidth for q… higher than interface" in some edge cases. #5721

3.43.19 Misc

- Allow wildcards in Certificate Subject Alternative Names. #3733
- Removed the "Certificate Authority" option on the **Certificates** tab of the Cert Manager when creating a **Certificate**. To make a Certificate Authority, use the **CAs** tab instead. #5924
- Adapted gitsync to new repo structure. #4999
- Changed the packet capture output in the GUI so that when the protocol is set for CARP, tcpdump interprets it as CARP for more accurate output
- Added pfsync protocol option to packet capture page. #5866
- Added "GoTo line #" control to Diagnostics > Edit File
- Corrected help in pfSsh.php to properly reflect how recording works
- Fixed validation of playback file passed to pfSsh.php #5657
- Fixed disabling of filter.log logging where local logging is disabled. #6018
- Updated included software on licenses.php page. #5903
- Internationalization improvements. #5777
- Fixed use of IP aliases on Test Port page. #5185
- Fixed key map, screen map and font selection in installer. #4387
- Prevent deletion of certificates in use by packages. #4142

3.43.20 Update Patches

This section lists the changes contained in patch updates post-release.

2.3_1

The 2.3_1 update upgrades NTP to fix FreeBSD security advisory SA-16:16.ntp. The only change is upgrading ntpd from 4.2.8p6 to 4.2.8p7.

3.44 2.2.6 New Features and Changes

3.44.1 Security/Errata Notices

- Updated to FreeBSD 10.1-RELEASE-p25
  - FreeBSD-SA-15:26.openssl Multiple vulnerabilities in OpenSSL
- Updated to strongSwan 5.3.5
  - Includes fix for CVE-2015-8023 authentication bypass vulnerability in the eap-mschapv2 plugin.
- pfSense-SA-15_09.webgui: Local File Inclusion Vulnerability in the pfSense® WebGUI
- pfSense-SA-15_10.captiveportal: SQL Injection Vulnerability in the pfSense captive portal logout
- pfSense-SA-15_11.webgui: Multiple XSS and CSRF Vulnerabilities in the pfSense WebGUI

3.44.2 Logging

- Fixed log duplication for some log entries. #5606

3.44.3 IPsec

- strongSwan 5.3.5 update fixes several bugs.

3.44.4 Config sync

- Fixed config synchronization failure in some circumstances. #5509

3.44.5 Captive Portal

- Fixed captive portal database handling issue that could reset database instead of waiting for lock to clear. #5622
- Fixed problem with 0 byte files in captive portal file manager. #5642

3.45 2.2.5 New Features and Changes

3.45.1 Security/Errata Notices

- Updated to FreeBSD 10.1-RELEASE-p24
  - FreeBSD-SA-15:25.ntp
  - FreeBSD-SA-15:14.bsdpatch:
  - FreeBSD-SA-15:16.openssh:
  - FreeBSD-SA-15:18.bsdpatch:
  - FreeBSD-SA-15:20.expat:
  - FreeBSD-SA-15:21.amd64:
  - FreeBSD-SA-15:22.openssh:
- **pfSense-SA-15_08.webgui:**
  Multiple Stored XSS Vulnerabilities in the pfSense® WebGUI

  The complete list of affected pages and fields is listed in the linked SA.
- Updated strongSwan to 5.3.3
- Updated PHP to 5.5.30
- Updated miniupnpd to 1.9.20150721 to address a potential vulnerability in miniupnpd.

3.45.2 User Management/Authentication

- Added support for GUI auth from RADIUS to obtain group names from the RADIUS reply attribute "Class" as a string (local groups must exist, similar to LDAP). #935
- Added an LDAP server timeout field to address GUI access issues when the LDAP server is down/unreachable. #3383
- Added support for LDAP RFC 2307 style group membership. #4923
- Worked around a chicken-and-egg problem in user syncing which was preventing users from using ssh the first time the account was saved. #5152
- Prevent deletion of system users and groups by authenticated, authorized users using manually crafted POSTs. #5294

3.45.3 OpenVPN

- Fixed an incorrect netmask being sent to OpenVPN clients with static IP addresses set in RADIUS. #5129
- Changed the calculation of the OpenVPN point-to-point server IP address obtained from RADIUS to be consistent with CSC/Overrides (Server should be one IP address below the Client)

3.45.4 IPsec

- strongSwan upgraded to 5.3.3. strongSwan's change log
- Fixed missing DH group 22-24. #4918
- Fixed handling of IPv4 IPsec Phase 1 endpoints that resolve to an IPv6 address. #4147 (Fixed by strongSwan update to 5.3.3)
- Brought back "auto" IKE version and fixed problems with its previous implementation.
- Pre-shared keys configured as "any" under VPN>IPsec, Pre-Shared Keys tab are added as %any to ipsec.secrets now, as described in the note on the page. #5246
- Resolved memory leak by switching printf hooks to vstr. #5149
- Change to vstr to fix memory leak broke SMP status plugin. Switched to vici for status output.
- ID selectors omitted from ipsec.secrets for mobile PSK+XAuth configurations. Fixes pre-shared key mismatches with Apple iOS Cisco IPsec and other mobile clients. #5245
- Fixed logging default settings and ability to set logging to silent. #5340
- Logging settings applied correctly on clean start and stop/start of service. #5242
- Remove deleted CAs, certificates and CRLs from strongswan configuration. #5238
- Prevent over-matching of auto-added firewall rules for mobile IPsec configurations. #5211
- Added IPv6 virtual address pool support for mobile. #5284
- Allow both IPv4 and IPv6 in phase 2 entries on a single phase 1 when using IKEv2. #5305
- Omit NAT rules for disabled phase 1 and 2 configurations. #5320
- Only display certificate authority field for methods where it's relevant. #5323
- Only write out CA certificates for those specified in a Phase 1 configuration. #5243
- Fixed Hybrid RSA + xauth. #5207
- Fixed configuration of split tunnel attribute. #5327
- Specify rightca in ipsec.conf where relevant. #5241
- Specify leftsendcert=always in ipsec.conf for mobile profiles using IKEv2 to better accommodate iOS and macOS manual configurations. #5353
- Fix IKEv2 mobile client pool status display with small number of active leases

3.45.5 Rules/NAT

- Fixed handling of url_port alias types when processing items that should be handled by filterdns. #4888
- Fixed handling of line endings when parsing a URL table ports file.
- Fixed handling of empty bogon lists on NanoBSD.
- Fixed handling of 6rd rules so they are only added when there is an IPv4 IP defined for the gateway, otherwise the ruleset ends up invalid. #4935
- Added support for port ranges on Outbound NAT. #5156
- Added a check to prevent renaming an alias to an existing name. #5162
- Improved the fix for increasing the "self" table size in pf.

- Imported fixes from FreeBSD for a situation that could result in a panic/crash due to source address limits in pf rules ("pf_hashsrc: unknown address family 0"). #4874

3.45.6 Captive Portal

- Implemented an alternate method to find VIP targets that should be allowed for Captive Portal. #4903
- Improved handling of the captive portal database files for zones in cases when the database files may be corrupt or unreadable. #4904
- Improved handling of vouchers that are too short. In certain cases they were not being properly rejected. #4985
- Fixed handling of voucher database files, initializing the database properly when necessary. #5113
- Fixed loading of allowed hostnames at boot time. #4746, #5345

3.45.7 Packages

- Fixed handling of package install errors and connect timeouts during the install process. #4884
- Improved package version comparison. #4924
- Fixed an issue with package editing where the default value was not being populated for new fields.
- Fixed removal of syslog.conf entries during package uninstall #5210

3.45.8 DHCP

- Fixed handling of DHCP pools that are out of range, preventing them from creating an invalid dhcpd configuration. #4878
- Added support for UEFI network booting with arch 00:09. #5046
- Fixed a situation where dhcpleases could miss updates for hostnames in the leases file, delaying functional hostname resolution of new and updated DHCP leases. #4931
- Automatically add firewall rules to permit DHCP traffic when DHCP Relay is enabled, matching the behavior for DHCP Server. #4558

3.45.9 Interfaces

- Fixed identification of IPv6 interfaces with PPP-type interfaces and DHCP6 #3670
- Removed "Could not find gateway for interface…" log messages as they were largely useless. #4102
- Added OpenVPN interfaces to the list of available interfaces when reassignment is necessary during config.xml restoration.
- Fixed interface assignment menus running off VGA screen.
- Fixed preservation of MLPPP settings when saving interface settings. #4568
- Correct handling of SLAAC, DHCP6 and DHCP-PD with PPP interfaces. #5297

3.45.10 Dynamic DNS

- Fixed Cloudflare support for Dynamic DNS updates.
- Fixed GratisDNS support for hosts without subdomains.
- Disabled DHS provider. It had never worked.
- Fixed IPv4 dynamic DNS registrations on dual stack hosts to providers with AAAA records. #3858
- Update Dynamic DNS using gateway groups upon enable and disable of gateways. #5214
- Fixed Dynamic DNS using gateway groups specifying a CARP IP. #4990

3.45.11 Misc

- Fixed the configuration version comparison in XMLRPC sync to prevent more invalid synchronization cases. #4902
- Cleaned up old unused platforms referenced in a few areas of the code that were no longer relevant.
- Fixed killing of individual states in cases when the source and destination were reversed. #4907
- Fixed killing of individual states for IPv6. #4906
- Changed the "enableallowallwan" script to also allow bogons, which makes the use of RFC 5735 / RFC 6890 test networks easier in lab environments.
- Fixed handling of VIPs in source address selection for Diagnostics > Test Port. #4986
- Updated status.php to include more information. #5304
- Fixed handling of the description in Traffic Shaping.
- Fixed pfSense base version comparison. #4925
- Fixed handling of multiple notices in the same second. #4879
- Removed the routed service as it is being handled by the package.
- Set MIME type for SVG in lighttpd configuration.
- Improved handling of the cron service reconfiguration process.
- Added option to display monitor IP on Gateways widget #4782
- Added "Description" as a display option on Traffic Graphs. #4783
- Fixed handling of L2TP server interface selection. #4830
- Added /usr/bin/dc back into the build. #5111
- Fixed a crash/panic "Sleeping thread owns a non-sleepable lock" in ARP code when using Proxy ARP type VIPs. #4685
- Added support for Sierra Wireless 7355. #4863
- Updated time zones. #5254
- Added fsync of Unbound's root.key to ensure the file isn't corrupted if power is lost shortly after writing of the file. Code added to detect corrupt root.key and delete and recreate it. #5334
- Fix changing outbound NAT modes and uploading/downloading files on exec.php with non-English languages. #5342, #5343
- Associate intermediate internal CA certificates with the signing CA. #5313

3.46 2.2.4 New Features and Changes

3.46.1 Security/Errata Notices

- pfSense-SA-15_07.webgui: Multiple Stored XSS Vulnerabilities in the pfSense® WebGUI

  The complete list of affected pages and fields is listed in the linked SA.

- FreeBSD-SA-15:13.tcp:
- Further fixes for file corruption in various cases during an unclean shut down (crash, power loss, etc.). #4523
  - Fixed pw in FreeBSD to address passwd/group corruption
  - Fixed config.xml writing to use fsync properly to avoid cases when it could end up empty. #4803
  - Removed the 'sync' option from filesystems for new full installs and full upgrades now that the real fix is in place.
  - Removed softupdates and journaling (AKA SU+J) from NanoBSD, they remain on full installs. #4822

Note: The forcesync patch for #2401 is still considered harmful to the filesystem and has been kept out. As such, there may be some noticeable slowness with NanoBSD on certain slower disks, especially CF cards and to a lesser extent, SD cards. If this is a problem, the filesystem may be kept read-write on a permanent basis using the option on **Diagnostics > NanoBSD**. With the other above changes, risk is minimal. The best practice is to replace the affected CF/SD media by a new, faster card as soon as possible. #4814

- Upgraded PHP to 5.5.27 to address CVE-2015-3152 #4832
- Lowered SSH LoginGraceTime from 2 minutes to 30 seconds to mitigate the impact of MaxAuthTries bypass bug.

Note: *Sshlockout* will lock out offending IP addresses in all past, current and future versions. #4875

3.46.2 Certificates

- Changed the built-in certificate manager to specify keyUsage and extendedKeyUsage in certificates. Windows will now correctly function with IKEv2 using certificates from the built-in certificate manager without disabling EKU. #4580

Note: This change applies only to new certificates, created on 2.2.4 or newer, and the CN of the certificate must match the hostname or IP address to which clients connect.

- Added authorityKeyIdentifier to CRLs generated by the built-in certificate manager. (strongSwan requires it to match.) #4860

3.46.3 IPsec

- Fixed non-GCM AES modes with AES-NI enabled. #4791
- Fixed issues with keyid and some mobile IPsec identifiers. #4811 #4806
- Fixed includes so PHP shell session restartipsec script works.
- Fix dashboard hardware crypto display where AES-NI is enabled. #4809
- Fixed issues with IPsec with certificates/ASN1.DN. #4792 #4794
- Added code to write out CRLs from the built-in certificate manager for use by strongSwan.
- Added option for enabling Strict CRL Checking (strictcrlpolicy in strongSwan config).
- Fixed saving Advanced IPsec options before IPsec is enabled.
- Changed LAN bypass to be from "LAN subnet" to "LAN subnet" rather than from "LAN subnet" to "LAN address" to allow it to work for VIPs on the interface.
- Remove "Auto" key exchange option, and change upgraded configurations to IKEv2. #4873
- Specify rightid for mobile IPsec non-PSK configurations. Add peer ID option "any" for excluding peer identifier checks for mobile IPsec circumstances where peer ID matching is impossible or undesirable.

3.46.4 OpenVPN

- Fixed handling of OpenVPN automatic stop/start when bound to gateway groups using CARP VIPs. #4854

3.46.5 DHCP

- Fixed issues with IPv6 Prefix Delegation caused by an invalid prefix/subnet check added to the ISC DHCP daemon. Reported upstream and patched the checks out in FreeBSD ports. #4829

3.46.6 DNS Resolver

- Changed Unbound to use interface-automatic where interface list is empty so it replies correctly in a default HA configuration. #4807
- Fixed selection of a CARP VIP for outgoing interface. #4852
- Fixed some inconsistencies in text across the GUI in places that specified DNS Forwarder vs. Resolver. #4551

3.46.7 Load Balancer

- Improved handling of port ranges in relayd. #4810
- Fixed references to Load Balancer Virtual Server *redirect_mode*.

3.46.8 Traffic Shaping

- Fixed adding of VoIP rules from traffic shaper wizard where IP/alias was not specified. #4838
- Fixed default CoDel values.
- Corrected inverted target/interval values for CoDel.

3.46.9 Rules/NAT/Aliases

- Fixed a foreach() error when saving an empty alias.
- Fixed input validation on Alias import page.
- Fixed inconsistencies in descriptions in Alias editing for URL Table aliases.
- Added labels to more default firewall rules.
- Avoid an error loading the rules with a numeric hostname in an alias.

3.46.10 Misc

- Removed unnecessary deletion of rc.conf; Added an empty rc.conf with a note.
- Removed a check for a QinQ interface existing when deleting. The check unnecessarily made QinQ un-deletable where the parent interface no longer existed.
- Fixed GratisDNS support.
- Fixed glob for serial devices to match more accurately.
- Fixed a foreach() warning when editing PPP entries.
- Fixed GRE and GIF interface input validation so required fields and descriptions match.
- Changed the behavior of Cancel buttons to be consistent (return to referring page).
- Fixed display of advanced DHCP settings when present.
- Removed old, unused *NetUtils.js*.
- Retain */usr/bin/fsync* from FreeBSD in images.
- Added “netstat -ni” to /status.php output.
- Fixed a typo in upgrade code for Captive Portal.
- Fixed limiter upgrade code to allocate pipe numbers even if no rules are present.
- **Fixed upgrade code to remove old CA/Cert config entries that were** moved/relocated.

3.47 2.2.3 New Features and Changes

3.47.1 Security/Errata Notices

- pfSense-SA-15_06.webgui: Multiple XSS Vulnerabilities in the pfSense® WebGUI

  The complete list of affected pages and fields is very large and all are listed in the linked SA.
- FreeBSD-SA-15:10.openssl:
- Fixes for filesystem corruption in various cases during an unclean shut down (crash, power loss, etc.). #4523
  - Changed new filesystems to use the 'sync' option to avoid loss of data.
  - Added upgrade code to activate the 'sync' option on the root slice for existing installations.
  - Changed new filesystems to use softupdates and journaling (AKA SU+J).
  - Changed the way fsck is handled at boot time:
    * Followed best practice of using fsck from FreeBSD rc.d/fsck script. (Run preen mode first and later try forcefully fixing issues.)
    * Added as much information during boot on the status of the filesystem as possible.
    * Changed fsck to run with -C flag and always in foreground during boot to prevent issues that might schedule background mode.

Note: The forcesync patch for #2401 was considered harmful to the filesystem and removed. As such, there may be some noticeable slowness with NanoBSD on certain slower disks, especially CF cards and to a lesser extent, SD cards. If this is a problem, the filesystem may be kept read-write on a permanent basis using the option on **Diagnostics > NanoBSD**.

3.47.2 Rules/Aliases/NAT

- Fixed a problem with more than 64 IP addresses in the "self" table in pf.
- Fixed issues with FQDNs in aliases causing static entries to be lost. #4296
- Added the tracker ID rule number lookup to dynamic firewall log. #4730
- Fixed alias rename and delete not being propagated to outbound NAT. #4701
- Fixed tracker IDs of policy route negation rules which had been duplicating the tracker ID of the rule they were based upon. This confused the log parser and displayed the negation rule rather than the actual rule. #4651
- Fixed logging of passed IGMP traffic when the rule is not set to log. #4383
- Fixed a situation where a combination of L2TP, overlapping subnets, port forwards and NAT reflection could cause an invalid ruleset. #4772
- Added a GUI field to control the size of the pf fragment limit #4775

3.47.3 IPsec

- Updated strongSwan to 5.3.2. #4750
- Integrated a patch from https://wiki.strongSwan.org/issues/951 to solve IPsec SA rekey issues on strongSwan+FreeBSD. #4686
- Added patches from FreeBSD PR 200282 to help address IPsec rekey issues.
- Backported FreeBSD r283146 and patch from FreeBSD PR 192774 to address PF_KEY ACQUIRE missing port and protocol information.
- Added reply-to/route-to rules for mobile-ipsec. #4235
- Removed the manual specification of reqid in the IPsec configuration because strongSwan 5.3.0 has fixed issues with its handling, which caused the existing code to misbehave. #4665
- Fixed the display and behavior of the LAN bypass option for IPsec. #4655
- Fixed IPsec LAN bypass toggling every time save is pressed. #4640
- Changed how charon is started and restarted to fix a various issues with IPsec configuration reloading. #4268
- Added new modes for IPsec Phase 1 according to RFC 5903 (Ecliptic Curve groups). #4260
- Implemented the "make before break" feature available in strongSwan 5.3.0, which is useful for IKEv2. #4626
- Fixed vpn_ipsec_configure so it always performs a filter reload to ensure the ruleset is updated where necessary in every IPsec change scenario. #4631
- Added support for EAP-RADIUS to IKEv2 Mobile Clients. #4614
- Fixed a panic/crash when accessing services on the firewall over mobile IPsec on 32-bit installations (set net.inet.ipsec.directdispatch=0 on i386). #4537
- Fixed an issue with FQDN hosts and PSKs. #4785

3.47.4 OpenVPN

- Added a space to the OpenVPN TLS Verify script to avoid appended parameters appearing the same as existing parameters.
- Fixed get_interface_ip() to return the IP address correctly for gateway groups specifying a VIP, which fixed OpenVPN clients not working with gateway groups specifying VIPs. #4661
- Changed the OpenVPN client settings to allow just one of either the username or password to be specified. #3633
- Fixed OpenVPN servers listening on an associated IPv6 addresses.

3.47.5 Captive Portal

- Fixed filterdns to use the proper API for ipfw changes on FreeBSD 10.1+ to correct captive portal allowed hostnames not being loaded into tables at boot time. #4746
- Fixed Captive Portal RADIUS accounting. #4131
- Fixed Captive Portal Idle-Timeout causing a value of 2147483647 for acctsessiontime. #4652
- Fixed disconnection of active voucher users, and corrected disconnection of users especially when triggered via XMLRPC. #4625

3.47.6 Operating System

- Fixed both the kernel and choparp to better handle I/O and prevent issues in the way it handles BPF, which can contribute to a panic when using Proxy ARP VIPs. #4685
- Merged a patch that avoids a panic on sockbuf module. #4689
- Fixed AESNI to be SMP friendly to avoid various decryption errors and possible encryption mistakes. Also present critical_enter/critical_exit to avoid preemption of the currentrunning thread which should fix panics. #4702
- Updated time zone data from FreeBSD 10.1-RELEASE. #4459
- Fixed creation of */var/spool/lock* on NanoBSD at boot time. #4532
- Removed boot_serial='yes' from loader.conf when serial is disabled. #4617
- Fixed an issue where mtree would fail during an upgrade from a previous version of FreeBSD when moving to 2.2.x. #4653

3.47.7 Interfaces/NIC Drivers

- Added support for Sierra Wireless MC7354.
- Added support for Intel X552, ixgbe changes from stable/10, and moved altq changes for ixgbe to the large ixgbe patch.
- Enabled ix/ixv/ixl modules in the kernel
- Fixed duplication of statistics on vlan(4) interfaces for outgoing bytes #3314
- Fixed updating wireless statistics so that the output bytes are not always zero. #4028
- Added a patch from FreeBSD PR 200722 for mpd5 to preventing it from printing a warning when renaming an interface to an existing name.
- Fixed SLAAC/DHCPv6 handling for cases where the global SLAAC IPv6 address might be present when using DHCPv6. #4483
- Corrected descriptions on Key Rotation and Master Key Regeneration for wireless interfaces.
- Removed the "insert my MAC" feature from interfaces.php.
- Defined $var_path as a global key since it is being used in interfaces.inc, but it was not declared.
- Fixed issues setting the MTU on certain interfaces. #4397

3.47.8 Packages

- Fixed various issues with PBI generation.
- Synchronized and cleaned up various pfPorts, eliminated several that had changes pushed back into FreeBSD ports.
- Fixed an issue where rebuild_package_binaries_pbi.php could fail due to missing build files. #4600
- Backported patches from FreeBSD stable/10 to fix a crash when stopping squid. #4592
- Fixed pfflowd to use the correct version for parsing the new pfsync header and corrected the pfsync version check. #4304
- Updated pkg_edit.php with fixes for usecolspan2 and combinedfields.

- Fixed pagination on pkg.php.
- Fixed boot-time log file initialization for package logs. #4603

3.47.9 DHCP/RA

- Clarified that DNS Forwarder and Resolver both apply in DHCP/DHCPv6 and router advertisements. #3730
- Removed unnecessary filtering on the DHCP static mappings table.
- Added appropriate RA Flags for "Stateless DHCP".
- Added error checking to avoid warnings about DHCP relay during boot.
- Fixed hostname validation for static DHCP leases such that only fully qualified hostnames must be unique, not only short names.
- Fixed adding DHCP static mappings from the DHCP leases view to non-default pools. #4649
- Stopped invalid DHCP settings from being applied when input errors exist.
- Removed DHCP static lease overlap cleanup and its associated function and killing of the DHCP daemon. This behavior could cause problems with failover scenarios, especially when adding/editing/removing static mappings.

3.47.10 Web GUI

- Fixed language selection. #4705
- Changes to status.php to make it easier to gather and submit support information:
  - Added sanitization of OpenVPN static/tls keys to status.php.
  - Cleaned up, organized, and expanded the info presented by status.php.
  - Changed status.php to additionally save the output to individual
  - text files and compress them into a .tgz for later download.
- Fixed setup wizard LAN DHCP pool calculation to avoid an invalid pool.
- Improved the setup wizard hostname check. #4712
- Fixed some minor text issues in wizards.
- Changed the wizard to use the current WAN gateway name rather than assuming the name. #4713
- Updated and corrected the wireless status flags and capabilities list. There are many more possible flags, now documented at *Wireless Status*.
- Added a fall back to look up local user privileges and groups if the groups could not be found from LDAP and there is a local user.
- Fixed Crash Reporter submissions when symlinks were present as part of crash report, which would fail to save the report on the server. #4650
- Set a user agent for the Crash Reporter.
- Cleaned up code logic in status_upnp.php.

3.47.11 CARP

- Changed CARP so that it does not trigger a carp demotion taskqueue if the value is 0, which can cause the cluster to misbehave.
- Fixed issues for CARP+Bridges where pfSense would crash or freeze. #4607
- Fixed the CARP plugin call for packages. The "interface" parameter was coming through as NULL during CARP events.
- Added INIT event for CARP in devd.conf as an alternate for 'backup', otherwise scripts would not take down services during a MASTER->INIT transition. (e.g. interface unplug, link loss)
- Fixed NTP so that it properly uses selected CARP IP addresses. #4370
- Fixed CARP packet flow after initial interface creation. #4633

3.47.12 Traffic Shaper/Limiters

- Fixed limiters when used with IPv6. #2526
- Corrected handling of NAT when RDR/BINAT is applied on packet and it is being sent to limiters. #4596

3.47.13 DNS

- Consistently handle clear_subsystem_dirty after an Unbound restart.
- Added a call to clear_subsystem_dirty('staticmaps') when using Unbound, otherwise DHCP static mappings would not fully apply when Unbound was in use. #4678
- Fixed an Unbound warning when "dnsallowoverride" was off and port forwarding was on. #4682
- Re-enabled verification for selfhost DynDNS since their chain issue has been resolved. #4545

3.47.14 Misc

- Updated PHP to 5.5.26
- Fixed various issues in the installer for GEOM mirrors (mirror slice detection, gmirror cleanup on non-clean disks.) #4658
- Fixed new user creation to use skel as the source of new user files rather than copying from the home directory of *root*.
- Changed growl so it will not be called if the configured address isn't an IP address or resolvable hostname. This avoids 1 minute timeout delay in fsockopen in growl.class. This change cuts that down to about a 20 second timeout. #4739
- Added a reboot after restoring a full backup in the GUI. #4107
- Deprecated */usr/local/bin/3gstat* as it was no longer used. It was replaced by *3gstats.php* long ago.
- Started using the "host!" flag when setting CURLOPT_INTERFACE, as recommended by the CURL documentation.
- Started passing the interface to CURLOPT_INTERFACE instead of the IP address, also started using the "if!" flag to avoid CURL trying to resolve the interface name.
- Fixed NTP serial configuration to setup the serial port before attempting to configure a GPS unit.

- Cleaned up various HTML/XHTML issues.
- Fixed a check for deleting a VIP when in use by OpenVPN.
- Fixed issues with backup/restore of a config.xml breaking the serial console on ADI installs. #4720
- Fixed several issues with boot speed when WAN was disconnected. #4442
- Removed some unused/obsolete files.

3.48 2.2.2 New Features and Changes

3.48.1 Security/Errata Notices

- pfSense-SA-15_05.webgui: Multiple XSS Vulnerabilities in the pfSense® WebGUI
- FreeBSD-SA-15:09.ipv6:
- FreeBSD-SA-15:06.openssl:

3.48.2 Rules / NAT

- Added hidden config option to disable blocking of link-local IPv4 (169.254.0.0/16) for the rare instances where it's required. Not recommended, violates RFC 3927.
- Fixed invalid ruleset generation when using port forwards with destination "any" on a DHCP client WAN-type interface, have pure NAT mode reflection enabled, and have the interface with link up but unable to reach a DHCP server for an extended period. #4564
- Allow the use of version IPv4+IPv6 on firewall rules without restrictions on protocol. The former restrictions date back to earlier base software versions, and are no longer applicable.
- Omit route-to from rules specifying a specific gateway when that gateway is forced down. #4566
- Use the subnet address when forming rules for networks, rather than the interface IP address
- Added SCTP to the protocol drop-down for firewall rules

3.48.3 IPsec

- Enforce disabling of "prefer old SAs" option.Having this option enabled will cause connectivity problems after rekeying in many circumstances. Upgrading to 2.2.2 will fix this.
- strongSwan upgraded to 5.3.0
- Don't apply mobile IPsec phase 2 PFS configuration to non-mobile IPsec. #4538
- Correct applying of uniqueid configuration. #4359
- Bring back automatic exclusion of LAN subnet to LAN IP for scenarios where remote IPsec overlaps with local LAN subnet. #4504
- Enable ike_name for daemon logging, adding connection identifiers to IPsec logs that can be correlated to output of 'ipsec statusall' (GUI log viewer integration to come).

3.48.4 DNS Forwarder/Resolver

- Fix DNS registration of hostname "0" #4573
- Domain overrides to multiple server IPs are possible in DNS Resolver. Add message noting this, and how to achieve it. #4350
- Always configure user-specified DNS servers in the Unbound configuration, to make its behavior consistent with dnsmasq
- Only list nameservers once in resolv.conf

3.48.5 Wireless

- Atheros wireless driver updated to latest from FreeBSD 11-CURRENT. Not many changes since 2.2.1-RELEASE. #4582
- Wireless cards removed from ALTQ-capable interfaces (traffic shaper capability) since that isn't supported at the moment. #4406
- New option "auto" added for Standard. This omits configuring mode with ifconfig, which currently can trigger driver problems that don't exist when not specified. Standard "auto" is preferred, and possibly required, for BSS and IBSS wireless modes with Atheros cards (at a minimum, potentially others).

3.48.6 IPv6

- Make sure 'DHCPv6 Prefix Delegation size' is provided if 'Send IPv6 prefix hint' flag is checked to avoid generating invalid dhcp6c configuration file.
- DHCPv6 Relay fixed. #4572
- Allow "0" for id-assoc na ID, id-assoc pd ID, sla-id and sla-len DHCP6 configuration options. #4547
- Fix the use of multiple prefixes in IPv6 router advertisements. #4468

3.48.7 Other

- Clean up logic in OpenVPN resync code. Discussion here and additional change here.
- SSL certificate validation disabled for selfhost - their certificate chain had a problem that made OpenSSL fail verification, making the service non-functional. #4545 The provider fixed the issue after 2.2.2-RELEASE, so verification has been re-enabled for 2.2.3 and newer.
- Fix error in traffic shaping wizard. #4529
- Fix broken image path. #4530
- A variety of minor text clean up in web interface.
- Remove some code no longer used in a few places.
- Clean up of code path when adding a new user. #4620
- Make sure RRD backup is not restored when /var memory disk is not in use. #4531
- Show friendly name of the interface on custom RRD graph drop-down selection
- PHP upgraded to 5.5.23
- Prevent a user from adding a VLAN using the invalid ID "0"

- Cleanup display of times in DHCP leases
- Use the correct field for voucher “expired” and “no access” messages
- Fix traffic shaper wizard bandwidth input validation calculations https://redmine.pfsense.org/issues/4259
- Changed Diagnostics > Sockets to display sockets bound to localhost
- Allow single interface bridges, useful for span ports and when migrating interfaces to a bridge

3.49 2.2.1 New Features and Changes

3.49.1 Security/Errata Notices

- pfSense-SA-15_02.igmp: Integer overflow in IGMP protocol (FreeBSD-SA-15:04.igmp)
- pfSense-SA-15_03.webgui: Multiple XSS Vulnerabilities in the pfSense® WebGUI
- pfSense-SA-15_04.webgui: Arbitrary file deletion vulnerability in the pfSense WebGUI
- FreeBSD-EN-15:01.vt: vt(4) crash with improper ioctl parameters
- FreeBSD-EN-15:02.openssl.asc: Update to include reliability fixes from OpenSSL

Potentially Relevant

The following updates are included from upstream in FreeBSD, but are not directly relevant. Neither pfSense software nor its packages include SCTP services, but such services may have been manually added by the user.

- FreeBSD-SA-15:02.kmem: SCTP SCTP_SS_VALUE kernel memory corruption and disclosure
- FreeBSD-SA-15:03.sctp: SCTP stream reset vulnerability

Not Relevant

- OpenSSL “FREAK” vulnerability:
  - Does not affect the web server configuration on the firewall as it does not have export ciphers enabled.
  - pfSense 2.2 already included OpenSSL 1.0.1k which addressed the client-side vulnerability.
  - If packages include a web server or similar component, such as a proxy, an improper user configuration may be affected. Consult the package documentation or forum for details.

3.49.2 Known Issues

- Some cases remain where filterdns does not properly handle hostnames in multiple aliases properly. Most of the cases have been fixed, so the situation is better than 2.2-RELEASE, but it is not 100% resolved. See issue #4296 for details. Placing hostname aliases into a separate alias so they are not mixed with static entries effectively works around the issue.

3.49.3 General

- Updated the default SSL cipher list to be stronger, obsoletes the need for a "BEAST protection" option #4230
- Fixed gen_subnet_max returning an incorrect result on 32 bit (i386) versions, which in turn fixed Wake on LAN and other areas on 32 bit (i386) versions. #4318
- Fixed crash on boot with some hardware, caused by gpioapu on systems where smbios.system.product is null. Mostly seemed to be the recycled Watchguard users affected by this issue. #4363
- Updated ufslabels.sh to handle a wider variety of disk layouts.
- Added a choice of SMTP authentication protocols for notifications, Office365 mail support. #4176
- Removed latin-1 encoding of RSS feed to fix display issues of RSS items.
- Fixed an issue where the GUI setting for PAP or CHAP in L2TP Server was not being respected.
- Fixed changing source tracking value separate from changing the Sticky option.
- Added input validation to force a minimum *100000* byte log file size to prevent undersizing the logs.
- Added more cleanup to the **Restart PHP-FPM** console menu action.
- Removed PTR records for aliases in host overrides.
- Fixed *diag_arp.php* to allow underscore in resolved host names.
- Fixed an issue in DHCP settings where the "add routers" value was not being preserved across a loop for each interface.
- Added capability to handle reverse lookup domain overrides.
- Fixed issues with NTP RRD graph state changes.
- Added input validation to require RADIUS protocol and server IP address/host in Captive Portal when RADIUS authentication is selected. #4384
- Fixed swap size calculation in the installer to avoid creating improperly sized partitions in systems with lots of RAM but not much disk space.
- Fixed test for comconsole when matching for enabling serial console. #4464
- Updated pfSense PHP shell help to current configuration structure. #4492
- Fixed switching from a PPP type WAN to "None" or "DHCP".
- Disables SNMP hostres module on APU boards due to crashes. #4403
- Removed -U from mtree call used to restore files permissions as it was breaking symlinks on upgrade. #4328
- Added input validation for Wireless configurations to prevent problematic combinations of settings. #4178
- Improved handling of FQDN entries in aliases with filterdns, but not 100% resolved. #4296
- Fixed various typo, style, and formatting issues.

3.49.4 Rules / NAT

- Fixed ordering of DHCPv6 client and bogon rules so the bogon rules can't block DHCPv6 requests. #3395
- Fixed a bug where applying NAT changes in Hyper-V could break the running NAT configuration. #4445
- Fixed a bug where marking a packet with only a number resulted in a broken rule. #4274
- Fixed DSCP choices that were non-functional and resulted in a broken ruleset. #4302
- Fixed PHP memory exhaustion on NAT pages with VIP ranges on a 32 bit (i386) versions. #4317 (Related to #4318)
- Fixed input validation on Outbound NAT to accept a port range. #4300
- Removed Carrier-Grade NAT subnet from "Block private networks" as it was in 2.0.x and earlier releases since it specifically notes RFC 1918 and CGN is more closely related to bogon networks. #4379
- Removed code that set adaptive.start and end to 0, now they are left at their defaults (60% and 120% of the state limit, respectively) if not user-overridden.
- Added configuration options for state timeout values under System>Advanced, Firewall/NAT. #4509

3.49.5 IPsec

- Added MOBIKE control, now disabled by default. #3979
- Fixed page rendering so MOBIKE is only shown with IKEv2 selected, NAT-T only shown with IKEv1 selected.
- Removed *Prefer older IPsec SAs* option from the GUI, and existing configurations with it enabled will not have that setting applied. #4349
- Added input validation to prevent use of AES key lengths larger than 128-bit when the *glxsb* cryptographic accelerator is enabled. #4361
- Added an option for an IPsec tunnel to act as a responder only. #4360
- Added a filter reload when IPsec is disabled. #4245
- Fixed RSA cert handling in IPsec to use double quotes on asn1dn specification so it is properly interpreted by strongSwan. #4275
- Added an option to allow controlling unique ID handling in IPsec advanced settings. #4359
- Fixed *restartipsec* command line script.
- Fixed handling of IPsec with Gateway Groups #4482
- Added a workaround to disable the strongSwan Unity plugin. #4178
- Added error logging when an IPsec Phase 1 cannot be located.

3.49.6 OpenVPN

- Added encoding for username and password to avoid issues with special characters. #4340
- Fixed issues with OpenVPN TLS and authentication scripts. #4329
- Fixed issues with handling of the Authentication Mode if the user changes the value after changing other incompatible settings.

3.49.7 DNS Resolver

- Upgraded to Unbound 1.5.3.
- Added correct scaling of *rrset-cache-size* in *unbound.conf*. #4367
- Added support for 0x20 DNS random bit. #4205
- Changed DNS Resolver default values to be a bit more strict: Enable Hide Identity, Hide Version, Harden DNSSEC data.
- Force harden glue configuration option, and remove GUI control of that option. Problem with Unbound pre-1.5.2 means in 2.2-RELEASE, having this option enabled, and DNSSEC disabled, could lead to DNS cache poisoning. #4402
- Added a check to test if Unbound is enabled and using the same port before allowing dnsmasq to be enabled. #4332
- Removed hard-coded value for *harden-referral-path*. #4399

3.49.8 Logging

- Fixed GUI log parser handling for IGMP log entries. #4343
- Fixed syslogd issues where the daemon stopped and failed to restart during boot in some cases. #4393

3.49.9 Traffic Shaping

- Fixed input validation errors in the Traffic Shaper wizard due to old data not being cleared. #4333
- Fixed handling of Upstream SIP Server in the Traffic Shaper wizard. #4314, #4427
- Fixed crash when using limiters and pfsync. #4310
- Fixed limiters used with IPv6. #2526

3.49.10 IPv6

- Fixed calculation of the 6rd default gateway honoring netmasks other than /32.
- Fixed recording of the IPv6 interface's new IP address and do not issue commands that cannot succeed. #3669
- Fixed not being able to save custom and custom-v6 DynDNS entries.
- Added IPv6 IP addresses to */etc/hosts* in the same manner IPv4 IP addresses are added. #4395
- Fix computation of the displayed DHCPv6 range start to be consistent with the actual check.
- Added *dhcp6.name-servers* option with DHCPD-PD regardless of PD length.

- Fixed Net_IPv6::compress() to properly handle all-zeros address.
- Enabled `UnicastOnly` in radvd for `ovpnX` interfaces. #4455
- Removed requesting a prefix delegation when there are no tracking interfaces setup to use it. #4436
- Added code to destroy stf interface when a 6rd or 6to4 tunnel is disabled. #4471

3.49.11 VIP/CARP

- Added input validation to prevent the VIP "interfaces" from being assigned since they are just an identification of the VIP for tracking and not actual interfaces. #4389
- Fixed functions to properly return the VIP subnet now that the CARP might not match its parent interface subnet. #4390
- Fixed a bug that caused the status icon from previous CARP VIP to be shown in cases where the IP address was not present on an interface.
- Changed the carp demotion factors slightly to avoid CARP transitions that are most likely unnecessary. (Do not demote on NIC send errors or pfsync errors)
- Expanded the CARP demotion error
- Added button to reset demotion status
- Fixed handling of IP Alias deletion from a secondary node using XMLRPC configuration sync #4446

3.49.12 Misc Binary/OS Changes

- Upgraded PHP to 5.5.22.
- Re-enabled Suhosin in PHP.
- Updated 802.11 code and Atheros wireless driver from FreeBSD 11-CURRENT
- Added patch to fix crash with Ralink wireless cards in access point mode. #4117
- Added athstats, cryptostats and cryptodev back. #4239
- Fixed AESNI module checks when used inside a virtual machine.

3.50 2.2 New Features and Changes

3.50.1 Special Notes

Due to CSS and JavaScript changes, forcing the browser to clear its cache or reload the pages after an update is advised. This is especially true if any cosmetic anomalies are observed, such as alignment problems or spurious bits of text in widgets.

3.50.2 Security Fixes

- Update to openssl 1.0.1k to address FreeBSD SA-15:01
- Multiple XSS vulnerabilities in web interface pfSense-SA-15_01
- OpenVPN update for CVE-2014-8104
- NTP update FreeBSD-SA-14:31.ntp though these circumstances don't seem to impact pfSense® software.

3.50.3 Default Configuration Changes

- **DNS Resolver (unbound) enabled for new installs**. #3396
- **DNS Forwarder (dnsmasq) disabled for new installs**. #3396
- **Change default NICs from vr to em** – vr is on the way out and em is the most common NIC in use today.
- Default config.xml has been cleaned up. Outdated comments have been removed that used to loosely document the config file, but had been neglected for quite some time and aren't all that useful anyway.
- Default sysctls have moved out of config.xml and now reside in globals.inc to reduce the size of config.xml
- Default sysctl values do not need to be set in config.xml. The default values are obtained from sysctl now. Also to reduce config.xml size.
- Tracking IDs added to default rules

3.50.4 Security Enhancements

- Verify SSL certificates for HTTPS URLs
- Detect if an unofficial package repository is in use and warn the user. Warning is displayed on the dashboard and package management pages. #484
- Check and verify the package server's SSL certificate if using HTTPS. #484
- For dyndns providers that support HTTPS, use it when performing updates.
- Replaced lots of GET actions with POST actions in various places in the GUI as they were touched.
- Update jquery to 1.11.1
- Remove almost all calls to history.back() and make Cancel button back to HTTP_REFERER
- Hide FreeBSD version from sshd banner. #3840
- Disable SSLv3 in lighttpd
- Disable RC4 ciphers in lighttpd
- Teach the certificate generation code how to make a self-signed certificate, and change the GUI cert generation code to use it.

  Also, move the GUI cert generation code to its own function so we can add a GUI option to regenerate it later. Also use some more sane defaults for the contents of the default self-signed certificate's fields so it will be more unique and less likely to trigger problems in browser certificate storage handling.
- Add command line script to generate and activate a new GUI certificate (generateguicert)
- Catch some more sensitive information when sanitizing the contents of config.xml output on /status.php.

3.50.5 OS Changes

- Updated base OS to FreeBSD 10.1-RELEASE
- PHP backend switched from FastCGI to PHP-FPM
- PHP Moved to 5.5
- Migrate captive portal code to SQLite3 PHP module
- Fix some lingering call-time pass-by-reference instances that fail on PHP 5.5
- Default serial speed is now 115200 #3715
- Sync gettytab and etc/ttys with FreeBSD 10-STABLE and reduce customizations
- Log pfSense version to syslog after bootup
- Set the sysctl net.inet.icmp.reply_from_interface to 1 to use the incoming interface to send ICMP replies. #3666
- Switched the hash method in pf to XXHASH for speed improvements

3.50.6 DNS

- Imported Unbound for use as the default DNS Resolver. The old dnsmasq DNS Forwarder is available as a non-default option. Upgraded systems will retain existing settings.
- Various changes to Unbound and supporting programs to complete its integration.
- Removal of bind from FreeBSD base necessitated the switch to alternate programs for DNS utilities (e.g. drill for dig, different nsupdate)
- AJAX DNS updates for firewall logs (when clicked)
- Make sure that the DNS Forwarder/Resolver is always capable of accepting queries on localhost before using it as a DNS server.
- If localhost is configured to be included in resolv.conf, force its selection in Unbound. The resolv.conf logic prevents that from being a problem, but users don't seem to realize they have to pick that to use Unbound for the host itself.
- IPv6 support in Unbound
- Check port of dnsmasq/unbound and skip 127.0.0.1 in resolv.conf if not port 53. #4022
- Add a note to the wizard about the DNS Resolver ignoring manual name servers by default. (They are still used as secondary/tertiary servers for the firewall itself, however)
- Domain and search should not both be defined in resolv.conf per FreeBSD man page and handbook (only the latter is actually used). Only search is set now.

3.50.7 CARP

- Changes to CARP for new FreeBSD 10 CARP system
- Provide a way to 'permanently' set CARP to 'maintenance mode' (advskew 254) persisting through a reboot.
- Key off net.inet.carp.demotion and display a warning to the user if the system has self-demoted its CARP status.
- Allow CARP IP address to be outside interface and alias subnets

3.50.8 Interfaces

- Implement an option to allow using the IPv4 connectivity interface for sending the dhcpv6 information. Usually useful for PPP[oE] type links and some ISPs
- Add gre and gif checks for IPv4 function interface_has_gateway($friendly), like they are already for IPv6
- Do not allow the user to set IPs for GRE interfaces on interface edit page. #3575
- On interfaces_assign.php, let user select network port to add instead of picking the first available #3846
- When changing an existing VIP, use previous configured interface for checking, this fixes the issue that happens when trying to change a VIP to a new interface. #3807
- Validate the GIF interface MTU (must be something between 1280 and 8192) #3927
- Properly set MTU for lagg(4) interface #3922
- Fix formatting of the Interfaces Widget on the Dashboard. #3937
- Don't allow interface descriptions that are strictly numbers as that generates an invalid ruleset. #4005
- Disable delete_old_states in dhclient-script. rc.newwanip handles this correctly in 2.2, and this killed states in multiple circumstances where that isn't necessary nor desirable.
- Do not unset configuration values from PPP config if not needed. #3727
- Overhaul handling of flags for hardware offloading and make it work correctly for system_advanced page settings. Lagg is still a special case that may require a reboot initially to apply. #1047
- Don't try to launch 3gstats unless it's on a valid device.
- Updated list of mobile service providers

3.50.9 Gateways/Routing

- Add an option to force a gateway to be down. #2847
- List GWGs in Interface to send DynDNS update from
- Allow reordering, batch delete, and disable of static routes
- Option to disable a gateway added
- Check gateway for IPv6 also for reply-to rules.
- Fix issue where ICMP6 messages sometimes have the wrong source IP address when a monitor IP address has been set #3607
- Improve look of gateways widget
- Provide a toggle for apinger debug messages to be logged to syslog
- Setting an interface IP to 0.0.0.0 with mask 0.0.0.0 overwrites the default route with that interface's link route. Follow FreeBSD 10.1 and use a /8 mask instead. #3941
- Use static route with -iface option for PPPoE to help when more than one PPPoE connection has the same gateway. #4040
- net.inet6.ip6.rfc6204w3 needs to be 1 for dhcpv6 to work correctly. #3361
- Add a route debug option to log info about route commands executed (where those aren't already logged) to help with troubleshooting various routing scenarios.
- Make sure srcip and target have scope when link-local addresses are used in apinger. #3969

- Properly generate and use the default gw for 6rd.

3.50.10 Firewall Rules

- Custom logging daemon that provides easy-to-parse output on a single line
- Persistent tracking ID for firewall rules so that logs may always be traced back to their corresponding rules
- Removed settings for maximum tables and maximum table entries since pf on FreeBSD 10 does not have any limits for these.
- Expose all p0f OS types that it supports so that subtypes of various Operating Systems can be detected (e.g. blocking Windows XP)
- The "(self)" concept of "Any IP address on this firewall" is now a choice for firewall rule destination (and floating rule source for out direction rules), port forward destination, and outbound NAT source.
- Can now optionally log default pass rules as well as default block rules
- Add IP alias subnets to interface subnet macro on GUI. #983
- Adjust states summary for new pfctl -ss output. #2121
- Add a more obvious note on group rules about how they do not work as expected for WANs
- Block IPv4 link-local/APIPA 169.254.0.0/16. #2073

Note: Per RFC 3927, hosts "MUST NOT send the packet to any router for forwarding", and "any network device receiving such a packet MUST NOT forward it". FreeBSD won't route it (route-to can override in some circumstances), so it can't be in use as a real network anywhere with the possible exception of local-only networks. Unlikely any such situation exists anywhere

---

- Fix JavaScript confirmation dialog for EasyRule.
- Use 'clog -f /var/log/filter.log' to view firewall log entries from the console so they are displayed in the new format.
- Set MSS clamping on VPNs in both directions rather than requiring it be set on both ends.
- Add option to kill all states on IP change, currently a hidden option for more testing. #1629
- Kill states associated with the old WAN IP when WAN IP has changed. #1629

3.50.11 NAT

- Hybrid outbound NAT style that allows the user to keep the existing automatic behavior but layer manual rules on top of it.
- Option to disable outbound NAT without disabling pf
- Display networks used in automatic outbound NAT when using that mode
- Allow reordering, batch delete, and disable of 1:1 NAT rules
- Take virtual IPs into consideration for automatic outbound NAT rules #983
- Outbound NAT can apply to any type of interface, make WAN-type specific reference generic

3.50.12 Aliases

- Allow individual line descriptions on alias bulk import
- Implement URL Table aliases for ports
- Optimizations for URL table aliases to use less memory and be more robust in general
- Alias name cannot have more than 31 chars, add maxlength to the field as an extra check. #3827
- Prevent Internal Server Error if an IP range is entered backwards.
- Expand range or subnet entered into a host type alias.
- Warn that IPv6 address ranges are not supported in aliases.
- When an alias contain hosts, add IPs and networks to filterdns too, otherwise the ruleset ends up with a predefined and non-persistent table. #3939

3.50.13 Dashboard & General GUI

- Various fixes for XHTML compliance
- Various fixes for typos
- Add a setting to allow the user to specify the clog file size so more (or less) entries may be kept in the raw logs.
- Add an option for users to be able to adjust how many configuration revisions are kept in the local backup cache.
- Show backup file size in config history.
- Display pfSense interface name on status interfaces
- Dashboard cleanups/fixes for jQuery
- Add "pfsense_ng_fs" full screen/widescreen theme
- GUI redirect works on both IPv4 and IPv6 #3437
- Disk usage section of the System Information widget now shows all UFS, ZFS, and cd9660 filesystems, not just the root (/) slice, and also indicates if they are a RAM disk.
- Add a message about premium content to the setup wizard and add a link in the menu to the signup page.
- Add pages missing from the Status > Traffic Graph privilege that are required for the full page to load
- Fix traffic graph widget default autoscale
- Be more strict on user and group removal to avoid removing accidentally removing additional users #3856
- Add an option to restart php-fpm from console
- Add .inc file for gmirror status widget to give it a better title and link to the management page.
- Allow the Virtual IP list table to be sorted (cosmetic only)

3.50.14 Translations

- Change default charset on pages to utf-8
- Updates to pt_BR translation
- Added Japanese translation
- Added Turkish translation
- Fixes for gettext

3.50.15 Captive Portal

- Add a way to download CP portal, error and logout html pages. #3339
- Add an option to restore default logout/error/portal custom pages on Captive Portal. #3362
- For more than 100 MAC pass-through entries create pipes in line with the rules file to speedup the process. #3932
- Zone backend changed from text-based (e.g. "cpzone") to using the zone id (e.g. "2") for specifying the context.
- ipfw_context has been removed. To list zones, use "ipfw zone list"
- Default lighttpd daemon port for a Captive Portal zone is based on the zone ID. For example, zone ID 2 uses port 8002. There may not be a daemon on port 8000.

3.50.16 IPsec

- IPsec backend changed from racoon to strongSwan
- IKEv2 settings have been enabled in the GUI
- Default IPsec configuration settings for newly created site to site configurations updated to use main mode and AES 256 on both phase 1 and 2.
- IPsec status page and dashboard widget changes to accommodate different output from strongSwan
- Move the IPsec settings from System > Advanced, Misc tab to "Advanced Settings" tab under VPN > IPsec.
- It is now possible to configure *L2TP/IPsec*
- Add AES-GCM and AES-XCBC to the list of available IPsec algorithms and hashes, respectively. Expand P1 DH groups up to 24.
- Allow hash algorithms to be empty for phase 2 where the encryption is AES-GCM
- Allow to reorder IPsec Phase 1 and Phase 2 items, remove multiple P1/P2 items, toggle enable/disable status of P1/P2 items #3328
- Provide a first implementation of EAP-TLS authentication with IKEv2. It is a start and might not work on all cases
- Do not accept non-ASCII characters on IPsec PSK #3931
- Fix ping_hosts.sh to not ping IPsec if CARP is in backup.
- Allow accept_unencrypted_mainmode_messages to be enabled for IPsec if needed.
- Check that subnet masks are equal when choosing binat type for IPsec to avoid errors on ruleset. #3198
- Change NAT Traversal options as strongSwan only has two options: force or auto.
- Don't allow P2 local+remote network combinations that overlap with interface+remote-gateway of the P1. #3812

3.50.17 OpenVPN

- Allow entering OpenVPN client credentials in the GUI
- Add fields for local (push route) and remote (iroute) network definitions in an OpenVPN client-specific override entry.
- Change OpenVPN compression settings to cover the full range of allowed settings on OpenVPN (unset, off, on, adaptive) rather than a simple off/on switch that either doesn't set the value or enables it with adaptive (OpenVPN's default).
- Add an Authentication Digest Algorithm drop-down to OpenVPN server/client and to the wizard (SHA1 is the default since that is OpenVPN's default)
- Add option to specify client management port for OpenVPN client export use
- Ensure e-mail address carries over from the CA screen to the Cert screen in the OpenVPN wizard.
- Allow the user to select "None" for OpenVPN client certificate, so long as they supply an auth user/pass. #3633
- Byte counts on OpenVPN status are now human readable rather than huge unformatted numbers.
- OpenVPN instances have new options: "Disable IPv6", route-nopull, route-noexec, verb selector
- Use stronger defaults in the OpenVPN wizard.
- Fix ovpn-linkup for tun + topology subnet case setting router as ifconfig_local envvar when route_vpn_gateway and ifconfig_remote are both not defined. #3968

3.50.18 DHCP

- Add code for UEFI booting and DHCP
- Advanced RFC 2136 configuration for DHCPd service
- Add ability to not supply a DHCP gateway to clients
- Allow defining DHCP static mappings using dhcp-client-identifier
- Do not call write_config() when Applying Changes on DHCP settings #3797

3.50.19 Packages

- Package signing to ensure validity/authenticity
- Single package manifest (XML) file rather than one per architecture
- Various improvements to PBI setup/structure from upstream (PC BSD)
- Added the capability for package hooks in /etc/rc.carpmaster and /etc/rc.carpbackup
- Split package category display into separate tabs for categories, and provide an "All" tab
- Move the fetching of a package's config file and additional files to separate functions.
- Clarify logs generated by newwanip(v6) when restarting packages, it's not only IP changes that end up here (by design).
- When reinstalling a package, try to start it after the install completes.

3.50.20 Dynamic DNS

- Added support for DynDNS Provider "City Network"
- Added support for DynDNS Provider "OVH DynHOST"
- Added support for DynDNS Provider "GratisDNS"
- Added support for DynDNS Provider "Euro DNS"
- Added support for DynDNS Provider "CloudFlare"
- Add support for custom IPv6 DDNS.
- Add backend support for HE.net AAAA record updates.
- Add additional options to Custom DynDNS
- Allow hostname to start with '@.' for namecheap #3568
- Do not disable certificate verification in DynDNS. Proper CA certificates are now in place to validate SSL in these cases.
- "+" is a valid character in some dynamic DNS providers' usernames. #3912

3.50.21 GEOM Mirrors (gmirror)

- New gmirror library to perform various gmirror tasks and get information, using some of the former widget logic to start.
- Added a Diag > GEOM Mirrors page that displays information about existing mirrors and performs various management tasks.
- Also included is a notification setup. Mirror status is polled every 60 seconds, and if any aspect of the mirror changes, notifications are issued that alert in the GUI and by SMTP, etc.

Warning: If a manual gmirror configuration was performed post-install and not using the pfSense software installer gmirror option before install, there is a chance that the mirror will not function on pfSense software version 2.2 because the manual post-install method did not create a completely proper mirror setup. If the upgraded mirror does not function on 2.2, the following `/boot/loader.conf.local` entry may be used to work around the integrity check that would otherwise fail:

```
kern.geom.part.check_integrity=0
```

If one of these configurations is present, the best practice is backing up the configuration and reinstalling using the built-in gmirror option in the pfSense software installer.

3.50.22 Traffic Shaping

- Fix DSCP values and provide a config upgrade to fix values stored in config.xml. #3688
- Remove 'multi lan/single wan' and 'multi wan/single lan' traffic shaper wizards, multi lan/wan can be used to replace any of them.
- Only show the correct type of interfaces (LAN/WAN) on traffic shaper wizards #3535
- Shaper wizard will automatically attempt to guess the correct number of WANs and LANs.
- Updated and expanded traffic shaping for games, game consoles, and other applications.

- Allow up to 2900 limiters. This was set to 30. #3213
- Fix logic to find available next number for limiters and queues. #3998
- Add vmx and hn to list of ALTQ capable interfaces.
- Remove the "Limiter burst" parameter as it currently doesn't work with dummynet in pf.

3.50.23 Misc

- Cleaned up various older files/scripts that were no longer being used
- Dropped all support for cvsup. cvs is dead, long live svn and git.
- Optimizations/changes to the XML Parsing code
- NTP updates to handle a wider ranges of GPS devices and more NTP options
- Move to zerocopy_enable for bpf to optimize logging which uses bpf interface. This should increase the general performance since pflog is always enabled.
- Add sshd service to list (if enabled)
- Add a "status" subcommand to the svc php shell script.
- When using the reset webConfigurator password option on the console, if authentication server is not Local Database, ask user if they want to revert back to it. #3341
- Fix interface selections on UPnP to show the customized descriptions entered by the user. While here, add an external interface selection knob. Fixes #3141
- Layer 7 Pattern: EAOrigin.pat
- Layer 7 Pattern: SWF (Flash)
- Remove some old obsolete code that referred to the now-defunct "embedded" platform that was replaced with NanoBSD back in 1.2.x.
- Sometimes fsck requires a second run, teach rc script to call it more than once when it's necessary
- Add column for internal port on UPnP status page
- Make listening on interface rather than IP optional for UPnP
- Use interface name for miniupnpd rather than IPv4 address #3874
- Packet Capture: Host field supports rudimentary boolean logic.
- Packet Capture: Protocol, host, and port now support negation.
- Added interface column to Diagnostics > States
- Change is_port() to only validate a single port, is_portrange() for specific cases. #3857
- Fix guess_interface_from_ip() to account for differences in netstat output. #3853
- Fix Certificate Authority SAN name handling #3347
- Add a basic command line password reset script.
- Use configured proxy URL/port for downloading bogon list. Does not use credentials. #3789
- Underscores are valid characters in domains. #3219
- Let user decide to proceed with upgrade when sha256 fails to download. #3576
- Remove the command number shown in the shell prompt.

- Use a better method of finding disks for SMART.
- Process obsolete files in shell script instead of PHP.
- Do not allow FQDN in fields that should only accept a hostname.
- Set proxy environment variables on interactive shell and also on crontab so that they may be used by all scripts. #3789
- Add input checkboxes to remove multiple users and groups
- Make sure an empty group or user is not created when editing
- Update URLs in help.php.
- Change wording at the end of the wizard to remove "donate" since that is no longer an option.
- Put the booting signal in globals.inc since it makes all the other scripts detect we are booting. Otherwise separate PHP instances will not detect that. rc.bootup clears this flag so all should work correctly
- Force serial console when it was selected by the installer. #4009
- Wait 10 minutes before retrying bogon fetch on soft failures to avoid us getting DoSed if something is wrong there (like someone's system can't validate the cert)
- Use IPv4 for ntpq if IPv6 is not allowed

3.50.24 HEADS UP for Xen Users

The FreeBSD 10.1 base used by pfSense 2.2 includes PVHVM drivers for Xen in the kernel. This can cause Xen to automatically change the disk and network device names during an upgrade to pfSense 2.2, which the hypervisor should not do but does anyway.

The disk change can be worked around by running /usr/local/sbin/ufslabels.sh *before* the upgrade to convert the fstab to UFS labels rather than disk device names.

The NIC device change issue has no workaround. Manual reassignment is required at this time. Note there have been performance issues reported in Xen with this NIC device change.

3.51 2.1.5 New Features and Changes

The pfSense® software version 2.1.5 release follows shortly after *2.1.4* and is primarily a security release.

3.51.1 Security Fixes

- pfSense-SA-14_14.openssl
  - See http://www.openssl.org/news/secadv_20140806.txt
  - Updated to OpenSSL 0.9.8zb and 1.0.1i
- pfSense-SA-14_15.webgui
- pfSense-SA-14_16.webgui
- pfSense-SA-14_17.webgui

3.51.2 Other Fixes

- Handle a missing DHCPD config section properly during a configuration upgrade
- Fix a regression that broke CARP+IP alias VIP functionality
- Fix the Pass, Block, Reject and Interface filters in the Firewall Logs Widget #3725
- Use HTTPS for dyndns providers that support it
- Avoid resetting the firewall hostname from a WAN DHCP server #3746
- Add missing qlimit keyword in some shaper rules
- Change Cancel button to call history.back() when editing firewall aliases to fix issues with IE 11 #3728
- Allow hostnames in bulk import since they are valid entries in a network type alias
- Fix input validation logic on diag_testport.php, escape more shell arguments for good measure
- Escape the individual dnsmasq advanced/custom options
- Encode the detail field of an alias entry before displaying its contents back to the user
- Encode interface/VIP descriptions before displaying them on the NTP daemon settings, and GIF/GRE interfaces
- Per the dhcpd.conf man page and other documentation from ISC, mclt must not be defined on the secondary
- Shorten the wait at "reload" in startup wizard to 5 seconds from 60
- Do not execute DNS lookups on GET, only pre-fill Host box so the user can press the button to execute
- Turn alias creation links from DNS lookups into submit buttons for POST
- Remove javascript alert DNS resolution action from the firewall log view. It was already removed from 2.2, and it's better not to allow a GET action to perform that action
- Require click-through POST confirmation when restoring or deleting a configuration from the backup history page
- Avoid a "Cannot use string offset as an array" error if the packages section of the config is missing
- Avoid generating an invalid IPsec (racoon) config if the user specified a mobile pool that is too small
- IPsec phase 2 pinghost was not used if the source IP was a virtual IP address #3798
- Move dhcp6c log to dhcpd.log #3799
- Do not reset source and destination port range values when it's an associated rule created by NAT port forward. #3778
- Added filter.so to list of extensions loaded for filter_var() support.
- The pfSense PHP module was setting the subnet mask of lo0 to /0, which could break some routes and cause other unintended routing side effects.

3.52 2.1.4 New Features and Changes

pfSense® software version 2.1.4 follows very shortly after *2.1.3* and is primarily a security release. Refer to the *2.1.1 release notes*, *2.1.2 release notes*, and *2.1.3 release notes* for other recent changes.

3.52.1 Security Fixes

- pfSense-SA-14_07.openssl
  - FreeBSD-SA-14:14.openssl
- pfSense-SA-14_08.webgui
- pfSense-SA-14_09.webgui
- pfSense-SA-14_10.webgui
- pfSense-SA-14_11.webgui
- pfSense-SA-14_12.webgui
- pfSense-SA-14_13.packages

Packages also had their own independent fixes and need updating. During the firmware update process the packages will be reinstalled properly. Otherwise, uninstall and then reinstall packages to ensure that the latest version of the binaries is in use.

3.52.2 Other Fixes

- Patch for Captive Portal pipeno leaking issue which leads to the 'Maximum login reached' on Captive Portal. #3062
- Remove text not relevant to Allowed IPs on the Captive Portal. #3594
- Remove units from burst as it is always specified in bytes. (Per ipfw(8)).
- Add column for internal port on UPnP status page.
- Make listening on interface rather than IP optional for UPnP.
- Fix highlighting of selected rules. #3646
- Add guiconfig to widgets not including it. #3498
- /etc/version_kernel and /etc/version_base no longer exist, use php_uname to get the version for XMLRPC check instead.
- Fix variable typo. #3669
- Delete all IP Aliases when an interface is disabled. #3650
- Properly handle RRD archive rename during upgrade and squelch errors if it fails.
- Convert protocol ssl:// to https:// when creating HTTP headers for XMLRPC.
- Show disabled interfaces when they were already part of an interface group. This avoids showing a random interface instead and letting the user add it by mistake. #3680
- The client-config-dir directive for OpenVPN is also useful when using OpenVPN's internal DHCP while bridging, so add it in that case also.
- Use curl instead of fetch to download update files. #3691

- Escape variable before passing to shell from stop_service().
- Add some protection to parameters that come through _GET in service management.
- Escape argument on call to is_process_running, also remove some unnecessary mwexec() calls.
- Do not allow interface group name to be bigger than 15 chars. #3208
- Be more precise to match members of a bridge interface, it should fix #3637
- Do not expire already disabled users, it fixes #3644
- Validate starttime and stoptime format on firewall_schedule_edit.php
- Be more careful with host parameter on diag_dns.php and make sure it's escaped when call shell functions
- Escape parameters passed to shell_exec() in diag_smart.php and elsewhere
- Make sure variables are escaped/sanitized on status_rrd_graph_img.php
- Replace exec calls to run rm by unlink_if_exists() on status_rrd_graph_img.php
- Replace all `hostname` calls by php_uname('n') on status_rrd_graph_img.php
- Replace all `date` calls by strftime() on status_rrd_graph_img.php
- Add $_gb to collect possibly garbage from exec return on status_rrd_graph_img.php
- Avoid directory traversal in pkg_edit.php when reading package xml files, also check if file exists before try to read it
- Remove id=0 from miniupnpd menu and shortcut
- Remove . and / from pkg name to avoid directory traversal in pkg_mgr_install.php
- Fix core dump on viewing invalid package log
- Avoid directory traversal on system_firmware_restorefullbackup.php
- Re-generate session ID on a successful login to avoid session fixation
- Protect rssfeed parameters with htmlspecialchars() in rss.widget.php
- Protect servicestatusfilter parameter with htmlspecialchars() in services_status.widget.php
- Always set httponly attribute on cookies
- Set 'Disable webConfigurator login autocomplete' as on by default for new installs
- Simplify logic, add some protection to user input parameters on log.widget.php
- Make sure single quotes are encoded and avoid javascript injection on exec.php
- Add missing NAT protocols on firewall_nat_edit.php
- Remove extra data after space in DSCP and fix pf rule syntax. #3688
- Only include a scheduled rule if it is strictly before the end time. #3558

3.53 2.1.3 New Features and Changes

pfSense® software version 2.1.3 follows very shortly after *2.1.2* and is primarily a security release. Refer to the *2.1.1 release notes* for changes from 2.1 to 2.1.1 and *2.1.2 release notes* for changes from 2.1.1 to 2.1.2.

3.53.1 Security Fixes

- pfSense-SA-14_05.tcp
  - FreeBSD-SA-14:08.tcp
- pfSense-SA-14_06.openssl
  - FreeBSD-SA-14:09.openssl

Packages also had their own independent fixes and need updating. During the firmware update process the packages will be reinstalled properly. Otherwise, uninstall and then reinstall packages to ensure that the latest version of the binaries is in use.

Although these security issues warrant updating as soon as possible, they are of relatively minor impact to the average user. According to the FreeBSD SA, the TCP flaw is mitigated by scrub in pf which is enabled by default in pfSense. The OpenSSL flaw is not used by any daemons in the pfSense base system and only certain packages make use of the affected feature, so the impact there is also minimal.

3.53.2 Other Fixes

- Various fixes to accommodate recent changes/optimizations in the tools repository
- Move clog binary to its proper place in /usr/local/ to respect hier(7)
- Fix remove button on Diagnostics > Tables #3627
- Fix more potential places for interface looping in OpenVPN and with normal interfaces
- Fixes for URL table alias updates (locking, reload)
- Fix IPsec Phase 1 duplication
- Fix 'add rule on top of the list' allowing after param to be -1
- Correct Captive Portal redirection URL to unbreak ones passed through Radius attributes and respect user choices.
- Make miniupnpd listen on interface instead of IP
- Don't refuse to delete a bridge in the GUI just because its bridge interface doesn't exist, just log that it doesn't exist and don't attempt to ifconfig destroy it, delete it from config
- Fixes for DynDNS to allow configurable check host.
- Resolver has no option for remote syslog, remove wrong copy/paste that was adding it when apinger was enabled
- Fix typo for GIF tunnels to work over IPv6
- Fix for dhcrelay target using default GW
- List Gateway Groups in Interface to send update from for custom DynDNS entries

3.54 2.1.2 New Features and Changes

pfSense® software version 2.1.2 follows very shortly after *2.1.1* and is primarily a security release. Refer to the *2.1.1 release notes* for changes from 2.1 to 2.1.1.

3.54.1 Security Fixes

The Heartbleed OpenSSL bug and another OpenSSL bug were both covered by the following security announcements:

- pfSense-SA-14_04.openssl
  - FreeBSD-SA-14:06.openssl
  - CVE-2014-0160 (Heartbleed)
  - CVE-2014-0076 (ECDSA Flaw)

Packages also had their own independent fixes and need updating. During the firmware update process the packages will be reinstalled properly. Otherwise, uninstall and then reinstall packages to ensure that the latest version of the binaries is in use.

3.54.2 Other Fixes

- On packages that use row_helper, when user clicks on add or delete button the page scrolls to top. #3569
- Correct typo on function name in Captive Portal bandwidth allocation
- Make extra sure that the firewall does not start multiple instances of dhcpleases if, for example, the PID is stale/invalid and there is still a running instance.
- Fix CRL editing. Use an alphanumeric test rather than purely is_numericint because the ID is generated by uniqid and is not purely numeric. #3591

3.55 2.1.1 New Features and Changes

3.55.1 Security Fixes

- FreeBSD-SA-14:01.bsnmpd / CVE-2014-1452
- FreeBSD-SA-14:02.ntpd / CVE-2013-5211
- FreeBSD-SA-14:03.openssl / CVE-2013-4353, CVE-2013-6449, CVE-2013-6450
- Use HTTPS to get updates. #2952
- Escape necessary chars to avoid XSS injection. #2952
- Add escapeshellarg() calls on more exec parameters.
- Replace some exec() calls by php functions like symlink, copy, unlink, etc.
- Use HTTPS for pfsense.org URLs.
- Protect output to browser by using htmlspecialchars. #3461
- Improve checks for params 'id', 'dup' and other similar ones to make sure they are numeric integer, also, pass them through htmlspecialchars before printing.

- Remove special characters that can lead to shell/XSS compromises from submitted input when installing packages. #3461
- Ask for validation when real package operation will be done and ask for the operation with POST to get protection from CSRF. #3460
- Use HTTPS for fetching packages.

3.55.2 Interfaces

- Updated em/igb/ixgb/ixgbe drivers that add support for i210 and i354 NICs and fix issues with `ix(4)` cards.
- Prevent assigned vlans from having their tag changed.
- Fix ifconfig error on gif in certain cases.
- If rc.newwanip is run on an interface that should not have an IP address, do not take any action. This could lead to certain interfaces bouncing link if they had no IP address.
- In rc.newwanip, if the interface is configured and not enabled, bail. The firewall does not need to change settings for disabled interfaces. #3313
- Skip processing in rc.newwanip if the interface has no IP address.
- Fix pkg_edit.php to show interface description instead of interface name
- Make sure vlan interface exist when they are configured #3270
- Limit CIDR choices for IPv4 on GRE interface. #3277
- Do not destroy an interface when it's being disabled #3350
- Prevent network or broadcast address to be set on interface (console, GUI and wizard). #3196
- Reduce unnecessary operations and other fixes to MTU code. This fixes slow boot times and proper handling of mtu for VLANs.
- Provide a dynamic gateway for GIF and GRE v6 tunnels so it can be used on firewall rules etc. #3484
- Bring up appropriate interface for GRE/GIF. #3281
- Prevent removing the IP from the underlying GRE interface in the OS when assigning GRE interface and configuring an IP address. #3280
- When an interface goes down try to shut the RAs and dhcpd6 service on that interface. #2627
- Sync up ALTQ-capable interfaces list
- Trigger rc.newwaipv6 from pppoe when it gets an inet6 configuration
- Update list of mobile service providers.
- Correct check to enable ieee8021x.

3.55.3 Gateways/Routing

- Respect default gateway option when adding a gateway from interfaces page. #3230
- Use a more accurate error message when attempting to add/edit a gateway that does not have an appropriate IP address for the type. #3282
- Make return_gateways_array() return all disabled gateways when $disabled is true. #3291
- Don't flush interface cache on each call of the function when looping through all gateways.
- Fix an issue that changes wrong gateway entry when items are hidden
- Delete static route when monitor IP is removed, also save monitor IP even when it's disabled
- Return Gateway Group IP protocol version even when no gateway IP can be located.
- Remove broken 'dynamic6' gateway, we already have ipprotocol to tell us the IP version, leave it more simple using only 'dynamic'

3.55.4 NAT/Firewall Rules/Aliases

- Reload filter rules when activate or deactivate dhcpdv6 #3218
- Make sure no extra spaces end up in the parsed IP in the filter logs as it can lead to issues in other places (Easy Rule, etc)
- Use (self) rather than any as the destination for the lockout rules
- Use (self) instead of any for web lockout
- Avoid pf table names conflict. #3268
- Fix display of full URL in URL table listing as seen in an Alias popup. #3242
- Make it more explicit that 'update freq.' for URL table aliases unit is days
- Fix situation where removing an alias entry and then adding a new one resulted in an entry box with broken formatting. #3283
- Make sure pf rule labels never have more than 63 chars. #3208
- Rewrite the display_host_results() function to use spaces instead of tabs. It does a much better job of aligning the fields in each column and works in all the browsers, particularly chrome which doesn't support the tab character.
- Handle comma-separated list of remote networks when making vpn_networks table
- Fix rules that pass out traffic for Proxy ARP VIP entries which had incorrect destination #3331
- Load only the options rather than clearing the whole ruleset.
- Validate IP address ranges correctly on Alias Bulk Import
- Fix display of CIDR/Update Freq in Alias Edit
- In the filter log, the protocol might also say "icmpv6" so account for that when making a rule using Easy Rule.
- Move 'allow dhcpv6 client' rules above block bogonsv6 ones. #3395
- Only add dhcpv6 client allow rules if ipv6allow is set
- Add all advanced options to rule table hover text.
- Open up Firewall Rules Advanced Options section if any values have been set.
- Validate rule Advanced Options numeric entries properly

- Disable default allow incoming rules for 6to4 and 6rd interfaces. This rule unintentionally allows all services on the interface.
- Skip OpenVPN interfaces when creating the first set of manual rules to be consistent with the behavior of Automatic Outbound NAT. #3528
- Try to restore last working ruleset rather than staying without configuration at all if an invalid ruleset is encountered.
- Fix days and weeks selection on schedules
- Prevent putting an subnet in the IPv6 address field since it breaks the filter generation process.
- Put a timeout of 30 seconds on the bogon update download. #3412
- Before downloading file to process urltable, there is a random wait time between 5 and 60 seconds. Because of this, the difference between file mtime and current time can be less than $freq * 86400 and it'll be skipped. Add 90 seconds (60 of max random wait + 30 to be sure) to avoid skipping a file that should be updated. #3469
- Validate if src OR dst have IP address set when protocol is IPv4+v6. #3499
- Improve data validation to avoid save a host/subnet or a IPv4 with invalid mask. The reported error is on javascript and only happen on IE8, but this fix will prevent the same issue happening in the future on a different browser. #3449

3.55.5 Traffic Shaping

- Fixed typo in CoDel wiki link
- Fix codel not being applied on non-priq queue types
- Fix saving and range checking of 'Packet loss rate' and 'Bucket Size' in limiters.
- Add previously missing DSCP VA.
- Clarify note on limiter queue weight to state that higher values get a larger share.

3.55.6 Dashboard & General GUI

- Convert mac address to lowercase when saving to avoid duplicates. It fixes #3195
- Include the CP zone in the form parameters if one is defined. Fixes access to concurrent graph on zones other than the first/default.
- Miscellaneous HTML cleanup
- Fix interface names shown in the traffic graphs widget. #3245
- Send the help links to HTTPS destinations on web servers that support HTTPS.
- Specify favicon in pages directly
- Add some missing privileges to the list. #3279
- Many fixes on privileges. #3216
- Allow setting a default scale type preference for the traffic graphs widget
- Account for a widget being null/not defined, and not just closed/open when deciding if a widget function should be called. This allows the system information dashboard widgets to update properly.
- Avoid dashboard divide by zero errors
- Detect Zones and Cores for thermal sensors using regex. #3337

- Do not sort users when adding privileges. It's unnecessary and lead to unintentional edits to the wrong account.
- Add specific privilege for easyrule.
- Return all stats when all or remote is selected on Traffic Graph and make the default query return "Local" traffic.
- Update year, links for 2.1.1.

3.55.7 Captive Portal

- Fix CP stats generation for concurrent users. #3225
- Remove redundant copies of getNasIP() #3234
- Set default captive portal RADIUS authentication value to radius_protocol during upgrade #3226
- Add Captive Portal Zones privileges definition. #3216
- Prevent a possible division by zero in Captive Portal. #3212
- Fix saving of voucher sync settings
- Reduce the total minutes by the remote minutes used, do not use the value directly. Otherwise the voucher will be cut short or listed invalid when it otherwise should have time left over.
- Make sure to give the Captive Portal zone a name during the upgrade, or else it comes through with a blank/null name.
- Properly set zone dedicated rules in the rules/pipes DBs to properly release when a zone is deactivated
- Don't generate rules for disabled captive portal instances
- Do some more error checking and put secondary radius attributes only if configured on a Captive Portal instance.
- If set use the default bandwidth setting on the Captive Portal even for MAC passthrough.
- Fix various problems with Captive Portal voucher synchronization introduced during conversion to zones.
- Properly compile the Captive Portal database query to insert the values.
- Fix deletion of IPFW rules and pipes for passthru MAC. #3538
- Use the 11th column for the radius context rather than overriding the interim interval field with it. #3447
- Use descr as the field name for voucher description so it gets CDATA protection. #3441
- Consider setting of noconcurrent login for passthrough expiration of users. #3340
- Use the default bandwidth specification if configured even for allowed IP address and hostname.
- Properly detect when there are issues with communicating with syncip and to use the local DB for this. Otherwise detect if the remote says the voucher is not valid say its not valid.

3.55.8 VPN

- Fix find_service_by_openvpn_vpnid() on OpenVPN Status
- Allow special characters to be used on IPsec mobile login banner. #3247
- Fix cisco-avpair processing for IPsec and OpenVPN, and route processing from avpair replies.
- Fix logic in detecting if OpenVPN resync needed
- Fix vpn_pppoe_get_id and stop duplicating pppoeid for multiple servers. #2286
- Use env var provided by openvpn to determine if it's tun or tap. #3475

- Add an option to verify IPsec peers_identifier when it's ASN.1 distinguished name. #2904

3.55.9 Certificates

- Certificate Manager, for 'Create an internal Certificate' use the correct 'Digest Algorithm'
- OpenSSL does not like country codes longer than two letters, so remove entries that are not actually country codes.
- Perform a much more accurate comparison between two certificates to determine if they are identical when checking their revocation status. #3237
- Allow an "empty" CRL to be exported, since this is still a valid action.
- Fixes for "Alternative Names" on certificates.
- Fix issue with CSR generation. #2820
- Increase default openssl to bits 2048.

3.55.10 DHCP

- Optimize DHCPv4 lease display online status for static leases. Do not re-parse complete ARP table for each lease, as it can be slow with large ARP tables.
- Add upgrade code to change the DHCP next-server value to nextserver since it was renamed sometime in 2.1 but upgrade code didn't follow.
- Give clients the IPV6 address of the DNS server via DHCPv6 Server
- Check if dhcp start and end addresses are inside interface subnet. #3196
- Remove 'deny unknown clients' option from DHCPv6 since it's not supported. #3364
- Fix DHCP lease time display, strftime already convert it to local timezone, so no need to calc offset
- Use correct parameter (bootfile-url) to configure netboot on DHCPdv6. #3421
- Only use IPv4 DNS servers in IPv4 DHCP configuration. #3483
- Fix PHP error when saving DHCP settings if no manually configured DNS servers exist.
- Send a HUP to dhcp6 to signal a reload. #3514

3.55.11 Load Balancing

- Prevent a Fall Back Pool from being selected when the DNS protocol is in use. If one is present in the config, ignore it. #3300
- Fix display of pools in the LB status widget and on the LB Virtual Server status.

3.55.12 Time

- Allow multiple valid time servers to be entered in the wizard, as they are allowed under System > General
- Update time zone data to 2013i
- Teach system_timezone_configure() to deal with symlinks to avoid having timezone misconfigured. #3293
- Add 'limited' to ntpd restrict list to workaround FreeBSD-SA-14:02.ntpd/CVE-2013-5211. #3384
- Use "disable monitor" in NTP config to mitigate FreeBSD-SA-14:02.ntpd/CVE-2013-5211.
- Update ntp to ntp-devel for FreeBSD-SA-14:02.ntpd/CVE-2013-5211.
- Avoid placing an empty "interface listen" directive in ntpd.conf.

3.55.13 Misc

- Fix ALIX upgrade crash during RRD processing
- Fix "Could not open shared memory for read 1000" issue on Diagnostics > NanoBSD. #3235
- Fix ufslabels.sh logic to avoid trying to convert slices which are already using appropriate labels. Fixes #3207
- Fix removal of the first cron job entry in the list.
- Remove unused newsyslog cron job from the default configuration and on upgrade.
- Split SSL/TLS into separate checkboxes so that plaintext connections can be made secured by using STARTTLS. Support for SMTPS connections should probably be done away with in future. #3180
- Add source address selection to syslog settings, so it can work more effectively over a VPN. #355
- Rework the usage of the shell i/o during stop_packages(), fixes the "Syntax error: bad fd number" for the remaining people who still saw it on shutdown
- Switch to rw mode before file operations on RFC2136 cache. Fixes #3201
- Make the RADIUS settings respect the description of the timeout field. If the timeout value is left blank, use 5 seconds, don't print an error.
- Call conf_mount_rw before deleting a user. #3294
- Handle the reinstallall case with confirmation. #3548
- Do not list the same CARP ip as an option for its own Interface.
- Accept adding an IP Aliases on top of CARP VIP when the parent interface does have a valid IP address in the alias subnet.
- Simplify log filtering logic calling grep less times, as done on mail_reports.inc on 2c6efc9.
- Fix console recent config restore, allow restoration of the last backup listed. #3438
- Enhanced validation of general DNS servers and gateways
- Add a mechanism by which the serial port can be forced on always regardless of the config setting. (useful for nano+vga setups)
- Add a knob to let the user select which console (video or serial) is preferred in cases where there are multiple consoles present.
- Skip input validation when choosing an existing certificate in the User Manager. #3505
- pfSense_interface_deladdress() only knows how to delete an ip address, not a subnet. #3513

- Make is_linklocal case-insensitive. #3433
- Errors in RRD graph calculations
- Delete /var/crash content when the user clicks 'No'. #3486
- Make sure filesystem is read-write when operating on groups. #3492
- Fix OpenVPN XML section name for selective configuration backup.
- Remove TRIM_set and TRIM_unset support. This method isn't very elegant and isn't necessary in the long run. It's better handled during the install process or while booted off other media (e.g. CD or Memstick).

3.56 2.1.0 New Features and Changes

3.56.1 Security Fixes

Three FreeBSD security advisories are applicable to prior pfSense® software releases. These aren't remotely exploitable in and of themselves, but anyone who can execute arbitrary code on the firewall could use one or more of these to escalate privileges.

- FreeBSD-SA-13:13.nullfs
- FreeBSD-SA-13:12.ifioctl.asc
- FreeBSD-SA-13:09.ip_multicast.asc

3.56.2 IPv6 Support

IPv6 Added to many areas of the GUI. At least the following areas/features are IPv6-enabled. Others may work as well

- Aliases (Firewall) - Aliases can contain both IPv4 and IPv6, only addresses relevant to a given rule will be used
- CARP RA
- CARP Failover
- DHCP Server w/Prefix Delegation
- SLAAC WAN
- 6to4 WAN
- 6to4 WAN w/Prefix Delegation
- 6rd WAN
- 6rd WAN w/Prefix Delegation
- DHCP6 WAN
- DHCP6 WAN w/Prefix Delegation
- DHCPv6 Relay
- DNS Forwarder
- Firewall Rules
- Gateway Groups/Multi-WAN - See *Configuring Multi-WAN for IPv6*
- Gateway Status (apinger)
- GIF Tunnels

- GRE Tunnels
- GUI Access
- IPsec
- L2TP
- NPt
- NTP
- OpenVPN
- Packet Capture
- PPPoE WAN
- Router Advertisements
- Routing
- Server LB
- Static IP
- Syslog (remote)
- Limiters (dummynet pipes)
- Virtual IPs - IP Alias
- Virtual IPs - CARP
- DNS from RA
- Accept RA when forwarding
- Auth via RADIUS
- Auth via LDAP
- XMLRPC Sync
- RRD Graphs
- DHCP Static Mapping - Works by DUID
- DynDNS (HE.net hosted DNS, RFC2136, custom)
- MAC OUI database lookup support for NDP and DHCPv6. (Was already present for DHCP leases and ARP table) requires the nmap package to be installed to activate

Note: Unlike earlier snapshots, BETA, etc, currently the upgrade does NOT flip the "Allow IPv6" checkbox on upgrade, to preserve existing behavior. To activate IPv6 traffic, a user will have to flip this setting manually

3.56.3 Packages

- PBI (push button installer) package support - all of a package's files and dependencies are kept in an isolated location so packages cannot interfere with one another in the way that was possible on 2.0.x and before using tbz packages
- RIP (routed) moved to a package
- OLSRD moved to a package
- Unbound moved back to a package (Will try integration again for 2.2)
- Increase the verboseness of the package reinstallation process in the system logs for a post-firmware-update package reinstallation operation

3.56.4 OS/Binary/Supporting Program Updates

- Based on FreeBSD 8.3
- Updated Atheros drivers
- OpenSSL 1.0.1e (or later) used by OpenVPN, PHP, IPsec, etc
- PHP to 5.3.x
- OpenVPN to 2.3.x
- Added mps kernel module
- Added ahci kernel module
- Updated ixgbe driver
- Many other supporting packages have been updated

3.56.5 Dashboard & General GUI

- Switch from Prototype to jQuery
- Improved navigation and service status in the GUI (shortcut icons in each section to quickly access config, logs, status, control services, etc)
- Multiple language support, a mostly-complete translation for Brazilian Portuguese is included
- Read-only privilege to create a user that cannot modify config.xml
- Dashboard update check can be disabled
- Fixed theme inconsistencies between the login form and other parts of the GUI
- Various fixes to pages to reduce potential exposure to certain CSRF/XSS vectors
- Updated CSRF Magic
- Set CSRF Magic token timeout to be the same as the login expiration
- Added IE Mobile for WP8 to list of browsers that get an alternate theme at login
- Truncate service status so long package descriptions cannot break formatting of the status table
- Many fixes to HTML/XHTML to improve rendering and validation
- Added a note to the setup wizard letting the user know that it can be canceled at any time by clicking the logo image

- Make dashboard update check respect nanobsd-vga #3078
- Firewall Logs Widget filtering and column changes
- Added totals for some dashboard widget meters (memory, swap, disk usage)
- Changed dashboard display for states and mbufs to be meters, and to show usage as a percentage
- Update dashboard mbuf count via AJAX
- Show a count and layout of CPUs in the dashboard if multiple CPUs are detected

3.56.6 Captive Portal

- Multi instance Captive Portal
- Multiple Captive Portal RADIUS authentication sources (e.g. one for users, one for cards)
- Logic fixes for voucher encryption
- Many optimizations to Captive Portal processing, including a database backend and moving functions to a php module to improve speed Optional Captive Portal user privilege
- Add checks to make sure CP hard timeout is less than or equal DHCP server default lease time, to avoid issues with CP sessions being valid for incorrect IPs, and users switching IPs while they should still be connected to the portal
- Fixes for captive portal voucher syncing on HTTPS with a custom port #3001
- Fixes for custom Captive Portal files leaving symlinks on the filesystem after files were removed
- Added MAC OUI database lookup support to CP status (requires nmap package to be installed)

3.56.7 OS/System Management

- Ability to select serial port speed
- Added a manual way to enable TRIM if someone needs it
- Added a manual way to trigger a fsck on reboot
- AES-NI support (Cryptographic Accelerator feature on new Intel/AMD CPUs)
- Support for certain thermal sensors via ACPI, coretemp, and amdtemp
- System startup beep can be disabled
- Separate powerd setting for when on battery
- Add optional ability to change the size of RAM disks for /var/ and /tmp/ for systems that have RAM to spare
- Add optional ability for full installs to use RAM disks for /var/ and /tmp/ as is done on NanoBSD. Reduces overall writes to the media, should be more SSD-friendly
- Use a custom sysDescr for snmp similar to m0n0wall's format. Fixes #2893
- Added tunable to allow disabling net.inet.udp.checksum - disabling UDP checksums can improve performance, but can also have negative side effects
- Added an mtree database with the correct default permissions, owner, sha256 sum, and some other information that is used to verify file permissions post-install and post-upgrade
- APC is not started for PHP unless the system has over 512MB RAM, to reduce memory usage on systems with low RAM

3.56.8 Multi-WAN

- DynDNS multi-WAN failover
- IPsec multi-WAN failover
- OpenVPN multi-WAN failover
- Changed descriptions of the values for gateway monitoring
- Display apinger (gateway monitoring daemon) as a service when it is enabled
- Fixes for apinger to reload via SIGHUP properly, to avoid unnecessary restarts and loss of gateway status data
- "State Killing on Gateway Failure" now kills ALL states when a gateway has been detected as down, not just states on the failing WAN. This is done because otherwise the LAN-side states were not killed before, and thus some connections would be in limbo, especially SIP.
- Due to the change in its behavior, "State Killing on Gateway Failure" is now disabled by default in new configurations and is disabled during upgrade. If the feature is desired, it must be manually re-enabled post-upgrade.

3.56.9 NTP

- NTP daemon now has GPS support

3.56.10 IPsec

- More IPsec hash algorithms and DH key groups added, "base" negotiation mode added
- Mobile IPsec supports separate "split dns" field and doesn't assume the default domain for split DNS domains
- Properly ignore disabled IPsec phase 2 entries
- NAT before IPsec (1:1 or many:1) outbound
- Set default Proposal Check setting to Obey for mobile IPsec
- LDAP and RADIUS are now possible authentication sources for IPsec mobile xauth
- Delete the SPDs for an old IPsec entry when it is disabled or removed #2719
- Manage active SPDs on CARP secondary during sync #2303
- Add an option to force IPsec to reload on failover, which is needed in some cases for IPsec to fail from one interface to another. #2896

3.56.11 OpenVPN

- OpenVPN can accept attributes from RADIUS via avpairs for things like inacl, outacl, dns-server, routes
- OpenVPN checkbox for "topology subnet" to use one IP per client in tun mode
- OpenVPN local/remote network boxes can accept multiple comma-separated networks
- OpenVPN status for SSL/TLS server instances can now display the routing table for the VPN instance
- OpenVPN now allows selecting "localhost" as the interface
- Gateways are created for assigned OpenVPN server instances as well as clients
- OpenVPN instances can run on the same port on different interfaces

- OpenVPN status page now has service controls to show the status of the daemon running each instance, and allow for stop/start/restart from that page
- Changed wording of the error displayed when a daemon is not running or the management interface of OpenVPN cannot be reached for an instance
- OpenVPN client-specific Override cleanup fixes
- Fixed double-click to edit of OpenVPN Client-Specific Overrides

3.56.12 NAT/Firewall Rules/Alias

- Aliases separated into tabs for Hosts, Ports, and URLs to improve manageability
- NAT reflection options re-worded to be less confusing
- Adjustable source tracking timeout for Sticky connections
- Firewall rules now support matching on ECE and CWR TCP flags
- Filtering on ECE and CWR TCP flags is now possible
- Added ICMP to protocol list when creating rdr (port forward) rules
- Keep proper positioning of duplicated outbound NAT rules #1118
- When using the + at the top of Outbound NAT rules, add the rule to the top of the list and not the bottom
- Fix ordering of interface group rules in the ruleset #2837
- Track time and user@host which created or updated a firewall, NAT port forward, or outbound NAT rule. If timestamp records are present, display them at the bottom of the rule page when editing. Have the created time/user pre-filled for automated rules such as NAT port forward associated rules and the switch from automatic to manual outbound NAT
- Fix generation of manual outbound NAT rules so that localhost and VPN rules are not unnecessarily duplicated
- Prevent using "block" for an alias name, as it is a pf reserved keyword
- Allow TCP flags to be used on block or reject rules, since they are also valid there
- Updates/fixes to DSCP handling
- Allow advanced options state-related parameters to be used for TCP, UDP, and ICMP – Formerly only allowed on TCP
- Respect ports found in rules when policy route negation rules are made, #3173
- Do not include disabled OpenVPN networks in generated policy route negation rules

3.56.13 Certificates

- Improved denoting of certificate purposes in the certificate list
- Imported CRLs can be edited and replaced
- Can set digest algorithm for CA/Certs (sha1, sha256, etc)
- Default digest algorithm is now SHA256
- Show CA and certificate start and end dates in the their listings
- Correct tooltip description when adding a certificate #3017

- Relax input validation on a CA/Cert description since it is only used cosmetically in pfSense and not in the actual CA/cert subject
- Allow removing blank/empty CA and Cert entries

3.56.14 Logging

- More system log separation, Gateways, Routing, Resolver split into their own tabs
- Firewall logs can now be filtered by many different criteria
- Firewall logs can be sorted by any column
- Firewall logs can optionally show the matching rule description in a separate column or in between rows
- Firewall logs now show an indicator icon if the direction of a log entry is OUT rather than IN
- Add popup DNS resolution method to firewall log view
- Reduced logging output from IGMP proxy
- Reduced logging output from DynDNS
- Relocated filterdns logs to the resolver log file/tab
- Relocated DHCP client logs to the DHCP tab
- Fix system script logging so the correct script filename is printed in the log, rather than omitting the script name entirely
- Add independent logging choices to disable logging of bogon network rules and private network rules. Add upgrade code to obey the existing behavior for users (if default block logging was disabled, so is bogon/private rule blocking)
- Add a checkbox to disable the lighttpd log for people who don't want their system log full of messages from lighttpd in some cases where they are filling the log unnecessarily

3.56.15 Notifications

- Add the ability to disable Growl or SMTP notifications but keep their settings intact, so the mail settings can be used for other purposes (packages, etc)
- Add a test button to selectively test Growl or SMTP notifications without re-saving settings
- Do not automatically generate a test notification on saving notification settings, as there are now individual test buttons

3.56.16 High Availability (CARP, pfSync, XML-RPC)

- High Availability Synchronization options (Formerly known as "CARP Settings" under Virtual IPs Promoted to its own menu entry, System > High Avail. Sync
- Ensure that the user does not remove only the last IP alias needed for a CARP VIP in an additional subnet
- Disable pfsync interface when state synchronization is not in use
- Fixed issues with DHCP server config synchronization ordering on secondary nodes #2600
- Restart OpenVPN servers when CARP transitions to master (clients were already restarted), otherwise if CARP was disabled, the servers would never recover

- Removed the automatic pfsync rule, since the documentation always recommends adding it manually, and to add it behind the scenes with no way to block it can be counter-productive (and potentially insecure). **If the documentation was not followed and a pfsync or allow all rule was not added on the sync interface, then state synchronization may break after this upgrade. Add an appropriate rule to the sync interface and it will work again.**
- Allow XMLRPC to sync IP Alias VIPs set to Localhost for their interface
- In DHCP leases view, use the internal interface name (lan/opt1/etc) for the failover pool name, rather than a number. In certain cases the number can get out of sync between the two nodes, but the interface names will always match
- Print the user-configured interface description next to the DHCP failover pool name, rather than only the internal name (lan/opt1/etc)
- Add option to synchronize authentication servers (RADIUS, LDAP) via XMLRPC

3.56.17 NanoBSD

- Fixes for conf_mount_ro/conf_mount_rw reference checking/locking
- Diag > NanoBSD now has button to switch media between read/write and read-only
- Diag > NanoBSD now has a checkbox option to keep the media read/write
- Fixed an issue with NanoBSD time zones not being properly respected by all processes the first reboot after a firmware upgrade

3.56.18 DHCP Server

- DHCP can support multiple pools inside a single subnet, with distinct options per pool
- DHCP can allow/deny access to a DHCP pool by partial (or full) MAC address
- DHCP static mappings can have custom settings for gateway, DNS, etc
- DHCP static mappings can optionally have a static ARP entry created
- Fix Dynamic DNS updates from DHCP (ISC changed the config layout and requires zone declarations)
- When crafting DHCP Dynamic DNS zones, do not use invalid DNS servers for the IP type (e.g. skip IPv6 DNS servers, because the DHCP daemon rejects them)
- Added a config backup section choice for DHCPv6

3.56.19 Traffic Shaper

- Schedules can now be used with limiters
- Traffic shaper queues view updated
- CoDel AQM Shaper Discipline
- Allow PRIQ queues to be deleted. #3037
- Limiters now allow the user to set the mask they want to use, rather than assuming masking will always be per-IP. This allows per-subnet limits and similar
- Limiters now allow setting masking for IPv6

- Limiters now allow setting a burst size. This will pass X amount of data (TOTAL, NOT a rate) after an idle period before enforcing the limit

3.56.20 DNS Forwarder

- In DNS forwarder, DNS query forwarding section with options for sequential and require domain
- Allow a null forwarding server in DNS Forwarder domain overrides to ensure that queries stay local and never go outside the firewall
- Add DNS Forwarder option to not forward private reverse lookups
- DNS Forwarder domain overrides can now specify a source address for the query, to help resolve hostnames over VPN tunnels
- DNS Forwarder now can change the port upon which it listens, for better cohabitation with other DNS software such as tinydns or unbound, if both are needed
- DNS Forwarder now has an option to select the interfaces/IP Addresses upon which it will respond to queries
- DNS Forwarder can now be set to only bind to specific IPv4 IPs (the underlying software, dnsmasq, does not support selectively binding to IPv6 IPs)
- Improved handling of some dnsmasq custom config options

3.56.21 User Manager

- Configurable RADIUS authentication timeout in User Manager
- Print the error message from LDAP in the log for a bind failure. Helps track down reasons for authentication failures
- Re-enable admin user if it's disabled when 'Reset webConfigurator password' option is used. Fixes #2877
- Restrict maximum group name length to 16 characters or less (OS restriction)
- Added option to UTF-8 encode LDAP parameters to improve handling of international characters
- CDATA protected LDAP fields in config to avoid invalid XML with international characters

3.56.22 DynDNS

- Fixed handling of DynDNS 25-day update and add ability to configure update interval
- Added DynDNS No-IP Free Account Support
- Add AAAA support to RFC2136 updates
- Add cached IP support to RFC2136, add GUI button to force update for single host
- Fix double click row to edit for RFC2136
- Add option to RFC2136 to find/use the public IP if the interface IP is private. (Off by default to preserve existing behavior on upgrade)
- Add server IP column and cached IP display to RFC2136 host list
- Include RFC2136 hosts in DNS rebinding checks
- Include both dyndns and RFC2136 hosts in referer check

3.56.23 Graphs

- Add ability to reverse-resolve IPs on Status > Traffic Graph in the rate table
- Add ability to filter local or remote IPs on Status > Traffic Graph in the rate table
- Change maximum values for RRD throughput to account for 10G links. Previous maximums would have caused blank spots on the graph during periods of high throughput
- Fixes to RRD data resolution/retention
- Added RRD Graph for mbuf clusters
- Changed default RRD graph colors to be more visually distinct to help avoid ambiguity between multiple values on the same graph

3.56.24 Misc

- Add option to the packet capture page to control whether or not promiscuous mode is used on the NIC. Certain drivers have issues with promiscuous mode
- Make parent interface and all VLANs share MTU #2786
- Fix cellular signal strength indicator
- Fix PPP config cleanup when removing an interface #2758
- Disallow adding IP Alias or CARP VIP that would be the network or broadcast address of a subnet
- Diagnostics > Sockets page to show open network sockets on the firewall
- Diagnostics > Test Port page to perform a simple TCP connection test to see if a port is open
- The pftop page has additional options to display more detailed information and sort it
- Fixed conflict between static IP and static route in the same subnet #2039
- Do not apply static ARP entries to disabled interfaces #1988
- Do not allow bridge members to be assigned to itself #1153
- Changed Diag > Ping to use more available source addresses (CARP VIPs, IP Alias VIPs, OpenVPN interfaces, IPv6 Link-Local IPs)
- Changed Diag > Traceroute to use more available source addresses (CARP VIPs, IP Alias VIPs, OpenVPN interfaces, IPv6 Link-Local IPs)
- Changed shell prompt to not force background color, to be kinder to those not using black as a background in their terminal
- Add a field to allow rejecting DHCP leases from a specific upstream DHCP server. #2704
- Updated the help system to handle some recent added files for 2.x and clean out some old/obsolete files
- Allow selecting “Localhost” as an interface for IP Alias VIPs - this way IP Alias VIPs may be used for binding firewall services (e.g. Proxy, VPN, etc) in routed subnets without burning IPs for CARP unnecessarily
- Updated list of mobile service providers
- Fix max length for wpa passphrase. A 64-char passphrase would be rejected by hostapd and leave an AP in an open state #3034
- Added MSS clamping to the setup wizard
- Add a setting to configure the filterdns hostname resolution interval (defaults to 300s, 5 minutes)

- Omit IP mismatch warnings (e.g. behind a port forward, VPN IP, etc) if HTTP_REFERER protection is disabled
- Fixes for selecting/detecting PPP devices such as 3G/4G modems
- Rather than doing auto-detection to find serial PPP devices, use a glob when listing potential PPP serial devices
- Prevent sshlockout from a crash/coredump if a format string like %s is present in the buffer
- Fix SMART to see adaX devices
- Fix SMART interpretation of output from SCSI devices
- Fixed display of user SSH keys when present
- Updated p0f database from FreeBSD
- Fix UPnP Interface name selection to show the configured description entered by the user
- Allow setting the external UPnP interface (must be default route WAN)
- Fix Diag > Tables AJAX fadeOut after deletion for rows with CIDR mask format
- Improve Diagnostics > Routes to fetch output via AJAX and have configurable filtering and sizes. Improves handling of large routing tables, such as a full BGP feed
- When deleting or renaming a virtual server from the Load Balancer (relayd) manually clean up the NAT rules it leaves behind to avoid conflicts
- Many, many bug fixes
- Various fixes for typos, formatting, input validation, etc

3.56.25 SH/PHP Shell Scripts

- Git package for gitsync is now pulled in as a pfSense-style PBI package
- Shell scripts added to enable/disable CARP:

```
pfSsh.php playback enablecarp
pfSsh.php playback disablecarp
```

- Shell scripts to add and remove packages from the command line:

```
pfSsh.php playback installpkg "Some Package"
pfSsh.php playback uninstallpkg "Some Package"
pfSsh.php playback listpkg
```

- Added shell script to remove shaper settings:

```
pfSsh.php playback removeshaper
```

- Add shell script to control services from the command line:

```
pfSsh.php playback svc start <service name>
pfSsh.php playback svc restart <service name>
pfSsh.php playback svc stop <service name>
```

- Add a simple CLI mail script capable of sending an SMTP message using echo/piped input (uses SMTP notification settings for server details):

```
ifconfig -a | mail.php -s"ifconfig output"
```

- Added a script to convert a user's filesystem from device names to UFS labels, for easier portability in case the disk device changes names (e.g. adX to adY, adX to daY, or adX to adaX). ONLY FOR FULL INSTALLS. NanoBSD already uses labels.

```
/usr/local/sbin/ufslabels.sh
```

3.57 2.0.3 New Features and Changes

pfSense® software 2.0.3 is a maintenance release with some bug fixes since 2.0.2 release. It is possible to upgrade from any previous release to 2.0.3.

Because this release shortly followed after 2.0.2, review the *2.0.2 New Features and Changes* document as well.

The changelog for pfSense 2.0.3-RELEASE follows.

3.57.1 Security Advisories

- Updated to OpenSSL 0.9.8y to address FreeBSD-SA-13:03

3.57.2 PPP

- Fix obtaining DNS servers from PPP type WANs (PPP, PPPoE, PPTP, L2TP)

3.57.3 Captive Portal

- Fix Captive Portal Redirect URL trimming
- Voucher sync fixes
- Captive portal pruning/locking fixes
- Fix problem with fastcgi crashing

3.57.4 OpenVPN

- Clear the route for an OpenVPN endpoint IP when restarting the VPN, to avoid a situation where a learned route from OSPF or elsewhere could prevent an instance from restarting properly
- Always clear the OpenVPN route when using shared key, no matter how the tunnel network "CIDR" is set
- Use the actual OpenVPN restart routine when starting/stopping from services rather than killing/restarting manually
- Allow editing an imported CRL, and refresh OpenVPN CRLs when saving. #2652
- Fix interface assignment descriptions when using > 10 OpenVPN instances

3.57.5 Logging

- Put syslogd into secure mode so it refuses remote syslog messages
- If syslog messages are in the log, and the hostname does not match the firewall, display the supplied hostname
- Fix PPP log display to use the correct log handling method
- Run IPsec logs through htmlspecialchars before display to avoid a potential persistent XSS from racoon log output (e.g. username)

3.57.6 Traffic Shaper

- Fix editing of traffic shaper default queues. #1995
- Fix wording for VoIP address option in the shaper. Add rule going the other direction to catch connections initiated both ways

3.57.7 Dashboard & General GUI

- Use some tweaks to PHP session management to prevent the GUI from blocking additional requests while others are active
- Remove cmd_chain.inc and preload.php to fix some issues with lighttpd, fastcgi, and resource usage
- Firmware settings manifest (Site list) now bolds and denotes entries that match the current architecture, to help avoid accidental cross-architecture upgrades
- Add header to DHCP static mappings table
- When performing a factory reset in the GUI, change output style to follow halt.php and reboot.php so the shutdown output appears in the correct location on the page
- Better validation of parameters passed during S.M.A.R.T. operations for testing HDDs
- Fixed SNMP interface binding glitch (Setting was active but not reflected when viewed in GUI)
- Add a new class called addgatewaybox to make it easier to respect custom themes #2900

3.57.8 Console Menu Changes

- Correct accidental interface assignment changes when changing settings on the console menu
- Console menu option 11 now kills all active PHP processes, kills lighttpd, and then restarts the GUI. This is a more effective way to restart the GUI since if a PHP process is hung, restarting lighttpd alone will not recover from that
- Fix port display after LAN IP reset

3.57.9 Misc Changes

- Change how the listening address is passed to miniupnpd, the old method was resulting in errors for some users
- Fix "out" packet count reporting
- Be a little smarter about the default kernel in rare cases where it cannot determine what was in use
- Pass -S to tcpdump to avoid an increase in memory consumption over time in certain cases
- Minimise rewriting of /etc/gettytab (https://forum.netgate.com/post/51581)
- Make is_pid_running function return more conistent results by using isvalidpid
- Fix ataidle error on systems that have no ATA HDD. #2739
- Update Time Zone database zoneinfo to 2012.j to pick up on recent zone/DST/etc changes
- Fix handling of LDAP certificates, the library no longer properly handles files with spaces in the CA certificate filename
- Bring in the RCFILEPREFIX as constant fixes from HEAD, since otherwise rc.stop_packages was globbing in the wrong dir and executing the wrong scripts. Also seems to have fixed the "bad fd" error
- NTP restart fixes
- Gitsync now pulls in git package from pfSense package repository rather than FreeBSD
- Fixed handling of RRD data in config.xml backups when exporting an encrypted config #2836
- Moved apinger status to /var/run instead of /tmp
- Fixes for FTP proxy on non-default gateway WANs
- Fixes for OVA images
- Use new pfSense repository location (http://github.com/pfsense/pfsense/)
- Add patch to compensate apinger calculation for down gateways by time taken from other tasks like rrd/status file/etc

3.57.10 lighttpd changes

- Improve tuning of lighttpd and php processes
- Use separate paths for GUI and Captive Portal fastcgi sockets
- Always make sure php has its own process manager to make lighttpd happy
- Make mod_fastcgi last to have url.rewrite work properly
- Enable mod_evasive if needed for Captive Portal
- Simplify lighttpd config
- Send all lighttpd logs to syslog

3.57.11 Binary changes

- dnsmasq to 2.65
- rsync to 3.0.9
- links 2.7
- rrdtool to 1.2.30
- PHP to 5.2.17_13
- OpenVPN 2.2 stock again (Removed IPv6 patches since those are only needed on 2.1 now)
- Fix missing “beep” binary on amd64
- Fix potential issue with IPsec routing of client traffic
- Remove lighttpd spawnfcgi dependency
- Add splash device to wrap_vga kernels (It’s in GENERIC so full installs already have it). #2723

filterdns

- Correct an issue with unallocated structure
- Avoid issues with pidfiles being overwritten, lock the file during modifications
- Make filterdns restartable and properly cleanup its tables upon exit or during a reconfiguration

dhcpleases

- Correct use after free and also support hostnames with other DNS suffix
- Reinit on any error rather than just forgetting. Also the difftime checks are done after having complete view, no need to do them every time
- Typo fixes
- Log that a HUP signal is being sent to the pid file submitted by argument
- Prevent bad parsing of empty hostnames in lease file. Add an f option to run dhcplease in foreground. The only option needed while in foreground is h parameter and the only usable one as well

3.58 2.0.2 New Features and Changes

pfSense® software 2.0.2 is a maintenance release with some bug and security fixes since 2.0.1 release. It is possible to upgrade from any previous release to 2.0.2.

What follows is a mostly-complete changelog for pfSense 2.0.2-RELEASE

3.58.1 FreeBSD Security Advisories

Base OS updated to 8.1-RELEASE-p13 to address the following FreeBSD Security Advisories:

- FreeBSD-SA-12:01.openssl (v1.0/v1.1) http://security.freebsd.org/advisories/FreeBSD-SA-12:01.openssl.asc
- FreeBSD-SA-12:02.crypt http://security.FreeBSD.org/advisories/FreeBSD-SA-12:02.crypt.asc
- FreeBSD-SA-12:04.sysret (v1.0/v1.1) http://security.FreeBSD.org/advisories/FreeBSD-SA-12:04.sysret.asc
- FreeBSD-SA-12:07.hostapd https://www.freebsd.org/security/advisories/FreeBSD-SA-12:07.hostapd.asc

3.58.2 PPTP

- Added a warning to PPTP VPN configuration page

> **Warning: PPTP is no longer considered a secure VPN technology because it relies upon MS-CHAPv2 which has been compromised. Be aware that intercepted traffic can be decrypted by a third party, so it should be considered unencrypted. Migrate to another VPN type such as OpenVPN or IPsec.**
>
> More information on this can be found at https://isc.sans.edu/diary/End+of+Days+for+MS-CHAPv2/13807 and https://www.cloudcracker.com/blog/2012/07/29/cracking-ms-chap-v2/

- Fix reference to PPTP secondary RADIUS server shared secret.
- PPTP upgrade fixes.

3.58.3 NTP Changes

- OpenNTPD was dropped in favor of the ntp.org NTP daemon, used by FreeBSD.
- Status page added (Status > NTP) to show status of clock sync
- NTP logging fixed.

Note: `ntpd` will bind/listen to all interfaces by default, and it has to in order to receive replies. Selective interface binding may still be used to control which IP addresses will accept traffic, but be aware that the default behavior has changed.

3.58.4 Dashboard & General GUI Fixes

- Various fixes for typos, wording, and so on.
- Do not redirect on saving services status widget.
- Don't use $pconfig in widgets, it has unintended side effects.
- Fix display of widgets with configuration controls in IE.
- Changed some padding/margin in the CSS in order to avoid wrapping the menu.
- #2165 Change to embed to prevent IE9 from misbehaving when loading the Traffic Graph page

3.58.5 OpenVPN Fixes

- Safer for 1.2.3 upgrades to assume OpenVPN interface == any, since 1.2.3 didn't have a way to bind to an interface. Otherwise people accepting connections on opt interfaces on 1.2.3 will break on upgrade until the proper interface is selected in the GUI
- Don't ignore when multiple OpenVPN DNS, NTP, WINS, etc servers were specified in 1.2.3 when upgrading. 1.2.3 separated by ;, 2.x uses separate vars.
- Fix upgrade code for 1.2.3 with assigned OpenVPN interface.
- Fix LZO setting for Upgraded OpenVPN (was turning compression on even if old config had it disabled.)
- Be more intelligent when managing OpenVPN client connections bound to CARP VIPs. If the interface is in BACKUP status, do not start the client. Add a section to rc.carpmaster and rc.carpbackup to trigger this start/stop. If an OpenVPN client is active on both the master and backup system, they will cause conflicting connections to the server. Servers do not care as they only accept, not initiate.

3.58.6 IPsec fixes

- Only do foreach on IPsec p2's if it's actually an array.
- #2201 Don't let an empty subnet into racoon.conf, it can cause parse errors.
- #2201 Reject an interface without a subnet as a network source in the IPsec Phase 2 GUI.
- Add routes even when IPsec is on WAN, as WAN may not be the default gateway.
- #1986 Revamped IPsec status display and widget to properly account for mobile clients.
- Fixed a bug that caused the IPsec status and widget to display slowly when mobile clients were enabled.

3.58.7 User Manager Fixes

- #2066 Improve adding/removing of users accounts to the underlying OS, especially accounts with a numeric username.
- Include admin user in bootup account sync
- Fix permission and certificate display for the admin user
- Fix ssh key note to refer to DSA not just RSA since both work.
- ":" chars are invalid in a comment field, filter them out.
- When renaming a user, make sure to remove the previous user or it gets left in /etc/passwd.
- #2326 Do not allow empty passwords since this might cause problems for some authentication servers like LDAP.

3.58.8 Captive Portal Fixes

- Take routing table into account when figuring out which IP address to use for talking to CP clients.
- Prevent browser auto-fill username and password on voucher config, as it can interfere with the settings being properly saved if sync isn't fully configured, which this can make happen accidentally.
- Correct the Called-Station-Id attribute setting to be the same on STOP/START packets
- Correct the Called-Station-Id attribute setting to be consistent on the data sent
- #2082 Correct the log to display the correct information about an existing session

- #2052 Remove duplicate rule
- Fix which roll to write when writing the active voucher db
- Always load ipfw when enabling CP to ensure the pfil hooks are setup right
- #2378 Fix selection of CP interfaces when using more than 10 opt interfaces.
- Strengthen voucher randomization.

3.58.9 NAT/Firewall Rules/Alias Fixes

- #2327 Respect the value of the per-rule "disable reply-to" checkbox.
- #1882 Fix an invalid pf rule generated from a port forward with dest=any on an interface with ip=none
- #2163 1:1 Reflection fixes for static route subnets and multiple subnets on the same interface.
- Better validation on URL table alias input from downloaded files.
- #2293 Don't put an extra space after "pass" when assuming it as the default action or later tests will fail to match this as a pass rule.
- Update help text for Host aliases to indicate FQDNs are allowed.
- #2210 Go back to scrub rather than "scrub in", the latter breaks MSS clamping for egress traffic
- Fix preservation of the selection of interfaces on input errors for floating rules.
- Fix URL table update frequency box.
- Fix input validation for port forwards, Local Port must be specified.
- Added a setting to increase the maximum number of pf tables, and increased the default to 3000.
- Properly determine active GUI and redirect ports for anti-lockout rule, for display and in the actual rule.
- Handle loading pf limits (timers, states, table/entry limits, etc) in a separate file to avoid a chicken-and-egg scenario where the limits would never be increased properly.

3.58.10 Interface/Bridging Fixes

- Correct checking if a gif is part of bridge so that it actually works correctly adding a gif after having created it on bootup
- Use the latest functions from pfSense module for getting interface list
- Use the latest functions from pfSense module for creating bridges
- Implement is_jumbo_capable in a more performant way. This should help with large number of interfaces
- Since the CARP interface name changed to "vipN" from "carpN", devd needs to follow that change as well.
- #2242 Show lagg protocol and member interfaces on Status > Interfaces.
- #2212 Correctly stop dhclient process when an interface is changed away from DHCP.
- Fixed 3G SIM PIN usage for Huawei devices
- Properly obey MTU set on Interface page for PPP type WANs.

3.58.11 Other Misc. Fixes

- #2057 Add a checkbox that disables automatically generating negate rules for directly connected networks and VPNs.
- Mark "Destination server" as a required field for DHCP Relay
- Clarify the potential pitfalls when setting the Frequency Probe and Down parameters.
- Add a PHP Shell shortcut to disable referer check (playback disablerefercheck)
- #2040 Make Wireless Status tables sortable
- #2068 Fix multiple keys in a file for RFC2136 dyndns updates.
- Check to see if the pid file exists before trying to kill a process
- #2144 Be smarter about how to split a Namecheap hostname into host/domain.
- Add a small script to disable APM on ATA drives if they claim to support it. Leaving this on will kill drives long-term, especially laptop drives, by generating excessive Load Cycles. The APM bit set will persist until the drive is power cycled, so it's necessary to run on each boot to be sure.
- #2158 Change SNMP binding option to work on any eligible interface/VIP. If the old bindlan option is there, assume the lan interface for binding.
- Fix reference to PPTP secondary RADIUS server shared secret.
- PPTP upgrade fixes.
- #2147 Add button to download a .p12 of a cert+key.
- #2233 Carry over the key length on input errors when creating a certificate signing request.
- #2207 Use PHP's built-in RFC 2822 date format.
- Allow specifying the branch name after the repository URL for gitsync command-line arguments and remove an unnecessary use of the backtick operator.
- Correct send_multiple_events to conform with new check_reload_status behaviour
- Do not wipe logs on reboot on full install
- Set FCGI_CHILDREN to 0 since it does not make sense for php to manage itself when lighttpd is doing so. This makes it possible to recover from 550-Internal… error.
- Support for xmlrpcauthuser and xmlrpcauthpass in $g.
- Fix Layer 7 pattern upload, button text check was incorrect.
- Correct building of traffic shaping queue to not depend on parent mask
- #2239 Add alias support to static routes
- Use !empty instead of isset to prevent accidental deletion of the last used repository URL when firmware update gitsync settings have been saved without a repository URL.
- Better error handling for crypt_data and also better password argument handling
- Stop service needs to wait for the process to be stopped before trying to restart it.
- Use a better default update url
- Fix missing description in rowhelper for packages.
- #2402, #1564 Move the stop_packages code to a function, and call the function from the shell script, and call the function directly for a reboot.

- #1917 Fix DHCP domain search list
- Update Time Zone zoneinfo database using latest zones from FreeBSD
- Handle HTTPOnly and Secure flags on cookies
- Fixed notifications for firmware upgrade progress
- Removed an invalid declaration that considered 99.0.0.0/8 a private address.
- Fixed redirect request for IE8/9
- #1049 Fix crashes on NanoBSD during package removal/reinstall. Could result in the GUI being inaccessible after a firmware update.
- Fix some issues with upgrading NanoBSD+VGA and NanoBSD+VGA Image Generation
- Fix issues upgrading from systems with the old "Uniprocessor" kernel which no longer exists.
- Fix a few potential XSS/CSRF vectors.
- Fixed issue with login page not showing the correct selected theme in certain configurations.
- Fix limiters+multi-wan

3.58.12 Binary/Supporting Program Updates

- Some cleanup to reduce overall image size
- Fixes to ipfw-classifyd file reading and handling
- Updated miniupnpd
- ISC DHCPD 4.2.4-P1
- mdp5 upgraded to 5.6
- pftop updated
- lighttpd updated to 1.4.32, for CVE-2011-4362 and CVE-2012-5533.

3.59 2.0.1 New Features and Changes

This is a maintenance release with bug and security fixes since 2.0 release. It is possible to upgrade from any previous release to 2.0.1.

For those who use the built in certificate manager, pay close attention to the notes below on a potential security issue with those certificates.

3.59.1 Change Log

The following changes were made after 2.0-RELEASE and were included in 2.0.1-RELEASE.

- Improved accuracy of automated state killing in various cases (#1421)
- Various fixes and improvements to relayd
  - Added to Status > Services and widget
  - Added ability to kill relayd when restarting (#1913)
  - Added DNS load balancing

  - Moved relayd logs to their own tab
  - Fixed default SMTP monitor syntax and other send/expect syntax
- Fixed path to FreeBSD packages repo for 8.1
- Various fixes to syslog:
  - Fixed syslogd killing/restarting to improve handling on some systems that were seeing GUI hangs resetting logs
  - Added more options for remote syslog server areas
  - Fixed handling of 'everything' checkbox
  - Moved wireless to its own log file and tab
- Removed/silenced some irrelevant log entries
- Fixed various typos
- Fixes for RRD upgrade/migration and backup (#1758)
- Prevent users from applying NAT to CARP which would break CARP in various ways (#1954)
- Fixed policy route negation for VPN networks (#1950)
- Fixed "Bypass firewall rules for traffic on the same interface" (#1950)
- Fixed VoIP rules produced by the traffic shaper wizard (#1948)
- Fixed uname display in System Info widget (#1960)
- Fixed LDAP custom port handling
- Fixed Status > Gateways to show RTT and loss like the widget
- Improved certificate handling in OpenVPN to restrict certificate chaining to a specified depth – CVE-2011-4197
- Improved certificate generation to specify/enforce type of certificate (CA, Server, Client) – CVE-2011-4197
- Clarified text of serial field when importing a CA (#2031)
- Fixed MTU setting on upgrade from 1.2.3, now upgrades properly as MSS adjustment (#1886)
- Fixed Captive Portal MAC passthrough rules (#1976)
- Added tab under Diagnostics > States to view/clear the source tracking table if sticky is enabled
- Fixed CARP status widget to properly show "disabled" status.
- Fixed end time of custom timespan RRD graphs (#1990)
- Fixed situation where certain NICs would constantly cycle link with MAC spoofing and DHCP (#1572)
- Fixed OpenVPN ordering of client/server IPs in Client-Specific Override entries (#2004)
- Fixed handling of OpenVPN client bandwidth limit option
- Fixed handling of LDAP certificates (#2018, #1052, #1927)
- Enforce validity of RRD graph style
- Fixed crash/panic handling so it will do textdumps and reboot for all, and not drop to a db> prompt.
- Fixed handling of hostnames in DHCP that start with a number (#2020)
- Fixed saving of multiple dynamic gateways (#1993)
- Fixed handling of routing with unmonitored gateways

- Fixed Firewall > Shaper, By Queues view
- Fixed handling of spd.conf with no phase 2's defined
- Fixed synchronization of various sections that were leaving the last item on the slave (IPsec phase 1, Aliases, VIPs, etc)
- Fixed use of quick on internal DHCP rules so DHCP traffic is allowed properly (#2041)
- Updated ISC DHCP server to 4.2.3 (#1888) – this fixes a denial of service vulnerability in dhcpd.
- Added patch to mpd to allow multiple PPPoE connections with the same remote gateway
- Lowered size of CF images again fix newer and ever-shrinking CF cards.
- Clarified text for media selection (#1910)

3.59.2 Notes for certificate generation vulnerability

Certificates generated with the built-in certificate manager in all 2.0 versions prior to 2.0.1 are excessively permissive for non-CA certificates. These certificates can be used as a certificate authority, meaning a user can use their own certificate to create chained certificates. The firewall defaults OpenVPN on 2.0.1 and newer versions to not accept chained certificates, which mitigates this. However, if untrusted users have certificates generated from 2.0 release, the best practice is to regenerate all certificates and issuing new ones. Certificates generated by easy-rsa and imported into 2.0 are not affected. If using certificates generated on pfSense® for other purposes, revoke those and issue new certificates generated on 2.0.1. A CRL must be utilized in that case. To be on the safe side, start from scratch with a new CA and certificates after deleting all existing ones.

3.59.3 Upgrade considerations

It is very important to read the *Upgrade Guide* before performing an upgrade for those still on 1.2.x versions.

3.60 2.0 New Features and Changes

This is a partial list of the new features and major changes in the pfSense® software 2.0 release.

3.60.1 Operating System

- Based on FreeBSD 8.1 release.
- i386 and amd64 variants for all install types (full install, nanobsd/embedded, etc.)
- USB memstick installer images available

3.60.2 Interfaces

- GRE tunnels
- GIF tunnels
- 3G support
- Dial up modem support
- Multi-Link PPP (MLPPP) for bonding PPP connections (ISP/upstream must also support MLPPP)
- *LAGG Interfaces*
- Interface groups
- IP Alias type Virtual IPs
- IP Alias VIPs can be stacked on CARP VIPs to go beyond the 255 VHID limit in deployments that need very large numbers of CARP VIPs.
- QinQ VLANs
- Can use Block Private Networks / Block Bogon Networks on any interface
- All interfaces are optional except WAN
- All interfaces can be renamed, even LAN/WAN
- Bridging enhancements - can now control all options of if_bridge, and assign bridge interfaces

3.60.3 Gateways/Multi-WAN

- Gateways, including dynamic gateways, are specified under System > Routing
- Gateways can have custom monitor IPs
- Gateways can have a custom weight, allowing load balancing to have ratios between WANs of different speeds
- Gateways can have custom latency, loss, and downtime trigger levels.
- Gateway monitoring via icmp is now configurable.
- Multiple gateways may exist per interface
- Multi-WAN is now handled via gateway groups
- Gateway groups can include multiple tiers with any number of gateways on each, for complex failover and load balancing scenarios.

3.60.4 General Web GUI

- Set to HTTPS by default, HTTP redirects to HTTPS port
- Dashboard and widgets added
- System > Advanced screen split into multiple tabs, more options available.
- SMTP email alerts and growl alerts
- New default theme - pfsense_ng
- Some community-contributed themes added

- Contextual help available on every page in the web interface, linking to a webpage containing help and documentation specific to that page.
- Help menu for quick access to online resources (forum, docs, paid support, etc.)

3.60.5 Aliases

- Aliases may be nested (aliases in aliases)
- Alias autocomplete is no longer case sensitive
- IP Ranges in Aliases
- More Alias entries supported
- Bulk Alias importing
- URL Aliases
- URL Table Aliases - uses a pf persist table for large (40,000+) entry lists

3.60.6 Firewall

- Traffic shaper rewritten - now handles any combination of multi-WAN and multi-LAN interfaces. New wizards added.
- Layer7 protocol filtering
- *EasyRule - add firewall rules from log view (and from console!)*
- Floating rules allow adding non-interface specific rules
- Dynamically sized state table based on amount of RAM in the system
- More Advanced firewall rule options
- FTP helper now in kernel
- TFTP proxy
- Schedule rules are handled in pf, so they can use all the rule options.
- State summary view, report shows states grouped by originating IP, destination IP, etc.

3.60.7 NAT

- All of the NAT screens were updated with additional functionality
- Port forwards can now handle create/update associated firewall rules automatically, instead of just creating unrelated entries.
- Port forwards can optionally use “rdr pass” so no firewall rule is needed.
- Port forwards can be disabled
- Port forwards can be negated (“no rdr”)
- Port forwards can have source and destination filters
- NAT reflection improvements, including NAT reflection for 1:1 NAT
- Per-entry NAT reflection overrides

- 1:1 NAT rules can specify a source and destination address
- 1:1 NAT page redesigned
- Outbound NAT can now translate to an address pool (Subnet of IPs or an alias of IPs) of multiple external addresses
- Outbound NAT rules can be specified by protocol
- Outbound NAT rules can use aliases
- Improved generation of outbound NAT rules when switching from automatic to manual.

3.60.8 IPsec

- Multiple IPsec p2's per p1 (multiple subnets)
- IPsec xauth support
- IPsec transport mode added
- IPsec NAT-T
- Option to push settings such as IP, DNS, etc, to mobile IPsec clients (mod_cfg)
- Mobile IPsec works with iOS and Android (Certain versions, see *IPsec Remote Access VPN Example Using IKEv1 with Xauth*)
- More Phase 1/2 options can be configured, including the cipher type/strength
- ipsec-tools version 0.8

3.60.9 User Manager

- New user manager, centralizing the various user configuration screens previously available.
- Per-page user access permissions for administrative users
- Three built-in authentication types - local users, LDAP and RADIUS.
- Authentication diagnostics page

3.60.10 Certificate Manager

- Certificate manager added, for handling of IPsec, web interface, user, and OpenVPN certificates.
- Handles creation/import of Certificate Authorities, Certificates, Certificate Revocation lists.
- Eliminates the need for using command line tools such as EasyRSA for managing certificates.

3.60.11 OpenVPN

- OpenVPN wizard guides through making a CA/Cert and OpenVPN server, sets up firewall rules, and so on. Greatly simplifies the process of creating a remote access OpenVPN server.
- OpenVPN filtering - an OpenVPN rules tab is available, so OpenVPN interfaces don't have to be assigned to perform filtering.
- OpenVPN client export package - provides a bundled Windows installer with certificates, Viscosity export, and export of a zip file containing the user's certificate and configuration files.
- OpenVPN status page with connected client list – can also kill client connections
- User authentication and certificate management
- RADIUS and LDAP authentication support

3.60.12 Captive Portal

- Voucher support added
- Multi-interface capable
- Pass-through MAC bandwidth restrictions
- Custom logout page contents can be uploaded
- Allowed IP addresses bandwidth restrictions
- Allowed IP addresses supports IP subnets
- "Both" direction added to Allowed IP addresses
- Pass-through MAC Auto Entry - upon successful authentication, a pass-through MAC entry can be automatically added.
- Ability to configure calling station RADIUS attributes

3.60.13 Wireless

- Virtual AP (VAP) support added
- more wireless cards supported with the FreeBSD 8.1 base

3.60.14 Server Load Balancing

- relayd and its more advanced capabilities replace slbd.

3.60.15 Other

- L2TP VPN added
- DNS lookup page added
- PFTop and Top in GUI - realtime updates
- Config History now includes a diff feature
- Config History has download buttons for prior versions
- Config History has mouseover descriptions
- CLI filter log parser (/usr/local/bin/filterparser)
- Switched to PHP 5.2.x
- IGMP proxy added
- Multiple Dynamic DNS account support, including full multi-WAN support and multi-accounts on each interface.
  - DynDNS Account Types supported are:

    DNS-O-Matic, DynDNS (dynamic), DynDNS (static), DynDNS (custom), DHS, DyNS, easyDNS, No-IP, ODS.org, ZoneEdit, Loopia, freeDNS, DNSexit, OpenDNS, Namecheap.com
- More interface types (VPNs, etc) available for packet capture
- DNS Forwarder is used by the firewall itself for DNS resolution (configurable) so the firewall benefits from faster resolution via multiple concurrent queries, sees all DNS overrides/DHCP registrations, etc.
- DHCP Server can now handle arbitrary numbered options, rather than only options present in the GUI.
- Automatic update now also works for NanoBSD as well as full installs
- More configuration sections can be synchronized via XMLRPC between CARP nodes.

3.61 General Release Information

3.61.1 Versions of pfSense software and FreeBSD

The tables in this document contain detailed information on pfSense® software releases.

Versions are grouped up by major/minor number changes so they are easier to locate. The most recent versions are listed first, and the rest are in descending order by release date.

pfSense Plus software

25.x

Version	Support	Released	Config Rev	FreeBSD Version	Branch
25.11		TBD	24.0	15.0-CURRENT@bf06074106cf	plus-RELENG_25_11
25.07		TBD	24.0	15.0-CURRENT@bf06074106cf	plus-RELENG_25_07

24.x

Version	Support	Released	Config Rev	FreeBSD Version	Branch

2.0.x

Version	Support	Released	Config Rev	FreeBSD Version	Branch
2.0.3		2013-04-15	8.0	8.1-RELEASE-p13	RELENG_2_0
2.0.2		2012-12-21	8.0	8.1-RELEASE-p13	RELENG_2_0
2.0.1		2011-12-20	8.0	8.1-RELEASE-p6	RELENG_2_0
2.0		2011-09-17	8.0	8.1-RELEASE-p4	RELENG_2_0

1.2.x

Version	Support	Released	Config Rev	FreeBSD Version	Branch
1.2.3		2009-12-10	3.0	7.2-RELEASE-p5	RELENG_1_2
1.2.2		2009-01-09	3.0	7.0-RELEASE-p8	RELENG_1_2
1.2.1		2008-12-26	3.0	7.0-RELEASE-p7	RELENG_1_2
1.2		2008-02-25	3.0	6.2-RELEASE-p11	RELENG_1_2

Legend

Version
The pfSense Plus or CE software version number. When possible, the version number links to the release notes detailing what was changed in that particular release.

See also:

See *Understanding pfSense Plus and CE software version numbers* later in this document for an explanation of the version number formats.

Support
The support status.

Current supported release

Previous unsupported release

Future release

TBD
To Be Determined, not yet known.

Released
The date a specific version of pfSense software was released to the public.

Config Rev
The internal `config.xml` revision number, which indicates changes to the configuration format that may make a configuration file incompatible with older versions.

FreeBSD Version
Each version of pfSense software is based on a specific version of FreeBSD. The underlying FreeBSD version is listed for each corresponding version of pfSense software.

Branch
A link to the pfSense software source code branch used to build a specific release.

Understanding pfSense Plus and CE software version numbers

pfSense Plus and CE software utilize different version number formats. This makes it easier to distinguish between them and also makes it clear that the releases do not necessarily happen at the same time, even if they share a common code base.

pfSense Plus software version numbers use the format `<year>.<month>.<patch>` where the `<patch>` suffix is omitted when the value is `0`. This version numbering scheme follows the format used by TNSR software, also produced by Netgate, which in turn is modeled after the version format used by the Linux Foundation FD.io project. This change happened at the start of 2021 when the name changed from "pfSense Factory Edition" to "pfSense Plus".

pfSense CE software version numbers use the format `<major>.<minor>.<patch>`, and each component is present even if the value is `0`. This version numbering scheme is similar to the format used by FreeBSD software. In the past, this format was also used for releases of pfSense Factory Edition software before it was renamed to pfSense Plus.

3.62 Current and Upcoming Supported Releases

3.62.1 pfSense Plus Software

- *25.07*
- *24.11*
- *24.03*

3.62.2 pfSense CE Software

- *2.8.0*
- *2.7.2*

3.63 Older/Unsupported Releases

3.63.1 pfSense Plus Software

- *23.09.1*

- *2.2.2*
- *2.2.1*

CHAPTER

FOUR

PRODUCT MANUALS

The pfSense Security Gateway Manuals help those who purchased appliances from Netgate get started with a new device running pfSense® software, or help get it back up and running in the case that something breaks.

Below is a list of active appliances:

- All Manuals
- Amazon AWS
- Microsoft Azure
- Netgate 1100
- Netgate 2100
- Netgate 4100
- Netgate 4200
- Netgate 6100
- Netgate 8200
- Netgate 8300
- Netgate 1537
- Netgate 1541

CHAPTER

FIVE

NETWORKING CONCEPTS

5.1 Understanding Public and Private IP Addresses

5.1.1 Private IP Addresses

The network standard RFC 1918 defines reserved IPv4 subnets for use only in private networks (Table *RFC 1918 Private IP Address Space*). RFC 4193 defines Unique Local Addresses (ULA) for IPv6 (Table *RFC 4193 Unique Local Address Space*). In most environments, a private IP subnet from RFC 1918 is chosen and used on all internal network devices. The devices are then connected to the Internet through a firewall or router implementing Network Address Translation (NAT) software, such as pfSense® software. IPv6 is fully routed from the internal network without NAT by Global Unicast Addresses (GUA). NAT will be explained further in *Network Address Translation*.

Table 1: RFC 1918 Private IP Address Space

CIDR Range	IP Address Range
10.0.0.0/8	10.0.0.0 - 10.255.255.255
172.16.0.0/12	172.16.0.0 - 172.31.255.255
192.168.0.0/16	192.168.0.0 - 192.168.255.255

Table 2: RFC 4193 Unique Local Address Space

Prefix	IP Address Range
fc00::/7	fc00:: - fdff:ffff:ffff:ffff:ffff:ffff:ffff:ffff

A complete list of special-use IPv4 networks may be found in RFC 3330. There are private IPv4 addresses, such as `1.0.0.0/8` and `2.0.0.0/8`, that have since been allocated to the dwindling IPv4 pool. Use of these addresses are problematic and not recommended. Also, avoid using `169.254.0.0/16`, which according to RFC 3927 is reserved for "Link-Local" auto configuration . It should not be assigned by DHCP or set manually and routers will not allow packets from that subnet to traverse outside a specific broadcast domain. There is sufficient address space set aside by RFC 1918, so there is no need to deviate from the list shown in Table *RFC 1918 Private IP Address Space*. Improper addressing will result in network failure and should be corrected.

5.1.2 Public IP Addresses

With the exception of the largest networks, public IP addresses are assigned by Internet Service Providers. Networks requiring hundreds or thousands of public IP addresses commonly have address space assigned directly from their Regional Internet Registry (RIR). An RIR is an organization that oversees allocation and registration of public IP addresses in a designated regions of the world.

Most residential Internet connections are assigned a single public IPv4 address. Most business class connections are assigned multiple public IP addresses. A single public IP address is adequate in many circumstances and can be used in conjunction with NAT to connect hundreds of privately addressed systems to the Internet. This documentation will assist in determining the number of public IP addresses required.

Most IPv6 deployments will give the end user at least a /64 prefix network to use as a routed internal network. For each site, this is roughly 2^{64} IPv6 addresses, or 18 *quintillion* addresses, fully routed from the Internet with no need for NAT.

5.1.3 Reserved and Documentation Addresses

In addition to blocks defined in RFC 1918, RFC 6890 describes blocks reserved for other special purposes such as documentation, testing, and benchmarking, including address space for Carrier-grade NAT allocated in RFC 6598. These special networks include:

Table 3: RFC 6890 IPv4 Reserved Address Space

CIDR Range	Purpose
192.0.2.0/24	Documentation and example code
198.51.100.0/24	Documentation and example code
203.0.113.0/24	Documentation and example code
198.18.0.0/25	Benchmarking network devices
169.254.0.0/16	Link Local
100.64.0.0/10	Carrier-grade NAT space
192.0.0.0/24	IETF Protocol Assignments
192.0.0.0/29	DS-Lite
192.88.99.0/24	6to4 Relay Anycast
240.0.0.0/4	Reserved

See also:

For a similar list for IPv6 prefixes, see *Special IPv6 Subnets*.

The documentation uses examples with addresses from the above documentation ranges as well as RFC 1918 networks since they are more familiar to users.

Some find these addresses tempting to use for VPNs or even local networks. Though the best practice is to only use them for their intended purposes, they are much less likely to be seen “in the wild” than RFC 1918 networks.

5.2 IP Subnetting Concepts

When configuring TCP/IP settings on a device, a subnet mask (Or prefix length for IPv6) must be specified. This mask enables the device to determine which IP addresses are on the local network, and which must be reached by a gateway in the routing table. The default LAN IP address of `192.168.1.1` with a mask of `255.255.255.0`, or `/24` in CIDR notation has a network address of `192.168.1.0/24`. CIDR is discussed in *Understanding CIDR Subnet Mask Notation*.

5.3 IP Address, Subnet and Gateway Configuration

The TCP/IP configuration of a host consists of the address, subnet mask (or prefix length for IPv6) and gateway. A host identifies which IP addresses are on its local network by using the IP address combined with the subnet mask. A host sends packets for addresses outside the local network to the host's configured default gateway which it assumes will pass the traffic on to the desired destination. An exception to this rule is a static route which instructs a device to contact specific non-local subnets reachable via locally connected routers. This list of gateways and static routes is kept on the routing table of each host. To see the routing table used by pfSense® software, see *Route Table Contents*.

See also:

More information about routing can be found in *Routing*.

In a typical deployment of pfSense software hosts on the LAN are assigned an IP address, subnet mask and gateway within the LAN range of the firewall running pfSense software. The LAN IP address on the firewall becomes the default gateway for hosts on the LAN. For hosts connecting by an interface other than LAN, use the appropriate configuration for the interface to which the device is connected.

Hosts within a single network communicate directly with each other without involvement from the gateway. This means that no firewall, including one running pfSense software, can control host-to-host communication within a network segment. If this functionality is a requirement, hosts must be segmented via the use of multiple switches, VLANs, or employ equivalent switch functionality like PVLAN.

See also:

VLANs are covered in *Virtual LANs (VLANs)*.

5.4 Understanding CIDR Subnet Mask Notation

pfSense® software uses CIDR (Classless Inter-Domain Routing) notation rather than the common subnet mask `255.x.x.x` when configuring addresses and networks. Refer to the *CIDR Subnet Table* to find the CIDR equivalent of a decimal subnet mask.

Table 4: CIDR Subnet Table

Subnet Mask	CIDR Prefix	Total IP Addresses	Usable IP Addresses	Number of /24 networks
255.255.255.255	/32	1	1	1/256th
255.255.255.254	/31	2	2*	1/128th
255.255.255.252	/30	4	2	1/64th
255.255.255.248	/29	8	6	1/32nd
255.255.255.240	/28	16	14	1/16th
255.255.255.224	/27	32	30	1/8th
255.255.255.192	/26	64	62	1/4th
255.255.255.128	/25	128	126	1 half

continues on next page

Table 4 – continued from previous page

Subnet Mask	CIDR Prefix	Total IP Addresses	Usable IP Addresses	Number of /24 networks
255.255.255.0	/24	256	254	1
255.255.254.0	/23	512	510	2
255.255.252.0	/22	1024	1022	4
255.255.248.0	/21	2048	2046	8
255.255.240.0	/20	4096	4094	16
255.255.224.0	/19	8192	8190	32
255.255.192.0	/18	16,384	16,382	64
255.255.128.0	/17	32,768	32,766	128
255.255.0.0	/16	65,536	65,534	256
255.254.0.0	/15	131,072	131,070	512
255.252.0.0	/14	262,144	262,142	1024
255.248.0.0	/13	524,288	524,286	2048
255.240.0.0	/12	1,048,576	1,048,574	4096
255.224.0.0	/11	2,097,152	2,097,150	8192
255.192.0.0	/10	4,194,304	4,194,302	16,384
255.128.0.0	/9	8,388,608	8,388,606	32,768
255.0.0.0	/8	16,777,216	16,777,214	65,536
254.0.0.0	/7	33,554,432	33,554,430	131,072
252.0.0.0	/6	67,108,864	67,108,862	262,144
248.0.0.0	/5	134,217,728	134,217,726	524,288
240.0.0.0	/4	268,435,456	268,435,454	1,048,576
224.0.0.0	/3	536,870,912	536,870,910	2,097,152
192.0.0.0	/2	1,073,741,824	1,073,741,822	4,194,304
128.0.0.0	/1	2,147,483,648	2,147,483,646	8,388,608
0.0.0.0	/0	4,294,967,296	4,294,967,294	16,777,216

Note: The use of `/31` networks is a special case defined by RFC 3021 where the two IP addresses in the subnet are usable for point-to-point links to conserve IPv4 address space. Not all operating systems support RFC 3021, so use it with caution. On systems that do not support RFC 3021, the subnet is unusable because the only two addresses defined by the subnet mask are the null route and broadcast and no usable host addresses.

pfSense software supports the use of `/31` networks for interfaces and Virtual IP addresses.

5.4.1 Where do CIDR numbers come from?

The CIDR number comes from the number of ones in the subnet mask when converted to binary.

The subnet mask `255.255.255.0` is `11111111.11111111.11111111.00000000` in binary. This adds up to `24` consecutive ones, or `/24` (pronounced "slash twenty four").

A subnet mask of `255.255.255.192` is `11111111.11111111.11111111.11000000` in binary, or `26` ones, hence `/26`.

5.5 CIDR Summarization

In addition to specifying subnet masks, CIDR can also be employed for IP or network summarization purposes. The "Total IP Addresses" column in *CIDR Subnet Table* indicates how many addresses are summarized by a given CIDR mask. For network summarization purposes, the "Number of /24 networks" column is useful. CIDR summarization can be used in several parts of the pfSense® web interface, including firewall rules, NAT, virtual IPs, IPsec, and static routes.

IP addresses or networks that can be contained within a single CIDR mask are known as "CIDR summarizable".

When designing a network, ensure all private IP subnets in use at a particular location are CIDR summarizable. For example, if three `/24` subnets are required at one location, a `/22` network subnetted into four `/24` networks should be used. The following table shows the four `/24` subnets used with the subnet `10.70.64.0/22`.

Table 5: CIDR Route Summarization

10.70.64.0/22 split into /24 networks
10.70.64.0/24
10.70.65.0/24
10.70.66.0/24
10.70.67.0/24

This keeps routing more manageable for multi-site networks connected to another physical location via the use of a private WAN circuit or VPN. With CIDR summarizable subnets, one route destination covers all the networks at each location. Without it, there are several different destination networks per location.

The previous table was developed using a network calculator found at the subnetmask.info website.

The calculator converts from dotted decimal to CIDR mask, and vice versa, as shown in Figure *Subnet Mask Converter*. If the *CIDR Subnet Table* provided in this chapter is not available, this tool can be used to convert a CIDR prefix to dotted decimal notation. Enter a CIDR prefix or a dotted decimal mask and click the appropriate **Calculate** button to find the conversion.

Fig. 1: Subnet Mask Converter

Enter the dotted decimal mask into the Network/Node Calculator section along with one of the `/24` networks. Click **Calculate** to populate the bottom boxes with the range covered by that particular `/24` as demonstrated in Figure *Network/Node Calculator*. In this example, the network address is `10.70.64.0/22`, and the usable `/24` networks are `64` through `67`. The term "Broadcast address" in this table refers the highest address within the range.

Fig. 2: Network/Node Calculator

5.5.1 Finding a matching CIDR network

IPv4 Ranges in the format of `x.x.x.x-y.y.y.y` are supported in Aliases. For Network type aliases, an IPv4 range is automatically converted to the equivalent set of CIDR blocks. For Host type aliases, a range is converted to a list of IPv4 addresses. See *Aliases* for more information.

If an exact match isn't necessary, numbers can be entered into the Network/Node Calculator to approximate the desired summarization.

5.6 Broadcast Domains

A broadcast domain is the portion of a network sharing the same layer 2 segment. Broadcast messages from hosts are sent to every port in their broadcast domain, thus hosts inside a broadcast domain can reach each other directly. For example hosts can use ARP or NDP to locate neighbors within a broadcast domain and communicate directly at layer 2 without involving an intermediate gateway router.

In a network with a single switch without VLANs, the broadcast domain is that entire switch. In a network with multiple interconnected switches without the use of VLANs, the broadcast domain includes all of those switches. When using VLANs, each VLAN is typically its own broadcast domain. The exact size of the broadcast domain in that case varies depending on how many access ports are in the VLAN, along with interconnected switches (trunked, stacked, etc).

Some switches also support special modes which segment a broadcast domain into multiple smaller isolated broadcast domains. This is sometimes called "Private VLANs", and they are typically used for security purposes. In these modes, hosts can only directly communicate between a specific set of ports, commonly limited to the host and the gateway for the segment, even if they are a part of a subnet with many other hosts. This is similar in concept to wireless AP client isolation.

Since broadcast messages are sent to every port in the broadcast domain, large broadcast domains should be avoided as they are "noisy" and do not scale well. Depending on the type of broadcast messages, some switches can optimize this behavior but it's best to plan for the worst case. For example in a network with thousands of ports on a single broadcast domain, thousands of hosts communicating among each other generate large amounts of broadcast traffic which is copied everywhere in the broadcast domain. The best practice is to keep each segment as small as possible, where feasible, to prevent switches and hosts from having to process large amounts of unnecessary broadcast traffic.

A single broadcast domain *can* contain more than one IPv4 or IPv6 subnet, however, that is generally not considered good network design. Though it appears on the surface that multiple subnets in the same broadcast domain are separate, there is no true isolation or security between them. IP subnets should be segregated into different broadcast domains via the use of separate switches or VLANs. The exception to this is running both IPv4 and IPv6 networks within a single broadcast domain. This is called dual stack and it is a common and useful technique using both IPv4 and IPv6 connectivity for hosts.

Broadcast domains can be combined by *bridging* two network interfaces together. In this scenario care must be taken

to avoid switch loops where a switch ends up with a connection back to itself, creating an infinite traffic loop (*Bridging and Layer 2 Loops*). Another reason to avoid bridging is that by combining broadcast domains, both networks and the bridge between them must carry broadcast traffic for every network on the bridge. The increased load, especially for larger networks, can be significant, especially if broadcast domains are being bridged using a VPN. There are also proxies for certain protocols which do not combine broadcast domains but yield the same net effect, such as a DHCP relay which relays DHCP requests into a broadcast domain on another interface.

5.7 IPv6

5.7.1 Basics

IPv6 allows for exponentially more IP address space than IPv4. IPv4 uses a 32-bit address, which allows for 2^{32} or over 4 billion addresses, less if the sizable reserved blocks and IPs burned by subnetting are removed. IPv6 uses a 128-bit address, which is 2^{128} or 3.403 x 10^{38} IP addresses. The standard size IPv6 subnet defined by the IETF is a /64, which contains 2^{64} IPs, or 18.4 *quintillion* addresses. The entire IPv4 space can fit inside a typical IPv6 subnet many times over with room to spare.

One of the more subtle improvements with IPv6 is that no IP addresses are lost to subnetting. With IPv4, two IP addresses are lost per subnet to account for a null route and broadcast IP address. In IPv6, broadcast is handled via the same mechanisms used for multicast involving special addresses sent to the entire network segment. Additional improvements include integrated packet encryption, larger potential packet sizes, and other design elements that make it easier for routers to manage IPv6 at the packet level.

Unlike IPv4, all packets are routed in IPv6 without NAT. Each IP address is directly accessible by another unless stopped by a firewall. This can be a very difficult concept to grasp for people who are used to having their LAN exist with a specific private subnet and then performing NAT to whatever the external address happens to be.

There are fundamental differences in the operation of IPv6 in comparison to IPv4, but mostly they are only that: differences. Some things are simpler than IPv4, others are slightly more complicated, but for the most part it's simply different. Major differences occur at layer 2 (ARP vs. NDP for instance) and layer 3 (IPv4 vs. IPv6 addressing). The protocols used at higher layers are identical; only the transport mechanism for those protocols has changed. HTTP is still HTTP, SMTP is still SMTP, etc.

Firewall and VPN Concerns

IPv6 restores true peer-to-peer connectivity originally in place with IPv4 making proper firewall controls even more important. In IPv4, NAT was misused as an additional firewall control. In IPv6, NAT is removed. Port forwards are no longer required in IPv6 so remote access will be handled by firewall rules. Care must be taken to ensure encrypted VPN LAN to LAN traffic is not routed directly to the remote site. See *IPv6 VPN and Firewall Rules* for a more in-depth discussion on IPv6 firewall concerns with respect to VPN traffic.

5.7.2 Requirements

IPv6 requires an IPv6-enabled network. IPv6 connectivity delivered directly by an ISP is ideal. Some ISPs deploy a dual stack configuration in which IPv4 and IPv6 are delivered simultaneously on the same transport. Other ISPs use tunneling or deployment types to provide IPv6 indirectly. It is also possible to use a third party provider such as Hurricane Electric's tunnelbroker service.

In addition to the service, software must also support IPv6. pfSense® software has been IPv6-capable since 2.1-RELEASE. Client operating systems and applications must also support IPv6. Many common operating systems and applications support it without problems. Microsoft Windows has supported IPv6 in production-ready state since 2002 though newer versions handle it much better. macOS has supported IPv6 since 2001 with version 10.1 "PUMA". Both FreeBSD and Linux support it in the operating system. Most web browsers and mail clients support IPv6, as do recent versions of other common applications. To ensure reliability, it is always beneficial to employ the latest updates.

Some mobile operating systems have varying levels of support for IPv6. Android and iOS both support IPv6, but Android only has support for stateless auto configuration for obtaining an IP address on Wi-Fi and not DHCPv6. IPv6 is part of the LTE specifications so any mobile device supporting LTE networks supports IPv6 as well.

5.7.3 IPv6 WAN Types

Details can be found in *IPv6 Configuration Types*, but some of the most common ways of deploying IPv6 are:

Static Addressing
: Native and using IPv6 either on its own or in a dual stack configuration alongside IPv4.

DHCPv6
: Address automatically obtained by DHCPv6 to an upstream server. Prefix delegation may also be used with DHCPv6 to deliver a routed subnet to a DHCPv6 client.

Stateless address auto configuration (SLAAC)
: Automatically determines the IPv6 address by consulting router advertisement messages and generating an IP address inside a prefix. This is not very useful for a router, as there is no way to route a network for the "inside" of the firewall. It may be useful for appliance modes.

6RD Tunnel
: A method of tunneling IPv6 traffic inside IPv4. This is used by ISPs for rapid IPv6 deployment.

6to4 Tunnel
: Similar to 6RD but with different mechanisms and limitations.

GIF Tunnel
: Not technically a direct WAN type, but commonly used. Customer builds an IPv4 GIF tunnel to a provider to tunnel IPv6 traffic.

While not technically a WAN type, IPv6 connectivity can also be arranged over a VPN such as IPsec, WireGuard, or OpenVPN. Most VPNs are capable of carrying IPv4 and IPv6 traffic simultaneously, so they can deliver IPv6 over IPv4, though with more overhead than a typical tunnel broker that uses GIF. These are good options for a company that has IPv6 at a datacenter or main office but not at a remote location.

5.7.4 Address Format

An IPv6 address consists of 32 hexadecimal digits, in 8 sections of 4 digits each, separated by colons. It looks something like this: `1234:5678:90ab:cdef:1234:5678:90ab:cdef`

IPv6 addresses have several shortcuts that allow them to be compressed into smaller strings following certain rules.

If there are any leading zeroes in a section, they may be left off. `0001:0001:0001:0001:0001:0001:0001:0001` could be written as `1:1:1:1:1:1:1:1`.

Any number of address parts consisting of only zeroes may be compressed by using `::` but this can only be done once in an IPv6 address to avoid ambiguity. A good example of this is local host, compressing `0000:0000:0000:0000:0000:0000:0000:0001` to `::1`. Any time `::` appears in an IPv6 address, the values between are all zeroes. An IP address such as `fe80:1111:2222:0000:0000:0000:7777:8888`, can be represented as `fe80:1111:2222::7777:8888`. However, `fe80:1111:0000:0000:4444:0000:0000:8888` cannot be shortened using `::` more than once. It would either be `fe80:1111::4444:0:0:8888` or `fe80:1111:0:0:4444::8888` but it *cannot* be `fe80:1111::4444::8888` because there is no way to tell how many zeroes have been replaced by either `::` operator.

Determining an IPv6 Addressing Scheme

Because of the increased length of the addresses, the vast space provided in even a basic /64 subnet, and the ability to use hexadecimal digits, there is more freedom to design device network addresses.

On servers using multiple IP address aliases for virtual hosts, jails, etc, a useful addressing scheme is to use the seventh section of the IPv6 address to denote the server. Then use the eighth section for individual IPv6 aliases. This groups all of the IPs into a single recognizable host. For example, the server itself would be `2001:db8:1:1::a:1`, and then the first IP alias would be `2001:db8:1:1::a:2`, then `2001:db8:1:1::a:3`, etc. The next server would be `2001:db8:1:1::b:1`, and repeats the same pattern.

Some administrators like to have fun with their IPv6 addresses by using hexadecimal letters and number/letter equivalents to make words out of their IP addresses. Lists of hexadecimal words around the web can be used to create more memorable IP addresses such as `2001:db8:1:1::dead:beef`.

Decimal vs. Hexadecimal Confusion

Creating consecutive IPv6 addresses with a hexadecimal base may cause confusion. Hexadecimal values are base 16 unlike decimal values which are base 10. For example, the IPv6 address `2001:db8:1:1::9` is followed by `2001:db8:1:1::a`, *not* `2001:db8:1:1::10`. By going right to `2001:db8:1:1::10`, the values `a-f` have been skipped, leaving a gap. Consecutive numbering schemes are not required and their use is left to the discretion of the network designer. For some, it is psychologically easier to avoid using the hexadecimal digits.

Given that all IPv4 addresses can be expressed in IPv6 format, this issue will arise when designing a dual stack network that keeps one section of the IPv6 address the same as its IPv4 counterpart.

5.7.5 IPv6 Subnetting

IPv6 subnetting is easier than IPv4. It's also different. Want to divide or combine a subnet? All that is needed is to add or chop off digits and adjust the prefix length by a multiple of four. No longer is there a need to calculate subnet start/end addresses, usable addresses, the null route, or the broadcast address.

IPv4 had a subnet mask (dotted quad notation) that was later replaced by CIDR masking. IPv6 doesn't have a subnet mask but instead calls it a Prefix Length, often shortened to "Prefix". Prefix length and CIDR masking work similarly; The prefix length denotes how many bits of the address define the network in which it exists. Most commonly the prefixes used with IPv6 are multiples of four, as seen in Table *IPv6 Subnet Table*, but they can be any number between `0` and `128`.

Using prefix lengths in multiples of four makes it easier for humans to distinguish IPv6 subnets. All that is required to design a larger or smaller subnet is to adjust the prefix by multiple of four. For reference, see Table *IPv6 Subnet Table* listing the possible IPv6 addresses, as well as how many IP addresses are contained inside of each subnet.

Table 6: IPv6 Subnet Table

Prefix	Subnet Example	Total IP Addresses	# of /64 nets
4	x::	2^{124}	2^{60}
8	xx::	2^{120}	2^{56}
12	xxx::	2^{116}	2^{52}
16	xxxx::	2^{112}	2^{48}
20	xxxx:x::	2^{108}	2^{44}
24	xxxx:xx::	2^{104}	2^{40}
28	xxxx:xxx::	2^{100}	2^{36}
32	xxxx:xxxx::	2^{96}	4,294,967,296
36	xxxx:xxxx:x::	2^{92}	268,435,456
40	xxxx:xxxx:xx::	2^{88}	16,777,216
44	xxxx:xxxx:xxx::	2^{84}	1,048,576
48	xxxx:xxxx:xxxx::	2^{80}	65,536
52	xxxx:xxxx:xxxx:x::	2^{76}	4,096
56	xxxx:xxxx:xxxx:xx::	2^{72}	256
60	xxxx:xxxx:xxxx:xxx::	2^{68}	16
64	xxxx:xxxx:xxxx:xxxx::	2^{64} (18,446,744,073,709,551,616)	1
68	xxxx:xxxx:xxxx:xxxx:x::	2^{60} (1,152,921,504,606,846,976)	0
72	xxxx:xxxx:xxxx:xxxx:xx::	2^{56} (72,057,594,037,927,936)	0
76	xxxx:xxxx:xxxx:xxxx:xxx::	2^{52} (4,503,599,627,370,496)	0
80	xxxx:xxxx:xxxx:xxxx:xxxx::	2^{48} (281,474,976,710,656)	0
84	xxxx:xxxx:xxxx:xxxx:xxxx:x::	2^{44} (17,592,186,044,416)	0
88	xxxx:xxxx:xxxx:xxxx:xxxx:xx::	2^{40} (1,099,511,627,776)	0
92	xxxx:xxxx:xxxx:xxxx:xxxx:xxx::	2^{36} (68,719,476,736)	0
96	xxxx:xxxx:xxxx:xxxx:xxxx:xxxx::	2^{32} (4,294,967,296)	0
100	xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:x::	2^{28} (268,435,456)	0
104	xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xx::	2^{24} (16,777,216)	0
108	xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxx::	2^{20} (1,048,576)	0
112	xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx::	2^{16} (65,536)	0
116	xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:x::	2^{12} (4,096)	0
120	xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xx::	2^{8} (256)	0
124	xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxx::	2^{4} (16)	0
128	xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx:xxxx	2^{0} (1)	0

A `/64` is a standard size IPv6 subnet as defined by the IETF. It is smallest subnet that can used locally if auto configuration is desired.

Typically, an ISP assigns a /64 or smaller subnet to establish service on the WAN. An additional network is routed for LAN use. The size of the allocation depends upon the ISP, but it's not uncommon to see end users receive at least a /64 and even up to a /48.

A tunnel service provider such as tunnelbroker.net run by Hurricane Electric will allocate a /48 in addition to a routed /64 subnet and a /64 interconnect.

Assignments larger than /64 usually adopt the first /64 for LAN and subdivide the rest for requirements such as VPN tunnel, DMZ, or a guest network.

Special IPv6 Subnets

Special use networks are reserved in IPv6. A full list of these can be found in the Wikipedia IPv6 article. Six examples of IPv6 special networks and their addresses are shown below in *IPv6 Special Networks and Addresses*.

Table 7: IPv6 Special Networks and Addresses

Network	Purpose
::1	Localhost
2001:db8::/32	Documentation prefix used for examples (RFC 3849)
3fff::/20	Documentation prefix used for examples (RFC 9637)
64:ff9b::/96	*NAT64*
fc00::/7	Unique Local Addresses (ULA) - also known as "Private" IPv6 addresses.
fe80::/10	Link Local addresses, only valid inside a single broadcast domain.
ff00::0/8	Multicast addresses
::ffff:0:0/96	IPv4 Mapped Addresses

Neighbor Discovery

IPv4 hosts find each other on a local segment using ARP broadcast messages, but IPv6 hosts find each other by sending Neighbor Discovery Protocol (NDP) messages. Like ARP, NDP works inside a given broadcast domain to find other hosts inside of a specific subnet.

By sending special ICMPv6 packets to reserved multicast addresses, NDP handles the tasks of neighbor discovery, router solicitations, and route redirects similar to IPv4's ICMP redirects.

pfSense® software automatically adds firewall rules on IPv6 enabled interfaces that permit NDP to function. All current known neighbors on IPv6 can viewed in the firewall GUI at **Diagnostics > NDP Table**.

Router Advertisements

IPv6 routers are located through their Router Advertisement (RA) messages instead of by DHCP. IPv6-enabled routers that support dynamic address assignment are expected to announce themselves on the network to all clients and respond to router solicitations. When acting as a client (WAN interfaces), pfSense software accepts RA messages from upstream routers. When acting as a router, pfSense software provides RA messages to clients on its internal networks. See *Router Advertisements (Or: "Where is the DHCPv6 gateway option?")* for more details.

Address Allocation

Client addresses can be allocated by static addressing through SLAAC (*Router Advertisements (Or: "Where is the DHCPv6 gateway option?")*), DHCP6 (*IPv6 Router Advertisements*), or other tunneling methods such as OpenVPN.

DHCP6 Prefix Delegation

DHCP6 Prefix Delegation delivers a routed IPv6 subnet to a DHCP6 client. A WAN type interface can be set to receive a prefix over DHCP6 (*DHCP6*, *Track Interface*). A router functioning at the edge of a large network can provide prefix delegation to other routers inside the network (*DHCPv6 Prefix Delegation*).

5.7.6 IPv6 and NAT

Though IPv6 removes most any need for NAT, there are rare situations that call for the use of NAT with IPv6 such as Multi-WAN for IPv6 on residential or small business networks.

IPv6 all but eliminates the need for traditional port translated NAT (PAT) where internal addresses are translated using ports on a single external IP address.

Outbound NAT

While it is possible to perform *Outbound NAT* on IPv6 traffic, the best practice is to allow IPv6 traffic to pass without performing any address or port translation.

Prefix Translation (1:1 NAT)

It is possible to translate one IPv6 prefix to another, which is Network Prefix Translation (NPt). This is available in the pfSense® software WebGUI under **Firewall > NAT** on the **NPt** tab. For example, NPt can translate `2001:db8:1111:2222::/64` to `2001:db8:3333:4444::/64` while maintaining the host portion of the address. For more on NPt, see *IPv6 Network Prefix Translation (NPt)*.

NAT64

pfSense software includes support for NAT64 which is useful as a transition mechanism to allow IPv6-only hosts access to IPv4-only resources. Several different functions must be configured for a full NAT64 configuration. See *NAT64* and *Configuring NAT64 for IPv6-only Clients* for details.

IPv4 Mapped Addresses

There is also a mechanism built into IPv6 to access IPv4 hosts using a special address notation, such as `::ffff:192.168.1.1`. The behavior of these addresses can vary between OS and application and can be unreliable.

5.7.7 NAT64

NAT64 is a form of *NAT* which enables clients with only IPv6 addresses to reach remote hosts using IPv4 addresses. NAT64 accomplishes this by mapping IPv4 addresses into a special IPv6 prefix dedicated to this purpose, such as the default NAT64 prefix, `64:ff9b::/96`.

Note: Though NAT64-related settings allow this prefix to be set to a custom value, in practice the value rarely if ever deviates from the default prefix of `64:ff9b::/96`.

See also:

- *NAT64 Configuration Recipe*

Requirements

To perform NAT64 there are a few prerequisites:

- The device performing NAT64 must have an external IPv4 address.
- If using this firewall for DNS, it must use the DNS Resolver.
- The internal interface with IPv6 clients **does not** need to have IPv4 configured.
- The local IPv6 interface must be properly configured, have appropriate firewall rules, etc. This can be a tracked WAN configuration or manually configured.

NAT64 Components

Several components come together to allow a fully-functioning NAT64 environment:

- *NAT64 Firewall Rules on the local interface*
- *PREF64 in Router Advertisements*
- *DNS64 in the DNS Resolver*
- Optionally configure DHCPv4 option `108` / `v6-only-preferred` if the segment has local/private IPv4.
- Configure DHCPv6 to at least advertise DNS servers to clients as not all clients support RDNSS/DNSSL and NAT64 requires working DNS.

See also:

See *NAT64 Configuration Recipe* for a complete walk-through of configuring each component in NAT64.

How NAT64 Works

This is a basic summary of the process for an IPv6 client to successfully make NAT64 requests:

- IPv6 client discovers the NAT64 prefix via *PREF64*.
- IPv6 client performs a DNS lookup for a host.
- The DNS Resolver uses *DNS64* to include mapped IPv4 addresses in its responses using the configured NAT64 prefix.

  For example, the client requests `www.example.com` which resolves to `203.0.113.5` and has no IPv6 address. The DNS response to the client will include both `203.0.113.5` and the IPv6 mapped equivalent, `64:ff9b::cb00:7105`.

- IPv6 client contacts the IPv4 host using the mapped address returned via DNS64.
- The firewall translates this request using NAT64 so the incoming IPv4 packet has both its source and destination translated to appropriate IPv4 addresses. This is a stateful mapping which allows the firewall to appropriately handle return packets for ongoing connections.

This entire process is transparent to the client software, such as a web browser. It will act as though it is communicating directly to IPv6 hosts even when using hostnames for sites with no IPv6 connectivity.

Contacting Remote IPv4 Hosts

IPv6 clients can contact IPv4 hosts using mapped addresses without DNS64 by manually appending the IPv4 address to the NAT64 prefix. For example, to contact the IPv4 address `203.0.113.5` the client would instead contact `64:ff9b::203.0.113.5`. The client could also use the fully-IPv6 equivalent address, `64:ff9b::cb00:7105`, but that is much more difficult for humans.

NAT64 **does not** enable IPv6 clients to talk to IPv4 hosts directly using IPv4 address notation. However, IPv6 clients may be able to do so if they have a customer-side translator (CLAT). This is completely dependent on the client and the firewall is not involved in that functionality. The availability of a CLAT is up to the operating system and its enabled features, installed software, etc.

Note: NAT64 on pfSense software only allows IPv6 clients to contact IPv4 servers and exchange two-way traffic. NAT64 **does not** allow IPv4 remote hosts to reach local IPv6 hosts.

NAT64 and Policy Routing

NAT64 is compatible with policy routing. For example, if an IPv4 destination has a static route out through an alternate path, a NAT64 rule can be configured to match. The NAT64 rule should match the equivalent mapped destination with a gateway configured to ensure it takes the expected path.

NAT64 and other NAT

NAT64 translates traffic when it reaches a rule **inbound** on an interface. This happens **before** the firewall processes Outbound NAT rules. As a result, while the packets *can* be translated again by Outbound NAT, the packets would not likely match in a way that makes performing additional Outbound NAT practical as the packet would already have an external address and may not be distinguishable from other connections.

5.7.8 IPv6 and pfSense Software

Unless noted otherwise, it safe to assume that IPv6 is supported by pfSense® in a given area or feature.

Some noteworthy areas of pfSense software that *do not* support IPv6 are: Captive Portal and most DynDNS providers.

Note: On systems upgraded from versions of pfSense software prior to 2.1, IPv6 traffic is blocked by default.

To allow IPv6:

- Navigate to **System > Advanced** on the **Networking** tab
- Check **Allow IPv6**
- Click **Save**

Packages

Some packages are maintained by the community, so IPv6 support varies. In most cases IPv6 support depends upon the capabilities of the underlying software. It is safe to assume a package does not support IPv6 unless otherwise noted. Packages are updated periodically so it is best to test a package to determine if it supports IPv6.

5.7.9 Controlling IPv6 Preference for traffic from the firewall itself

By default, pfSense® software prefers IPv6 when possible. If IPv6 routing is not functional but the system believes it is, pfSense software may fail to check updates or download packages properly.

To change this behavior, pfSense software provides a method in the GUI to control whether services on the firewall prefer IPv4 over IPv6:

- Navigate to **System > Advanced** on the **Networking** tab
- Check **Prefer to use IPv4 even if IPv6 is available**
- Click **Save**

Once the settings have been saved, the firewall itself will prefer IPv4 for outbound communication.

See also:

- *Configuring IPv6 Through A Tunnel Broker Service*

Around the world, the availability of new IPv4 addresses is declining. The amount of free space varies by region, but some have already run out of allocations and others are rapidly approaching their limits. As of January 31, 2011, IANA allocated all of its space to regional internet registries (RIRs). In turn, these RIR allocations have run out in some locations such as APNIC (Asia/Pacific), RIPE (Europe), and LACNIC (Latin America and Caribbean) for /8 networks. Though some smaller allocations are still available, it is increasingly difficult to obtain new IPv4 address space in these regions. ARIN (North America) ran out on September 24th, 2015.

To account for this, IPv6 was created as a replacement for IPv4. Available in some forms since the 1990s, factors like inertia, complexity, and the cost of developing or purchasing compatible routers and software has slowed its uptake until the last few years. Even then, it's been rather slow with only 8% of Google users having IPv6 connectivity by July 2015 and slightly over 40% of users in 2022.

Over the years, support for IPv6 in software, operating systems, and routers has improved so the situation is primed to get better. Still it is up to ISPs to start delivering IPv6 connectivity to users. It's a catch-22 situation: Content providers are slow to provide IPv6 because few users have it. Meanwhile, users don't have it because there isn't a lot of IPv6 content and even less content available only over IPv6. Users don't know they need it so they don't demand the service from their ISPs.

Some providers are experimenting with *Carrier Grade NAT (CGN)* to stretch their IPv4 networks farther. CGN places their IPv4 residential customers behind another layer of NAT further breaking protocols that already don't deal with one layer of NAT. Mobile data providers have been doing this for some time, but the applications typically found on mobile devices aren't affected since they work as if they're behind a typical SOHO router style NAT. While solving one problem, it creates others as observed when CGN is used as a firewall's WAN, when tethering on a PC, or in some cases attempting to use a traditional IPsec VPN without NAT-T, or PPTP. ISPs employing CGN should be used only if there is no other choice.

There are many books and web sites available with volumes of in-depth information on IPv6. The Wikipedia article on IPv6 is a great resource for additional information and links to other sources. It's worth using as a starting point for more information on IPv6. There are also many good books on IPv6 available, but be careful to purchase books with recent revisions. There have been changes to the IPv6 specification over the years and it's possible that the material could have changed since the book's printing.

See also:

Hangouts Archive to view the July 2015 Hangout on IPv6 Basics

This documentation is not an introduction to networks but there are certain networking concepts that need to be addressed.

Note: Readers without basic fundamental networking knowledge should locate additional introductory material as this chapter will not adequately provide all necessary information.

IPv6 concepts are introduced later in *IPv6*. For clarity, traditional IP addresses are referred to as IPv4 addresses. Except where otherwise noted, most functions will work with either IPv4 or IPv6 addresses. The general term IP address refers to either IPv4 or IPv6.

5.8 Brief introduction to OSI Model Layers

The OSI model has a network framework consisting of seven layers. These layers are listed in hierarchy from lowest to highest. A brief overview of each level is outlined below. More information can be found in many networking texts and on Wikipedia (http://en.wikipedia.org/wiki/OSI_model).

Layer 1 - Physical
Refers to either electrical or optical cabling that transports raw data to all the higher layers.

Layer 2 - Data Link
Typically refers to Ethernet or another similar protocol that is being spoken on the wire. This documentation often refers to layer 2 as meaning the Ethernet switches or other related topics such as ARP and MAC addresses.

Layer 3 - Network Layer
The protocols used to move data along a path from one host to another, such as IPv4, IPv6, routing, subnets etc.

Layer 4 - Transport Layer
Data transfer between users, typically refers to TCP or UDP or other similar protocols.

Layer 5 - Session Layer
Manages connections and sessions (typically referred to as “dialogs”) between users, and how they connect and disconnect gracefully.

Layer 6 - Presentation Layer
Handles any conversions between data formats required by users such as different character sets, encodings, compression, encryption, etc.

Layer 7 - Application Layer
Interacts with the user or software application, includes familiar protocols such as HTTP, SMTP, SIP, etc.

CHAPTER

SIX

HARDWARE

6.1 Minimum Hardware Requirements

The minimum hardware requirements for pfSense® software on hardware not sold by Netgate are:

- 64-bit amd64 (x86-64) compatible CPU
- 1GB or more RAM
- 8 GB or larger disk drive (SSD, HDD, etc)
- One or more compatible network interface cards
- Bootable USB drive or high capacity optical drive (DVD or BD) for initial installation

Note: The minimum requirements are not suitable for all environments; see *Hardware Sizing Guidance* for details.

6.2 Hardware Selection

The use of open source operating systems with untested hardware may create hardware/software conflicts. *Hardware Tuning and Troubleshooting* offers tips on resolving various issues.

6.2.1 Preventing hardware headaches

Use Genuine Netgate Hardware

The best practice is to use hardware from the Netgate Store. Netgate hardware has been developed to assure that specific hardware platforms have been thoroughly tested and validated.

Search for the experiences of others

The experiences of others are a valuable source of knowledge which can be found by researching pfSense software and hardware compatibility online, especially on the Netgate Forum. Reports of failure are not necessarily considered definitive because problems can arise from a number of issues other than hardware incompatibility.

If the hardware in question is from a major manufacturer, an internet search by make, model, and `site:netgate.com` will search the Netgate website for relevant user experiences. Searching for the make, model, and `pfSense` will find user experiences on other websites. Repeating the same search with `FreeBSD` instead of `pfSense` can also turn up useful experiences.

6.2.2 Naming Conventions

This documentation refers to the 64-bit hardware architecture as `amd64`, the architecture designation used by FreeBSD. Intel adopted the architecture created by AMD for x86-64, thus the name amd64 refers to all x86 64-bit CPUs.

Netgate sells ARM appliances compatible with its Plus edition of pfSense software. This hardware is based on the `armv6` and `armv7` architectures (also called `arm`) and `aarch64` (also called `arm64`). Items specific to those unique architectures will be called out as necessary. The generic term ARM may be considered to apply to all of these, but **only** for the specific ARM-based appliances sold by Netgate, such as the 2100 and 3100.

6.3 Hardware Sizing Guidance

When sizing hardware for pfSense® software, required throughput and necessary features are the primary factors that govern hardware selection.

The information on Netgate Store now contains up-to-date specifications and performance data on all hardware sold by Netgate. The data on the Netgate Store is updated as needed and it is always the most accurate and current source of performance data.

Tip: Contact Netgate Sales for personalized help in selecting the most suitable model for any implementation.

Estimating throughput of third party / whitebox hardware is difficult and inaccurate. In some cases, ballpark estimates may be made by comparing hardware specifications with those found on the Netgate Store for comparable models.

6.3.1 Throughput Considerations

In real networks the traffic flow will likely contain packets of varying size, not all maximum size packets, but it completely depends on the environment and the type of traffic involved. IMIX testing attempts to approximate a mixture of traffic that more closely resembles real-world environments. Simple IMIX traffic is sets of 7 (40) byte packets, (4) 576 byte packets, 1 (1500) byte packets, plus Ethernet framing overhead.

Note: The Netgate Store entries for hardware include data for both maximum size packet size ("IPERF3") as well as results for IMIX traffic patterns.

As a general reference, table *500,000 PPS Throughput at Various Frame Sizes* lists a few common packet sizes and the throughput achieved at an example rate of 500,000 packets per second.

Table 1: 500,000 PPS Throughput at Various Frame Sizes

Frame size	Throughput at 500 Kpps
64 bytes	244 Mbps
500 bytes	1.87 Gbps
1000 bytes	3.73 Gbps
1500 bytes	5.59 Gbps

Performance difference by network adapter type

The choice of NIC has a significant impact on performance. Inexpensive, low end cards consume significantly more CPU than better quality cards such as Intel. The first bottleneck with firewall throughput is the CPU. Throughput improves significantly by using a better quality NIC with slower CPUs. By contrast, increasing the speed of the CPU will not proportionally increase the throughput when coupled with a low quality NIC.

6.3.2 Feature Considerations

Features, services and packages enabled on the firewall can lower the total potential throughput as they consume hardware resources that could otherwise be used to transfer network traffic. This is especially true for packages that intercept or inspect network traffic, such as Snort or Suricata.

Most base system features do not significantly factor into hardware sizing but a few can potentially have a considerable impact on hardware utilization.

Large State Tables

Active network connections through the firewall are tracked in the firewall state table. Each connection through the firewall consumes two states: One entering the firewall and one leaving the firewall. For example, if a firewall must handle 100,000 simultaneous web server client connections the state table must be able to hold 200,000 states.

See also:

States are covered further in *Firewall*.

Firewalls in environments which require large numbers of simultaneous states must have sufficient RAM to contain the state table. Each state takes approximately 1 KB of RAM, which makes calculating the memory requirements relatively easy. Table *Large State Table RAM Consumption* provides a guideline for the amount of memory required for larger state table sizes. This is solely the memory used for the state tracking. The operating system itself along with other services will require at least 175-256 MB additional RAM and possibly more depending on the features used.

Table 2: Large State Table RAM Consumption

States	Connections	RAM Required
100,000	50,000	~97 MB
500,000	250,000	~488 MB
1,000,000	500,000	~976 MB
3,000,000	1,500,000	~2900 MB
8,000,000	4,000,000	~7800 MB

It is safer to overestimate the requirements. Based on the information above, a good estimate would be that 100,000 states consume about 100 MB of RAM, or that 1,000,000 states would consume about 1 GB of RAM.

VPN (all types)

The question customers typically ask about VPNs is "How many connections can my hardware handle?" That is a secondary factor in most deployments and is of lesser consideration. That metric is a relic of how other vendors have licensed VPN capabilities in the past and has no specific direct equivalent in pfSense software. The primary consideration in hardware sizing for VPN is the potential throughput of VPN traffic.

Encrypting and decrypting network traffic with all types of VPNs is CPU intensive. pfSense software offers several cipher options for use with IPsec. The various ciphers perform differently and the maximum throughput of a firewall is dependent on the cipher used and whether or not that cipher can be accelerated by the hardware.

See also:

The Netgate Store contains VPN performance data for each device sold by Netgate using the most optimal cipher for each device based on its capabilities.

Hardware *cryptographic accelerators*, such as those found on most Netgate hardware, greatly increase maximum VPN throughput and largely eliminate the performance difference between accelerated ciphers. For IPsec, ciphers may be accelerated by onboard cryptographic accelerators. For example, AES-GCM is accelerated by AES-NI and it is faster not only for that, but because it also does not require a separate authentication algorithm. IPsec also has less per-packet operating system processing overhead than OpenVPN, so for the time being IPsec will nearly always be faster than OpenVPN.

Where high VPN throughput is a requirement for a firewall, hardware cryptographic acceleration is of utmost importance to ensure not only fast transmission speeds but also reduced CPU overhead. The reduction in CPU overhead means the VPN will not lower the performance of other services on the firewall.

The current best available acceleration is available by using pfSense Plus software on hardware with a QAT device, followed by a CPU which includes support for IPsec-MB (SSE, AVX2, AVX512), or failing that, a CPU which includes AES-NI support combined with AES-GCM in IPsec.

Packages

Certain packages have a significant impact on hardware requirements, and their use must be taken into consideration when selecting hardware.

Snort/Suricata

Snort and Suricata are pfSense software packages for network intrusion detection. Depending on their configuration, they can require a significant amount of RAM. 1 GB should be considered a minimum but some configurations may need 2 GB or more, not counting RAM used by the operating system, firewall states, and other packages.

Suricata is multi-threaded and can potentially take advantage of NETMAP for inline IPS if the hardware offers support.

6.4 Memory Management

FreeBSD manages memory by dividing it into multiple areas or "pools" and moving memory pages between these areas as needed when allocating memory and taking other actions. These areas are visible in places such as the memory graphs (*Memory Graph*), system utilities such as `top` (*System Activity (Top)*), in `sysctl` OIDs, and elsewhere.

See also:

For more details on FreeBSD memory management and structure, see https://wiki.freebsd.org/Memory.

6.4.1 Memory Pools

The different memory pools in FreeBSD currently are:

Active
Active (in use) memory pages referenced by userland (non-kernel). If this memory is unreferenced, after a while it will eventually be marked inactive.

Inactive
Memory pages which were in use but have not been referenced recently are considered Inactive. Inactive pages can return to active status if they are referenced again. If the pages are "clean" (not in need of swapping or writing to disk), they may be freed directly. Otherwise they are considered "dirty" and may be moved to the Laundry queue.

Free
Memory available for immediate use.

Cache
Memory used by the operating system for caching. On systems using ZFS, this is the ZFS ARC cache (23.05+). On UFS systems, it is the UFS directory hash.

Note: On current versions this is only present in the memory graphs, and not reported in other places such as `top`.

The OS will attempt to use RAM when possible for caching rather than allowing it to sit idle and free, so the percentage of free RAM will often appear lower than expected.

Typically cache memory, such as the ZFS ARC, will be released by the OS when there is a shortage of free memory for other processes. However this may not happen fast enough if a process attempts to allocate a large chunk of memory all at once. In environments where that is a frequent concern, a good practice is to limit the ZFS ARC size as described in *ZFS Tuning*.

Wire
Memory allocated by the kernel, including the kernel itself, which cannot be paged/swapped and cannot be freed until explicitly released.

Note: In the OS and system utilities such as `top`, the ZFS ARC cache and UFS buffers sizes are included in wired memory. The `top` utility also prints a separate line breaking down ZFS ARC usage.

In the graphs on pfSense Plus software version 23.05 and later, however, these values are removed from the Wired total and graphed separately. ZFS ARC usage is graphed under Cache and UFS buffers are graphed under Buffers.

UserWire
Similar to Wired, but memory wired by user processes, not the kernel.

Laundry
Memory pages which are considered "dirty" and are due to be "cleaned". This means they may be eligible for swap (still in use but not recently referenced) or written to disk (e.g. file cache). After cleaning, the pages may be returned to active memory if referenced recently, or to an inactive state otherwise.

Buffers
Memory used for UFS buffers.

6.4.2 Memory Usage Notes

Free RAM is Wasted RAM

A common mantra among FreeBSD developers is "Free RAM is Wasted RAM". While free RAM is available for use by new/large processes, letting that RAM sit idle and unused is wasting the potential of the system. Allowing the OS to use that free RAM for caching will result in overall higher performance with minimal, if any, consequences.

If a system appears to have low amounts of free memory but is not experiencing any memory allocation failures, the best practice is usually to leave it alone and let the OS use what it can.

On the other hand, if there are problems running scheduled tasks or certain daemons because of low memory, then it may be best to reduce the amount of RAM available for caching. On ZFS systems, see *ZFS Tuning* for advice.

ZFS Disk Activity Increases Memory Usage

On systems using ZFS, large volumes of filesystem activity can lead to an increase in ZFS ARC usage which consumes memory temporarily to boost filesystem performance.

The most common scenario where this becomes a factor is during the first boot after a upgrading to a newer version of pfSense software. During an upgrade, large portions of the operating system are rewritten on disk, which can lead to a large chunk of wired memory being allocated to the ZFS ARC to speed up the process.

A similar effect can be observed from other tasks which scan or check large portions of the disk, such as from packages or certain periodic jobs.

In many cases this is harmless because the operating system will yield memory as needed if other processes require more memory. However, that does not always happen quickly. See *ZFS Tuning* for advice on limiting the memory available for the ZFS ARC and tuning the thresholds at which it will yield memory.

Rebooting the firewall after one of these events will return the reported memory usage to a normal level.

Not All Swap Usage is Bad

Installations containing disk partitions dedicated to swap can expand the amount of memory usable by the operating system. Using swap allows idle or unused areas of allocated memory to be relocated to disk instead of RAM. If those areas are requested again, they can be read back into RAM on demand. This is useful for ensuring processes do not run out of memory, but since it involves using disks, it is significantly slower than RAM.

Given that knowledge, one might assume that any usage of swap is bad and should be avoided at all costs, however, that is not universally true.

For example, there are daemons which run at all times but only periodically require the resources they have allocated. While the process is idle, there is little harm in allowing it to be swapped in favor of something that needs RAM at that moment, or even for caching.

Swap consumption generally only becomes a concern when there is significant usage, such as near 50% or higher. At that point it becomes necessary to inspect everything consuming memory to see what can be reduced or tuned.

Additionally, allowing the operating system to have swap space enables the ability to save kernel panic text dumps which facilitate debugging kernel problems. Without swap space to use as a dump device, the operating system will print the crash dump to the console and cannot store it anywhere.

6.5 Hardware Tuning and Troubleshooting

The underlying operating system beneath pfSense® software can be fine-tuned in several ways. A few of these tunables are available under **Advanced Options** (See *System Tunables*). Others are outlined in the FreeBSD main page tuning(7).

The default installation includes a well-rounded set of values tuned for good performance without being overly aggressive. There are cases where hardware or drivers necessitate changing values or a specific network workload requires changes to perform optimally.

The hardware sold in the Netgate Store is tuned further since Netgate has detailed knowledge of the hardware, removing the need to rely on more general assumptions.

Note: Refer to *Managing Loader Tunables* for making edits to define loader tunables persistently.

Changes in loader tunables require a firewall reboot to take effect.

6.5.1 General Issues

Filesystem Tuning

For information on tuning ZFS memory usage, see *ZFS Tuning*.

Mbuf Exhaustion

A common problem encountered by users of commodity hardware is mbuf exhaustion. To oversimplify, "mbufs" are network memory buffers; portions of RAM set aside for use by networking for moving data around.

The count of active mbufs is shown on the dashboard and is tracked by a graph under **Status > Monitoring**.

See also:

For details on mbufs and monitoring mbuf usage, see *Mbuf Clusters*.

If the firewall runs out of mbufs, it can lead to a kernel panic and reboot under certain network loads that exhaust all available network memory buffers. In certain cases this condition can also result in expected interfaces not being initialized and made available by the operating system. This is more common with NICs that use multiple queues or are otherwise optimized for performance over resource usage.

Additionally, mbuf usage increases when the firewall is using certain features such as *Limiters*.

To increase the amount of mbufs available, add the following as a *Loader Tunable*:

```
kern.ipc.nmbclusters="1000000"
```

On 64 bit systems with multiple GB of RAM, 1 million (1000000) mbuf clusters is a safe starting point. Should mbuf clusters become fully allocated, that would consume about 2.3 GB of physical memory:

```
1000000 memory buffer clusters available × (2048 KB per cluster + 256 bytes per
memory buffer)
```

The amount of available clusters can be reduced for systems with low amounts of physical RAM, or increased further as needed, as long as the value does not exceed available kernel memory.

Some network interfaces may need other similar values raised such as `kern.ipc.nmbjumbop`. In addition to the graphs mentioned above, check the output of the command `netstat -m` to verify if any areas are near exhaustion.

Disable MSIX

Message Signaled Interrupts are an alternative to classic style Interrupts for retrieving data from hardware. Some cards behave better with MSI, MSIX, or classic style Interrupts, but the card will try the best available choice (MSIX, then MSI, then Interrupts).

MSIX and MSI can be disabled via loader tunables. Add the following as *Loader Tunables*:

```
hw.pci.enable_msix="0"
hw.pci.enable_msi="0"
```

To nudge the card to use MSI, disable only MSIX. To nudge the card to use regular Interrupts, disable both MSI and MSIX.

PPPoE with Multi-Queue NICs

Tip: Before attempting this tuning, try the `if_pppoe` backend for PPPoE WANs. It is much faster and more efficient and may eliminate the need for additional tuning. For details, see *Use if_pppoe Kernel Module*.

Network cards which support multiple queues rely on hashing to assign traffic to a particular queue. This works well with IPv4/IPv6 TCP and UDP traffic, for example, but fails with other protocols such as those used for PPPoE.

This can lead to a network card under performing with the default network settings, as noted on #4821 and FreeBSD PR 203856. This problem primarily affects systems with multiple CPUs and/or CPU cores, as those are the systems which benefit most from multiple NIC queues.

Adding a **System Tunable** or *Loader Tunable* entry for `net.isr.dispatch=deferred` can lead to performance gains on affected hardware.

Tuning the values of `net.isr.maxthreads` and `net.isr.numthreads` may yield additional performance gains. Generally these are best left at default values matching the number of CPU cores, but depending on the workload may work better at lower values.

Warning: In the past, `deferred` mode has led to issues on 32-bit platforms, such as crashes/panics, especially with ALTQ. There have been no recent reports, however, so it should be safe on current releases.

TSO/LRO

The settings for **Hardware TCP Segmentation Offload** (TSO) and **Hardware Large Receive Offload** (LRO) under **System > Advanced** on the **Networking** tab default to **checked** (disabled) for good reason. Nearly all hardware/drivers have issues with these settings, and they can lead to throughput issues. Ensure the options are checked. Sometimes disabling via sysctl is also necessary.

Add the following as a *Loader Tunable*:

```
net.inet.tcp.tso="0"
```

IP Input Queue (intr_queue)

This will show the current setting:

```
sysctl net.inet.ip.intr_queue_maxlen
```

However, in largely loaded installations this may not be enough. Here is how to check:

```
sysctl net.inet.ip.intr_queue_drops
```

If the above shows values above `0`, try doubling the current value of `net.inet.ip.intr_queue_maxlen`.

For example:

```
sysctl net.inet.ip.intr_queue_maxlen="3000"
```

Keep performing the above until the point is found where drops are eliminated without any adverse effects.

Afterwards, add an entry under **System > Advanced**, **System Tunables** tab to set `net.inet.ip.intr_queue_maxlen` to `3000`

6.5.2 Card-Specific Issues

Broadcom bce(4) Cards

Several users have noted issues with certain Broadcom network cards, especially those built into Dell hardware. If `bce` interfaces are behaving erratically, dropping packets, or causing crashes, then the following tweaks may help.

Add the following as *Loader Tunables*:

```
kern.ipc.nmbclusters="1000000"
hw.bce.tso_enable="0"
hw.pci.enable_msix="0"
```

That will increase the amount of network memory buffers, disable TSO directly, and disable msix.

Packet loss with many (small) UDP packets

If a lot of packet loss is observed with UDP on bce cards, try changing the `netisr` settings. These can be set as system tunables under **System > Advanced**, on the **System Tunables** tab. On that page, add two new tunables:

```
net.isr.direct_force="1"
net.isr.direct="1"
```

Broadcom bge(4) Cards

See above, but change "bce" to "bge" in the setting names.

Chelsio cxgbe(4) Cards

Rate Limiting

By default the Chelsio driver implements rate limiting capabilies which can be undesirable for routing performance. To disable this rate limiting capability, add the following as a *Loader Tunable*:

```
hw.cxgbe.niccaps_allowed="1"
```

Resource Allocation

It is possible to disable the allocation of resources that are not related to the router so that the network adapter can use its entire set of resources for the corresponding functions:

Add the following as *Loader Tunables*:

```
hw.cxgbe.toecaps_allowed="0"
hw.cxgbe.rdmacaps_allowed="0"
hw.cxgbe.iscsicaps_allowed="0"
hw.cxgbe.fcoecaps_allowed="0"
```

Chelsio TCP Offload Engine (TOE)

There is experimental support for the Chelsio TCP Offload Engine (TOE) via the `t4_tom` kernel module. TOE offloads the entire TCP connection to hardware, but this also can cause problems with connection handling.

Warning: According to analysis of Chelsio TCP Offload Engine behavior by Calomel, under certain circumstances traffic handled by TOE bypasses the FreeBSD TCP stack and will not be filtered nor logged by pf.

Users have observed this behavior particularly when using reroot instead of a full reboot, which left services exposed.

While this feature could, in theory, reduce CPU usage for handling TCP connections, it should not be used in any role where security is a primary concern. For internal routing-only or private endpoint roles it may be acceptable.

Intel igb(4) and em(4) Cards

Certain intel igb cards, especially multi-port cards, can easily exhaust mbufs and cause kernel panics. The following tweak will prevent this from being an issue. Add the following as a *Loader Tunable*:

```
kern.ipc.nmbclusters="1000000"
```

That will increase the amount of network memory buffers, allowing the driver enough headroom for its optimal operation.

Intel ix(4) Cards

Autonegotiate Non-default Speeds

The `ix(4)` hardware may be capable of linking at non-default speeds such as 2.5G and 5G, depending on the chipset, installed SFP module, and so on. However, the driver will not autonegotiate at these speeds by default.

To negotiate at these speeds the driver must be configured to advertise them as supported rates.

This is managed using the sysctl *Runtime Tunable* OID `dev.ix.<X>.advertise_speed` where <X> is the interface number. For example, to adjust the advertised speeds of `ix3`, use `dev.ix.3.advertise_speed`. Use `sysctl -x <oid>` at the CLI to view the values in hexadecimal instead of decimal.

Table 3: `ix(4)` Driver Speed Values

Speed	Hex	Decimal
100M	0x1	1
1G	0x2	2
10G	0x4	4
10M	0x8	8
2.5G	0x10	16
5G	0x20	32

The default value of the sysctl OID varies by hardware and SFP modules. Common defaults include `0x6` (hex) or `6` (decimal) to advertise 1G and 10G, and `0xb` (hex) or `11` (decimal) to advertise 10M, 100M, and 1G.

To autonegotiate at the non-default speeds, add the value of the desired speeds to the existing value.

For example, to advertise speeds of 1G, 2.5G, 5G, and 10G, add their corresponding values: `0x2+0x10+0x20+0x4` (hex) or `2+16+32+4` (decimal) for a total of `0x36` (hex) or `54` (decimal). Values in hexadecimal must start with `0x`.

When setting the value at the CLI, the command will print an error message if the value is not valid for the interface. The tunables GUI does not currently validate the content.

General Tuning

Add the following as *Loader Tunables* if the values are not already this large, or larger:

```
kern.ipc.nmbclusters="1000000"
kern.ipc.nmbjumbop="524288"
```

As a sysctl (*Runtime Tunable*) if the value are not already this large, or larger, or set to `0` (automatic):

```
hw.intr_storm_threshold="10000"
```

VMware vmx(4) Interfaces

VMware VMXNET interfaces support multiple queues when using MSI-X. Multiple queues enable network performance to scale with the number of vCPUs and allows for parallel packet processing. Transmit and Receive descriptors may also be increased to help with throughput.

Add the following *Loader Tunables*:

Note: Some options have a separate set of tunables for each individual network interface. In these cases, replace <id> replace with the device ID such as `0`, `1`, etc. where the ID number matches the interface number. For example, tunables for `vmx3` are under `dev.vmx.3`.

```
hw.pci.honor_msi_blacklist="0"
dev.vmx.<id>.iflib.override_ntxds="0,4096"
dev.vmx.<id>.iflib.override_nrxds="0,2048,0"
```

Save the file, then reboot and check the change with `dmesg | grep -Eiw 'descriptors|queues'` at a command prompt.

Flow Control

In some circumstances, flow control may need to be disabled. The exact method depends on the hardware involved, as in the following examples:

These example entries are *Loader Tunables*:

cxgbe(4)

```
hw.cxgbe.pause_settings="0"
```

ixgbe(4) (aka ix)

```
hw.ix.flow_control="0"
```

These example entries go in **System > Advanced**, on the **System Tunables** tab (*System Tunables*):

Note: Some options have a separate set of tunables for each individual network interface. In these cases, replace <id> replace with the device ID such as 0, 1, etc. where the ID number matches the interface number. For example, tunables for igc3 are under dev.igc.3.

igc(4)

```
dev.igc.<id>.fc="0"
```

igb(4)

```
dev.igb.<id>.fc="0"
```

em(4)

```
dev.em.<id>.fc="0"
```

For ix and others, the flow control value can be further tuned:

0
No Flow Control

1
Receive Pause

2
Transmit Pause

3
Full Flow Control, Default

6.6 ZFS Tuning

ZFS on pfSense® software is much more robust than UFS and enables a variety of handy ZFS features, such as ZFS Boot Environments. Some ZFS features are not relevant on systems acting as a firewall, however. For example, ZFS can be tuned to use much less memory and sacrifice performance because filesystem performance is not as critical in a firewall role as compared to others.

Note: This is **not** a general purpose ZFS tuning guide. The suggestions in this document primarily apply to ZFS on a device acting in a firewall role. The tuning requirements for other use cases, such as for file or database servers, can be vastly different.

6.6.1 ZFS Memory Tuning

Installations utilizing ZFS may encounter higher than expected memory usage. This memory may appear as "Wired", "Cache", or "ARC" depending on how the memory usage is being checked (*Memory Management*). In each case the usage is the same, but may be reported differently. This memory is considered "Wired" because it cannot be paged out (e.g. swap) so it has the appearance of consuming large portions of memory that other things may need..

ZFS attempts to optimize performance with its Adaptive Replacement Cache (ARC) which can be aggressive in its consumption of RAM. The classic phrase *"Free RAM is wasted RAM"* also applies here, and ZFS will make good use of the memory when allowed to do so. ZFS *will* yield this RAM if other processes require more memory, but it may not give up memory fast enough for every use case. For example, if a process starts and attempts to allocate a large block of memory rapidly, and there is not sufficient free RAM or swap, then it may fail.

Tip: It's normal and OK to see a little swap usage when ARC usage is high, as items swapped are generally idle and not actively used, whereas the RAM can be put to better use caching until such time as those pages are needed.

If the swap usage is high or nearly full, however, that is likely a sign that there is too much contention for memory and if the ARC usage is also high, it likely needs tuned to a much lower maximum.

ARC Maximum/Minimum

The ARC size has default limits which allow it to consume large portions of the system RAM:

Default Maximum
: The default maximum ARC size (`vfs.zfs.arc.max`) is automatic (`0`) and uses 1/2 RAM or the total RAM minus 1GB, whichever is **greater**.

  As the default processes on pfSense software can easily consume 1GB of RAM given the opportunity, this situation can become problematic in some cases!

Default Minimum
: The default minimum ARC size (`vfs.zfs.arc.min`) is automatic (`0`) and is 1/32 of all RAM or 64M, whichever is **greater**.

To tune the **maximum**, configure a system tunable (*System Tunables*) for `vfs.zfs.arc.max` and set it to a size expressed in **bytes**.

Tip: For `X` MB RAM, use `X * 1024 * 1024`. For example, 1GB is `1073741824` bytes, 512M is `536870912`, 256M is `268435456`, 128M is `134217728`, and 64M is `67108864`.

The exact amount depends on the available resources, but to be conservative on systems with low RAM, set it to 25% of the total RAM or less.

The **minimum** rarely would need tuning, but can be lowered if necessary.

Note: The ZFS ARC limit will take effect immediately, but the OS may not free the wired memory previously used by the ARC right away. Rebooting after configuring the limits will ensure they are fully respected.

Prefetch

ZFS prefetch attempts to read more blocks than initially requested into the ARC in case they are needed in the near future. This can also cause increased ARC usage.

To disable prefetch, configure a system tunable (*System Tunables*) and set `vfs.zfs.prefetch.disable` to `1`

Free Target

The ARC Free Target is the amount of **free** RAM under which the ARC will start to give up memory. This can be awkward to calculate since it is dealing with a remaining amount, not a total, and the fact that this must be given in pages (chunks of 4096 bytes).

For example, to trigger ARC cleanup when the system hits 60% RAM usage, this number should be 40% of total RAM bytes divided by 4096.

On a system with 4GB RAM, this would be when the system has 1.6GB free. To find the equivalent pages value, calculate it with `(<percent> * <total bytes>)/<page size>`.

Tip: The page size is almost always `4096`, but check the value of `sysctl hw.pagesize` to be certain.

In this case that would be `(0.40 * (1024 * 1024 * 1024 * 4))/4096` which results in `419430` pages.

Configure a system tunable (*System Tunables*) to set `vfs.zfs.arc.free_target` to the desired number of pages (e.g. `419430`).

6.7 Console Types

There are two console types available with pfSense® software, VGA and Serial. The active default console depends on the image/installer used and configuration settings. The difference between the two console types is explained in more detail below.

6.7.1 VGA Console

The VGA (video) console is a console with a monitor and keyboard. The video console requires hardware with a connection for a monitor (e.g. HDMI, VGA) and keyboard (USB, PS/2). In some cases a serial BIOS that does VGA redirection may work.

The VGA console is active by default using the normal memstick installer or ISO.

6.7.2 Serial Console

The serial console uses a serial/COM port to communicate with a serial client. It is primarily intended for systems without a monitor or keyboard. The serial console can also be used on systems where those are either not available or not wanted, so long as the hardware has at attached (non-USB) serial port.

The serial console is active by default when installing using the *serial* memstick and may be enabled under **System > Advanced** on VGA images.

Accessing the serial console requires a null modem serial cable attached between the `COM1` port on the firewall and a serial client. A hardware serial port is required on the firewall, but the client may use a USB serial adapter if needed.

Serial clients are quite common, often pre-installed on an operating system or easily available. The free PuTTY client is the most popular GUI choice. Other choices include GNU `screen`, `tip`, `cu` and `minicom`.

See also:

See *Connect to the Console* for details on how to connect to a serial console.

The default speed of the serial port is `115200/8/N/1`. The serial port speed may be changed under **System > Advanced**.

If the device has a BIOS accessible over serial console, it is also possible that it will not be using the same serial speed that the OS is using.

The most common serial speeds to try would be: `115200`, `38400`, and `9600`.

If the BIOS serial speed does not match the OS serial speed, the best practice is to adjust one or the other to match, so that POST messages may be viewed as well as the OS messages without having to adjust the client

6.8 Connect to the Console

A connection to the console on the target hardware is a requirement to run the installer.

6.8.1 Connecting to a VGA Console

For hardware with a VGA console, this is as simple as connecting a monitor and keyboard.

6.8.2 Connecting to a Serial Console

For hardware with a serial console, the process is more involved and requires a client PC with an appropriate port and terminal software. Follow the instructions below to connect using a serial console.

The instructions in this section cover general serial console topics. Some devices, such as firewalls from the Netgate Store, require slightly different methods to connect to the serial console. For devices from the Netgate Store, visit the Netgate Documentation for model-specific serial console instructions.

Serial Console Requirements

Connecting to a serial console on most firewalls requires the correct hardware on every part of the link, including:

- The client PC must have a physical serial port or a USB-to-Serial adapter
- The firewall must have a physical serial port
- A null modem serial cable and/or adapter, or a device-specific serial cable
- A terminal program on the client, such as PuTTY
- The correct serial settings for the client software

For most of the firewalls purchased from the Netgate Store, the only hardware requirement is a USB A to Mini-B cable. See Netgate Documentation for specifics.

In addition to the proper hardware connection, a serial console client program must also be available on the client PC, and the serial speed and other settings must be available.

Locating a Serial Port (Server/Firewall)

First, ensure the firewall hardware has a serial port. To use the serial console, the hardware must have a physical serial port at `COM1`. Embedded units typically have a DB9 (9-pin) serial port, but some have an RJ45 style console connector with an adapter cable that ends with a DB9 connector.

Connect a Serial Cable

First, a null modem serial cable must be connected between the firewall and a client PC. Depending on the serial port and cable being used, a serial cable gender changer may also be necessary to match the available ports.

If a real null modem serial cable is unavailable, a null modem adapter can be used to convert a standard serial cable into a null modem cable.

If the client PC does not have a physical serial port, use a USB-to-Serial adapter.

Locate the Client Serial Port

On the client PC, the serial port device name must be determined so that the client software can be used on the correct port.

Windows

On Windows clients, a physical serial port is typically `COM1`. With a USB-to-Serial adapter, it may be `COM3`. Open **Device Manager** in Windows and expand **Ports (COM & LPT)** to find the port assignment.

macOS

On macOS, the name can be tricky for a user to determine since it can vary based several factors. On recent versions of macOS, the devices are likely to be named `/dev/cu.usbserial-<id>` where the `<id>` is an identifier for the USB serial adapter, such as a serial number.

When in doubt, run `ls -l /dev/cu.*` from a Terminal prompt to see a list of available USB serial devices and locate the appropriate one for the hardware. If there are multiple devices, the correct device is likely the one with the most recent timestamp or highest ID.

Linux

The device associated with a USB-to-Serial adapter is likely to show up as `/dev/ttyUSB0`. Look for messages about the device attaching in the system log files or by running `dmesg`.

Note: If the device does not appear in `/dev/`, check to see if the device requires additional drivers.

FreeBSD

The device associated with a USB-to-Serial adapter is likely to show up as `/dev/cuaU0`. Look for messages about the device attaching in the system log files or by running `dmesg`.

Determine Serial Console Settings

The settings for the serial port, including the speed, must be known before a client can successfully connect to a serial console.

Whichever serial client is used, ensure that it is set for the proper Speed (`115200`), Data Bits (`8`), Parity (`No`), and Stop Bits (`1`). This is typically written as `115200/8/N/1`.

Note: Some hardware defaults to a slower speed. This is relevant to the BIOS and initial output, not to pfSense® software which defaults to `115200`.

Many serial clients default to `9600/8/N/1`, so adjusting these settings is required to connect. Use `115200/8/N/1` with pfSense software regardless of the setting of the hardware/BIOS.

For hardware using BIOS serial speeds other than `115200`, change the baud rate to `115200` in the BIOS setup so the BIOS and pfSense software are both accessible with the same settings. Refer to the hardware manual for information on setting its baud rate.

`115200` is the default speed pfSense software uses out of the box, but the serial speed used by pfSense software can be changed later. See *Serial Console Speed*.

Locate a Serial Client

A serial client program must be used on the client PC. The most popular client for Windows is PuTTY, which is free and works well. PuTTY is also available for Linux and can be installed on macOS using brew. On UNIX and UNIX-Like operating systems, the `screen` program is readily available or easily installed and it can also be used to connect to serial ports from a terminal program or system console.

Windows

PuTTY is the most popular free choice for serial communication on Windows. SecureCRT is another client that works well.

Warning: Do not use Hyperterminal. Even if it is already present on the client PC, it is unreliable and prone to formatting incorrectly and losing data.

macOS

On macOS clients, the GNU `screen` utility is the easiest and most common choice. ZTerm and `cu` (similar to FreeBSD) can be used as well.

Linux

On Linux clients, the GNU `screen` utility is the easiest and most common choice. Programs such as PuTTY, `minicom`, or `dterm` can be used as well.

FreeBSD

On FreeBSD clients, the GNU `screen` utility is the easiest and most common choice.

As an alternative, use the built-in program `tip`. Typing `tip com1` (Or `tip ucom1` if using a USB serial adapter) will connect to the first serial port. Disconnect by typing `~.` at the start of a line.

Start a Serial Client

Now that all of the requirements have been met, it is time to run the serial client.

If the client software is not covered in this section, consult its documentation to determine how to make a serial connection.

PuTTY

- Start PuTTY
- Select *Serial* for the **Connection Type**
- Enter the serial port device name for **Serial Line**, e.g. `COM3` or `/dev/ttyUSB0`.
- Enter the appropriate **Speed**, e.g. `115200`
- Click **Open**

MINICOM

```
$ minicom -D /dev/ttyUSB0 -R 115200
```

GNU screen

- Open a terminal / command prompt
- Invoke the `screen` command using the path to the serial port, for example:

```
$ sudo screen /dev/ttyUSB0 115200
```

In some cases there may be a terminal encoding mismatch. If this happens, run `screen` in UTF-8 mode:

```
$ sudo screen -U /dev/cu.usbserial-1234 115200
```

The standard screen controls apply. Press `Ctrl-A`, \ to quit, or `Ctrl-A`, `Ctrl-\` in some cases.

tip

The `tip` command on FreeBSD consults `/etc/remotes` and connects to serial ports based on the settings there. To setup a connection to a USB-to-serial adapter at `115200`, add a line such as the following to `/etc/remote`:

```
ucom1fast:dv=/dev/cuaU0:br#115200:pa=none:
```

To access the port, invoke `tip`:

```
$ tip ucom1fast
```

To quit, press **Enter**, then type `~.`. If connected through a terminal ssh client, `~~.` may need to be used instead so that the ssh client itself doesn't interpret the keys.

6.9 Cryptographic Accelerator Support

Cryptographic acceleration is available on some platforms, typically on hardware that has it available in the CPU like AES-NI, or built into the board such as the ones used on Netgate ARM-based systems. Most cryptographic accelerator hardware supported by FreeBSD will work, provided the drivers are in the kernel or available as loadable modules.

Note: Some modules and hardware are only supported by pfSense® Plus software.

6.9.1 Supported Devices

Currently supported cryptographic accelerator devices include:

AES-NI
: Supported natively by most modern CPUs.

IPsec Multi-Buffer (IPsec-MB, IIMB) Cryptographic Acceleration [Plus only]
: The Intel® Multi-Buffer Crypto for IPsec Library, often shortened to IPsec-MB or IIMB.

  IPsec-MB assists VPN performance by replacing the cryptographic functions provided by the kernel for AES-CBC, AES-GCM, and ChaCha20-Poly1305 with accelerated functions that utilize the optimal CPU SIMD instruction set (Single Instruction, Multiple Data), such as SSE, AVX, AVX2, and AVX512 (Advanced Vector Extensions). As such, this feature requires a CPU which supports one or more of these features, but they are common on current hardware.

  This offers faster speeds and lower CPU utilization not only for IPsec but for any VPN utilizing the accelerated algorithms in the kernel. In addition to IPsec this also includes OpenVPN DCO and WireGuard. Exact performance varies by hardware, workload, and available CPU instruction sets. IPsec-MB is faster than AES-NI and can even meet or exceed the performance of dedicated acceleration hardware such as QAT on current versions of pfSense software.

  IPsec-MB can be loaded alongside other cryptographic modules without conflicting, so it is separate from the other options. That said, when it is enabled it will take over acceleration of all its supported algorithms even if other options could potentially be faster (e.g. QAT).

There are several aspects of IPsec-MB behavior which can be fine-tuned. See *Tuning IPsec-MB* for details.

Intel QuickAssist Technology (QAT) [Plus only]
Intel QuickAssist Technology (QAT) accelerates many types of AES and SHA operations, such as AES-GCM encryption, and QAT is ideal for use with IPsec and OpenVPN DCO. It is currently the fastest acceleration option for the algorithms it supports.

QAT devices are supported on certain Intel-based platforms such as select models of c3000 and c2000 SoCs, and also by QAT add-on cards. Several Netgate hardware models include QAT devices, such as the 4100, 5100, 6100, 7100, 8200, and more.

CESA [Plus only]
Present on some ARM platforms such as the Netgate 3100.

SafeXcel [Plus only]
Present on some ARM platforms such as the Netgate 2100 and 1100.

Note: For specifics on which hardware accelerators are available on Netgate hardware, and relevant performance data, visit the Netgate Store.

6.9.2 Activating the Hardware

Some hardware acceleration is active at all times and there is no way to disable it short of removing the crypto card if it is a hardware add-on. For example, CESA acceleration cannot be disabled because it's an integrated feature of the system and the drivers are present the kernel.

Others, such as QAT, IPsec-MB, AES-NI, or SafeXcel require choosing the appropriate module under **System > Advanced** on the **Miscellaneous** tab (See *Cryptographic & Thermal Hardware*). Choose the appropriate module to match the hardware for **Cryptographic Hardware** and then Save. The module will be loaded and available immediately.

To deactivate a loaded module, select *None* for **Cryptographic Hardware**, Save, and then reboot the system.

6.9.3 Confirming Accelerator Use

Confirming that the cryptographic acceleration device is being used by the firewall can be tricky, depending on the hardware in question.

Most often the evidence of cryptographic accelerator use is apparent in one or more of the following observations:

- Increased VPN throughput
- Decreased system load (e.g. CPU utilization) for similar levels of VPN throughput

In cases where it is not clear, some cryptographic accelerators show signs of use by checking for interrupt activity on the device using `vmstat -i | grep <name>`, where `<name>` corresponds to the name of the device:

QAT
Use the shell command `vmstat -i | grep qat`

CESA
Use the shell command `vmstat -i | grep cesa`

SafeXcel
Use the shell command `vmstat -i | grep safexcel`

In each of these cases, first check that there is any output at all. If the device has not been used at all since the firewall last rebooted or loaded the device driver, there will be no output from the command.

Note: To see if the driver is loaded, check `kldstat -v | grep <name>` to ensure the driver is present, and check `dmesg | grep <name>` to see if the device was detected.

If there is output from `vmstat -i` for the device, check the third entry on the line, which is the total number of interrupts observed on the device(s). If this number is increasing with VPN activity, the device is being used by the firewall. For example:

```
# vmstat -i | grep qat
irq300: qat0                       5481147          3
```

In that output the `5481147` number represents the number of interrupts on the `qat0` device. Run the command again after transferring data across the VPN, and compare the number.

Note: If the command produces no output at all, the device is not being used or the device driver is not loaded.

6.9.4 Practical Use

IPsec

IPsec will take advantage of acceleration automatically when an active accelerator supports the cipher chosen for a tunnel. For QAT and AES-NI, the optimal cipher choice is AES-GCM.

OpenVPN

To take advantage of acceleration in OpenVPN, choose a cipher which is supported by the available acceleration hardware, such as AES-256-GCM.

When using OpenVPN in DCO mode on pfSense Plus software, OpenVPN can use QAT or IPsec-MB to accelerate its encryption automatically, assuming the features are enabled (QAT and/or IPsec-MB modules are loaded and active on supported hardware). If the hardware does not support QAT or IPsec-MB, but it does support AES-NI, then ensure the AES-NI module is **loaded** or DCO mode cannot use AES-NI.

See also:

DCO and Hardware Cryptographic Acceleration

In non-DCO mode, such as on pfSense CE, nothing needs selected for OpenVPN to utilize AES-NI. The OpenSSL engine has its own code for handling AES-NI in this mode that works well without using additional modules.

6.9.5 Tuning IPsec-MB

The behavior of IPsec-MB can be tuned by using one of several system tunables configurable on the *System Tunables*:

kern.crypto.iimb.enable_aescbc
Enables handling of AES-CBC. IIMB can be slower than QAT for CBC so this is a toggle to disable handling for AES-CBC while accelerating other algorithms so IPsec-MB and QAT can coexist in such environments. Supported on x86-64 only.

Default is enabled (`1`). To disable, set a value of `0`.

kern.crypto.iimb.enable_multiq
Uses multiple queues to handle encryption jobs, i.e. each session is bound to a job thread. There are only a small number of job threads available:

- 1 thread for < 4 CPUs
- 2 threads for < 8 CPUs
- 4 threads for >= 8 CPUs

Default is `1`.

kern.crypto.iimb.use_task (default 0)
Use a separate taskq for running the encryption job completion callbacks. The callbacks are functions in the VPN code that send the packets onto the next step, e.g. ip_output or netisr_queue for input into the local stack. This option helps on high-performance systems (fast CPU, fast NICs).

Default is disabled (`0`). To enable, set a value of `1`.

Developer Tunables

The following tunables are typically only needed during development or debugging:

kern.crypto.iimb.arch
Used to override the SIMD architecture on x86. By default it uses the best one available on the CPU. This option allows comparing different CPU feature benchmarks.

Options: `auto` (default), `sse`, `avx`, `avx2`, `avx512`.

kern.crypto.iimb.prefetch
Pre-fetch encryption keys before calling the crypto function, this might help with micro-performance, but thus far has not led to any significant measurable differences.

Default is enabled (`1`). To disable, set a value of `0`.

kern.crypto.iimb.max_jobs
Maximum number of batched jobs. The IIMB thread will collect up to this many jobs and handle them in a batch. Maximum is `256`, but it can be tuned to be smaller. Limited to `256` because thus far developers have not seen larger values lead to any significant measurable differences in performance, because it adds latency to the network stack.

Default value is `256`.

6.10 Disabling Sounds/Beeps

Some hardware has a PC Speaker which can be used as a means of notification. By default, the firewall will play a tone at startup/shutdown and will emit a beep when a user logs into the GUI. Additionally, some packages are capable of producing beeps for events.

6.10.1 Disable Startup/Shutdown Tune

The startup and shutdown tunes may be disabled as follows:

- Navigate to **System > Advanced**, **Notifications** tab
- Check **Disable the startup/shutdown beep**
- Click **Save**

6.10.2 Disable Login Beep

The GUI login beep happens because the GUI login event is recorded by syslog under the LOG_AUTH facility. Messages in this facility trigger the operating system to generate a beep. To disable the beep, the GUI login messages must be suppressed as follows:

- Navigate to **System > Advanced**, **Admin Access** tab
- Check **Disable logging of webConfigurator successful logins**
- Click **Save**

6.10.3 Disable All Sounds

As an alternative, the system bell may be disabled globally:

- Navigate to **System > Advanced**, **System Tunables** tab
- Click  to create a new tunable entry using the following values:

  Tunable
  `kern.vt.enable_bell`

  Description
  `Control system sounds`

  Value
  `0`

- Click **Save**

The pfSense® software distribution is compatible with most hardware supported by FreeBSD.

Current versions of pfSense software are compatible with 64-bit (amd64, x86-64) architecture hardware and Netgate ARM-based firewalls.

Alternate hardware architectures such as Raspberry Pi, other Non-Netgate ARM devices, PowerPC, MIPS, SPARC, etc. are not supported.

6.11 Hardware Compatibility

The best way to ensure that hardware is compatible with pfSense software is to buy hardware from the Netgate Store that has been tested and known to work well with pfSense software. The hardware in the store is tested with each release of pfSense software and is tuned for optimal performance.

For home-built solutions, the FreeBSD Hardware Notes for the FreeBSD version used in a given build of pfSense software is the best resource for determining hardware compatibility. pfSense software version 2.8.0-RELEASE is based on 15.0-CURRENT@bf06074106cf. Another good resource is the Hardware section of the FreeBSD FAQ.

6.11.1 Network Adapters

A wide variety of wired Ethernet Network Interface Cards (NICs) are supported by FreeBSD, and are thus compatible with pfSense software. However, not all NICs are created equal. The hardware can vary greatly in quality from one manufacturer to another.

The best practice is to use Intel NICs because they have solid driver support in FreeBSD and they perform well. Most hardware sold in the Netgate Store contains Intel NICs.

Of the various other PCIe/PCI cards supported by FreeBSD, some work fine, others may suffer from instability or poor performance. In some cases, FreeBSD may support a particular NIC but specific implementations of the chipset may be lower in quality or have poor driver support. When in doubt, search the Netgate Forum for experiences of others using the same or similar hardware.

When a firewall requires the use of VLANs, select adapters that support VLAN processing in hardware. This is discussed in *Virtual LANs (VLANs)*.

USB Network Adapters

USB network adapters of any make/model should not be used due to their unreliability and poor performance.

Wireless Adapters

Supported wireless adapters and recommendations are covered in *Wireless*.

CHAPTER

SEVEN

INSTALLING AND UPGRADING

Hardware from the Netgate Store is pre-loaded with pfSense® Plus software. To reinstall pfSense Plus software or to install pfSense Plus software or pfSense CE software to other hardware, download the Netgate Installer.

> **Warning:** Hardware pre-loaded with pfSense software from commercial vendors other than the Netgate Store or authorized partners must not be trusted. Third parties may have made unauthorized, unknown alterations or additions to the software. Selling pre-loaded copies of pfSense software is a violation of the Trademark Usage Guidelines.
>
> If pfSense software was pre-loaded on third party hardware by a vendor, wipe the system and reinstall it with a genuine copy.

See also:

If something goes wrong during the installation process, see *Troubleshooting Installation Issues*.

This chapter also covers upgrading pfSense software installations (*Upgrade Guide*) which keeps them up-to-date with the latest security, bug fixes, and new features. This includes the new ability to *Migrate from pfSense® CE software to Netgate pfSense Plus software*.

7.1 Netgate Installer

The Netgate Installer is the current supported method for installing pfSense® software on all devices.

The Netgate Installer image does not contain installation packages for pfSense software, it fetches them over the Internet. This allows a single installer to offer choices between multiple versions of pfSense software without needing to package them all into a gigantic single disk image or multiple separate images. This also means that when installing, the target device always receives the most up-to-date versions of available components. This offers a consistent experience no matter which type of device is the target.

> **Warning:** This installer checks if a system is eligible to access pfSense Plus software before proceeding. If a system is ineligible, the user can either follow the directions to become eligible or install pfSense CE Software instead.

See also:

For a full walkthrough of the installation process using the Netgate Installer, see *Perform the Installation*.

7.1.1 Limitations

The Netgate Installer has the following known limitations at this time:

- Limited support for PPP-based WANs

  The installer supports PPPoE, but it does not support other PPP types such as L2TP, PPTP, and PPP (e.g. 4G Cellular).

- No support for 32-bit ARM devices.

7.2 Download Installation Media

Installation images can be downloaded from the Netgate Store at https://shop.netgate.com/products/netgate-installer using a Netgate Store Account.

Note: The installer is free but uses the Netgate Store to handle the download process.

There are three installation images to support different types of hardware:

- AMD64 Memstick (Serial and VGA) for installing via USB media
- AMD64 ISO image for installing via IPMI or optical drive
- AARCH64 Memstick for installing on 64-bit ARM devices from Netgate, such as the Netgate 1100 and Netgate 2100.

Note: Customers who have purchased firewalls pre-loaded with pfSense Plus software from the Netgate Store already have a Netgate Store Account and access to the Netgate Installer. The Netgate Product Manuals contain specific instructions for each model.

Some Netgate devices can also run Community Edition, but pfSense Plus software offers the best user experience.

For other hardware, continue reading.

- Navigate to the Netgate Store in a web browser on a client device.
- Login using the Netgate Store Account
- Navigate to https://shop.netgate.com/products/netgate-installer
- Select an **Installation Image**:

  AMD64 Memstick USB
  : For 64-bit x86-64 Intel or AMD hardware to install via USB. This is the correct choice for most Netgate hardware and most third party hardware. This installer works with both serial and VGA consoles. Automatically detects known hardware which uses alternate serial console ports (e.g. Netgate 4200, ADI devices).

  AMD64 ISO
  : For 64-bit x86-64 Intel or AMD hardware to install via physical or virtual optical drive. This image works well for installing via IPMI and for virtual machines. This installer works with both serial and VGA consoles and like the memstick image, automatically adjusts the console settings to match known devices.

  AARCH64 Memstick ARM
  : For 64-bit ARM devices from Netgate, such as the Netgate 1100 and Netgate 2100.

- Click **Add To Cart**

  The installer is free, but uses the checkout process for delivery.

- Click **Enter Cart**
- Complete the checkout process and download the installation image.

> **Warning:** Be aware that Safari on macOS will, by default, automatically decompress downloaded files. This will make validating the integrity of the downloaded file impossible as the hashes are made against the compressed versions of the files. Disable this feature before proceeding or use an alternative browser.

See also:

Troubleshooting Installation Issues.

7.2.1 Verifying the integrity of the download

The integrity of the installer image can be verified by comparing a computed hash value of the original downloaded compressed file against a hash computed by Netgate when the files were created. The current hashes use SHA-256.

The pfSense Plus Installer Checksums page contains the SHA-256 sum of each current installer image. This is isolated from the image download for extra security. This file is plain text and can be opened in a text editor or viewed in a web browser.

Use the accompanying SHA-256 sum from the checksums page to verify that the download successfully completed and is an official release of pfSense software.

> **Warning:** The SHA-256 sums are computed against the compressed versions of the downloaded files. Compare the hash *before* decompressing the file.
>
> Safari on macOS will decompress files when downloading by default, making this validation impossible. Disable this feature before downloading or use an alternative browser.

Hash calculation programs vary by operating system, some common examples include:

Windows

PowerShell has a built-in cmdlet `Get-FileHash` which can compute file hashes easily without needing to install additional software.

Example:

```
PS> Get-FileHash -Algorithm SHA256 .\netgate-installer-amd64.img.gz
Algorithm       Hash                                                   [...]
---------       ----
SHA256          0FEC506A48DE95A698F4DFE531018E1D7F847E440DA64E5482A6EEAC965F6B40
```

The SHA256 hash in the output can be compared with the value in the **contents** of the pfSense Plus Installer Checksums page.

Note: It is also possible to use the Linux `sha256sum` command within Windows Subsystem for Linux, Cygwin, or similar mechanisms.

Alternately, use a GUI-based hash calculation program such as OpenHashTab to compare the value against the provided hash. With OpenHashTab installed, right click on the downloaded file to access the **File Hashes** tab containing the **SHA256** hash, among others.

Tip: If a SHA256 hash is not displayed, right click in the hash view and click **Settings**, then check the box for **SHA256** and click **OK**.

---

macOS

Use the `shasum` command line utility to generate a hash of the downloaded file.

Example:

```
$ shasum -a 256 netgate-installer-amd64.img.gz
0fec506a48de95a698f4dfe531018e1d7f847e440da64e5482a6eeac965f6b40  netgate-installer-
↪amd64.img.gz
```

The generated SHA256 hash can be compared with the contents of the pfSense Plus Installer Checksums page.

Linux

Use the `sha256sum` command line utility to generate a hash of the downloaded file.

Example:

```
$ sha256sum netgate-installer-amd64.img.gz
0fec506a48de95a698f4dfe531018e1d7f847e440da64e5482a6eeac965f6b40  netgate-installer-
↪amd64.img.gz
```

The generated SHA256 hash can be compared with the contents of the pfSense Plus Installer Checksums page.

FreeBSD

Use the `sha256` command line utility to generate a hash of the downloaded file.

Example:

```
$ sha256 netgate-installer-amd64.img.gz
SHA256 (netgate-installer-amd64.img.gz) =␣
↪0fec506a48de95a698f4dfe531018e1d7f847e440da64e5482a6eeac965f6b40
```

The generated SHA256 hash can be compared with the contents of the pfSense Plus Installer Checksums page.

7.3 Prepare Installation Media

The installation image downloaded in the previous section must first be transferred to the proper media. The files cannot be copied to media directly, but must be written using appropriate tools.

The primary difference between the USB memstick and ISO image is in how the images are written to an installation disk. Both types of images install pfSense® software to a target disk. Another difference is between the console types for the different USB memstick images. After installation, they each retain their appropriate console settings.

7.3.1 Decompress the Installation Media

The installation disk image is compressed when downloaded to save bandwidth and storage. Decompress the file before writing this image to an installation disk.

The `.gz` extension on the file indicates that the file is compressed with `gzip`. The image can be decompressed on Windows using 7-Zip, or on BSD/Linux/Mac with the `gunzip` or `gzip -d` commands.

7.3.2 Writing the Install Media

Creating an installation disk requires a different procedure depending on the type of media. Follow the instructions in the appropriate section for the chosen media type.

Prepare a USB Memstick

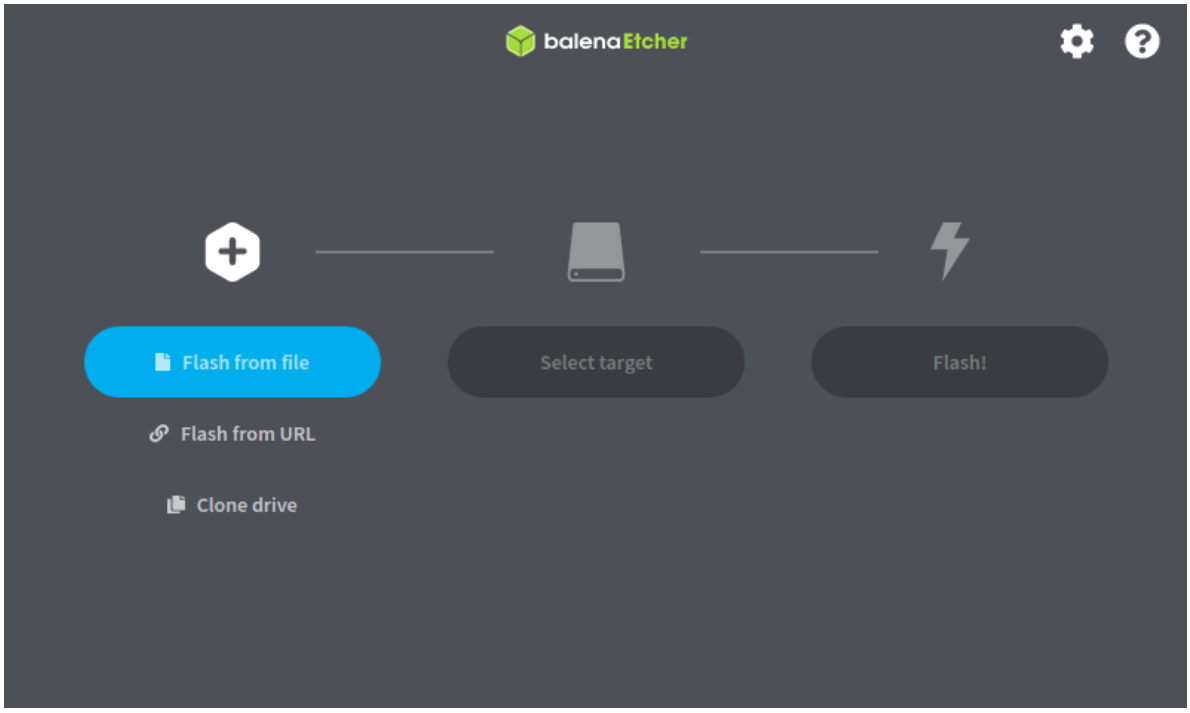
Warning: Be extremely careful when writing pfSense® software installation images! If the client PC contains other hard drives it is possible to select the wrong drive and overwrite a portion of that drive with the installer disk. This renders the disk completely unreadable except to certain disk recovery programs, if at all.

Using Etcher

The easiest way to create bootable installation media is to use Etcher. Etcher is available on Windows, macOS, and Linux so the procedure to write an image is the same across each supported platform. Etcher is simple to use, supports compressed image files, and has several features which help prevent users from making unintentional mistakes in the process such as selecting the wrong target drive. Additionally, unlike other methods there is no need to perform other steps before writing the image to prepare the image file or disk.

- Download and install Etcher from https://www.balena.io/etcher/
- Insert a USB flash drive into the client computer
- Start Etcher

  Etcher will display its main screen as shown in the following image:

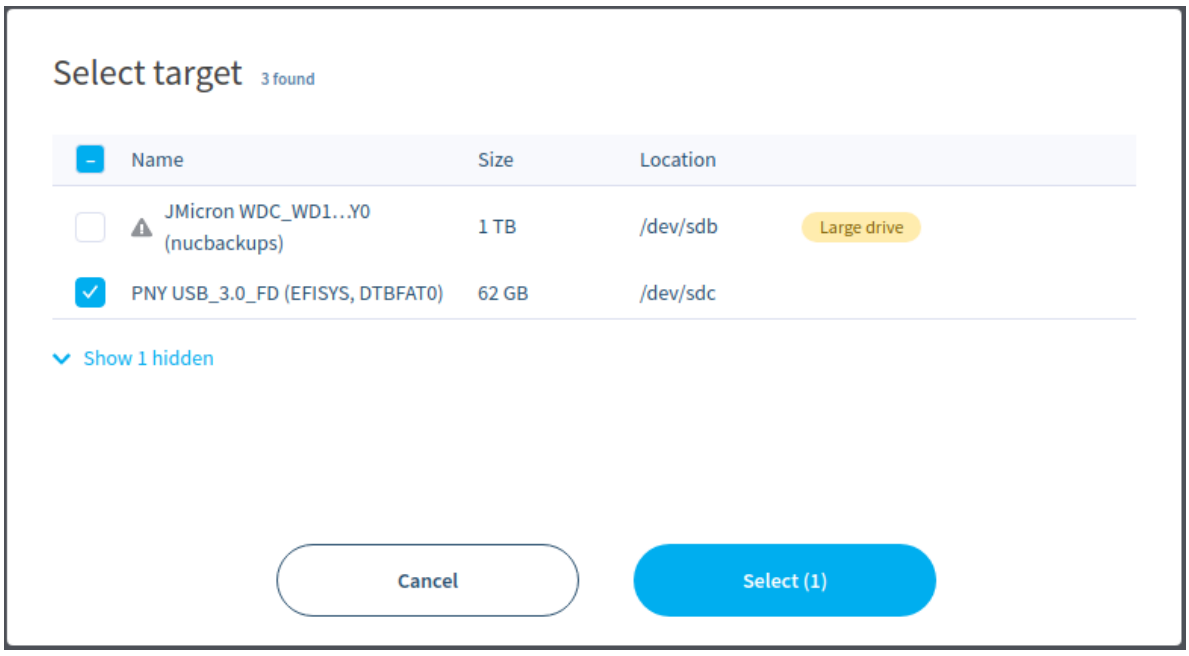


- Click **Flash from file**
- Locate and select the installation image file

Tip: Etcher can use compressed images directly, there is no need to manually decompress the image file first.

- Click **Select target**
- Click the USB flash drive to which Etcher should write the image

Note: Etcher attempts to hide and/or visibly mark potentially dangerous selections such as system drives, the drive containing the source image, and large drives. This makes it easier to identify the correct selection.



- Click **Select (1)** to continue
- Click **Flash!** to write the image to the target USB flash drive

  At this point there may be an authentication or UAC prompt to continue.

Note: Etcher requires elevated privileges to write USB drives. In the majority of cases, Etcher will trigger an operating system prompt for additional privileges as needed. If it does not, re-run Etcher as an administrator explicitly.

- Wait for the flash process to complete

  If there is an error from Etcher, try another USB flash drive or follow the advice given within Etcher to resolve the problem.

Warning: After writing the drive, the installation media will contain partitions which cannot be read by most operating systems. Ignore any operating system warnings about failing to mount the drive or prompts to format the drive.

- Close Etcher when complete
- Remove the USB flash drive from the client system

The installation media is now ready to use. Proceed to the installation instructions for the operating system.

Alternate Methods

For other techniques and additional guidance on writing disk images, see the reference document Writing an Installation Image to Flash Media.

Prepare a DVD

To use an ISO image file containing pfSense® software with an optical disk drive, the ISO image must be burned to a DVD disc by appropriate writing software.

Since the ISO image is a full-disc image, it must be burned appropriately for image files **not** as a data DVD containing the single ISO file. Burning procedures vary by OS and available software.

Decompress the ISO Image

Before the image can be burned, it must be decompressed. The `.gz` extension on the file indicates that it is compressed with `gzip`. This can be decompressed on Windows using 7-Zip, or on BSD/Linux/Mac with the `gunzip` or `gzip -d` commands.

Burn the DVD

Burning in Windows

Windows 7 and later include the ability to burn ISO images without extra software. On top of that, virtually every major DVD burning software package for Windows includes the ability to burn ISO images. Refer to the documentation for the DVD burning program. A Google search with the name of the burning software and `burn iso` also helps locate instructions.

Burning with Windows

To burn a disc image in Windows 7 or later:

- Open Windows Explorer and locate the decompressed ISO image file
- Right click the ISO image file
- Click **Burn disc image**
- Select the appropriate **Disc burner** drive from the drop-down list
- Insert a blank DVD disc
- Click **Burn**

Later versions such as Windows 10 also show a **Disc Image Tools** tab on the ribbon when an ISO image is selected in Windows Explorer. That tab has a **Burn** icon that also invokes the same disc burning interface.

Other Free Burning Software

Other free options for Windows users include ISO Recorder, CDBurnerXP, InfraRecorder and ImgBurn. Before downloading and installing any program, check its feature list to make sure it is capable of burning an ISO image.

Burning in Linux

Linux distributions such as Ubuntu typically include a GUI DVD burning application that can handle ISO images.

If a DVD burning application is integrated with the window manager, try one of the following:

- Right click on the decompressed ISO image file
- Choose **Open With**
- Choose **Disk image writer**

Or:

- Right click on the decompressed ISO image file
- Choose **Write disc to**

Other popular applications include K3B and Brasero Disc Burner.

If a GUI burning program is not available, it may be possible to burn from the command line.

First, determine the burning device's SCSI ID/LUN (Logical Unit Number) with the following command:

```
$ cdrecord --scanbus
scsibus6:
     6,0,0   600) 'TSSTcorp' 'CDDVDW SE-S084C ' 'TU00' Removable CD-ROM
```

Note the SCSI ID/LUN is `6,0,0` in this example.

Burn the image as in the following example, replacing `<max speed>` with the speed of the burner (e.g. `24`) and `<lun>` with the SCSI ID/LUN of the recorder:

```
$ sudo cdrecord --dev=<lun> --speed=<max speed> netgate-installer-amd64.iso
```

Burning in FreeBSD

FreeBSD can use the same `cdrecord` options as Linux above by installing `sysutils/cdrtools` from ports or packages, and can also use GUI applications such as K3B or Brasero Disc Burner if they are installed from ports.

See also:

For more information on creating DVDs in FreeBSD, see the DVD burning entry in the FreeBSD Handbook.

Verify the Disc Content

After writing the disc, verify it was burned properly by viewing the files on the disc. More than 20 folders should be visible, including `bin`, `boot`, `cf`, `conf`, and more. If only one large ISO file is visible, the disc was not burned properly. Repeat the burning steps listed earlier and be sure to burn the ISO file as a DVD image and **not** as a data file.

7.4 Perform the Installation

This section describes the process of installing pfSense® software to a target drive, such as an SSD or HDD. In a nutshell, this involves booting from the installation memstick, ISO, or optical disc and then completing the installer.

This procedure uses the *Netgate Installer*.

Note: If the installer encounters an error while trying to boot or install from the installation media, see *Troubleshooting Installation Issues*.

7.4.1 Prerequisites

The following items are requirements to run the installer:

- *Download Installation Media*
- *Prepare Installation Media*
- *Connect to the Console*
- A network connection capable of reaching the Internet

  This installer is an online installer and requires Internet connectivity to download installation data from Netgate servers. Currently the installer supports DHCP, static IP address, and PPPoE configurations. Connect the WAN port of the device into a live network connection supporting one of those connectivity types.

See also:

Virtual environments may have additional requirements, see the following documents for examples:

- *Virtualizing with Proxmox® VE*
- *Virtualizing pfSense Software with Hyper-V*
- *Virtualizing pfSense Software with VMware vSphere / ESXi*

See also:

Hangouts Archive also covers a variety of relevant topics.

7.4.2 Booting the Install Media

For USB memstick installations, insert the USB memstick and then power on the target system. The BIOS may require the disk to be inserted before the hardware boots.

For DVD installations, power on the hardware then place the CD into an optical drive.

Certain systems may need to be nudged to boot from the installer image in different ways. Typically this involves hitting a hotkey during boot to bring up a boot menu, going into the BIOS to pick a boot device, or invoking a special command from a BIOS prompt.

Consult the Netgate Product Manuals for information on booting install media on various Netgate hardware. For third party hardware, check with the OEM.

Once the device boots from the install media, the installer will launch automatically.

Specifying Boot Order in BIOS

If the target system will not boot from the USB memstick or CD, the most likely reason is that the given device was not found early enough in the list of boot media in the BIOS. Many newer motherboards support a one time boot menu invoked by pressing a key during POST, commonly `Esc` or `F12`.

Failing that, change the boot order in the BIOS. First, power on the hardware and enter the BIOS setup. The boot order option is typically found under a **Boot** or **Boot Priority** heading, but it could be anywhere. If support for booting from a USB or optical drive is not enabled, or has a lower priority than booting from a hard drive containing another OS, the hardware will not boot from the installer media. Consult the motherboard manual for more detailed information on altering the boot order.

7.4.3 Installing to the Target Drive

Serial Console Terminal Type

For installations using a serial console connection, the first prompt will ask for the terminal type to use for the installer. For PuTTY or GNU screen, `xterm` is the best type to use. The following terminal types can be used:

ansi
: Generic terminal with color coding

vt100
: Generic terminal without color, most basic/compatible option, select if no others work

xterm
: X terminal window. For modern terminal clients such as GNU screen, PuTTY, SecureCRT, Tabby, and other similar clients the `xterm` choice is most likely to produce the best looking output.

cons25w
: FreeBSD console style terminal

The installer assumes `cons25w` for VGA consoles.

Navigating the Installer

Once the installer launches, navigating its screens works as follows:

- To select items, use the arrow keys to move the selection focus until the desired item is highlighted.
- For installer screens containing a list, use the `up` and `down` arrow keys to highlight **entries** in the list.
- Use the `left` and `right` arrow keys to highlight an **action** button at the bottom of the screen such as **Select** and **Cancel**.
- Pressing `Enter` activates the selected action on the selected entry.

Performing the Installation

The installer contents are the same for both console types. The following document walks through the installation process in its entirety.

Installation Walkthrough

License Screen

When the installer starts the first screen it presents offers license terms for pfSense® software which the user must accept before installation.

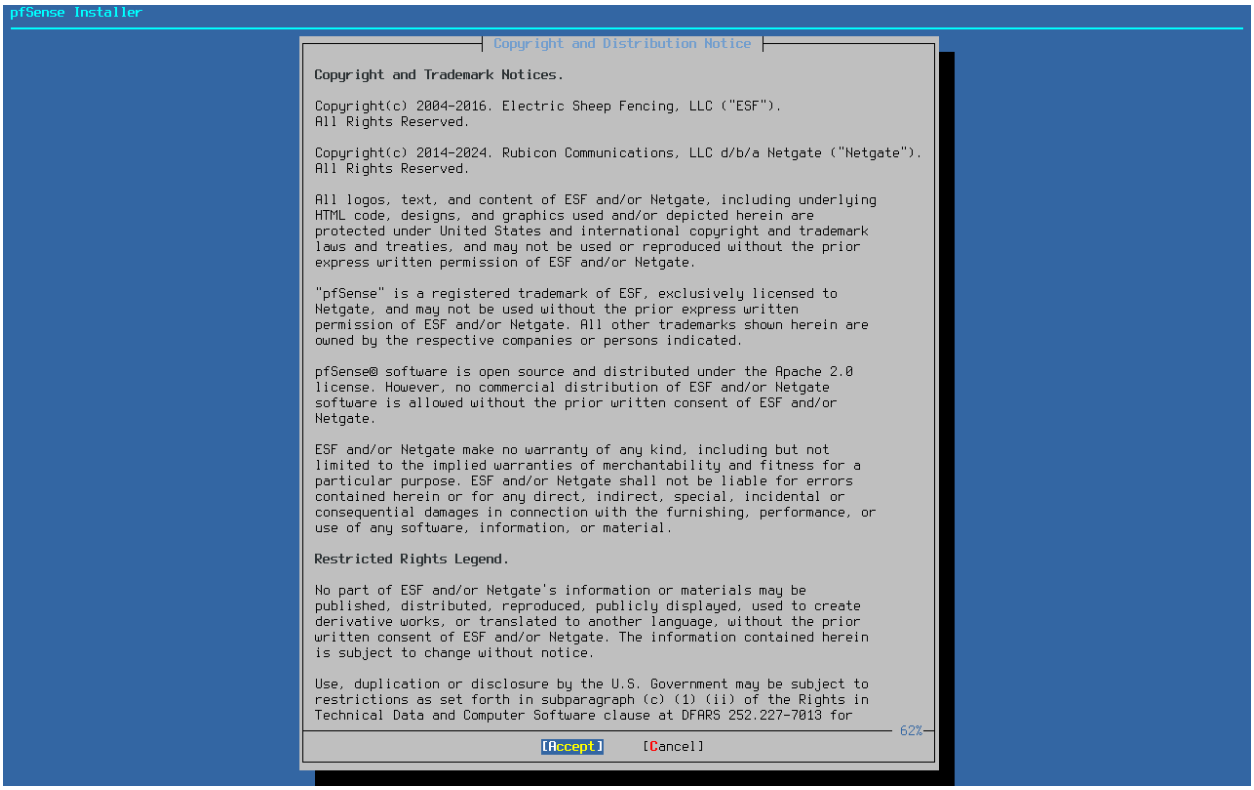


Fig. 1: Installer License

Read the terms carefully. Use the Page Down and Page Up keys to display additional license text. Press `Enter` to **Accept** the terms and proceed.

Welcome Menu

Next, the installer prompts to launch rescue options or start the **Install** process.

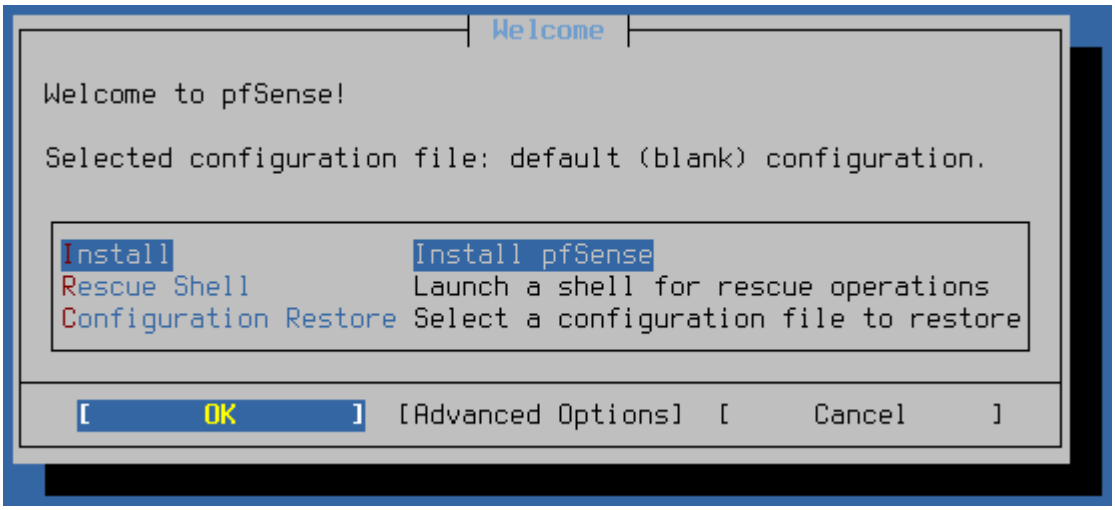

Fig. 2: Welcome Menu

Use the arrow keys to select an option, then press `Enter`. The options on this screen are:

Install
: Continue installing pfSense software

Rescue Shell
: Starts a basic shell prompt where advanced users can perform tasks to prepare the hardware in ways not fully supported by the installer, or to perform diagnostic tests or repairs on the firewall.

Configuration Restore
: Attempts to restore a configuration file recovered from a prior installation or copied from other media and then use that configuration in the target installation.

  The installer will hide this menu option if it cannot locate any configurations to restore.

  See *Configuration Restore* for details.

Advanced Options
: This option is in the bottom row of buttons. It loads another menu which contains extra options to control the behavior of the installer.

  See *Advanced Options* for details.

Configuration Restore

The installer searches for available configurations to recover and use for the target installation. This can be an existing prior installation of pfSense software or a configuration file on a FAT/FAT32 partition on a USB drive. The installer lists every configuration file it can locate and offers the user a choice of which to use, or to proceed without recovering a configuration.

Tip: When restoring a configuration from a prior installation, this option also searches for and copies SSH host keys and DHCP lease data to the new installation.

To recover a configuration and copy it to the target installation, use the arrow keys to select it from the list and press the `Enter` key.

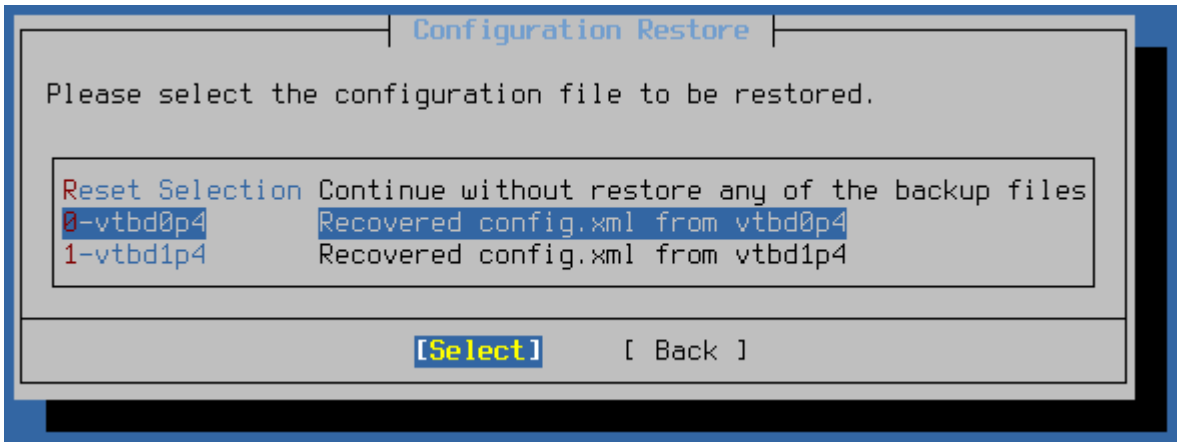

Fig. 3: Configuration Restore - List of Configuration Files

After selecting a configuration to restore, the installer displays this choice on the welcome screen:

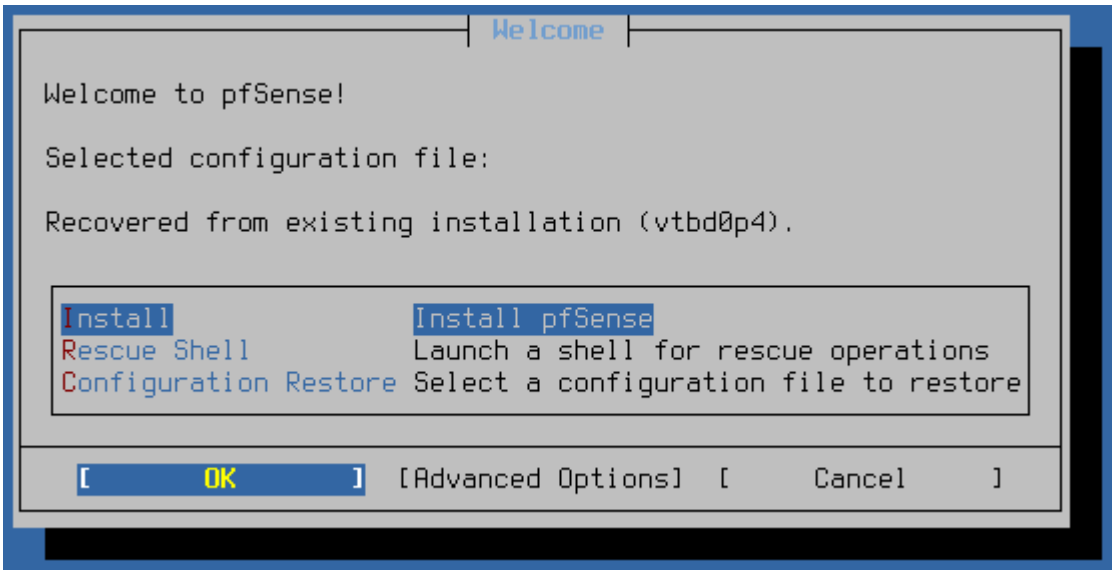

Fig. 4: Configuration Restore - Selected Configuration

To deselect the configuration file and proceed with a default configuration instead, enter the **Configuration Restore** menu again and choose **Reset Selection**.

Advanced Options

The options on the **Advanced Options** menu fine-tune the target installation.

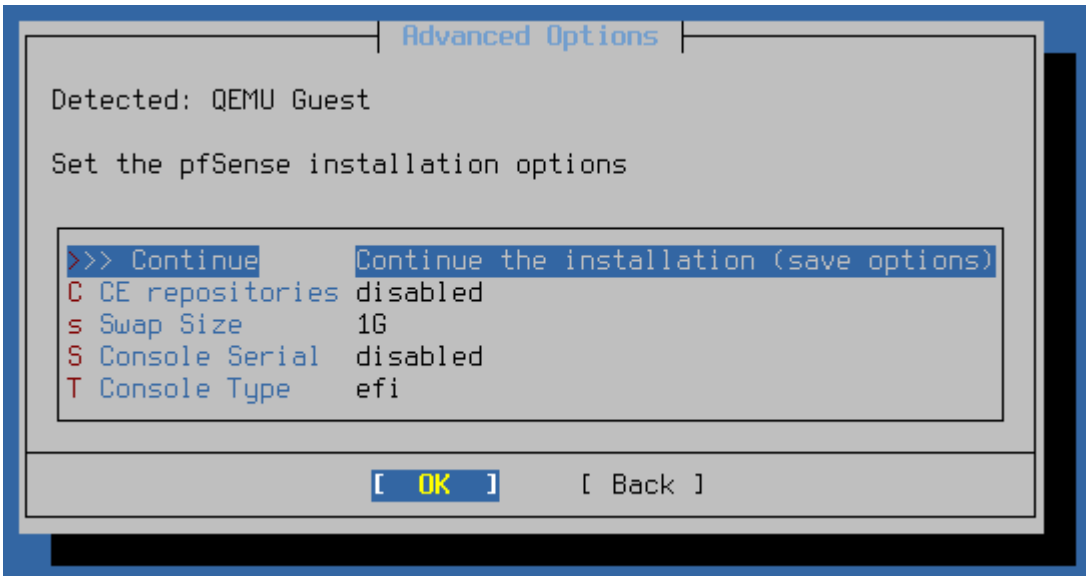

Fig. 5: Advanced Options

Use the arrow keys to select an option, then press `Enter` to set or toggle the value. The options on this screen are:

CE Repositories
: For devices eligible to install pfSense Plus software, this option toggles the availability of CE repositories in the list of versions the installer will offer.

  This allows someone with a device capable of running pfSense Plus software to install pfSense CE software instead.

Swap Size
: Sets the size of the swap partition the installer creates on the target disk.

  Swap space is used for holding crash dump data as well as for virtual memory to supplement available RAM.

  Enter a value with a size suffix, such as `1G` for 1 GiB of swap space. Use a value of `0` to disable swap.

  Note: Swap usage can cause a higher volume of disk writes, but the best practice is to at least keep a small swap partition for crash dump data.

Console Serial
: Controls whether or not the serial console should be enabled on the target installation. Toggles between `enabled` and `disabled`.

Console Type
: Sets a specific type of console for the target installation.

  EFI
  : EFI console, best suited for systems booting EFI with video and/or serial.

  Video
  : Traditional VGA style console.

None
Do not set a specific console type.

After setting options on this menu, choose **Continue** and **OK** and the installer will return to the *Welcome Menu*.

Network Setup

As this is an online installer it requires network connectivity to download installation packages from Netgate servers. To configure the network, the installer has to know at a minimum which port is a WAN with external connectivity, and configuration details to reach the Internet.

Note: The installer detects known models of Netgate hardware an automatically assigns the WAN and LAN to their default ports, skipping this manual assignment process and going right to *Confirm Network Configuration*.

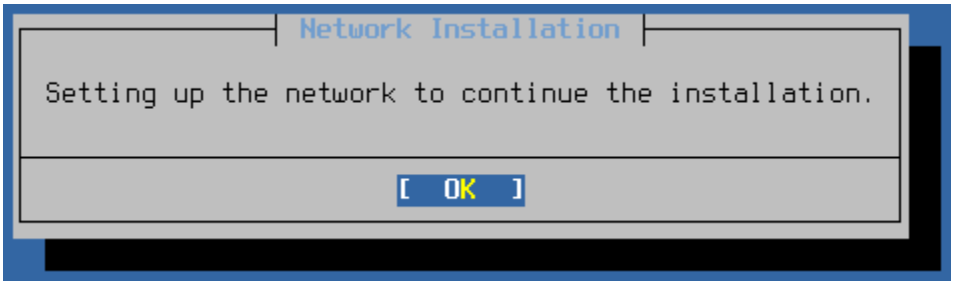

Fig. 6: Network Setup Prompt

Select WAN Interface

The first interface to assign is the WAN interface. This is the interface connected to the upstream network (e.g. Internet, modem, CPE, etc.). The installer presents a list of all detected interfaces and their MAC addresses, along with their current link state.

Use the up/down arrow keys to select the WAN interface and press `Enter` to continue.

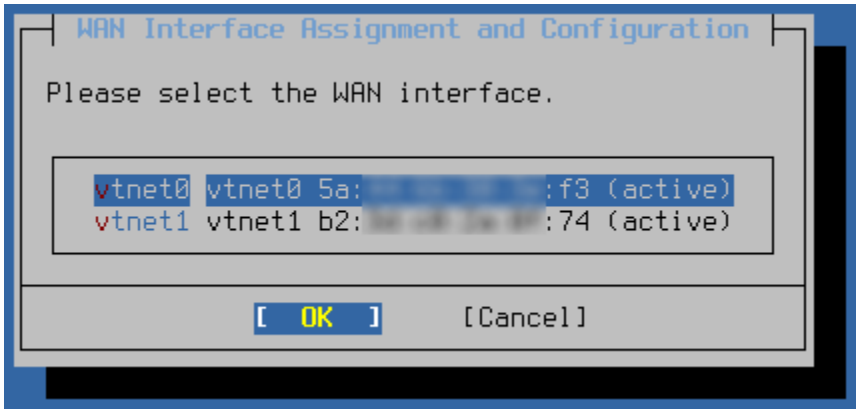

Fig. 7: Select WAN Interface

Note: When re-visiting this assignment screen later, for example to change the interface assignment or configuration, the list also includes the current assignment (e.g. WAN or LAN) at the end of each row.

Configure WAN Interface

The next step is to configure the WAN interface. The installer supports DHCP, static IP address, and PPPoE configurations for WAN interfaces. Additionally, interfaces may be VLAN tagged if necessary.

To change the type of interface configuration, select **Interface Mode** and press the `Enter` key. To configure a VLAN tag, select **VLAN Settings** and press the `Enter` key. To toggle use of the local resolver, select **Use local resolver**.

These options are explained in further detail in the following sections.

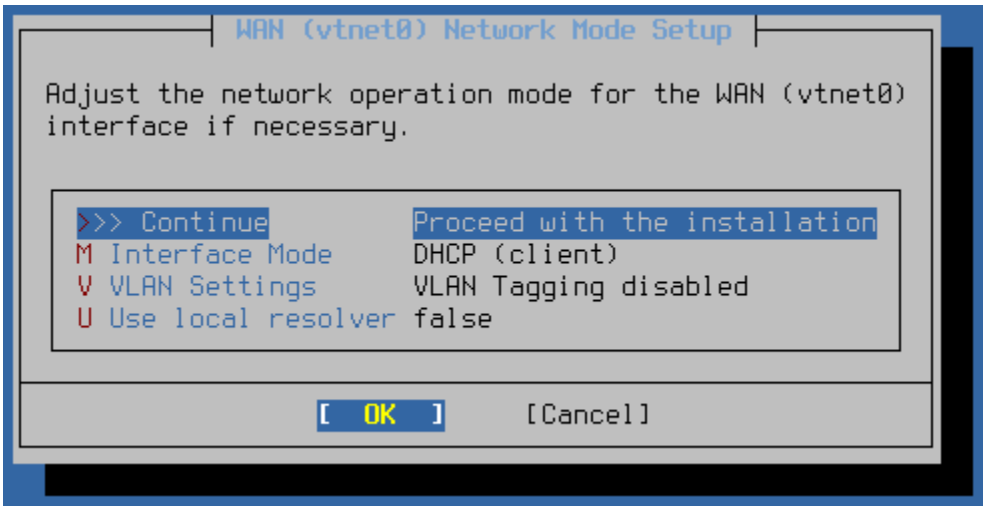

Fig. 8: WAN Interface Configuration

Interface Mode

The options on this screen change depending on the selected **Interface Mode** as certain types require additional configuration.

DHCP Client WAN

When the WAN interface is set to **DHCP (Client)** there are no additional options to configure, the behavior is automatic.

Static IP Address WAN

Changing the **Interface Mode** to **STATIC** presents several additional fields to configure static IP address WAN connectivity.

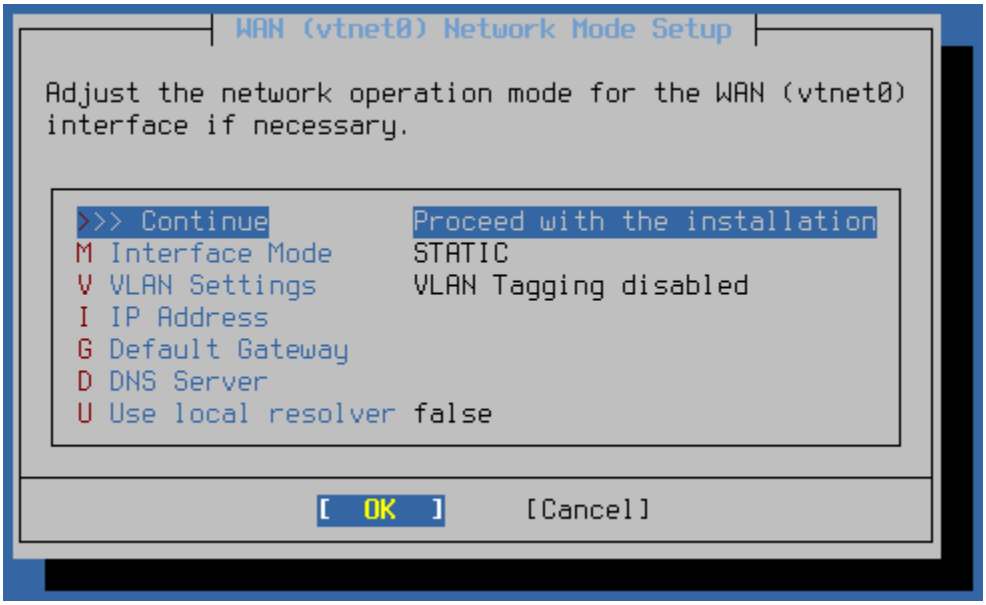

Fig. 9: Static IP Address

The available settings are:

IP Address
The IPv4 address and CIDR mask to use for external connectivity.

Note: The installer assumes a CIDR mask of `/24` if the address is given without a CIDR mask.

Default Gateway
The IPv4 address of the default gateway through which the installer can reach the Internet.

DNS Server
The IPv4 address of a DNS server, usually at the ISP or a public DNS server such as Google, CloudFlare, etc.

The figure above depicts a fully configured static IP address WAN.

PPPoE WAN

Changing the **Interface Mode** to **PPPoE** presents several additional fields to configure PPPoE WAN connectivity.

The available settings are:

PPPoE User
The username to use when logging into the upstream PPPoE service.

PPPoE Password
The password to use when logging into the upstream PPPoE service.

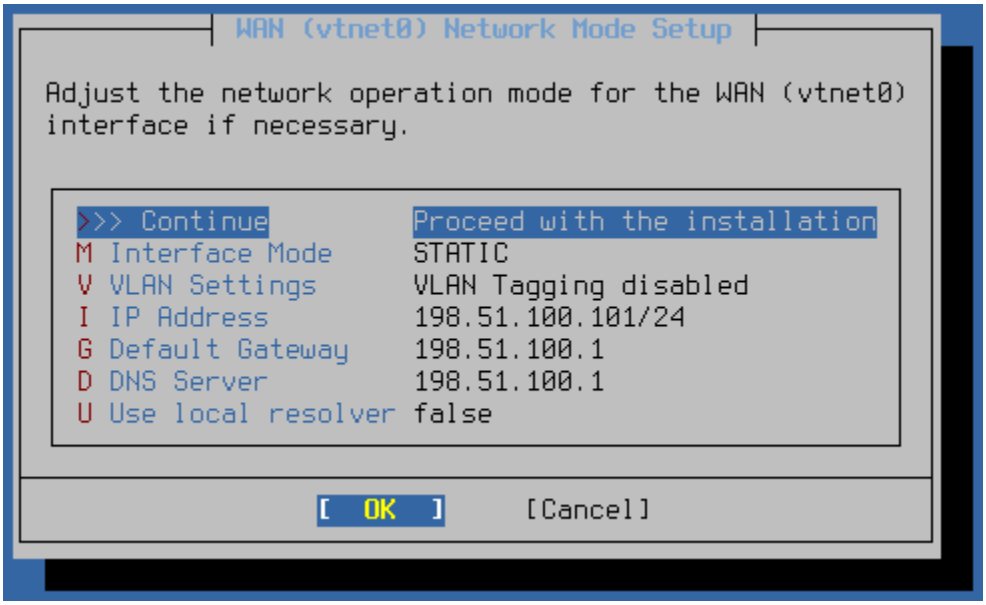

Fig. 10: Static IP Address (Configured)

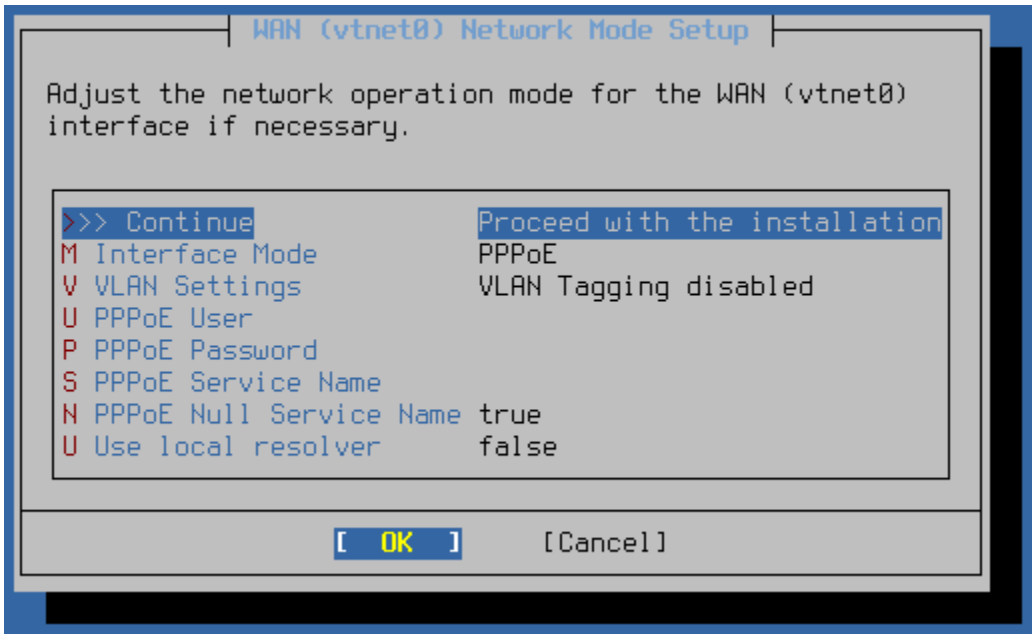

Fig. 11: PPPoE WAN

PPPoE Service Name
Some PPPoE providers require a specific service name to be set in authentication requests. If the provider requires such a value, set it here. Otherwise, leave it empty.

PPPoE Null Service Name
Configures the PPPoE client to send a null service name instead of an empty name when the **PPPoE Service Name** is empty. Certain providers may prefer one method or the other when they do not require a service name.

Entering a **PPPoE Service Name** automatically sets this to **false**.

Toggling this setting to **true** erases the **PPPoE Service Name**.

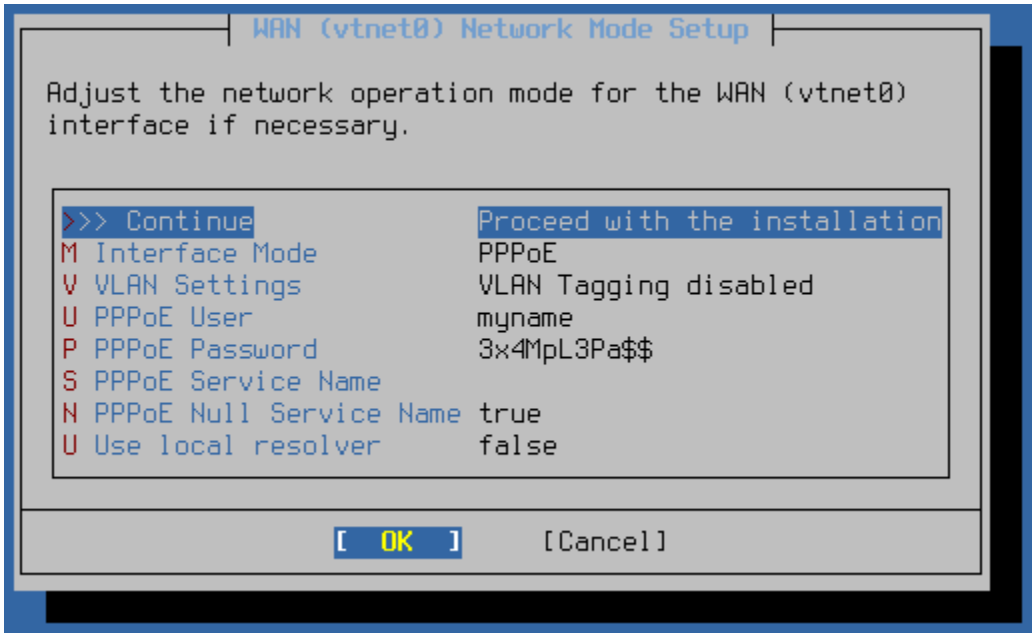

Fig. 12: PPPoE WAN (Configured)

The figure above depicts a configured PPPoE WAN.

VLAN Configuration

Each interface can be optionally configured to use a VLAN tag when communicating with the rest of the network connected to that interface.

To use a VLAN tag, first select **VLAN Settings** from the interface configuration screen to reach the VLAN settings screen.

The **VLAN configuration** screen controls how installer uses VLANs on an interface. The following options are available:

Enable VLAN
Enables or disables VLAN support for the interface.

VLAN Tag
Sets the VLAN tag for traffic on the interface.

Priority Tag
Sets a VLAN priority value.

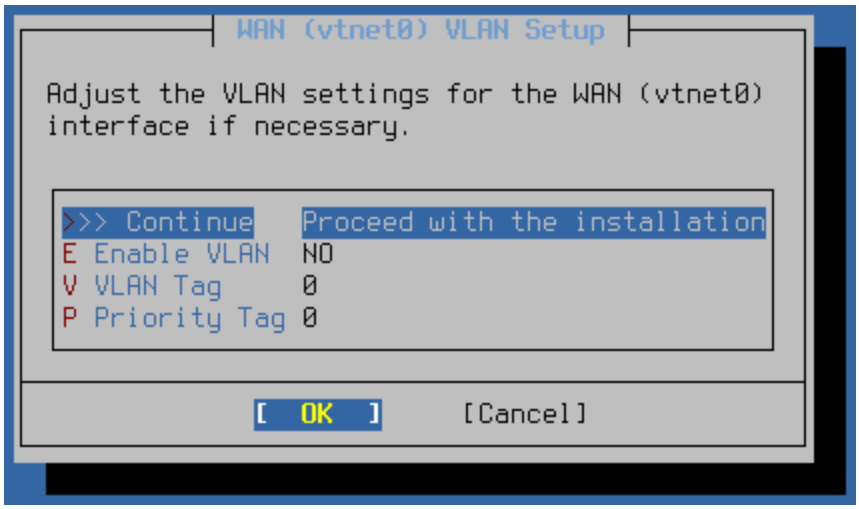

Fig. 13: VLAN Configuration

Select **OK** to return to the interface configuration.

Use Local Resolver

The **Use Local Resolver** option is present for every WAN type. It toggles the use of a local DNS resolver (Unbound) to handle DNS resolution rather than querying upstream DNS servers directly.

Select LAN Interface

The next step is to select the LAN interface. This is used for connecting to the installer from a local network if needed. While not used in this particular walkthrough, future installer features will rely on having a working LAN configuration, and it can also make obtaining information about installation problems easier to gather for support purposes.

Selecting **None** will proceed without configuring a LAN, which is acceptable for installing from the console.

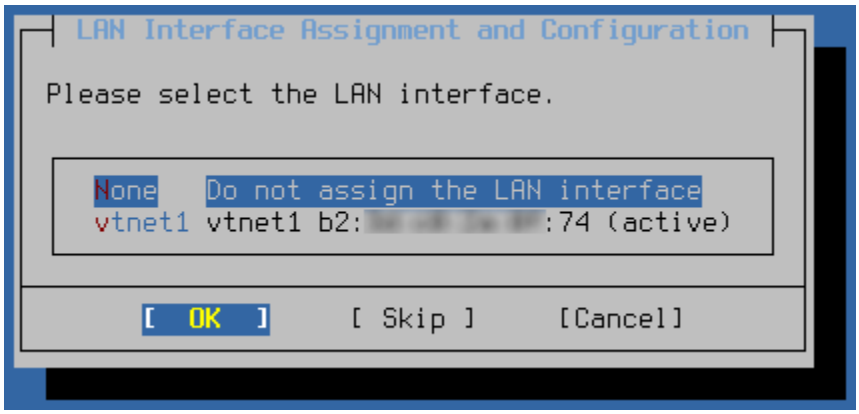

Fig. 14: Select LAN Interface if necessary

Note: When re-visiting this assignment screen later, for example to change the interface assignment or configuration,

the list also includes the current assignment (e.g. WAN or LAN) at the end of each row.

Configure LAN Interface

The options to configure the LAN are similar to a WAN but not identical.

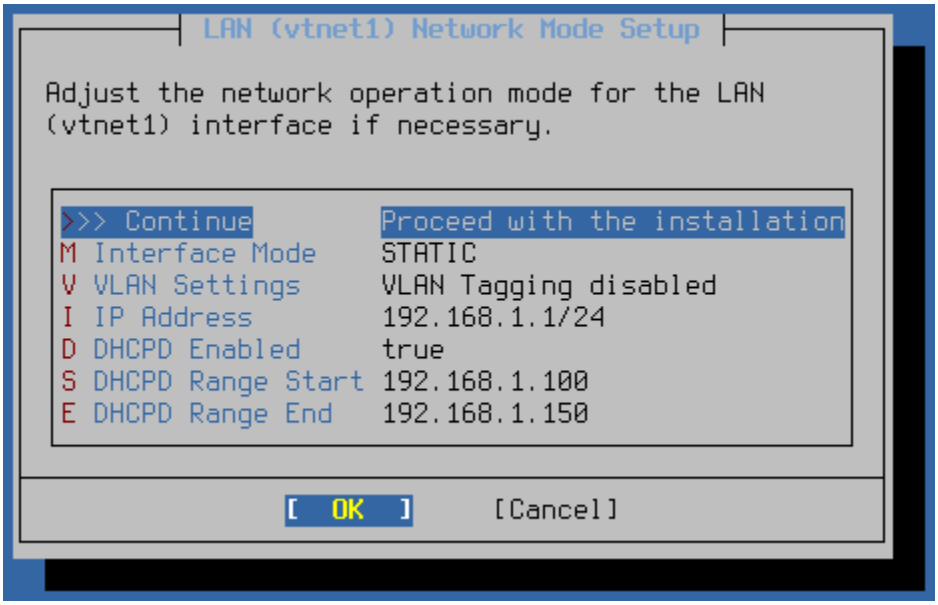

Fig. 15: LAN Interface Configuration

The following options are available when configuring the LAN interface:

Interface Mode
Select between DHCP Client and Static IP Address configuration types.

VLAN Settings
Enter *VLAN Configuration* mode for this interface.

IP Address
Configure a static IP address and CIDR mask for the LAN. Default is `192.168.1.1/24`.

DHCPD Enabled
Toggles DHCP server behavior off/on (default: on)

Note: This option, along with the range start/end, are only available when LAN is set to a static IP address configuration.

DHCPD Range Start
Sets the starting address of the LAN DHCP range. Default is `192.168.1.100`.

DHCPD Range End
Sets the ending address of the LAN DHCP range. Default is `192.168.1.150`.

Confirm Network Configuration

This screen lists the current interface assignments, either after manual assignment or from being assigned automatically for known models of Netgate hardware.

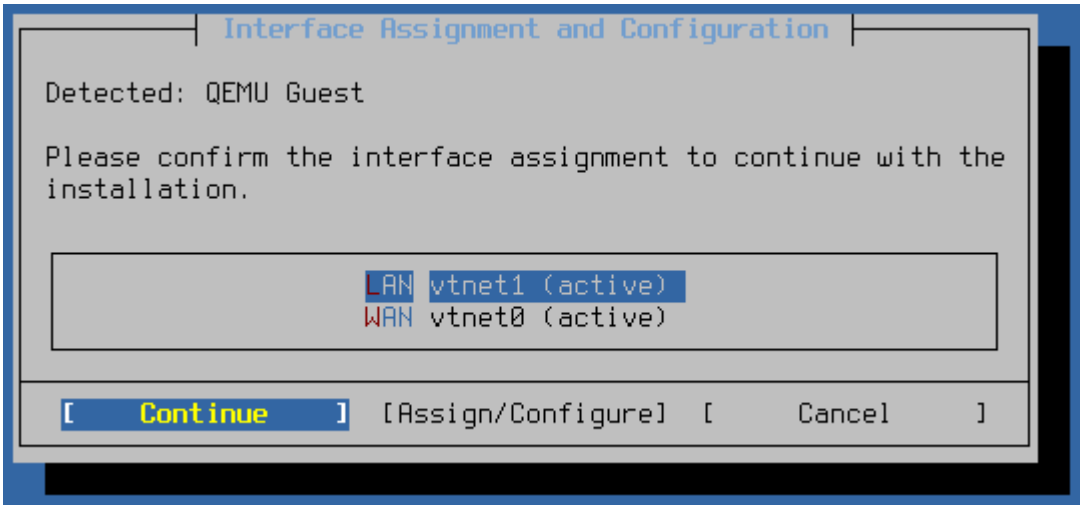

Fig. 16: Confirm Network Configuration

If the default settings are OK, then choose to **Continue** from here by selecting it with the left/right arrows and pressing the `Enter` key.

The default settings are a DHCP client WAN, static IP Address LAN on `192.168.1.1/24` with DHCP server enabled on LAN from `192.168.1.100` to `192.168.1.150`.

To change the interface assignments or configuration, select the interface with the up and down arrows and then use the left/right arrows to highlight **Assign/Configure** then press the `Enter` key. Refer to the previous sections for information on how to assign and configure each interface.

At this point the installer should have Internet connectivity.

Ineligible Device Prompt

The installer gathers information about the device and communicates with Netgate servers to determine if the device is eligible to run pfSense Plus software. If the device is eligible, it moves forward to the *filesystem selection* screen. If the device is *not* eligible, the installer displays a prompt informing the user of this fact.

> **Warning:** If the installer is unable to contact Netgate servers it will display an error saying "Cannot verify the eligibility of this system, please try again." For suggestions on how to correct that, see *Installer Network Connectivity Problems*.

If the device does not have an active subscription for pfSense Plus software, one can be purchased at this time by visiting https://www.netgate.com/purchase-plus and entering the Netgate Device ID (NDI), which is listed on this screen of the installer as well.

After subscribing, choose the **Retry Validation** option to allow the installer to check the subscription status again.

Alternately, users can choose the **Install CE** option to install pfSense CE Software, and that installation can upgrade to pfSense Plus software later after completing the subscription process.

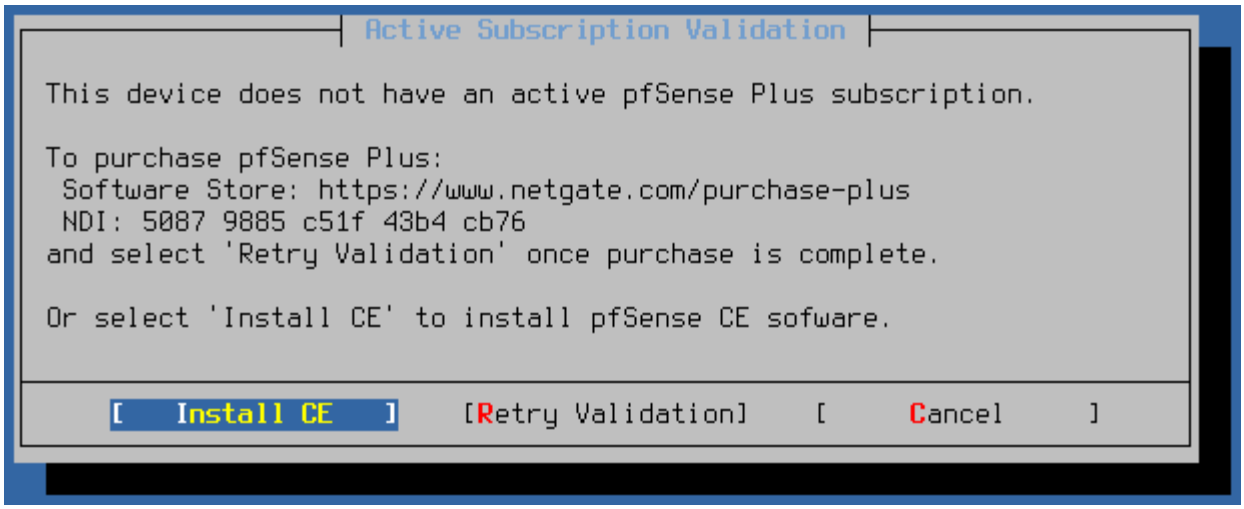

Fig. 17: Prompt displayed on systems not yet eligible to run pfSense Plus software

Filesystem and Partition Settings

After verifying the subscription, the next step is to choose the filesystem and partition type.

The available options are:

File System
The type of filesystem to use on the target disk.

ZFS
A robust modern filesystem that supports many advanced features, such as boot environments, but it uses a lot more resources. Even so, this is the default and best practice choice for nearly all cases.

UFS
An older filesystem that works well but can be fragile when it comes to sudden interruptions such as power loss. It uses less resources, but also doesn't support any modern features such as boot environments.

Partition Scheme
The partition scheme to use on the target disk.

GPT
A modern partitioning method which is well supported on modern AMD64 systems but in rare cases it can have issues with older BIOS implementations. This is the default choice as there are very few systems which do not support GPT.

MBR
A more basic partition scheme but one which is more widely compatible. This is also used on ARM-based systems.

The process varies slightly depending on the selected filesystem type, so follow the section below that matches the filesystem type to be used by this firewall and then return to this document to complete the steps after.

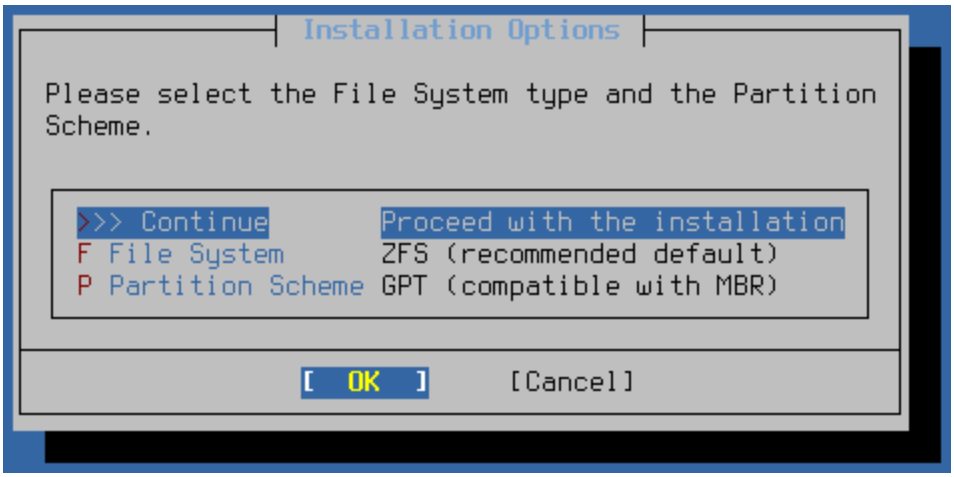

Fig. 18: Filesystem and Partition Options

ZFS

This section is a part of *Installation Walkthrough* and describes items specific to ZFS partitioning.

See also:

For information on tuning ZFS memory usage after installation, see *ZFS Tuning*.

Pool Type / Disks

When installing to ZFS the installer prompt to choose the **ZFS Configuration**. ZFS supports multiple disks in various ways for redundancy and/or extra capacity. Though using multiple disks with ZFS is software RAID, it is quite reliable and better than using a single disk.

The available types are:

stripe
A single disk, or multiple disks added together to make one larger disk (RAID 0).

Note: For devices with a single target disk, this is the correct choice.

---

mirror
Two or more disks that all contain the same content for redundancy. Can keep operating even if one disk dies. (RAID 1)

raid10
RAID 1+0, n x 2-way mirrors. A combination of stripes and mirrors, which gives redundancy and extra capacity. Can lose one disk from any pair at any time.

raidzX
Single, Double, or Triple redundant RAID. Uses 1, 2, or 3 parity disks with a pool to give extra capacity and redundancy, so either one, two, or three disks can fail before a pool is compromised. Though similar to RAID 5 and 6, the RAIDZ design has significant differences.

Select a type and press `Enter`

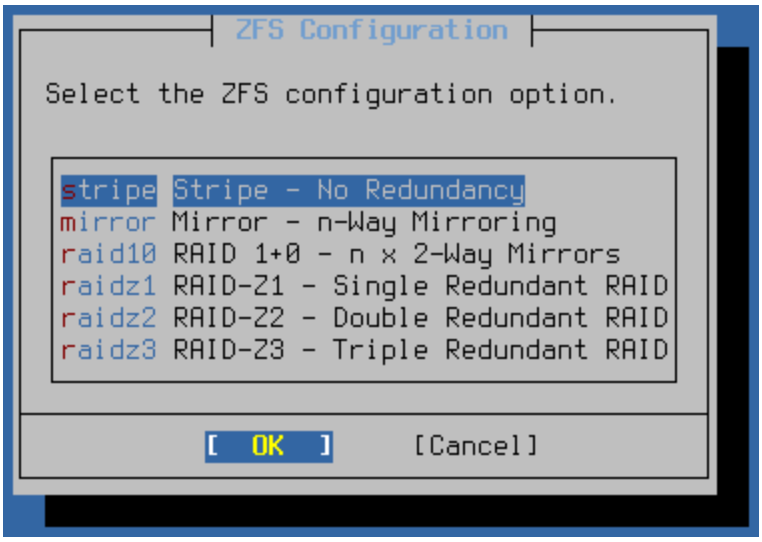

Fig. 19: ZFS Configuration Type

Select Disks

Next, the installer prompts for which disks it will include in the selected **ZFS Configuration**.

Use the `up` and `down` arrow keys to highlight a disk and `Space` to select disks. For mirrors or RAID types, select enough disks to fulfill the requirements for the chosen type.

Warning: Select a disk even if there is only one in the list!

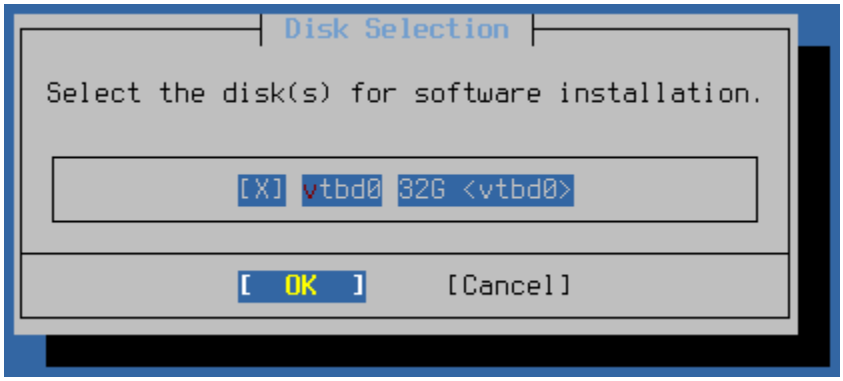

Fig. 20: ZFS Disk Selection

Note: If installer cannot find any drives, or if it shows incorrect drives, it is possible that the desired drive is attached to an unsupported controller or a controller set for an unsupported mode in the BIOS. See *Troubleshooting Installation Issues* for help.

Continue Install

Proceed to *Final Confirmation*.

UFS

This section is a part of *Installation Walkthrough* and describes items specific to the UFS choices for partitioning.

When installing to UFS, the installer will prompt to select the target disk where the installer will write out the pfSense® software, e.g. `ada0`. The installer will show all supported drives.

Note: Unlike ZFS, UFS only supports a single disk, though some setups such as those using a RAID controller may still use multiple disks, so long as they present a single virtual volume the installer can utilize.

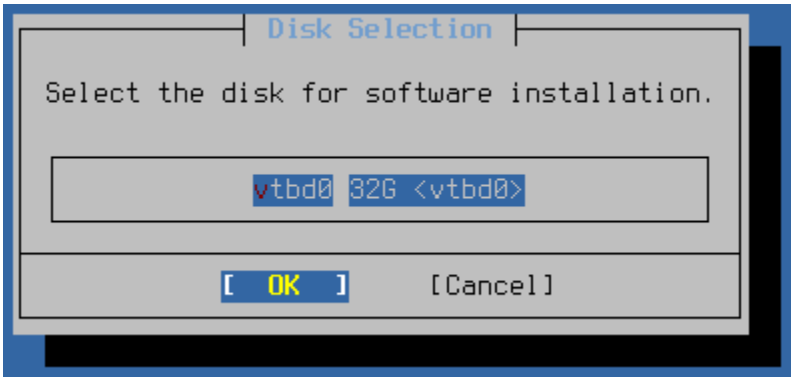

Fig. 21: UFS Disk Selection

Note: If installer cannot find any drives, or if it shows incorrect drives, it is possible that the desired drive is attached to an unsupported controller or a controller set for an unsupported mode in the BIOS. See *Troubleshooting Installation Issues* for help.

Continue Install

Proceed to *Final Confirmation*.

Final Confirmation

After selecting the target disk the installer prompts for confirmation one final time before it makes destructive changes to the disk.

Danger: Choosing to continue from this point will destroy anything left on the target disk!

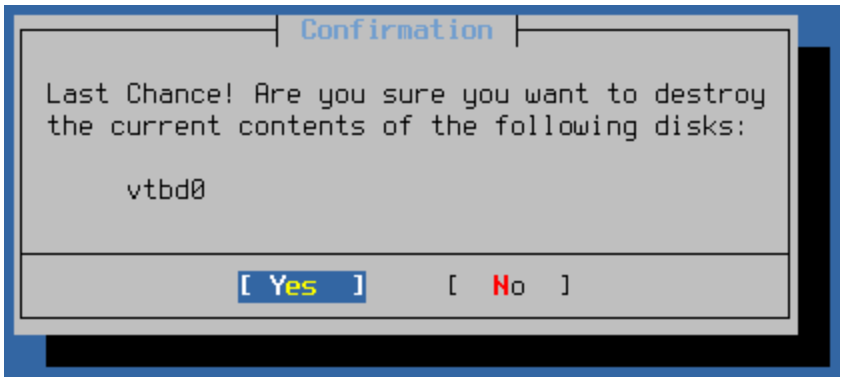

Fig. 22: Final Confirmation before Installing

Version Selection

At this point the installer presents a list of pfSense software that this device is eligible to run. This list will typically include the current version of pfSense software and one prior release. Depending on the current status of an upcoming release cycle, the installer may also offer development snapshots.

Select the version to install from the list with the up/down arrow keys, select OK with the left/right arrow keys, then press `Enter`

Tip: In most cases the correct selection will be the one labeled "Current Stable Version".

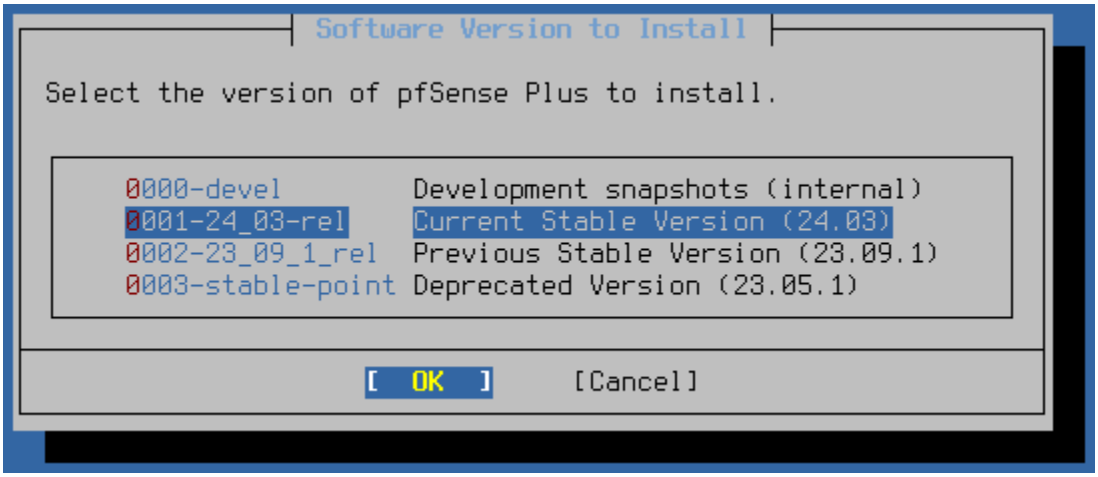

Fig. 23: Select Software Version to Install

Installation

After picking the version, the installer proceeds to download the installation data for that version and installs it on the target disk.

Sit back, wait, and have a few sips of a refreshing beverage while the installation process formats the drive(s) and copies pfSense software files to the target disk(s).

The installer displays the output from this process as it works. When finished, the installed presents an OK button which will continue to post-installation tasks.

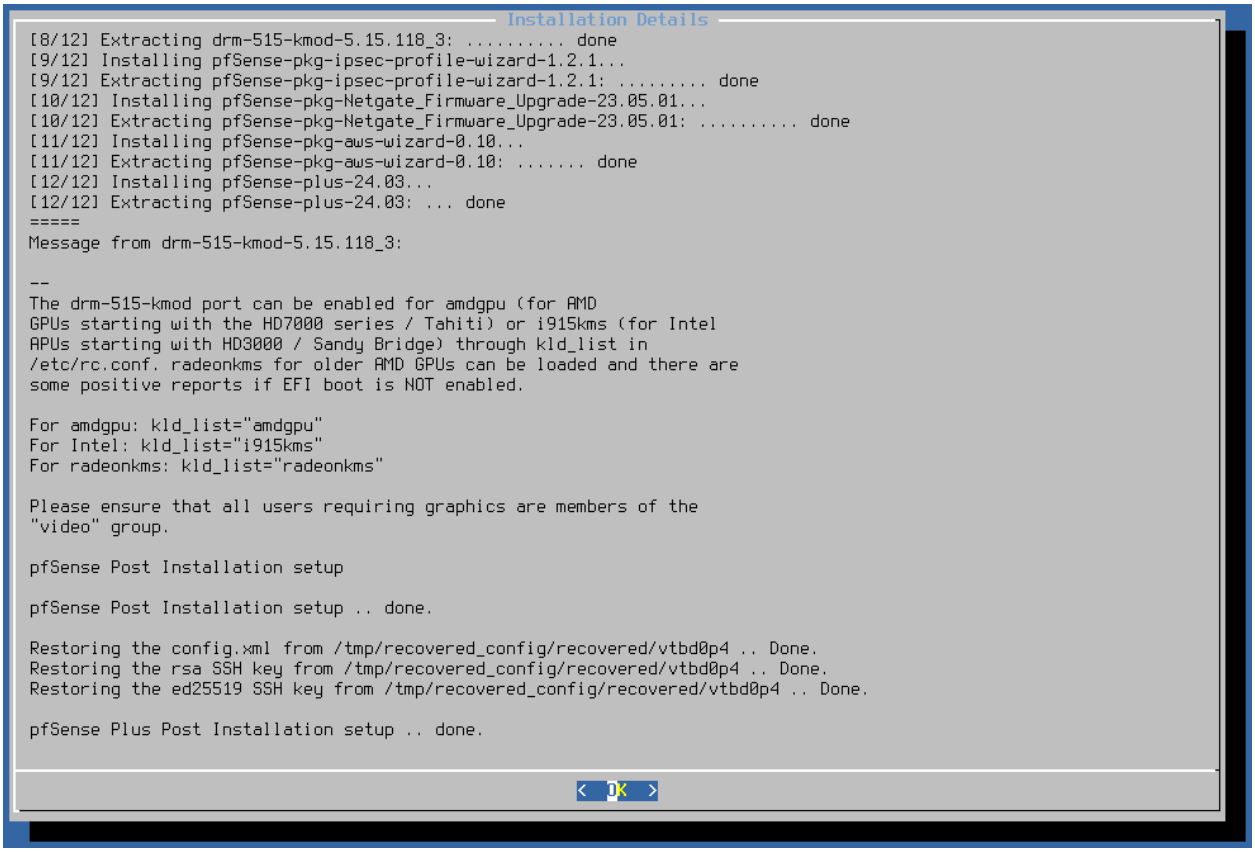

Fig. 24: Output After Installation Completes

Finish Up

At this point the installation is complete. The installer will prompt one final time to either reboot into the new installation or to start a shell prompt for any manual adjustments advanced users may wish to make.

Remove the installation media from the firewall during the reboot, when the hardware is starting back up but before it boots from the disk.

Once the device has booted from its own internal disk the device is ready for use.

Congratulations, the installation is complete!

The next step is to connect to the GUI and configure the device as described in *Configuration*.

- *Alternate Remote Backup Techniques* (for an example of using SCP)

pfSense Software Default Configuration

After installation and interface assignment, pfSense software has the following default configuration:

- WAN is configured as an IPv4 DHCP client.
- WAN is configured as an IPv6 DHCP client and will request a prefix delegation.
- LAN is configured with a static IPv4 address of **192.168.1.1/24**.
- LAN is configured to use a delegated IPv6 address/prefix obtained by WAN (Track IPv6) if one is available.
- All incoming connections to WAN are *blocked* by the firewall.
- All outgoing connections from LAN are *allowed* by the firewall.
- The firewall performs NAT on IPv4 traffic leaving WAN from the LAN subnet
- The firewall will act as an IPv4 *DHCP Server*
- The firewall will act as an IPv6 *DHCPv6 Server* if a prefix delegation was obtained on WAN, and also enables SLAAC
- The *DNS Resolver* is enabled so the firewall can accept and respond to DNS queries.
- SSH is disabled.
- WebGUI is running on port 443 using HTTPS.
- Default credentials are set as described in *Default Username and Password*.

7.5 Assign Interfaces

After the installer completes and the firewall reboots, the firewall software looks for network interfaces and attempts to assign interface mappings automatically.

The automatic interface assignment profiles used by the firewall are:

Netgate Hardware sold with pfSense® Plus Software
pfSense Plus software for devices from the Netgate Store includes default mappings appropriate to the hardware, which varies depending upon the hardware ordered with the device. Consult the Netgate Product Manuals for specific details on each model.

RCC-VE 4860/8860
WAN: igb1, LAN: igb0

RCC-VE 2220/2440
WAN: igb0, LAN: igb1

APU
WAN: re1, LAN: re2

Other Devices
For other devices the firewall looks for common interfaces and attempts to assign them appropriately, for example:

- WAN: igb0, LAN: igb1
- WAN: em0, LAN: em1
- WAN: re1, LAN: re2

If the firewall cannot automatically determine the network interface layout, it will present a prompt for interface assignment as in Figure *Interface Assignment Screen*. This is where the network cards installed in the firewall are given their roles as WAN, LAN, and Optional interfaces (OPT1, OPT2 … OPTn).

```
Valid interfaces are:

igb0   00:08:a2:09:95:b5   (up) Intel(R) PRO/1000 Network Connection, Version
igb1   00:08:a2:09:95:b6   (up) Intel(R) PRO/1000 Network Connection, Version
igb2   00:08:a2:09:95:b1 (down) Intel(R) PRO/1000 Network Connection, Version
igb3   00:08:a2:09:95:b2 (down) Intel(R) PRO/1000 Network Connection, Version
igb4   00:08:a2:09:95:b3 (down) Intel(R) PRO/1000 Network Connection, Version
igb5   00:08:a2:09:95:b4 (down) Intel(R) PRO/1000 Network Connection, Version

Do VLANs need to be set up first?
If VLANs will not be used, or only for optional interfaces, it is typical to
say no here and use the webConfigurator to configure VLANs later, if required.

Should VLANs be set up now [y|n]? n

If the names of the interfaces are not known, auto-detection can
be used instead. To use auto-detection, please disconnect all
interfaces before pressing 'a' to begin the process.

Enter the WAN interface name or 'a' for auto-detection
(igb0 igb1 igb2 igb3 igb4 igb5 or a):
```

Fig. 26: Interface Assignment Screen

The firewall displays a list of detected network interfaces and their MAC (Media Access Control) addresses, along with an indication of their link state if that is supported by the network card. The link state is denoted by `(up)` appearing after the MAC address if a link is detected on that interface.

Note: The Media Access Control (MAC) address of a network card is a unique identifier assigned to each card, and no two network cards *should* have the same MAC address. If a duplicate MAC address is present on a network, either by chance or by intentional spoofing, all conflicting nodes will experience connectivity problems.

After printing the network interface list, the firewall prompts for VLAN configuration. If VLANs are desired, answer `y`, otherwise, type `n`, then press `Enter`.

See also:

For information about configuring VLANs, see *Virtual LANs (VLANs)*.

The firewall prompts to set the WAN interface first. As the firewall typically contains more than one network card, a dilemma may present itself: How to tell which network card is which? If the identity of each card is already known, enter the proper device names for each interface. If the difference between network cards is unknown, the easiest way to figure it out is to use the auto-detection feature.

For automatic interface assignment, follow this procedure:

- Unplug all network cables from the firewall
- Type `a` and press `Enter`
- Plug a network cable into the WAN interface of the firewall
- Wait a few moments for the firewall to detect the link up event
- Press `Enter`

If all went well, the firewall can determine which interface to use for the WAN.

Repeat the same process for the LAN and optional interfaces, if any are necessary. If the firewall prints a message stating "No link-up detected", see *Manually Assigning Interfaces* for more information on sorting out network card identities.

Once the list of interfaces for the firewall is correct, press `Enter` at the prompt for additional interfaces. The firewall will ask **Do you want to proceed (y|n)?** If the network interface assignment list is correct, type `y` then press `Enter`. If the assignment is incorrect, type `n` and press `Enter` to repeat the assignment process.

Note: In addition to the normal routing/firewall mode with multiple interfaces, a firewall may also run in **Appliance Mode** where it has only a single interface (**WAN**). The firewall places the GUI anti-lockout rule on the WAN interface so a client may access the firewall web interface from that network. The usual routing and NAT functions are not active in this mode since there is no internal interface or network. This type of configuration is useful for VPN appliances, DHCP servers, and other stand-alone roles.

7.5.1 Manually Assigning Interfaces

If the auto-detection feature did not work, there is still hope of telling the difference between network cards prior to installation. One way is by MAC address, which the firewall prints next to the interface names on the assignment screen:

```
vmx0    00:0c:29:50:a4:04
vmx1    00:0c:29:50:ec:2f
```

The MAC address is sometimes printed on a sticker somewhere physically on the network card. For virtualized systems, the virtual machine configuration usually contains the MAC address for each network card. MAC addresses are assigned by manufacturer, and there are several online databases which offer reverse lookup functionality for MAC addresses in order to find the company which made the card: http://www.8086.net/tools/mac/, http://www.coffer.com/mac_find/, and http://aruljohn.com/mac.pl, among many others.

Network cards of different makes, models, or sometimes chipsets may be detected with different drivers. It may be possible to tell an Intel-based card using the `igb` driver apart from a Broadcom card using the `bge` driver by looking at the cards themselves and comparing the names printed upon the circuitry.

The probe order of network cards can be unpredictable, depending on how the hardware is designed. In a few cases, devices with a large number of ports may use different chipsets that probe in different ways, resulting in an unexpected order. Add-on and Multi-port NICs are generally probed in bus order, but that can vary from board to board. If the hardware has onboard NICs that are the same brand as an add-in NIC, be aware that some systems will list the onboard NIC first, and others will not. In cases when the probe order makes multiple NICs of the same type ambiguous, it may take trial and error to determine the port placements and driver name/number combinations.

After the network cards have been identified, type the name of each card at the interface assignment screen when prompted. In the above example, `vmx0` will be WAN and `vmx1` will be LAN. To assign them these roles, follow this procedure:

- Type `vmx0` and press `Enter` when prompted for the WAN address
- Type `vmx1` and press `Enter` when prompted for the LAN address
- Press `Enter` again to stop the assignment process, since this example does not contain any optional interfaces.
- Type `y` and press `Enter` to confirm the interface assignments

7.6 Upgrade Guide

pfSense® software can be reliably upgraded from an older release to a current release.

Netgate periodically release new versions that contain new features, updates, bug fixes, and various other changes. In most cases, updating an installation is easy. If the firewall is updating to a new release that is a only a point release (e.g 2.x.3 to 2.x.4), the update is typically minor and unlikely to cause problems.

Note: Only the most recent stable release of pfSense is officially supported, so updating is also important to ensure that any problems encountered may be resolved as needed.

Upgrades use the same software edition that the firewall is currently running. For example, pfSense CE software installations will upgrade to the latest version of pfSense CE software. pfSense Plus software will upgrade to the latest version of pfSense Plus software. The only exception to this is when following the special procedure to *Migrate from pfSense® CE software to Netgate pfSense Plus software*.

The most common problems encountered during upgrades are hardware-specific regressions from one FreeBSD version to another, though those are rare. Updated releases fix more hardware than they break, but regressions are always

possible. Larger jumps, such as from 2.3.x to 2.8.0-RELEASE must be handled with care, and ideally tested on identical hardware in a test environment prior to use in production.

Warning: Firewalls must be connected to the Internet to update.

7.6.1 Upgrade Process Overview

This is a brief overview of the process that takes place behind the scenes when an administrator initiates an upgrade. The process varies depending on the version of pfSense software and whether or not the firewall is capable of utilizing ZFS Boot Environments. Unless otherwise stated, all steps are performed by the firewall automatically.

See also:

- *ZFS Boot Environments (Plus Only)*
- *Boot Environments Settings*

Traditional Upgrade Process (CE, Plus with UFS)

This is the traditional upgrade process using `pkg`, which is used by pfSense CE software as well as installations of pfSense Plus software installed using UFS:

- Download update files
- Upgrade kernel
- Reboot (Offline down time starts)
- Upgrade base files (Operating System, PHP code, etc.)
- Upgrade base and add-on packages
- Finish boot (Offline down time ends, back online and ready)

ZFS Boot Environments (First Generation, Plus 22.05-23.09.1)

This is the first generation of ZFS Boot Environment upgrade support, available from pfSense Plus software version 22.05 until 23.09.1:

- Create and activate new ZFS Boot Environment from current point
- Download update files
- Upgrade kernel
- Reboot (Offline down time starts)
- Upgrade base files (Operating System, PHP code, etc.)

- Upgrade base and add-on packages
- Finish boot (Offline down time ends, back online and ready)

This process essentially makes an automatic local backup before starting so that administrators can manually roll back if there are problems with the upgrade.

ZFS Boot Environments (Second Generation, Plus 24.03 and later)

This is the second generation of ZFS Boot Environment upgrade behavior, which started on pfSense Plus software version 24.03:

- Create new ZFS Boot Environment from current point
- Download update files
- Upgrade kernel inside the new Boot Environment
- Upgrade base files (Operating System, PHP code, etc.) inside the new Boot Environment
- Upgrade base and add-on packages inside the new Boot Environment
- Check for errors inside the new Boot Environment and stop if any problems have occurred
- Activate the new Boot Environment
- Reboot (Offline down time starts)
- Monitor for problems during reboot
  - If problems are detected, automatically activate the last known good Boot Environment and reboot
- Finish boot (Offline down time ends, back online and ready)

This method involves less down time as the only down time is during the reboot and the bulk of the upgrade process is already complete by that point. It is more robust since it can automatically detect problems and roll back without manual intervention if need be, which makes remote upgrades safer. Prior ZFS Boot Environments are still available to roll back manually if users encounter problems not detected automatically.

7.6.2 Pre-Upgrade Tasks

Make a Backup . . . and a Backup Plan

Before making any modifications to a firewall, the best practice is to make a backup using the WebGUI:

- Navigate to **Diagnostics > Backup/Restore**
- Set the **Backup Area** to *All* in the **Backup Configuration** section of the page
- Click  **Download**
- Save this file somewhere safe

Keep multiple copies of the backup file in different secure locations. Consider using the free **Auto Config Backup** service (*Automatic Configuration Backup Service*). Auto Config Backup can create a manual backup with a note identifying the change, which is encrypted and stored on Netgate servers.

Another good practice is to have install media handy for the new release, in case something goes awry and a reinstall is required. Should that happen, have the backup file on hand and refer to *Backup and Recovery*.

Check and Clean Up ZFS Boot Environments

Systems running pfSense Plus software installed using ZFS will automatically create *ZFS Boot Environment* entries during the upgrade process as a safety measure so users can boot back into the previous version easily. These entries consume space which presents itself as shrinking disk capacity and less free space on the disk. Eventually if left unchecked there may not be sufficient room to contain an upgrade without removing older boot environments.

See also:

See *Boot Environment Disk Space Usage* for more information about ZFS Boot Environment space usage.

Tip: The amount of space consumed by a boot environment varies depending on how much the disk contents change during and after an upgrade. It is safer to estimate on the high side and consider it may use at least 1.5-2GB for a major upgrade. Upgrades that involve less changes on the filesystem will use less.

Before any upgrade, navigate to **System > Boot Environments** and review the list. Remove older entries which are no longer necessary (*Managing Boot Environments in the GUI*). Typically users only keep the latest 2-3 entries but preferences vary.

Low Memory Hardware and AWS/Azure Instances

Hardware with **1 GiB or less** available memory may have issues upgrading depending on which features, services, or packages are running. This includes some Netgate hardware such as the Netgate 1100 when running with ZFS and/or certain services/packages. For the best chance of success in these cases, temporarily disable any non-critical services before starting the upgrade.

Tip: A *Pre-Upgrade Reboot* can also temporarily reduce memory used for ZFS caching, which can help in this situation as well.

---

pfSense Plus software can no longer run on AWS ".nano" size instances as they lack sufficient RAM to upgrade properly. Attempting to upgrade a ".nano" instance to pfSense Plus software version 24.03 will fail before the upgrade is performed. Migrate the instance to a ".micro" or larger size **before** attempting to upgrade, or redeploy instead.

Similar to the above, pfSense Plus software can no longer run on Azure A0 instances. Migrate to instances with more memory.

Remove / Dismount any Installation Media

Some users leave an installation disk plugged in or mounted for various reasons, but this can interfere with the upgrade process. Be sure to dismount and remove any installation media such as a USB thumb drive, optical disk, or ISO in a virtual drive. This includes items mounted via Hypervisors/Virtual Machine emulated or passed-through hardware, IPMI virtual media, and other similar mechanism.

VM Snapshots

An easy fall-back plan for virtualized firewalls is to take a snapshot of the VM before performing an upgrade. This way, it can easily roll back to a known-good state if the VM encounters a problem.

Note: Before rolling back a VM due to problems, ensure the hardware compatibility of the VM is current and update the VM Guest operating system to match the upgraded OS if there is a matching choice in the Hypervisor.

Pre-Upgrade Reboot

Reboot the firewall before applying an update. This step is optional, but a best practice.

If the hardware has a problem, such as a disk issue, then performing a reboot before the upgrade will allow that to be identified early. Otherwise, a hardware issue could be confused with an issue that occurred as a result of the upgrade process.

If the installation is using ZFS, a reboot will reset the amount of memory the OS is using for ZFS caching as well, which can help ensure the upgrade runs smoothly.

There is still a chance that the upgrade could draw out a hardware issue, such as a disk failing from the writes that happen in the upgrade process, but that is much less common to see in practice.

Packages

Warning: When the firewall is configured to pull packages from a release newer than the one current running, **Do not upgrade packages before upgrading pfSense® software**. Either remove all packages or leave the packages alone before running the update.

The safest practice is to remove **all** packages before upgrading to a new release. The upgrade process will handle packages automatically, but packages are frequently a source of problems. To ensure a smooth upgrade, note the installed packages, remove them, perform the upgrade, and then reinstall when the upgrade is complete.

7.6.3 Version-Specific Notes

This document covers specific concerns which must be taken into account by administrators when upgrading pfSense® software from an older version.

Review sections for each intermediate version between the version running on the firewall and the current release.

Upgrading from versions older than pfSense Plus 21.02.2 or pfSense CE 2.5.1

Warning: WireGuard was removed from the base system in releases after pfSense Plus 21.02-p1 and pfSense CE 2.5.0, when it was removed from FreeBSD.

If upgrading from a version that has WireGuard active, the upgrade will abort until all WireGuard tunnels are removed. For more details, see the *Release Notes*

WireGuard is available as an add-on package on pfSense Plus 21.05, pfSense CE 2.5.2, and later versions. The settings for the WireGuard add-on package are not compatible with the older base system configuration.

Note: The WireGuard package is still under active development. Follow the development progress on the developer's YouTube channel

Upgrading from versions older than pfSense 2.5.0

- The built-in `relayd` load balancer has been deprecated and removed as it does not compile or run on pfSense 2.5.0. A copy of the load balancer configuration will be left in `/conf/deprecated_load_balancer.xml` for reference when converting to an alternate solution, such as HAProxy (*HAProxy package*).
- PHP was migrated from PHP 7.2 to PHP 7.4. A number of PHP errors were fixed along the way but certain combinations of configuration parameters may result in further errors. Note any problems on the Netgate Forum, and if possible, try to include relevant portions of `config.xml` with personal data removed.
- Due to the significant nature of the changes in this version of pfSense software, warnings and error messages, particularly from PHP and package updates, are likely to occur during the upgrade process. These errors are primarily seen on the console as the upgrade is applied, but may appear in a crash report once the upgrade completes. In nearly all cases these errors are a harmless side effect of the changes between FreeBSD 11.2 and 12.x and between PHP 7.2 and PHP 7.4.
- See the FreeBSD 12 Release Notes for information on deprecated hardware drivers that may impact firewalls upgrading to pfSense version 2.5.0. Some of these were renamed or folded into other drivers, others have been removed, and more are slated for removal in FreeBSD 13 in the future.
- OpenSSL was upgraded to 1.1.1a as a part of upgrading to FreeBSD 12.0, this will impact all packages which depend on OpenSSL, especially those not obtained from Netgate. Be aware that this will require obtaining new versions of such packages after the upgrade.

Upgrading from versions older than pfSense 2.4.5-p1

- Upgrading to pfSense software version 2.4.5-p1 requires `pfSense-upgrade` version 0.70 or later. Most installations will automatically pick up the new version and upgrade normally. If this does not happen automatically and the upgrade to version 2.4.5-p1 is not offered, use the following procedure:
  - Navigate to **System > Updates**
  - Set **Branch** to *Previous stable version*
  - Wait a few moments for the upgrade check to complete
  - Optional: Confirm that the latest version of *pfSense-upgrade* is present (version >= 0.70) using `pkg-static info -x pfSense-upgrade`.

If the correct version is not present, wait a bit longer and check again as that package may be updating in the background.

- Set **Branch** to *Latest stable version*
- Wait a few moments for the upgrade check to complete

At this point, the upgrade check should see 2.4.5-p1 and the upgrade can proceed.

- pfSense software version 2.4.5-p1 includes `pkg` version 1.13.x which introduces a new metadata version. Most installations will automatically pick up the new version and upgrade normally. In certain cases, especially coming from much older versions, the `pkg` utility may require a manual update before it can correctly process the new metadata.

  The `pkg` utility can be upgraded manually with the following command run from an ssh or console shell:

  ```
  # pkg-static bootstrap -f
  ```

  See *Repository Metadata Version Errors* for more details.

Upgrading from versions older than pfSense 2.4.4

- Third party packages from **alternate repositories** are causing problems for users with the upgrade process and also with post-upgrade behavior. These packages have never been supported, and had to be manually added by users outside of the GUI.

  Due to the major changes required for FreeBSD 11.2 and PHP 7.2, third party packages from alternate repositories cannot be present during the upgrade. There is no way to predict if a third party package supports the new version or will cause the upgrade itself to fail.

  The upgrade process will automatically remove `pfSense-pkg-*` packages installed from alternate repositories. After the upgrade completes, the user can reinstall these packages. Packages from **alternate repositories** will not appear in the **Installed Packages** list in the GUI, and must be entirely managed in the command line.

  This change does not affect packages installed from the official pfSense package repository.

- *Automatic Configuration Backup Service* is integrated into pfSense version 2.4.4 and free for all to use. It is no longer an add-on package. It is now located under **Services > Auto Config Backup**.
- PHP was migrated from PHP 5.6 to PHP 7.2. A number of PHP errors were fixed along the way but certain combinations of configuration parameters may result in further errors. Note any problems on the Netgate Forum or the pfSense subreddit, and if possible, try to include relevant portions of `config.xml` with personal data removed.
- Due to the significant nature of the changes in this version of pfSense software, warnings and error messages, particularly from PHP and package updates, are likely to occur during the upgrade process. These errors are primarily seen on the console as the upgrade is applied, but may appear in a crash report once the upgrade completes. In nearly all cases these errors are a harmless side effect of the changes between FreeBSD 11.1 and 11.2 and between PHP 5.6 and PHP 7.2.
- Gateway handling changes in 2.4.4 may result in different default gateway behavior than previous releases. Nearly all cases should behave properly, but be aware that it may be necessary to re-select the default gateway after upgrade.
- The FEC LAGG Protocol is deprecated and its options have been removed #8734
- The login protection daemon was changed from `sshlockout_pf` to `sshguard` and the behavior may be more sensitive in some cases to SSH and GUI login failures. For example, be aware of possible issues where probes from monitoring systems may end up triggering a block.

- Major changes to RADIUS for the base system and specifically Captive Portal could lead to behavior changes in certain cases. Read the release notes and associated bug reports for more details. Note any problems on the Netgate Forum or the pfSense subreddit.
- A crash report containing no data (empty) may appear after the upgrade completes. See #8915
- Intel Atom systems containing HD Graphics chipsets may experience console problems after the update. Affected systems will boot successfully, but fail to display console output after the boot menu. To fix the problem, add the following line as a *Loader Tunable* to use the `syscons` console type:

```
kern.vty=sc
```

  - Alternately, try using i915 driver with the standard VT console using these lines as *Loader Tunables*:

```
i915kms_load="YES"
drm.i915.enable_unsupported=1
```

> **Warning:** This driver will consume extra bus resources and may cause resource hungry add-on hardware to fail, such as multi-port network adapters.

  - Systems with similar console problems not containing a graphics chip supported by the i915 driver may need to reinstall 2.4.4 to use a UEFI console.
- An ISP that supplies a bogus interface MTU via DHCP may cause interface problems with certain network interface types when **Advanced Configuration** options are present on DHCP interfaces, such as a DHCP WAN. The typical default case is handled automatically, but advanced options override the corrected default behavior. To fix the problem, apply the patch from #8507 or add `supersede interface-mtu 0` to the **Option modifiers** box in the WAN interface advanced DHCP options. If a custom `dhclient.conf` is in use, add `supersede interface-mtu 0` on a line inside the `interface` block. See #8507. The **Advanced Configuration** case has been corrected for the next release.

Upgrading from versions older than pfSense 2.4.0

- To use ZFS, a reinstall of the operating system is required. It is not possible to upgrade in-place from UFS to ZFS at this time.
- **Wireless** interfaces **must** be created on the **Wireless** tab under **Interfaces > Assignments** before they are available for assignment
- Some hardware devices may not boot 2.4.0 installation images, for example, due to UEFI compatibility changes. These are primarily BIOS issues and not issues with the installer images. Upgrading in place from 2.3.x typically allows affected hardware to run version 2.4.
- To upgrade Firewalls in place which are running pfSense software version 2.2.x or earlier, first upgrade the firewall to pfSense 2.3.4 and then perform an update to pfSense 2.4.x afterward. Alternately, reinstall 2.4.x directly and restore the configuration.

> **Warning:** When upgrading to 2.4.x from 2.2.x or earlier, remove all packages before attempting the update. Even when upgrading from 2.3.x this is the best practice to ensure a smooth upgrade process. Package settings are retained.

Older Version Upgrade Notes

Versions of pfSense software prior to 2.3 used a different upgrade method. For "full" installations, a `tgz` file was used by the firewall to copy in the new files. This method was problematic and is no longer used.

The best practice in these cases is to take a backup and reinstall with a current, supported version of pfSense software.

The following information is for upgrading from outdated and unsupported versions of pfSense software. They may still be of use to users attempting to upgrade from an older release to a current, supported, release.

When upgrading from a very old release, read every document below that covers versions between the older one being upgraded and the new version.

Upgrading from versions older than pfSense 2.3

See also:

For information about upgrading to current versions, see *Upgrade Guide*.

> **Warning:** Uninstalling *all* packages is **required** when upgrading from old releases. Packages **must be removed** before the upgrade is performed. After the upgrade is complete, packages can be reinstalled. Package configuration is automatically retained.

See *2.3 New Features and Changes* for a larger list of changes.

- Due to the GUI overhaul, older themes have been removed. All previously chosen themes are reset on upgrade to the default "pfSense" 2.3 theme.
- **Status > RRD Graphs** moved to **Status > Monitoring** and has been revamped. The same data, and more, is still accessible but with a modern interface.
- **System > Firmware** is now **System > Update**
- **System > Packages** is now **System > Package Manager**

Limiters

- On pfSense® software versions 2.2 and 2.3, limiters cannot be used on firewall rules residing on interfaces where NAT applies. This limits their use to LAN-type interfaces only, and not WANs, in most circumstances. This has been fixed on pfSense 2.4. Bug #4326
- On pfSense software versions 2.2 and 2.3, limiters cannot be used where pfsync is enabled. This has been fixed on pfSense 2.4.3. Bug #4310

NanoBSD

> **Warning:** NanoBSD has been deprecated as of pfSense 2.4.0-RELEASE. This section remains only for users on i386 hardware with NanoBSD who must upgrade to pfSense 2.3.5-p2.
>
> In most cases, a normal installation may be used in place of NanoBSD. Activating the option to keep `/var` and `/tmp` in RAM can typically yield the same net benefits for older/slower CF and SD media. Firewalls with modern SSDs should have no concerns with writes.

1GB NanoBSD images have been removed as they were too small to properly function and upgrade. If a 1GB NanoBSD image is in use, it cannot be upgraded. It must be re-imaged on a larger card using the 4GB or 2GB image or converted to a full installation.

Package System

- Due to the package system overhaul, any custom package repository settings are removed so the firewall will pull package information directly from pfSense servers.
- We highly recommend uninstalling all packages before upgrading.

Removed features that are disabled on upgrade

- Groups with spaces are no longer permitted. They are not allowed at the OS level and were not functioning properly. On upgrade, such groups are renamed with an underscore ('_') in place of a space.
- The "Enable" checkbox for IPsec has been removed. If IPsec was disabled, all Phase 1 entries are disabled automatically on upgrade.
- The **Unity** plugin for IPsec has been disabled by default, where it was previously enabled by default. This is preferable for the vast majority of users, however those using mobile IPsec with IKEv1 may need to enable it under **VPN > IPsec**, **Advanced** tab.
- The `apinger` daemon for gateway monitoring has been replaced by `dpinger`. Due to the differences in settings between the two, many advanced gateway parameters are reset on upgrade.
- The PPTP *Server* has been removed, if the PPTP server was in use, seek alternate solutions such as IPsec or OpenVPN. **Do not continue to use PPTP**.
  - The PPTP server settings, firewall rules, and so on have all been removed
  - If the "Redirect" PPTP server type was in use, add manual NAT rules for TCP/1723 and GRE to point to the actual server.
- Layer 7 classification support has been removed and any configuration using L7 is automatically removed on upgrade.
- WEP support has been removed from Wireless interfaces, and if a wireless interface was using WEP, the interface is deactivated on upgrade.
- Single DES support has been removed from IPsec, if a Phase 1 or Phase 2 entry was using DES, it is deactivated on upgrade.
  - Note: 3DES support is still present. Only the older and insecure, **single** DES option was removed.
- The Live CD platform has been removed. The ISO is a bootable installer, as always, but it cannot run a live system.
  - For the very few people who were still using Live CD: If the hardware can boot from USB, install to a USB thumb drive and run from it instead. Use the options to keep `/var` and `/tmp` in RAM, and do not install packages, then net result should be similar but ultimately more functional.
- Some obsolete password hashes, such as nt-hash, are removed from users on upgrade. There was no remaining code on pfSense that utilized these hashes, so there should be no loss of functionality.
- Support for `fifolog` was removed, and will revert to clog format on upgrade.
- The `net.inet.ip.fastforwarding` tunable is no longer present, and is unset on upgrade.

- Some PHP modules, such as MySQL, were included by default on previous versions but are no longer a part of the base system on 2.3. They are available as packages that may be installed manually from the shell (e.g. `pkg install php56-mysql`)

New features that may require action

- The default system password hash has been changed to bcrypt. Current passwords will continue to work. Existing users need to reset their password to convert to the new, more secure, hash. #4120
- A new option was added to Captive Portal for FreeRADIUS-friendly stop/start RADIUS accounting updates that solves problems with user session time limits. If stop/start RADIUS accounting is being used with FreeRADIUS, the new option should be activated manually.

Upgrading from a 2.3 Snapshot

- If a firewall was upgraded to 2.3 before Jan 21, 2016, some files from 2.2.x or earlier packages may still be left behind that can prevent new packages from installing properly. Run the following command the clean up outdated symlinks that are not relevant for 2.3:

```
find / -type l -lname '/usr/pbi/*' -delete
```

Multi-WAN Weighted Load Balancing

There is a quirk in pf handling of weighted load balancing where Load balancing fails when one gateway has a weight of 1 and another gateway has a weight >1. Coming from 2.2.x, if this scenario applies, simply double the assigned weights. For example: WAN1 = 1, WAN2 = 5 on 2.2.x should be WAN1 = 2, WAN2 = 10 on 2.3.

Captive Portal

Due to the change in the web server from `lighttpd` to `nginx`, in some cases the portal HTML must be updated to include the zone parameter. On 2.3.1 and later the web server process attempts to handle this automatically, but it is best to include the HTML in the portal page directly, inside the form tag:

```
<input name="zone" type="hidden" value="$PORTAL_ZONE$">
```

Upgrading from versions older than pfSense 2.2

See also:

For information about upgrading to current versions, see *Upgrade Guide*.

Warning: Uninstalling **all** packages is **required** when upgrading from old releases. Packages **must be removed** before the upgrade is performed. After the upgrade is complete, packages can be reinstalled. Package configuration is automatically retained.

Limiters

- On pfSense® software versions 2.2 and 2.3, limiters cannot be used on firewall rules residing on interfaces where NAT applies. This limits their use to LAN-type interfaces only, and not WANs, in most circumstances. This has been fixed on pfSense 2.4. Bug #4326
- On pfSense software versions 2.2 and 2.3, limiters cannot be used where pfsync is enabled. This has been fixed on pfSense 2.4.3. Bug #4310

IPsec Changes

The IPsec daemon was changed from **racoon** to **strongSwan**. Existing configurations work the same as always, but if any unusual configurations are present, take care in testing after the upgrade. Changes in behavior because of this change may trigger bugs in remote endpoints that weren't previously an issue. Configurations that were always technically incorrect may exhibit problems now where they didn't previously. We have listed the circumstances we are aware of here, and will expand upon this list if anything new is found.

Problem in racoon with aggressive mode and NAT-D

Those using racoon (pfSense 2.1.x and earlier, among a variety of other similar products) on remote endpoints with aggressive mode may encounter a bug in racoon related to NAT-D and aggressive mode. Any site to site IPsec VPNs using aggressive mode with racoon as a remote endpoint should change to main mode to prevent this from being an issue. Main mode is always preferable for its stronger security.

glxsb Crypto Accelerator Warning

For those using the `glxsb` crypto accelerator in the ALIX and other devices with Geode CPUs, only AES 128 bit is supported by those cards. Any key length > 128 bit has never worked, and must not be configured. There appear to be circumstances where AES on "auto" with racoon preferred 128 bit where strongswan prefers the strongest-available and is choosing 256 bit, which glxsb breaks. Input validation in 2.2.1 prevents such invalid configurations when adding configurations or making changes, however existing configurations are not changed. If using glxsb and AES, ensure both phase 1 and phase 2 configurations all use AES 128 only and never auto.

Mobile client users, verify Local Network

For mobile IPsec clients, clients could pass traffic in certain circumstances without having specified the necessary matching local network in the mobile phase 2 configuration. The "Local Network" specified in mobile IPsec phase 2 must include all networks mobile clients need to reach. If mobile IPsec clients need to access the Internet via IPsec, the mobile phase 2 must specify `0.0.0.0/0` as the local network.

Stricter Phase 1 Identifier Validation

In 2.1.x and earlier versions, racoon could accept mismatched phase 1 identifiers where using *IP Address* as the identifier. This is most commonly a problem where one of the endpoints is behind NAT and phase 1 is using *My IP Address* and *Peer IP Address* for identifiers. On the side with the private IP WAN, *My IP Address* will be its private WAN IP address. On the opposite end, *Peer IP Address* will be the public IP address of the opposite side. Hence, these two values do not match, and should have resulted in a connection failure. racoon would fall back to checking the source IP address of the initiating host as an identifier, where it found the match. To resolve this issue, change the phase 1 identifiers so they actually match.

Phase 2 behavior change with incorrect network addresses

In 2.1.x and earlier versions a phase 2 configuration with an incorrect network address would still be presented by racoon with the corrected network address. e.g. if `192.168.1.1/24` is set in a phase 2, which should be `192.168.1.0/24`, racoon used it as `192.168.1.0/24`. In 2.2.x and newer versions, strongswan sends it exactly as configured. This may result in a phase 2 mismatch where configured with an incorrect network address.

Disk Driver Changes

The disk drivers in FreeBSD changed between the underlying OS versions and now the CAM-based ATA drivers and AHCI are used by default. As such, ATA disks are labeled as `/dev/adaX` rather than `/dev/adX`. The `ada` driver for ATA disks and GEOM keeps legacy aliases in place so that old disk references will still work post-upgrade. This does not always extend to virtualized disk drivers, however (see the Xen note below.). The upgrade process on pfSense 2.3 and 2.4 also attempts to automatically correct for this change.

A manual workaround is also possible. Running `/usr/local/sbin/ufslabels.sh` **before** the upgrade will convert `/etc/fstab` to UFS labels rather than disk device names bypassing any device name issues that could arise due to the switch.

There is a chance that the new driver stack will have issues with certain controller/disk combinations that were not present in prior releases. There may be BIOS changes or other workarounds to help. See *Boot Troubleshooting*.

The methods used to disable DMA and write caching have both changed on FreeBSD 10.x. For most, disabling these manually is no longer necessary.

If disabling DMA is necessary, the following may be used in a *Loader Tunable*:

```
hint.ata.X.mode=PIO4
```

Change `X` to be the ATA controller ID, typically `0` or `1`.

If write caching must be disabled, the following may be used as a *Loader Tunable*:

```
kern.cam.ada.write_cache=0
```

Xen Users

The FreeBSD base used by pfSense 2.2 and later includes PVHVM drivers for Xen in the kernel. This can cause Xen to automatically change the disk and network device names during an upgrade to pfSense 2.2 or later, which the Hypervisor should not do but does anyway.

The disk change can be worked around by running `/usr/local/sbin/ufslabels.sh` **before** the upgrade to convert `/etc/fstab` to UFS labels rather than disk device names.

The NIC device change issue has no workaround. Manual reassignment is required.

vmxnet3 (VMware/ESX) users

Users who manually installed *VMware Tools* to use `vmxnet3` network adapters may encounter an issue with interface name changes when upgrading to pfSense 2.2 or later, similar to those with Xen mentioned above. In pfSense 2.1.x the `vmxnet3` interfaces were named starting with `vmx3f` and on pfSense 2.2.x they are `vmx` using the built-in support. Manually reassigning the interfaces or correcting them in `config.xml` followed by a restore is required.

Old/Broken GEOM Mirrors

If a manual gmirror configuration was performed post-install and not using the pfSense installer gmirror option before install, there is a chance that the mirror will not function on pfSense 2.2 or later because the manual post-install method did not create a proper mirror setup. If an upgraded mirror does not boot or function on pfSense 2.2 or later, use the following entry to work around the integrity check that would otherwise fail.

Add the following line as a *Loader Tunable*:

```
kern.geom.part.check_integrity=0
```

If the disks are configured in this way, we **strongly** recommend backing up the configuration and reinstalling, using one of the mirrored disk options in the pfSense installer.

CARP Changes

Due to the new CARP subsystem, the old method of having a virtual interface for CARP VIPs is no longer available. CARP VIPs work more like IP Alias style VIPs, existing directly on the main interface. For most, the changes made to accommodate this new system will be transparent, but there are some potential issues, such as:

- With no separate interface available, monitoring a CARP VIP status via SNMP is no longer possible.

FTP Proxy

The FTP proxy is not included in pfSense 2.2-RELEASE or later, due to changes in the kernel and state table handling that made it more difficult to implement. Use of FTP is strongly discouraged as credentials are transmitted insecurely in plain text. #4210

See *FTP without a Proxy* for additional information and workarounds.

Another option is the recently added FTP Client Proxy package which leverages in FreeBSD to allow clients on local interfaces to reach remote FTP servers with active FTP.

LAGG LACP Behavior Change

LAGG using LACP in FreeBSD 10.0 and newer defaults to "strict mode", which means the lagg does not come up unless the attached switch is speaking LACP. This will cause a LAGG to not function after upgrade if the switch is not using active mode LACP.

To retain the lagg behavior in pfSense 2.1.5 and earlier versions, add a new system tunable under **System > Advanced**, **System Tunables** tab for the following:

```
net.link.lagg.0.lacp.lacp_strict_mode
```

With value set to `0`.

This can be added before upgrading to 2.2 to ensure the same behavior on first boot after the upgrade. It will result in a harmless cosmetic error in the logs on 2.1.5 since the value does not exist in that version.

If a firewall has more than one LAGG interface configured, enter a tunable for each instance since that is a per-interface option. For `lagg1`, add the following:

```
net.link.lagg.1.lacp.lacp_strict_mode
```

Also with the value set to `0`.

Intel 10Gbit/s ixgbe/ix users with Unsupported SFP modules

The sysctl to allow unsupported SFP modules changed in FreeBSD between the versions used for pfSense 2.1.x and 2.2.

The old *Loader Tunable* was:

```
hw.ixgbe.unsupported_sfp=1
```

This must be changed to:

```
hw.ix.unsupported_sfp=1
```

Edit the *Loader Tunable* before applying the update and the behavior will be retained.

Layer 7

Layer 7 is deprecated and has been removed. For layer 7 application identification and filtering we recommend using the *Snort IDS/IPS* package with OpenAppID detectors and rules.

Microsoft Load Balancing / Open Mesh Traffic

Windows Network Load Balancing and Open Mesh access points can use multicast MAC address destinations which rely on broken behavior that was incorrectly allowed by default in earlier versions of FreeBSD and pfSense. The fact it worked before was technically a bug, acting in violation of RFC 1812.

> A router MUST not believe any ARP reply that claims that the Link Layer address of another host or router is a broadcast or multicast address.

The default behavior on pfSense 2.2 is correct, but it may be changed.

If this behavior be required, manually add a tunable as follows:

- Navigate to **System > Advanced**, **System Tunables** tab
- Click 
- Enter the following values:
  - **Tunable**: `net.link.ether.inet.allow_multicast`
  - **Description**: Optional. It would be wise to enter the URL to this note or a similar note.
  - **Value**: 1
- Click **Save**

Upgrading from versions older than pfSense 2.1

See also:

For information about upgrading to current versions, see *Upgrade Guide*.

> **Warning:** Uninstalling **all** packages is **required** when upgrading from old releases. Packages **must be removed** before the upgrade is performed. After the upgrade is complete, packages can be reinstalled. Package configuration is automatically retained.

See the HA section at the end of this document for a High Availability-specific pfsync note about pfSense® software version 2.1 upgrades.

The **State Killing on Gateway Failure** feature (**System > Advanced**, **Miscellaneous tab**) now kills ALL states when a gateway has been detected as down, not only states on the failing WAN. This is done because otherwise the LAN-side states were not killed appropriately, and thus some connections would be in limbo, especially SIP. Due to the change in its behavior, **State Killing on Gateway Failure** is disabled by default in new configurations and is disabled during upgrade to pfSense 2.1.x from 2.0.x or before regardless of the user's previously chosen setting. If the feature is desired even with its new behavior, it must be manually re-enabled post-upgrade.

The **Allow IPv6** checkbox is **NOT** changed on upgrade unlike it was in early pfSense 2.1 BETA snapshots. This was changed so that the user's chosen existing behavior is preserved. To allow IPv6 traffic after an upgrade, the setting must be changed manually. This setting is located on **System > Advanced** on the **Networking** tab. It defaults to allowed for new configurations.

Changes to policy route negation between pfSense 2.0.x and 2.1 may result in local/private traffic hitting policy routing rules that would not have happened on pfSense 2.0.x. This most commonly presents as an inability to reach local networks after upgrading. The automatic policy route negation rules on pfSense 2.0.x were too lenient, and that behavior was corrected. To ensure proper routing to other local interfaces, VPNs, or static route networks rules must be added to the local interfaces to pass traffic to these destinations without a gateway set. And that rule must be above any others that would match and have a gateway set.

Upgrading High Availability Deployments

If upgrading from any previous version of pfSense (1.2.x, 2.0.x, etc) to pfSense 2.1 or later in an HA environment, ensure that the pfsync interface has a rule to pass the correct traffic for state synchronization to work properly. pfSense 2.1 removed the automatic pfsync rule, since the documentation always recommended adding it manually and to add it behind the scenes with no way to block it could be counter-productive and potentially insecure. If the documentation was not followed, and a pfsync or allow all rule was not created on the sync interface, state synchronization may break after this upgrade. Add an appropriate rule to the sync interface and it will work again.

At a minimum, pass traffic of the *pfsync* protocol from a source of the synchronization subnet to all cluster nodes.

Upgrading from versions older than pfSense® 2.0

See also:

For information about upgrading to current versions, see *Upgrade Guide*.

Warning: Uninstalling **all** packages is **required** when upgrading from old releases. Packages **must be removed** before the upgrade is performed. After the upgrade is complete, packages can be reinstalled. Package configuration is automatically retained.

Note for users of the OpenVPN Status Package

If a manual `management` directive was entered into the **Advanced Configuration** of an OpenVPN client or server, it must be removed. The OpenVPN status code is built into pfSense® software version 2.x and later, and it is handled internally. The management directive must be removed or the status of the VPN instance will not be properly reported.

Note for Captive Portal RADIUS WISPr Bandwidth Users

The WISPr RADIUS attributes were incorrectly applied to all versions prior to pfSense 2.0-RELEASE. They were applied as *Kbps* where WISPr is supposed to be *bps*, hence those using WISPr attributes will have one one-thousandth of the previous bandwidth unless the RADIUS server is corrected. The RADIUS server will need to have these values updated to bps for proper functionality once the firewall has been upgraded to pfSense 2.0-RELEASE or later.

International/Special Characters in 1.2.x Configurations

International characters, such as åäö and so on, were not supported on pfSense 1.2.x, but were allowed in some places due to overly lenient input validation and less strict XML parsing. These characters causes invalid XML when they are stored directly, and as such if pfSense 1.2.x did not crash and toss out the configuration with such characters, it will not upgrade to any current version of pfSense software.

pfSense software version 2.0 and later will reset and toss out the config.xml on every reboot if it contains these characters bare, leaving the firewall at an "assign interfaces" prompt since it does not have a valid configuration.

The *config.xml* file can be run through an XML parser such as `xmllint` and the parser will show where problems exist, if any. Fix the errors, and then the corrected configuration can be used for an upgrade. The good news is that these characters are handled properly in most areas of the current pfSense GUI, and they are CDATA escaped so they are safe from such errors.

Upgrading High Availability Deployments

When upgrading from pfSense 1.2.3 to 2.0 or later, Check the CARP VIPs to make sure they are actually on the proper interface. That is, that the interface chosen for the VIP properly matches the subnet in which the CARP VIP resides, and that the subnet mask is proper. pfSense 2.0 validates this more strictly than previous releases, and as a consequence if a CARP VIP was misconfigured on pfSense 1.2.3, it may not upgrade cleanly.

7.6.4 Perform the Upgrade

There are several methods available to update an installation of pfSense® software. Either the WebGUI or the console can be used.

Note: Before performing an upgrade, read through the entire *Upgrade Guide*.

If problems occur during the upgrade process, consult *Troubleshooting Upgrades* for assistance.

Upgrading using the GUI

The **Automatic Update** check feature contacts a Netgate server and determines if there is a release version newer than the version on the firewall. This check is performed when an administrator visits the dashboard or **System > Update**.

To perform the upgrade in the GUI:

- Navigate to **System > Update** or click  in the System Information dashboard widget next to the new version notification.
- Click  **Confirm** to start the update
- Wait for the upgrade to complete

The update takes a few minutes to download and apply, depending on the speed of the Internet connection being used and the speed of the firewall hardware. The firewall will reboot automatically when finished.

Tip: Monitor the firewall console during the upgrade if possible to watch for potential problems.

Upgrading using the Console

An update may also be run from the console. The console option is available from any means available for console access: Video/Keyboard, Serial Console, or SSH.

- Connect to the firewall console or login via ssh
- Enter menu option `13`
- Wait for the upgrade to complete

Alternately, from a shell prompt running as root, manually execute the following command:

```
# pfSense-upgrade
```

Tip: When upgrading from SSH, the GNU screen utility can be a useful tool to monitor the upgrade process in environments where the connection to the firewall is unstable:

```
# pkg install screen
# rehash
# screen pfSense-upgrade
```

Reinstalling / Upgrading Configuration

If an upgrade will not function properly on an existing installation, the configuration file can be restored to a freshly installed copy of pfSense software. An older configuration can always be imported into a new version. The upgrade code will make necessary changes to the configuration so it will work with the current version of the software. See *Backup and Recovery* for details.

7.6.5 Upgrading High Availability Clusters

This document provides guidance on upgrading redundant firewalls in a high availability configuration across major versions of pfSense® software.

Upgrading from one version to another generally follows the this procedure, exceptions are noted later in the page:

- Review release notes, blog, and upgrade guide.
- Take a backup from both nodes.

  Danger: Do not skip this step, backups are critical!

- Upgrade the secondary node as described in the *Upgrade Guide*.
- Test the secondary node to be sure it is operating as expected – correct packages present, services running, no obvious errors in logs, etc.
- Enter Persistent CARP maintenance mode on the primary node from **Status > CARP**.
- Ensure traffic is still flowing properly and that the network is functional.

  If it is not, then exit maintenance mode on the primary node, fix the secondary node, then try again.
- Upgrade the primary node as described in the *Upgrade Guide*.
- Check the primary node to ensure it upgraded and is operating as expected – correct packages present, services running, no obvious errors in logs, etc.
- Leave Persistent CARP maintenance mode on the primary node.
- Test everything again.

Tip: If this cluster is using the ISC DHCP backend, consider converting to the Kea DHCP backend as the ISC DHCP backend is deprecated and will be removed in the near future. See *Converting High Availability DHCP from ISC to Kea* for details.

XMLRPC Config Sync Considerations

Upgrade either the primary or the secondary first, leaving the other on the older version until testing is complete.

Supported versions of pfSense software from the last several years properly check for and prevent unintentionally synchronizing data between incompatible versions.

pfsync considerations

The underlying pfsync protocol often changes between FreeBSD versions. Versions of pfSense software with a different base OS version of FreeBSD may not be capable of synchronizing their states between each other. Failover will still function, but not stateful failover so all existing connections will be dropped.

pfsync and State Policy

The State Policy (*Firewall State Policy*) of the firewall can introduce a conflict in state synchronization if nodes using pfsync do not have identical hardware.

See *pfsync and Physical Interfaces* for details and a potential workaround.

CARP considerations

CARP is generally the same between versions and will fail over and back as expected.

See also:

- *Troubleshooting Upgrades*

7.6.6 Update Settings

Branch / Tracking Snapshots

By default, the update check looks for officially released versions of pfSense software, but this method can also be used to track development snapshots.

To change the branch used for updates:

- Navigate to **System > Update**
- Set the **Branch** to the desired type of updates
- Wait for the page to refresh and perform a new update check

The branch list will vary depending on the current development cycle. Examples of options that may be found in the list include:

Latest Stable Version
: Stable versions are the best option, as they see the most testing and are reasonably safe and trouble-free. However, as with any upgrade, read the *changelog* and *update notes* for that release.

pfSense Plus Upgrade
: Upgrade a system from pfSense CE software to pfSense Plus software. Present on registered systems with access to pfSense Plus software repositories.

See also:

See *Migrate from pfSense® CE software to Netgate pfSense Plus software* for details on migrating to pfSense Plus software.

Previous Stable Version (Deprecated)
A pointer to the previous release so that firewalls may pull packages and update files from the previous release while waiting for a maintenance window or similar upgrade opportunity. May also be labeled "Legacy".

Latest Development Snapshots
Tracks development snapshot builds. These may either be snapshots for the next minor or major version depending on the status of the development cycle.

Next Major Version
Tracks snapshots for the next major update version. This is riskier, but in some cases may be required for newer hardware or new features that are not yet released. Consult the forum and test in a lab to see if these snapshots are stable in a particular environment.

> **Warning:** Do not run development versions of pfSense software in production environments.

Boot Environments

There are a handful of options related to *ZFS Boot Environments* which only appear on systems running pfSense Plus software installed using ZFS.

See also:

- *How Boot Environments Work*
- *Upgrade Process Overview*

The available options are:

Defer Automatic Reboot
When checked, the firewall will not automatically reboot after finishing the upgrade. Instead, it will wait for an administrator to reboot it manually.

Boot Verification
These options control the boot time verification for a Boot Environment. If verification fails, the firewall will automatically roll back to a previous known-good Boot Environment and reboot.

The firewall displays a prompt on the Dashboard to verify or fail the Boot Environment.

Manual Boot Verification
When set, the Boot Environment is not automatically verified and must be verified manually before the verification interval expires.

Boot Verification Interval
This option defines the amount of time the administrator has to verify that the Boot Environment is in working order. If the timer expires, the firewall will automatically roll back to a previous known-good Boot Environment and reboot.

The default value is `300` seconds (5 minutes).

See also:

See *ZFS Boot Environments (Plus Only)* for more information.

Dashboard Check

The **Dashboard Check** checkbox on **System > Update**, **Update Settings** tab controls whether or not the **System Information** widget on the dashboard performs an update check. On firewalls with low resources or slow disks, disabling this check will reduce the load caused by running the check each time an administrator views the dashboard.

GitSync

This section is for developers and should not be used by end users. Leave settings in this area empty or disabled.

7.7 Migrate from pfSense® CE software to Netgate pfSense Plus software

Netgate now offers the ability to migrate from the Community Edition (CE) of pfSense® software to pfSense Plus software.

This enables users with virtual machines or hardware not sold by Netgate to utilize the advantages of pfSense Plus software.

pfSense Plus Software Migration Procedure

7.7.1 Requirements

To perform this migration:

- The firewall must be running pfSense CE software version 2.6.0 or later.

  Before starting, take one of the following steps:

  - Perform fresh install of at least pfSense CE software version 2.6.0 by following the *installation guide*.
  - Upgrade an existing installation of pfSense CE software to version 2.6.0 or later by following the *upgrade guide*.
- The firewall must be connected to the Internet to perform the migration.

Warning: The migration process preserves the existing filesystem type, so ensure that a firewall is in the intended state before upgrading. For example, install pfSense CE software using ZFS so that it can use pfSense Plus software with ZFS.

7.7.2 Obtain an Activation Token

Activation tokens are generated by the Netgate Store. To obtain a token, follow these steps:

- Visit the Netgate Store
- Create a new account or log into an existing account
- Visit the pfSense Plus Software Subscription product page
- Select the desired **Software Type**
- Add the product to the cart
- Complete the checkout process

After completing the checkout process the store will send an activation token by e-mail to the address on the Netgate Store account.

Tip: If the activation e-mail does not arrive in a timely manner, check spam or junk mail folders in the e-mail client.

Warning: Activation tokens are single use. Ensure the pfSense CE software installation is functional and is in the intended configuration before performing the migration.

7.7.3 Register and Migrate

- Navigate to **System > Register** in the pfSense CE software GUI
- Paste the **Activation Token** into the text area on the page
- Click **Register**

  The page will display a message indicating the registration results. If the registration was successful, continue. If registration failed, contact Netgate TAC.
- Navigate to **System > Update**

  The page will contain a message announcing the pfSense Plus software migration branch.
- Set **Branch** to *pfSense Plus Upgrade* as seen in figure *pfSense Plus Software Branch Selection*.
- Wait for the firewall to complete the update check
- Click **Confirm** to confirm and start the migration process

The migration process will proceed from there and reboot when it is complete. This may take several minutes to complete, especially in locations with slow download speeds. Monitor the console for progress.

Warning: Do not manually reboot or remove power from the device until the migration completes as this may interrupt the process and cause it to fail.

Congratulations, the firewall is now running pfSense Plus Software!

CHAPTER

EIGHT

CONFIGURATION

8.1 Setup Wizard

The first time a user logs into the pfSense® software GUI, the firewall presents the Setup Wizard automatically. The first page of the wizard is shown in Figure *Setup Wizard Starting Screen*.

Click » **Next** to proceed.

Tip: Using the setup wizard is optional. Click the logo at the top left of the page to exit the wizard at any time.

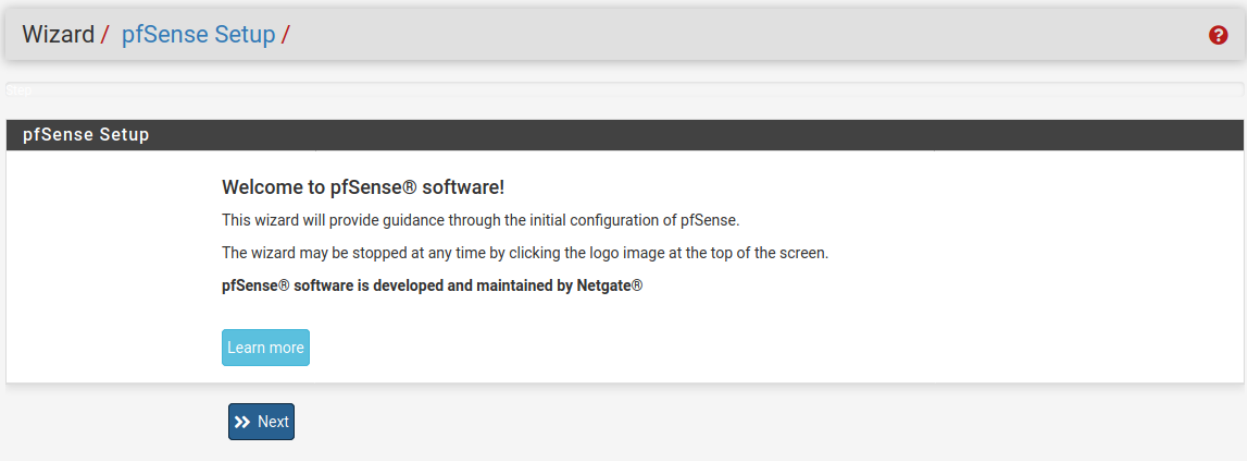

Fig. 1: Setup Wizard Starting Screen

The next screen of the wizard explains the availability of support from Netgate. Click » **Next** again to start the configuration process using the wizard.

8.1.1 General Information Screen

The next screen (Figure *General Information Screen*) configures the name of this firewall, the domain in which it resides, and the DNS servers for the firewall.

Hostname
The **Hostname** is a name that should uniquely identify this firewall. It can be nearly anything, but must start with a letter and it may contain only letters, numbers, or a hyphen.

Domain
Enter a Domain, e.g. `example.com`. If this network does not have a domain, use `<something>.home.arpa`, where `<something>` is another identifier: a company name, last name, nickname, etc. For example, `company.home.arpa` The hostname and domain name are combined to make up the fully qualified domain name of this firewall.

Primary/Secondary DNS Server
The IP address of the Primary DNS Server and Secondary DNS Server, if known.

These DNS servers may be left blank if the DNS Resolver will remain active using its default settings. The default configuration has the DNS Resolver active in resolver mode (not forwarding mode), when set this way, the DNS Resolver does not need forwarding DNS servers as it will communicate directly with Root DNS servers and other authoritative DNS servers. To force the firewall to use these configured DNS servers, enable forwarding mode in the DNS Resolver or use the DNS Forwarder.

If this firewall has a dynamic WAN type such as DHCP, PPTP or PPPoE these may be automatically assigned by the ISP and can be left blank.

Note: The firewall can have more than two DNS servers, add more under **System > General Setup** after completing the wizard.

Override DNS
When checked, a dynamic WAN ISP can supply DNS servers which override those set manually. To force the use of only the DNS servers configured manually, uncheck this option.

See also:

For more information on configuring the DNS Resolver, see *DNS Resolver*

Click » **Next** to continue.

8.1.2 NTP and Time Zone Configuration

The next screen (Figure *NTP and Time Zone Setup Screen*) has time-related options.

Time server hostname
A Network Time Protocol (NTP) server hostname or IP address. Unless a specific NTP server is required, such as one on LAN, the best practice is to leave the **Time server hostname** at the default `2.pfsense.pool.ntp.org`. This value will pick a set of random servers from a pool of known-good NTP hosts.

To utilize multiple time server pools or individual servers, add them in the same box, separating each server by a space. For example, to use three NTP servers from the pool, enter: `0.pfsense.pool.ntp.org 1.pfsense.pool.ntp.org 2.pfsense.pool.ntp.org`

This numbering is specific to how `.pool.ntp.org` operates and ensures each address is drawn from a unique pool of NTP servers so the same server does not get used twice.

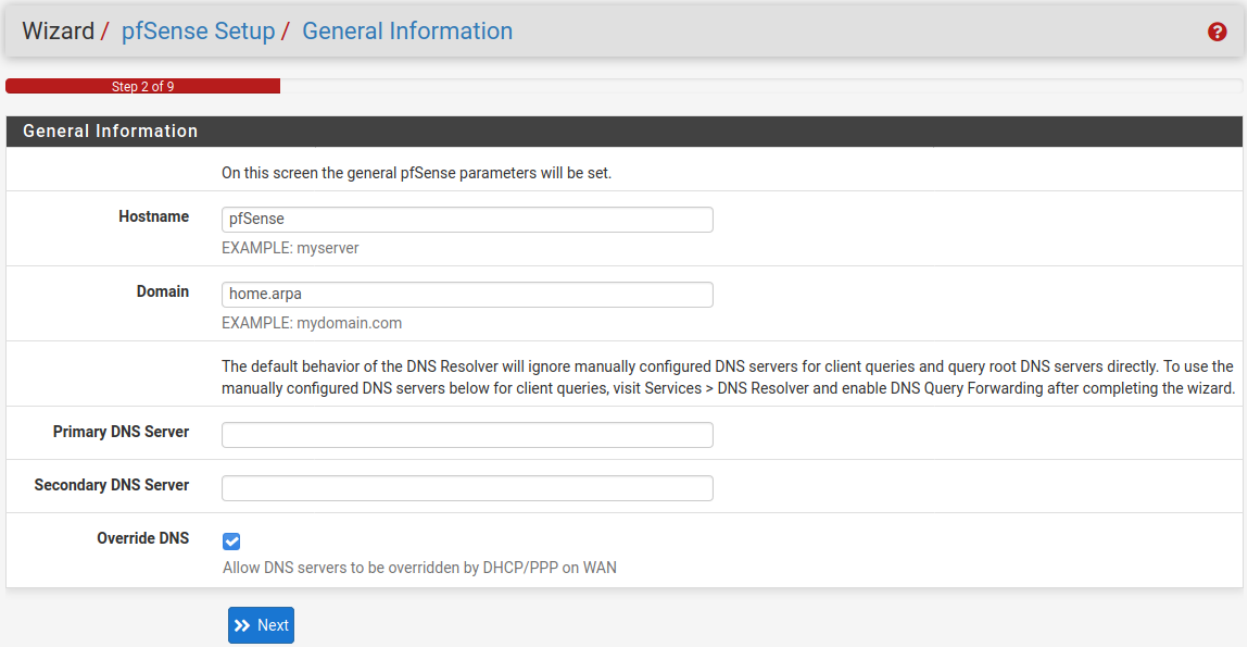

Fig. 2: General Information Screen

Timezone
: Choose a geographically named zone which best matches location of this firewall, or any other desired zone.

Click  **Next** to continue.

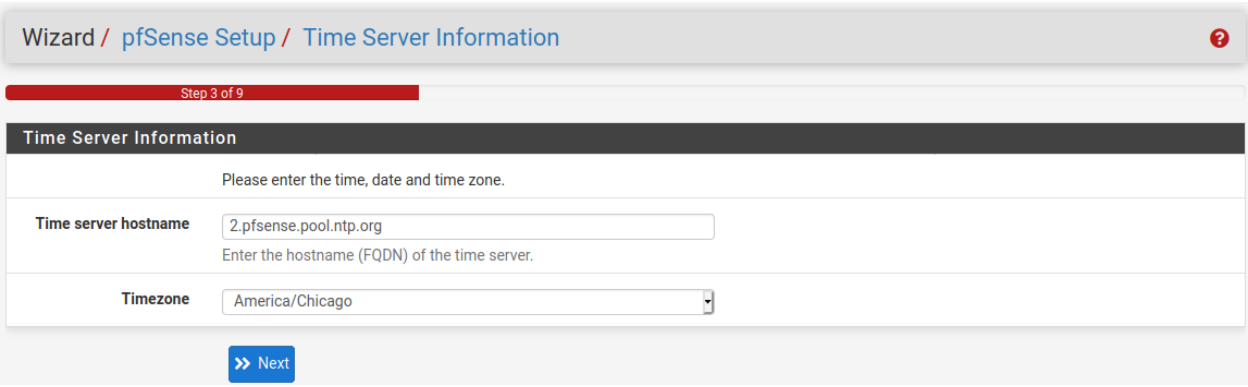

Fig. 3: NTP and Time Zone Setup Screen

8.1.3 WAN Configuration

The next page of the wizard configures the WAN interface of the firewall. This is the external network facing the ISP or upstream router, so the wizard offers configuration choices to support several common ISP connection types.

WAN Type

The **Selected Type** (Figure *WAN Configuration*) must match the type of WAN required by the ISP, or whatever the previous firewall or router was configured to use. Possible choices are *Static*, *DHCP*, *PPPoE*, and *PPTP*. The default choice is *DHCP* due to the fact that it is the most common, and for the majority of cases this setting allows a firewall to "Just Work" without additional configuration. If the WAN type is not known, or specific settings for the WAN are not known, this information must be obtained from the ISP. If the required WAN type is not available in the wizard, or to read more information about the different WAN types, see *Interface Types and Configuration*.

Note: If the WAN interface is wireless, additional options will be presented by the wizard which are not covered during this walkthrough of the standard Setup Wizard. Refer to *Wireless*, which has a section on Wireless WAN for additional information. If any of the options are unclear, skip the WAN setup for now, and then perform the wireless configuration afterward.

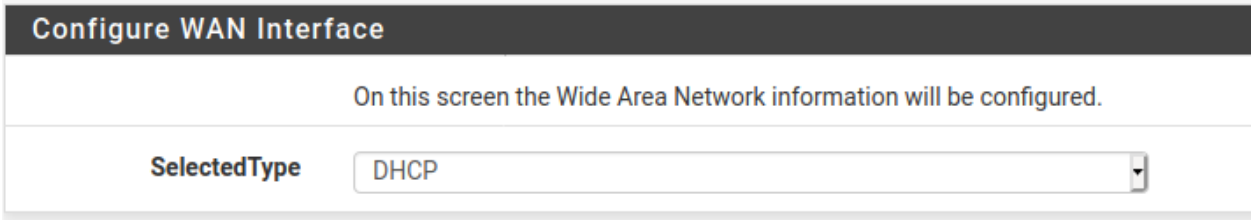

Fig. 4: WAN Configuration

MAC Address

This field, shown in Figure *General WAN Configuration*, changes the MAC address used on the WAN network interface. This is also known as "spoofing" the MAC address.

Note: The problems alleviated by spoofing a MAC address are typically temporary and easily worked around. The best course of action is to maintain the original hardware MAC address, resorting to spoofing only when absolutely necessary.

Changing the MAC address can be useful when replacing an existing piece of network equipment. Certain ISPs, primarily Cable providers, will not work properly if a new MAC address is encountered. Some Internet providers require power cycling the modem, others require registering the new address over the phone. Additionally, if this WAN connection is on a network segment with other systems that locate it via ARP, changing the MAC to match and older piece of equipment may also help ease the transition, rather than having to clear ARP caches or update static ARP entries.

Warning: If this firewall will ever be used as part of a *High Availability Cluster*, do not spoof the MAC address.

Maximum Transmission Unit (MTU)

The MTU field, shown in Figure *General WAN Configuration*, can typically be left blank, but can be changed when necessary. Some situations may call for a lower MTU to ensure packets are sized

appropriately for an Internet connection. In most cases, the default assumed values for the WAN connection type will work properly.

Maximum Segment Size (MSS)

MSS, shown in Figure *General WAN Configuration* can typically be left blank, but can be changed when necessary. This field enables MSS clamping, which ensures TCP packet sizes remain adequately small for a particular Internet connection.

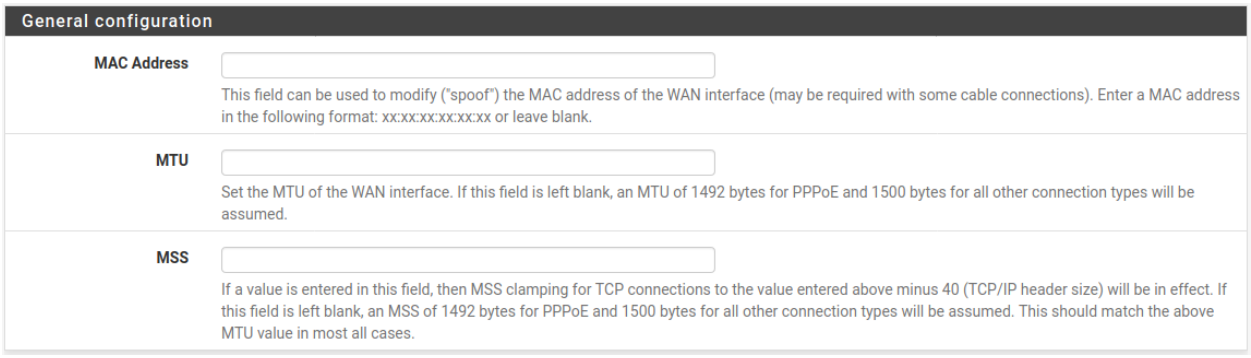

Fig. 5: General WAN Configuration

Static IP Configuration

If the "Static" choice for the WAN type is selected, the **IP address**, **Subnet Mask**, and **Upstream Gateway** must all be filled in (Figure *Static IP Settings*). This information must be obtained from the ISP or whoever controls the network on the WAN side of this firewall. The **IP Address** and **Upstream Gateway** must both reside in the same Subnet.

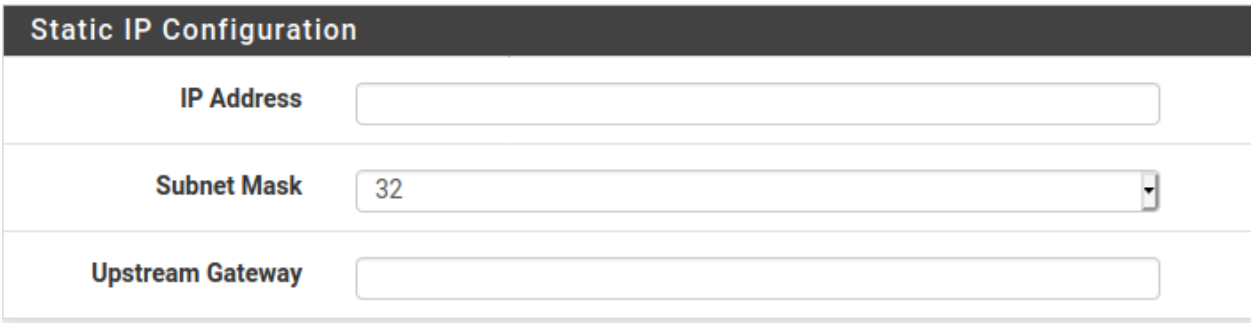

Fig. 6: Static IP Settings

DHCP Hostname

This field (Figure *DHCP Hostname Setting*) is only required by a few ISPs. This value is sent along with the DHCP request to obtain a WAN IP address. If the value for this field is unknown, try leaving it blank unless directed otherwise by the ISP.

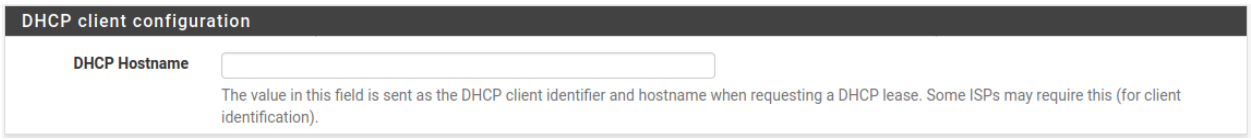

Fig. 7: DHCP Hostname Setting

PPPoE Configuration

When using the PPPoE (Point-to-Point Protocol over Ethernet) WAN type (Figure *PPPoE Configu-*

ration), The **PPPoE Username** and **PPPoE Password** fields are required, at a minimum. The values for these fields are determined by the ISP.

PPPoE Username
The login name for PPPoE authentication. The format is controlled by the ISP, but commonly uses an e-mail address style such as `myname@example.com`.

PPPoE Password
The password to login to the account specified by the username above. The password is masked by default. To view the entered password, check **Reveal password characters**.

PPPoE Service Name
The PPPoE Service name may be required by an ISP, but is typically left blank. When in doubt, leave it blank or contact the ISP and ask if it is necessary.

PPPoE Dial on Demand
This option leaves the connection down/offline until data is requested that would need the connection to the Internet. PPPoE logins happen quite fast, so in most cases the delay while the connection is setup would be negligible. If public services are hosted behind this firewall, do not check this option as an online connection must be maintained as much as possible in that case. Also note that this choice will not drop an existing connection.

PPPoE Idle Timeout
Specifies how much time the PPPoE connection remain up without transmitting data before disconnecting. This is only useful when coupled with Dial on demand, and is typically left blank (disabled).

Note: This option also requires the deactivation of gateway monitoring, otherwise the connection will never be idle.

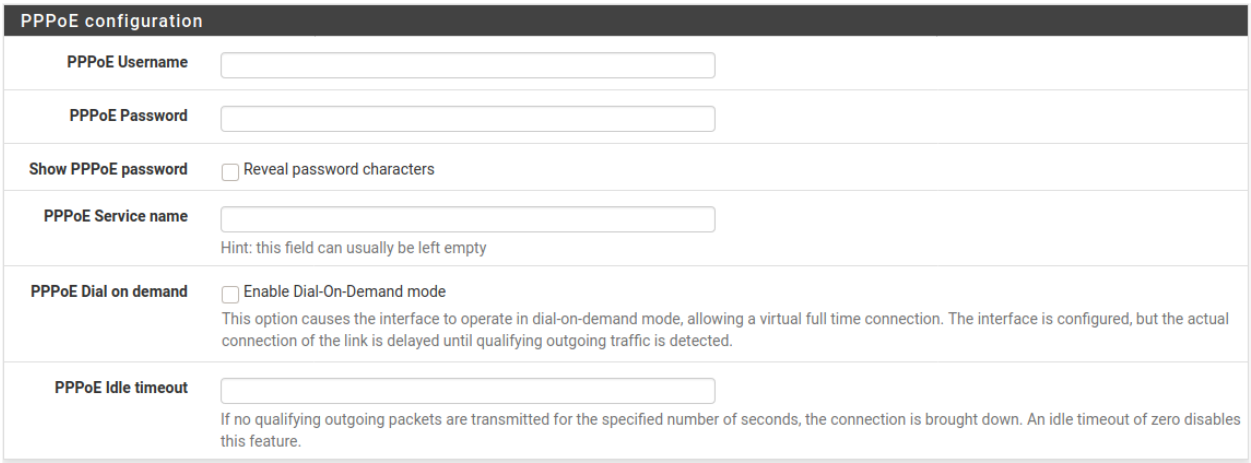

Fig. 8: PPPoE Configuration

PPTP Configuration
The PPTP (Point-to-Point Tunneling Protocol) WAN type (Figure *PPTP WAN Configuration*) is for ISPs that require a PPTP login, **not** for connecting to a remote PPTP VPN. These settings, much like the PPPoE settings, will be provided by the ISP. A few additional options are required:

Local IP Address

The local (usually private) address used by this firewall to establish the PPTP connection.

CIDR Subnet Mask
The subnet mask for the local address.

Remote IP Address
The PPTP server address, which is usually inside the same subnet as the **Local IP address**.

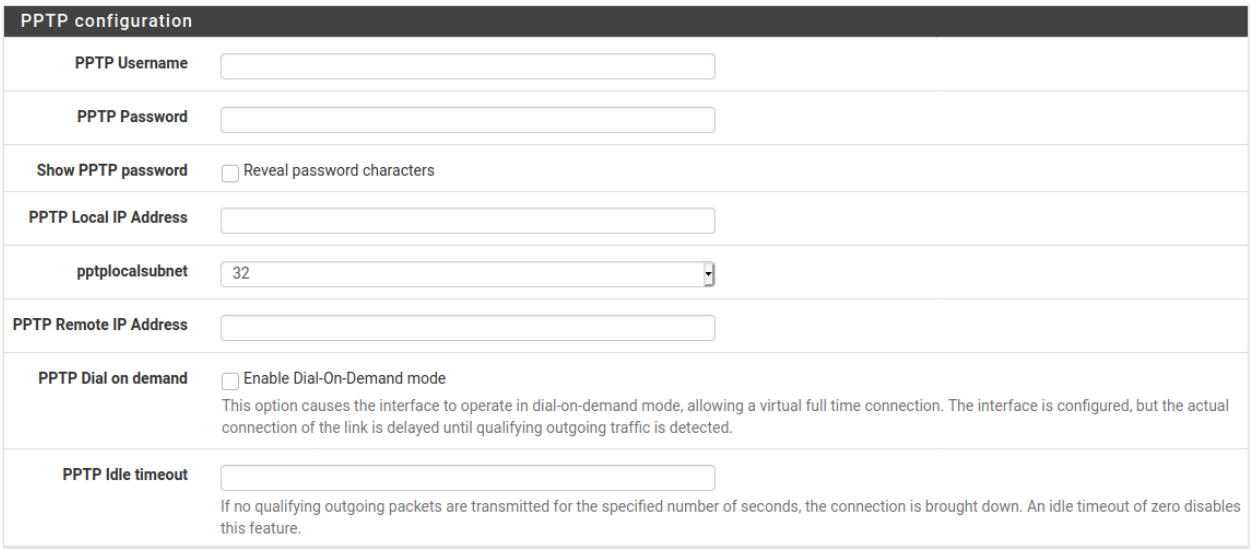

Fig. 9: PPTP WAN Configuration

These last two options, seen in Figure *Built-in Ingress Filtering Options*, are useful for preventing invalid traffic from entering the network protected by this firewall, also known as "Ingress Filtering".

Block RFC 1918 Private Networks
Blocks connections sourced from registered private networks such as `192.168.x.x` and `10.x.x.x` attempting to enter the WAN interface . A full list of these networks is in *Private IP Addresses*.

Block Bogon Networks
When active, the firewall blocks traffic from entering if it is sourced from reserved or unassigned IP space that should not be in use. The list of bogon networks is updated periodically in the background, and requires no manual maintenance. Bogon networks are further explained in *Block Bogon Networks*.

Click  **Next** to continue once the WAN settings have been filled in.

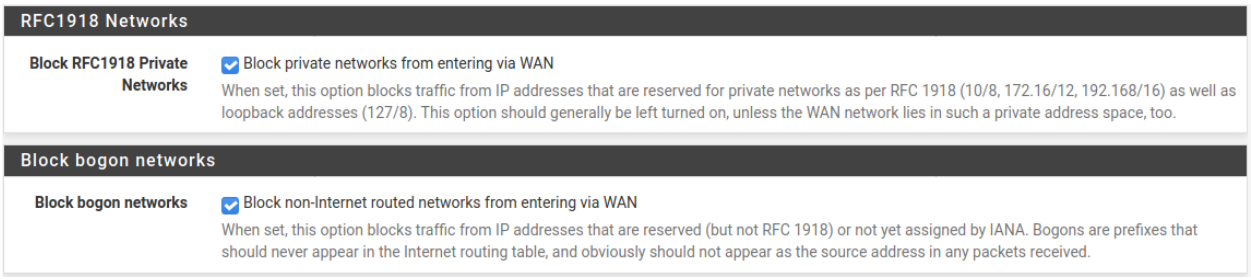

Fig. 10: Built-in Ingress Filtering Options

8.1.4 LAN Interface Configuration

This page of the wizard configures the **LAN IP Address** and **Subnet Mask** (Figure *LAN Configuration*).

If this firewall will not connect to any other network via VPN, the default `192.168.1.0/24` network may be acceptable. If this network must be connected to another network, including via VPN from remote locations, choose a private IP address range much more obscure than the common default of `192.168.1.0/24`. IP space within the `172.16.0.0/12` RFC 1918 private address block is generally the least frequently used, so choose something between `172.16.x.x` and `172.31.x.x` to help avoid VPN connectivity difficulties.

If the LAN is `192.168.1.x` and a remote client is at a wireless hotspot using `192.168.1.x` (very common), the client will not be able to communicate across the VPN. In that case, `192.168.1.x` is the local network for the client at the hotspot, not the remote network over the VPN.

If the **LAN IP Address** must be changed, enter it here along with a new **Subnet Mask**. If these settings are changed, the IP address of the computer used to complete the wizard must also be changed if it is connected through the LAN. Release/renew its DHCP lease, or perform a "Repair" or "Diagnose" on the network interface when finished with the setup wizard.

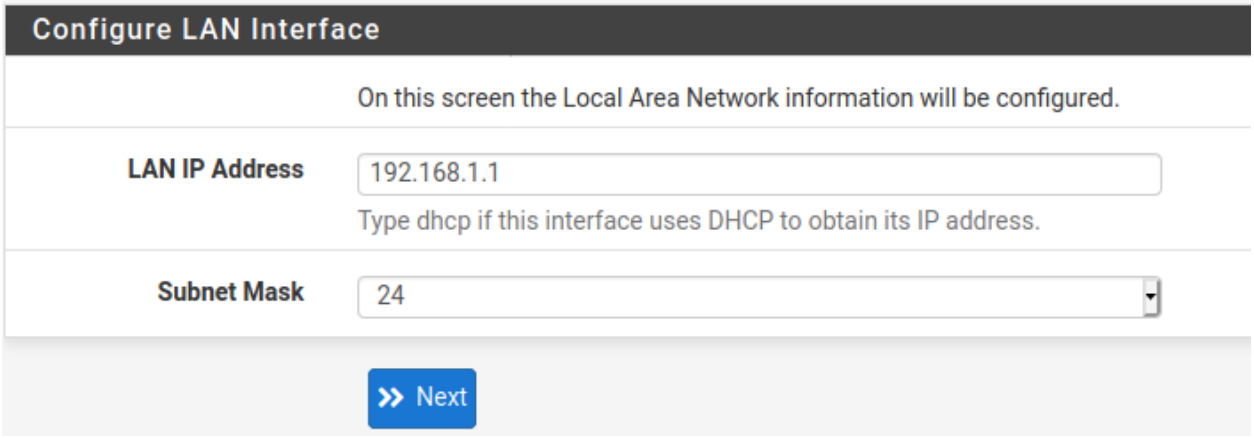

Fig. 11: LAN Configuration

Click » **Next** to continue.

8.1.5 Set admin password

Next, change the administrative password for the GUI as shown in Figure *Change Administrative Password*. The best practice is to use a strong and secure password.

> **Warning:** This password cannot be set to the same value as the username.
>
> Additionally, on pfSense Plus software version 24.03 and later, the password cannot be set to the default value (*Default Username and Password*).

Enter the password in the **Admin Password** and confirmation box to be sure that has been entered correctly.

> **Warning:** On pfSense Plus software version 24.03 and later changing the password is **mandatory**. The wizard will not proceed until the password is changed.

Click » **Next** to continue.

> **Warning:** **Do not leave the password set to the default** `pfsense`. If access to the firewall administration via GUI or SSH is exposed to the Internet, intentionally or accidentally, the firewall could easily be compromised if it still uses the default password.

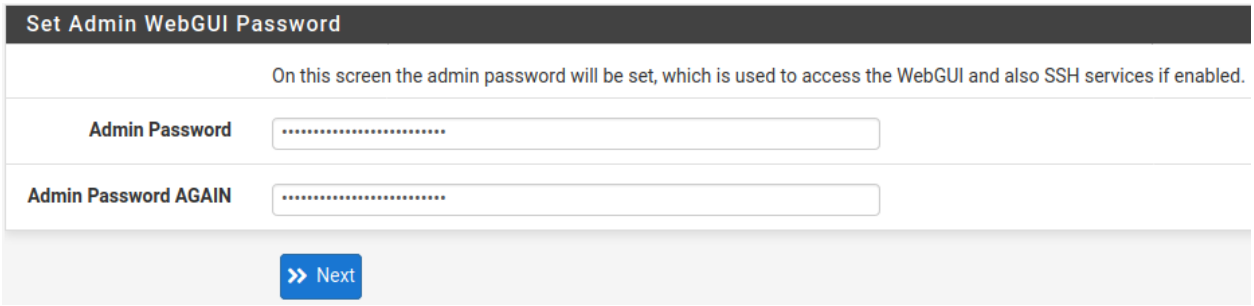

Fig. 12: Change Administrative Password

8.1.6 Completing the Setup Wizard

That completes the setup wizard configuration. Click **Reload** (Figure *Reload the GUI*) and the GUI will apply the settings from the wizard and reload services changed by the wizard.

Tip: If the LAN IP address was changed in the wizard and the wizard was run from the LAN, adjust the client computer's IP address accordingly after clicking **Reload**.

When prompted to login again, enter the new password. The username remains `admin`.

After reloading, the final screen of the wizard includes convenient links to check for updates, get support, and other resources. Click **Finish** to complete and exit the wizard.

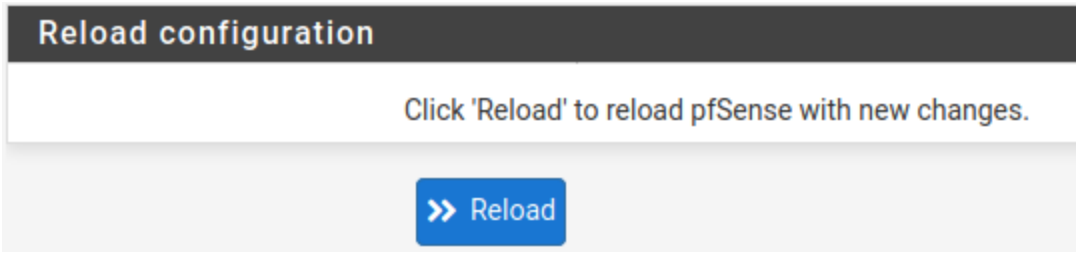

Fig. 13: Reload the GUI

At this point the firewall will have basic connectivity to the Internet via the WAN and clients on the LAN side will be able to reach Internet sites through this firewall.

If at any time this initial configuration must be repeated, revisit the wizard at **System > Setup Wizard** from within the GUI.

8.2 Interface Configuration

Basic aspects of interface configuration within pfSense® software can be performed at the console and in the setup wizard to start, but changes may also be made after the initial setup by visiting pages under the **Interfaces** menu. A few basics are covered here, the details can be found in *Interface Types and Configuration*.

8.2.1 Assign interfaces

Interfaces added after the initial setup may be assigned roles by visiting **Interfaces > Assignments**. There are numerous tabs on that page used for assigning and creating different types of interfaces. The two most commonly used tabs are **Interface assignments** and **VLANs**.

See also:

VLAN configuration is covered in *Virtual LANs (VLANs)*.

The **Interface assignments** tab shows a list of all currently assigned interfaces: WAN, LAN, and any OPTx entries configured on the firewall. Next to each interface is a drop-down list of all network interfaces/ports found on the system. This list includes hardware interfaces as well as VLAN interfaces and other virtual interface types. The MAC address, VLAN tag, or other identifying information is printed along side the interface name to aid in identification.

The other tabs, much like the **VLAN** tab, are there to create additional interfaces which can then be assigned. All of these interface types are covered in *Interface Types and Configuration*.

To change an existing interface assignment to another network port:

- Navigate to **Interfaces > Assignments**
- Locate the interface to change in the list
- Select the new network port from the drop-down list on the row for that interface
- Click **Save**

To add a new interface from the list of unused network ports:

- Navigate to **Interfaces > Assignments**
- Select the port to use from the drop-down list labeled **Available Network Ports**

- Click  **Add**

This action will add another line with a new OPT interface numbered higher than any existing OPT interface, or if this is the first additional interface, *OPT1*.

8.2.2 Interface Configuration Basics

Interfaces are configured by choosing their entry from under the **Interfaces** menu. For example, to configure the WAN interface, choose **Interfaces > WAN**.

Every interface is configured in the same manner and any interface can be configured as any interface type (Static, DHCP, PPPoE, etc). Additionally, the blocking of private networks and bogon networks may be performed on any interface. Every interface can be renamed, including WAN and LAN, to a custom name. Furthermore, every interface can be enabled and disabled as desired, so long as a minimum of one interface remains enabled.

See also:

For detailed interface configuration information, see *Interface Types and Configuration*

The **IPv4 Configuration Type** can be changed between *Static IPv4*, *DHCP*, *PPPoE*, *PPP*, *PPTP*, *L2TP*, or *None* to leave the interface without an IPv4 address. When *Static IPv4* is used, an **IPv4 Address**, subnet mask, and **IPv4 Upstream Gateway** may be set. If one of the other options is chosen, then type-specific fields appear to configure each type.

The **IPv6 Configuration Type** can be set to *Static IPv6*, *DHCP6*, *SLAAC*, *6rd Tunnel*, *6to4 Tunnel*, *Track Interface*, or *None* to leave IPv6 unconfigured on the interface. When Static IPv6 is selected, set an **IPv6 address**, prefix length, and **IPv6 Upstream Gateway**.

If this a wireless interface, the page will contain many additional options to configure the wireless portion of the interface. Consult *Wireless* for details.

Note: Selecting a **Gateway** from the drop-down list, or adding a new gateway and selecting it, will direct the firewall to treat this interface as a WAN type interface for NAT and related functions. This is not desirable for internal-facing interfaces such as LAN or a DMZ. Gateways may still be utilized on those interfaces for static routes and other purposes *without* selecting a **Gateway** here on the interfaces page.

8.3 Managing Lists in the GUI

The pfSense® software GUI has a common set of icons which are used for managing lists and collections of objects throughout the firewall. Not every icon is used in every page, but their meanings are consistent based on the context in which they are seen. Examples of such lists include firewall rules, NAT rules, IPsec, OpenVPN, and certificates.

Add a new item to a list

Add an item to the beginning of a list

Add an item to the end of a list

Edit an existing item

Copy an item (create a new item based on the selected item)

Disable an active item

Enable a disabled item

Delete an item

Used for moving entries after selecting one or more items. Click to move the selected items above this row. Shift-click to move the selected items below this row.

Sections may have their own icons specific to each area. Consult the appropriate sections of this documentation for specifics about icons found in other parts of the firewall.

Tip: To determine which action an icon will perform, hover over the icon with the mouse pointer and a tooltip will display a short description of the icon's purpose.

8.4 Quickly Navigate the GUI with Shortcuts

Many areas of the GUI have shortcut icons present in the area known as the "Breadcrumb Bar", as seen in Figure *Shortcuts Example*. These shortcut icons reduce the amount of hunting required to locate related pages, allowing a firewall administrator to navigate quickly between the status page of a service, its logs, and configuration. The shortcuts for a given topic are present on each page related to that topic.

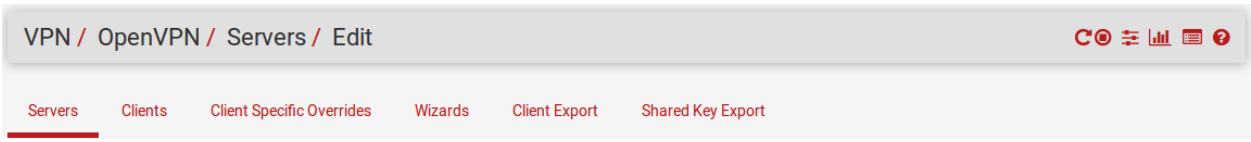

Fig. 14: Shortcuts Example

Note: Shortcut icons only appear when their respective actions are possible and the target pages exist. Not every section has every icon.

The shortcut icons have the following effects when they appear in the GUI:

Start Service
If the service is stopped, this icon starts the service.

Restart Service
If the service is running, this icon restarts the service.

Note: Some services will stop and start, others reload the configuration. Check the documentation of each service for details.

Stop Service
If the service is running, this icon stops the service.

Related Settings
This icon navigates to the **settings** page for this section.

Status Page Link
This icon navigates to the **status** page for this section.

Log Page Link
This icon navigates to the **logs** page for this section.

Help Link
This icon navigates to a related help topic for this page.

The *Service Status* page (**Status > Services**) also has shortcut controls for pages related to each service, as shown in Figure *Shortcuts on Service Status*. The icons have the same meaning as in the above section.

Fig. 15: Shortcuts on Service Status

8.5 General Configuration Options

System > General Setup contains basic configuration options for pfSense® software. A few of these options are also found in the *Setup Wizard*.

Hostname
The **Hostname** is the short name for this firewall, such as `firewall1`, `hq-fw`, or `site1`. The name must start with a letter and it may contain only letters, numbers, or a hyphen.

Domain
The **Domain** name for this firewall, e.g. `example.com` . If this network does not have a domain, use `<something>.home.arpa`, where `<something>` is another identifier: a company name, last name, nickname, etc. For example, `company.home.arpa`

The **Hostname** and **Domain** name are combined to make up the Fully Qualified Domain Name (FQDN) of this firewall. For example, if the **Hostname** is `fw1` and the **Domain** is `example.com`, then the FQDN is `fw1.example.com`.

8.5.1 DNS Server Settings

Options in this section control how the firewall resolves hostnames using DNS.

Note: The DNS Resolver is active by default and uses **resolver** mode (*DNS Resolver Mode*). When set this way the DNS Resolver does not need forwarding DNS servers as it will communicate directly with root DNS servers and other authoritative DNS servers.

To use the servers in this list, switch the DNS resolver to forwarding mode. The DNS Forwarder (*DNS Forwarder*) only supports forwarding mode and will always use the servers from this list.

DNS Servers

This page supports multiple DNS servers managed as a list. To add more DNS servers, click  **Add DNS Server**.

To remove an entry from the list click  **Delete**.

The DNS server list may be left blank if the DNS Resolver is active in its default resolver mode. If this firewall has a dynamic WAN type such as DHCP or PPPoE these servers may be automatically assigned by the ISP and can also be left blank.

Each DNS server entry has the following properties:

Address
: The IP address of the DNS Server.

Hostname
: The FQDN of the DNS server, used to validate DNS server certificates when using DNS over TLS (*DNS Resolver Configuration*).

Gateway
: The gateway through which the firewall will reach this DNS server.

  This is useful in a Multi-WAN scenario where, ideally, the firewall will have at least one DNS server configured per WAN. More information on DNS for Multi-WAN can be found in *DNS Forwarding and Static Routes*.

DNS Resolution Behavior

These options fine tune the way the firewall utilizes DNS servers.

DNS Server Override
: When checked, a dynamic WAN ISP can supply DNS servers which override those set manually. To force the use of only the DNS servers on this page, uncheck this option. This does not apply to the DNS Resolver when acting in resolver mode.

DNS Resolution Behavior
: This option controls how the firewall itself resolves DNS queries.

Use Local DNS (127.0.0.1), fall back to remote DNS Servers (Default)
By default, the firewall will consult the DNS Resolver or DNS Forwarder running on this firewall to resolve hostnames for itself. It does this by listing localhost (`127.0.0.1`) as its first DNS server internally. If the local DNS server is unreachable, the firewall will send queries directly to the DNS servers configured on this page, or those received from dynamic WANs.

This method gives the firewall the best chance of having working DNS.

Use Local DNS (127.0.0.1), ignore remote DNS Servers
Like the option above, this option will make the firewall use its own DNS Resolver or DNS Forwarder to resolve hostnames. However, it will not attempt to use any other server.

This option is more secure as it forces DNS to be resolved using the configuration on the DNS Resolver or DNS Forwarder, which may have special requirements restricting or redirecting name resolution. For example, if the DNS Resolver is configured for *DNS over TLS*, using this option ensures that the firewall will not send queries to DNS servers without using TLS.

Use remote DNS Servers, ignore local DNS
This option forces the firewall to use the DNS servers configured on this page or from dynamic WANs and it will not utilize the local DNS Resolver or DNS Forwarder.

This option is useful when the local DNS service is configured in a strict manner to control client behavior, but the firewall still needs unrestricted access to DNS for tasks such as updates and installing packages.

8.5.2 Localization

Options in this section control the firewall clock and language.

Time Zone
The time zone used by the firewall for its clock. Choose a geographically named zone which best matches location of this firewall, or a common zone such as UTC. The firewall clock, log entries, and other areas of the firewall base their time on this zone.

Note: Changing the zone requires a reboot to fully activate the new zone in all areas of the firewall.

Tip: Avoid using the GMT +/- zones as they do not operate in an intuitive manner. See *Troubleshooting Time Zone Configuration* for more information.

Time Servers
Network Time Protocol (NTP) server hostnames or IP addresses. Unless a specific NTP server is required, such as one on LAN, the best practice is to leave the **Time Servers** value at the default `2.pfsense.pool.ntp.org`. This value will pick random servers from a pool of known-good IPv4 and IPv6 NTP hosts.

To utilize multiple time servers or pools, add them in the same box, separating each entry by a space. For example, to use three NTP servers from the pool, enter:

```
0.pfsense.pool.ntp.org 1.pfsense.pool.ntp.org 2.pfsense.pool.ntp.org
```

This numbering is specific to how `.pool.ntp.org` operates and ensures each address is drawn from a unique pool of NTP servers so the same server does not get used twice.

Language
The language used by the GUI. The GUI has been translated into multiple languages in addition to the default *English* language.

8.5.3 webConfigurator

Options in this section control various behaviors of the web-based GUI, which can be referred to as the GUI, WebGUI, or webConfigurator.

Theme
The **Theme** controls the look and feel of the GUI. Several themes are included in the base system, and they only make cosmetic not functional changes to the GUI.

Top Navigation
This option controls the behavior of the menu bar at the top of each page. There are two possible choices:

Scrolls with page
The default behavior. When the page scrolls, the navigation remains at the top of the *page*, so it is no longer visible as it scrolls off the top of the window.

This is the best option for most situations.

Fixed
When selected, the navigation remains fixed at the top of the *window*, always visible and available for use.

This behavior can be convenient, but can be problematic on smaller screens such as tablets and mobile devices. On low resolution browsers long menus can be cut off, leaving options at the bottom unreachable.

Hostname in Menu
Chooses if and how the GUI includes the firewall hostname in the menu. This can aid in quickly identifying a firewall when managing multiple firewalls in separate tabs or windows, but it consumes extra space in the menu.

Default (No hostname)
The GUI does not display the hostname or FQDN in the menu.

Hostname Only
When set, the GUI includes the firewall **Hostname** (no domain name) in the menu.

If all firewalls are in the same domain, or if they have unique hostnames, this may be sufficient.

Fully Qualified Domain Name
When set, the GUI includes the Fully Qualified Domain Name of the firewall in the menu.

This takes more space than displaying the hostname portion alone, but may be necessary to properly distinguish firewalls if they use similar hostnames in multiple domains.

Dashboard Columns
The dashboard is limited to 2 columns by default. On wider displays, additional columns can utilize extra horizontal screen space. The maximum number of columns is 4.

Interfaces Sort
When unset (default), the GUI presents interfaces in their natural order from the configuration. This

is critical for functions such as High Availability which require specific interface ordering. When this option is set, the GUI sorts the interface list alphabetically.

Associated Panels Show/Hide
A few GUI pages contain collapsible panels with settings or functions. These panels take up extra screen space so they are hidden by default. For firewall administrators who use the panels frequently, this can be slow and inefficient. The options in this group make the GUI show these panels by default instead of hiding them.

Available Widgets
Controls the **Available Widgets** panel on the Dashboard.

Log Filter
Controls the log filtering () panel used for searching log entries under **Status > System Logs**.

Manage Log
Controls the per-log settings in the **Manage Log** () panel available for each log under **Status > System Logs**.

Monitoring Settings
Controls the options panel used to change the graphs at **Status > Monitoring**.

Require State Filter
When set, the state table contents at **Diagnostics > States** are suppressed by the GUI unless a filter string is present. This helps the GUI handle large state tables which otherwise may fail to load.

Left Column Labels
When checked, the option labels in the left column are set to toggle options when clicked. This can be convenient if the firewall administrator is used to the behavior, but it can also be problematic on mobile or in cases when the behavior is unexpected.

Alias Popups
When set, the tooltip presented by the GUI when hovering over an alias in a rule list only shows the alias description. When unset, the contents of the alias are included in the tooltip. For firewalls with large aliases, this may cause performance or browser rendering issues.

Disable Dragging
When set, the GUI disables drag-and-drop on rule lists. Most users find drag-and-drop to be convenient and beneficial, thus the feature is enabled by default. Users who find the behavior undesirable can set this option.

Login Page Color
Controls the color of the login page, which is independent of the theme.

Login Hostname
When set, the GUI includes the hostname on the login form.

> **Warning:** This can be considered a security risk since it exposes information about the firewall to users who have not yet authenticated. If the firewall GUI is only reachable by authorized management clients, the convenience may outweigh the potential risk.

8.6 Advanced Configuration Options

System > Advanced contains numerous options to customize behavior for more complex environments. Most administrators will not need to adjust these options for basic deployments.

Some of these options are covered in more detail in other sections of the documentation where their discussion is more topical or relevant, but they are all mentioned here with a brief description.

8.6.1 Admin Access

The options on **System > Advanced**, **Admin Access** tab govern various methods for administering the firewall, including via the web interface, SSH, serial, and physical console.

webConfigurator (GUI)

Protocol

The protocol for connections between web browsers and the GUI. May be one of:

HTTP
: Plain unencrypted HTTP. Insecure and basic, but widely compatible. Should not be used in most cases, and should **never** be exposed to insecure networks.

HTTPS (SSL/TLS)
: Encrypted ("Secure") HTTP. Protects communication between the client browser and the firewall GUI. Requires an **SSL/TLS certificate** to function. Depending on the browser and certificate configuration, there may be compatibility issues, but typically these are easily overcome, such as by clicking through warnings about self-signed certificates.

Note: The best practice is to use HTTPS so **only** encrypted traffic is exchanged between the GUI and clients.

SSL/TLS Certificate

The **SSL/TLS Certificate** to be used by the GUI in **HTTPS (SSL/TLS)** mode.

The firewall automatically generates a default self-signed certificate on the first boot and again if a referenced certificate is missing. A self-signed certificate is not ideal, but it does still encrypt traffic and is better than communicating without encryption.

The primary disadvantage of a self-signed certificate is the lack of assurance of the identity of the host, since the certificate is not signed by a Certificate Authority trusted by the browser. Additionally, because for the bulk of Internet users such an invalid certificate should be considered a risk, modern browsers may restrict how such certificates are handled. Firefox, for example, displays a warning screen and forces the user to import the certificate and allow a permanent exception. Chrome shows a warning screen with a link to continue.

Tip: To use an externally signed SSL certificate and key, import them using the *Certificate Manager*, then select the certificate here.

Tip: The *ACME Package* can utilize the free Let's Encrypt service to automatically obtain and update a signed certificate for the GUI or for other purposes on the firewall.

Tip: Another alternate technique is to generate a self-signed CA and then generate a GUI certificate from that CA. Export the CA from the firewall and then import that CA into client browsers manually. Using this method, all certificates signed by that CA will be trusted by browsers. Specifics vary by client platform.

Tip: To generate a new self-signed certificate for the GUI, connect using the console or ssh and from a shell prompt, run the following command:

```
# pfSsh.php playback generateguicert
```

TCP Port

The port upon which the GUI listens for incoming connections from browsers. By default the GUI uses HTTPS on port `443` with a redirect from port `80` for the best compatibility and ease of initial configuration. To change the port, enter a new port number into the **TCP Port** field.

Danger: **Do not** expose the GUI to untrusted networks such as the Internet even on non-default ports.

Some administrators move the GUI to an alternate port for security by obscurity reasons. Such practices **should not** be considered as offering any security benefit. It is trivial for port scanners to locate the service on any open port.

Tip: Moving the GUI to another port will free up the standard web ports for use with port forwards or other services such as HAProxy.

Max Processes

The number of web server worker processes used by the GUI when listening for client browser connections. The default value is `2`.

If multiple administrators view the GUI at the same time and pages take too long to load, or are failing to load, then increase the **Max Processes** value.

WebGUI Redirect

Controls whether or not the firewall runs a redirect on port `80` so that if a browser attempts to access the firewall with HTTP, the firewall will accept the request and then redirect the browser to the **TCP Port** used by the GUI (e.g. HTTPS on port `443`).

The redirect is enabled by default for ease of access and compatibility.

Disabling the redirect allows another daemon to bind to port `80`.

HSTS

Controls whether the GUI web server sends the `Strict-Transport-Security` HTTPS response header (HSTS) to the browser. Check this box to disable the behavior.

HSTS forces the browser to use only HTTPS for any future requests to the firewall FQDN to ensure it does not accidentally downgrade to an unencrypted connection.

> **Warning:** When disabling HSTS, clients which visited the GUI when HSTS was enabled must perform browser-specific steps for the change to take effect. Consult browser documentation for information on clearing cached HSTS behavior.

OCSP Must-Staple

Controls whether or not the GUI web server forcefully enables OCSP Stapling.

If the GUI **SSL/TLS Certificate** requires OCSP Stapling, this behavior is automatically enabled by the GUI web server. If the certificate property cannot be automatically determined by the firewall, this option can force the behavior.

Tip: Import the full CA and certificate chain or this option will be ignored by the GUI web server.

WebGUI Login Autocomplete

Controls whether or not the login form allows autocomplete so browsers can save login credentials locally, for convenience.

In high-security environments, such as those that must adhere to specific security compliance standards, that behavior is not acceptable.

Note: This only controls autocomplete on the login form.

Warning: Few modern browsers respect this option. Many still offer to save passwords even when the form specifies that the browser must not allow the behavior. This behavior must be controlled or changed using browser options.

GUI login messages

Lowers the system log level for successful GUI login events.

By default, login events are logged at an emergency level and on hardware with a PC speaker, these emergency console messages generate a beep from the speaker.

When this is checked, successful logins to the GUI will be logged as a lower non-emergency level. This lower level will not trigger console bells and may help with processing log events on remote syslog servers.

Note: Changing this option is not necessary if the only goal is suppressing speaker beeps. The console bell behavior can be controlled independently on the *Notifications tab*.

Anti-lockout

Controls whether or not the firewall adds special rules to permit access to the GUI port and SSH port on the LAN interface by default.

These special rules override user-defined filter rules and prevent the user from accidentally locking themselves out of the firewall GUI or SSH. To control which LAN IP addresses may access the GUI and SSH using firewall rules, disable the anti-lockout rules.

When two or more interfaces are present, the firewall puts anti-lockout rules on the LAN interface; If only one interface is configured, the firewall places rules on that interface instead.

Warning: Filter rules must be in place to allow GUI access before enabling this option! If the LAN rules do not allow access to the GUI, removing the anti-lockout rule will block access to the GUI, potentially leaving the administrator without a means to reach the firewall.

Note: Resetting the LAN IP address from the console also resets the anti-lockout rule. If administrative access is unavailable after enabling this option, choose the console menu option `2`, then choose to set the LAN IP address, and enter in the exact same IP address and accompanying information.

DNS Rebind Check

Controls whether or not the DNS resolver or forwarder performs DNS rebinding checks. These checks prevent the firewall from receiving DNS responses containing private IP addresses from DNS servers to prevent DNS rebinding attacks.

Note: When accessing the firewall by IP address, these checks are not enforced because the attack is only relevant when using a hostname.

Check this box to disable DNS rebinding protection if it interferes with GUI access or name resolution.

See also:

More detail on DNS rebinding attacks may be found on Wikipedia.

The most common case for disabling DNS rebinding checks is when the firewall is set to use an internal DNS server which will return private (RFC1918) answers for hostnames.

Tip: Instead of disabling all DNS rebinding protections, the checks can be selectively disabled on a per-domain basis in the DNS Resolver or DNS Forwarder. See *DNS Resolver* and *DNS forwarder*.

Note: The DNS Resolver or Forwarder must be restarted after changing this option.

Browser HTTP_REFERER enforcement

Controls whether or not the GUI checks and enforces `HTTP_REFERER` request header contents.

The GUI checks the referring URL sent by a client browser to ensure that the form was submitted from this firewall. This check prevents a form on another site from submitting a request to the firewall, changing an option when the administrator did not intend for that to happen.

This also breaks some convenience behaviors, such as having a page that links to various firewall devices, though the benefits of the check typically outweigh the advantage of those behaviors.

Alternate Hostnames

A list of **Alternate Hostnames** for the firewall allowed by **DNS Rebind Checks** and **HTTP_REFERER Enforcement**. To keep these features active, but alter their behavior slightly, add **Alternate Hostnames**.

By default the GUI allows access to the hostname configured on the firewall and all IP addresses configured on the firewall. Hostnames in this field are allowed by the firewall for GUI access and for referring URL purposes.

Browser Tab Text

By default the GUI prints the firewall hostname first in the page/tab title, followed by the page name. To reverse this behavior and show the page name first and hostname second, check **Display page name first in browser tab**.

Administrators who access many firewalls at the same time in separate tabs tend to prefer having the hostname first (default). Administrators who access one firewall with many pages in separate tabs may prefer having the page name first.

Secure Shell (SSH)

The Secure Shell (SSH) server provides remote console access and file management. A user can connect with any standard SSH client, such as the OpenSSH command line ssh client, PuTTY, SecureCRT, or iTerm2.

When using SSH, both the `admin` username and `root` username are accessible using the `admin` account credentials.

Users in the User Manager that have the `User - System - Shell account access` privilege are also allowed to login over SSH. These users do not have `root` access privileges, and do not print the menu when they login because many of the options require `root` privileges.

Tip: To grant users additional shell privileges, use the *sudo package*.

File transfers to and from the firewall are also possible by using a Secure Copy (SCP) client such as the OpenSSH command line `scp`, FileZilla, WinSCP or Fugu. To use SCP, connect as the `root` or `admin` user. If a custom user has the `User - System - Copy files` permission, or all access, then they may also utilize SCP.

Tip: SSH clients must be kept up-to-date. As time goes on, security standards evolve and the SSH server settings utilized by SSH servers will change. Outdated clients may not be able to connect using the strong security keys and algorithms required by `sshd`. If a client will not connect, check for an update from the vendor.

Enable Secure Shell

To enable the SSH daemon, check **Enable Secure Shell**. After saving with this option enabled, the firewall will generate SSH keys if they are not already present and then start the SSH daemon.

SSHd Key Only

This option controls which authentication methods the SSH daemon allows for clients. It can be set to one of the following values:

Password or Public Key
: Allows a user to authenticate with **either** a valid password or valid key. This is the default behavior.

Public Key Only
: Restricts authentication to only valid keys, passwords are not allowed.

Require Both Password and Public Key
: Requires a valid password **and** a valid key.

Key-based logins are a much more secure practice, though it does take more preparation to configure.

Add user keys for key-based login by editing users in the **User Manager** (*User Management and Authentication*). When editing a user, paste the allowed public keys into the **Authorized Keys** text field for the account.

Allow Agent Forwarding

Controls whether or not the SSH daemon allows agent forwarding for clients.

Agent forwarding allows a user to run an SSH agent on their client system and connect to the firewall, and then to other remote SSH servers using the key from their agent. In this case, the user does not need to have their private keys on the firewall but can still use key-based authentication to remote servers.

Use of an SSH agent can be considered a security issue in certain cases. Additionally, the firewall is not intended to be a general purpose SSH client or intermediate system, thus this feature is disabled by default.

SSH Port

Controls the port used by the SSH daemon to accept client connections. To change the port, type the new port into the **SSH Port** box.

Moving the SSH server to an alternate port provides a negligible security improvement, and frees up the port for other uses.

Tip: Brute force SSH scanners focus on hitting TCP port `22` but if the daemon is open to the Internet on another port, it will still be found and hit by scanners.

Best Practices for SSH

If this firewall is installed in an environment that requires leaving SSH access unrestricted by firewall rules, which is dangerous, the best practice is to take one of the following actions:

Change the SSH Port
: Moving to a random alternate port prevents log noise from many, but not all, brute-force SSH login attempts and casual scans. It can still be found with a port scan, however.

Force Key-Based Authentication
: Key-based authentication must always be used by publicly accessible SSH servers to eliminate the possibility of successful brute force attacks. Set **SSHd Key Only** to either *Public Key Only* or *Require Both Password and Public Key*.

Multiple unsuccessful logins from the same IP address will result in locking out the IP address trying to authenticate, but that alone is not considered sufficient protection.

Login Protection

pfSense software utilizes the `sshguard` daemon to protect against brute force logins for both the GUI and SSH connections. The options in this section fine-tune the behavior of this protection.

Threshold
: The total score value above which `sshguard` will block clients. Most attacks have a score of `10`, the default threshold value is `30`.

Blocktime
: The initial minimum number of seconds to block attackers who have exceeded the **Threshold** value. The default value is `120` seconds. Repeat offenders are blocked for increasingly longer amounts of time (1.5x for each repetition).

Note: Attackers are unblocked at random intervals so actual block time will be longer than stated. This prevents clients from predicting the timing to optimize targeted attacks.

Detection Time
The amount of time, in seconds, attackers are remembered by `sshguard` since their last offense before it resets their score. Default is `1800` seconds.

Pass list
A list of subnets which are excluded from login protection. This lowers security but is generally acceptable from specific secure management networks.

For example, it may be necessary to add entries for network monitoring systems which probe the SSH port but do not login. Otherwise such systems may be flagged as attackers.

Click  **Add address** to display additional form field lines for pass list entries.

Serial Communications

If the firewall hardware contains a hardware serial port, it can be used for a console connection. This is useful for running on hardware without video hardware or if it will be running "headless" (without keyboard and video attached). In these cases, the serial console can be enabled to maintain physical control, so long as the hardware has a viable serial port. The hardware visible to the operating system for such serial ports cannot be USB. Though some devices expose an external physical USB port dedicated to the console, typically such devices are wired to appear to the OS as a traditional non-USB serial port internally.

If hardware is detected which has no VGA port, the serial console is forced on and cannot be disabled, and the serial options are all hidden except for the speed.

Serial Terminal

When **Serial Terminal** is set, the operating system enables the console on the first serial port. This console will receive kernel boot messages and a menu after the firewall has finished booting. This will not disable the onboard keyboard and video console.

To connect to the serial console, use a null modem cable connected to a serial port or adapter on another PC or serial device.

See also:

For more information on connecting to a serial console, see *Connecting to a Serial Console* and *Start a Serial Client*.

When making any changes to the serial console, the firewall must be rebooted before they take effect.

Note: In some systems booting via EFI, the serial console can be activated or deactivated without a reboot.

Serial Console Speed

The default serial console speed is *115200* bps and almost all hardware works well at that speed. In rare cases, a slower speed may be required which can be set here by picking the desired speed from the **Serial Speed** drop-down.

When upgrading from an older version, this may remain at an older value such as *9600* or *38400* to match the BIOS on older hardware. Increasing the speed to *115200* is almost always safe and more useful than slower speeds.

Primary Console

On hardware with both the serial console enabled and a video port available, the **Primary Console** selector chooses which is the preferred console, so it will receive the boot log messages. Other OS kernel messages will show up on all console connections, and both consoles will have a usable menu.

In cases where the boot cannot complete, the preferred console must be used to resolve the problem, such as reassigning interfaces.

Console Menu

Normally the firewall always presents the menu on the console, and the menu will be available as long as someone has physical access to the console. In high-security environments this is not desirable.

This option adds password protection to the console. The console accepts the same usernames and passwords used to access the GUI. After setting this option, the firewall must be rebooted before it takes effect.

Note: While this will stop accidental key presses and keep out casual users, this is by no means a perfect security method. A knowledgeable person with physical access can still reset the passwords (see *Forgotten Password with a Locked Console*). Consider other physical security methods if console security is a requirement.

8.6.2 Firewall & NAT

The options on **System > Advanced**, **Firewall & NAT** tab control various aspects of how the firewall processes packets and connections.

Packet Processing

IP Do-Not-Fragment compatibility

This option is a workaround for operating systems which generate fragmented packets with the “don’t fragment” (DF) bit set. Linux NFS (Network File System) is known to do this, as well as some VoIP implementations.

When this option is enabled, the firewall will not drop these malformed packets but instead it will clear the DF bit. The firewall will also randomize the IP identification field of outgoing packets to compensate for operating systems that set the DF bit but set a zero IP identification header field.

IP Random ID generation

If **Insert a stronger ID into IP header of packets passing through the filter** is checked, the firewall replaces the IP identification field of packets with random values to compensate for operating systems that use predictable values. This option only applies to packets that are not fragmented after the optional packet reassembly.

Firewall Optimization Options

The optimization mode controls how the firewall expires state table entries:

Normal
: The standard optimization algorithm, which is optimal for most environments.

High Latency
: Used for high latency links, such as satellite links. Expires idle connections later than default.

Aggressive
: Expires idle connections quicker. More efficient use of CPU and memory but can drop legitimate connections earlier than expected. This option can also improve performance in high traffic deployments with lots of connections, such as web services.

Conservative
: Tries to avoid dropping any legitimate connections at the expense of increased memory usage and CPU utilization. Can aid in environments that require long-lived but mostly idle UDP connections, such as VoIP.

The table *Firewall Optimization Details* contains the values chosen by PF for each optimization algorithm. The values are taken from the PF source code. The first line is the raw value, second line is human readable:

Table 1: Firewall Optimization Details

	Normal	High Latency	Conservative	Aggressive
tcp.first First TCP packet	60 1min	180 3min	3600 60min	30 30sec
tcp.opening No response yet	30 30sec	35 35sec	900 15min	5 5sec
tcp.established Established	86400 24h	86400 24h	432000 5days	18000 5h
tcp.closing Half closed	900 15min	905 15min + 5sec	3600 1h	60 60sec
tcp.finwait Got both FINs	45 45sec	50 50sec	600 10min	30 30sec
tcp.closed Got an RST	90 90sec	95 95sec	180 3min	30 30sec
tcp.tsdiff Allowed TS diff	30 30sec	60 60sec	60 60sec	10 10sec

Disable Firewall Scrub

When set, the scrubbing option in `pf` is disabled. The `scrub` action in `pf` can interfere with NFS, and in rare cases, with VoIP traffic as well. By default, the firewall uses the `fragment reassemble` option which reassembles fragmented packets before sending them on to their destination, when possible. More information on the `scrub` feature of `pf` can be found in the OpenBSD PF Scrub Documentation.

Note: Disabling `scrub` also disables other features that rely on `scrub` to function, such as DF bit clearing and ID randomization. Disabling `scrub` does not disable MSS clamping if it is active for VPNs, or when an MSS value is configured on an interface.

Firewall Adaptive Timeouts

Adaptive Timeouts control state handling in `pf` when the state table is nearly full. Using these timeouts, a firewall administrator can control how states are expired or purged when there is little or no space remaining to store new connection states.

Adaptive Timeouts are enabled by default and the default values are calculated automatically based on the configured **Firewall Maximum States** value.

Adaptive Start
: Adaptive scaling is started once the state table reaches this level, expressed as a number of states. **Adaptive Start** defaults to 60% of **Firewall Maximum States**.

Adaptive End
: When the size of the state table reaches this value, expressed as a number of state table entries, all timeout values are assumed to be **zero**, which causes pf to purge all state entries immediately. This setting defines the scale factor, it should be set greater than the total number of states allowed. **Adaptive End** defaults to 120% of **Firewall Maximum States**.

When the number of connection states exceeds the threshold set by **Adaptive Start**, timeout values are scaled linearly with factor based on the number of states used between the Start and End state counts. The timeout adjustment factor is calculated as follows: (Number of states until the **Adaptive End** value is reached) / (Difference between the **Adaptive End** and **Adaptive Start** values).

Note: As an example, consider a firewall with **Adaptive Start** set to `600000`, **Adaptive End** set to `1200000` and **Firewall Maximum States** set to `1000000`. In this situation, when the state table size reaches `900000` entries the state timeouts will be scaled to 50% of their normal values.

(1,200,000 - 900,000) / (1,200,000 - 600,000) = 300,000 / 600,000 = 0.50, 50%

Continuing the example, when the state table is full at 1,000,000 states the timeout values will be reduced to 1/3 of their original values.

Tip: The state table usage indicator on the dashboard will change color and text when the state table size crosses these thresholds.

Firewall Maximum States

This value is the maximum number of connections the firewall can hold in its state table. The default size is calculated based on 10% of total RAM. This default value is sufficient for most installations, but can be adjusted higher or lower depending on the load and available memory.

Each state consumes approximately 1 KB of RAM, or roughly 1 MB of RAM for every 1000 states. The firewall must have adequate free RAM to contain the entire state table before increasing this value. Firewall states are discussed further in *Stateful Filtering*.

Tip: On a firewall with 8GB of RAM the state table would have a default size of approximately 800,000 states. A custom **Firewall Maximum States** value of 4,000,000 would consume about 4GB of RAM, half the available 8GB total.

Firewall Maximum Table Entries

This value defines the maximum number of entries that can exist inside of address tables used by the firewall for collections of addresses such as aliases, ssh/GUI lockout records, hosts blocked by snort alerts, and so on. By default this is 400,000 entries. If the firewall has features enabled which can load large blocks of address space into aliases such as URL Table aliases or the pfBlockerNG package, then increase this value to comfortably include at least double the total amount of entries contained in all aliases combined.

This maximum value of this setting depends on the amount of RAM available hold the entries. RAM usage for each alias entry is similar to, but less than, the state table. A safe assumption is approximately 1K of memory per entry to be conservative.

If the value of this setting is not large enough to contain the entire content all of the aliases, the firewall may fail to load the ruleset. The aliases must fit in **twice** in the total area because of the way the firewall loads and reloads aliases; The firewall loads the new list alongside the old list and then removes the old list for a smoother transition.

Firewall Maximum Fragment Entries

When scrub is enabled the firewall maintains a table of packet fragments waiting to be reassembled. By default this table can hold `5000` fragments. In rare cases a network may have an unusually high rate of fragmented packets which can require more space in this table. When this limit is reached, the following log message will appear in the main system log:

```
kernel: [zone: pf frag entries] PF frag entries limit reached
```

VPN Packet Processing

These settings affect traffic behavior with some types of VPNs, including IPsec and OpenVPN. It also affects the PPPoE Server.

IP Do-Not-Fragment compatibility

This option is the same as *IP Do-Not-Fragment compatibility* but this option only applies that behavior to VPN networks.

IP Fragment Reassemble

Reassemble IP Fragments for normalization. In this case, fragments are buffered until they form a complete packet, and only the completed packet is passed on to the filter. The advantage is that filter rules have to deal only with complete packets, and can ignore fragments. The drawback of caching fragments is the additional memory cost and potential introduction of latency.

MSS Clamping

Enable maximum segment size clamping on TCP flows over IPsec tunnels. This helps overcome problems with path MTU discovery (PMTUD) on IPsec VPN links.

This is useful if large TCP packets have problems traversing the VPN, or if slow/choppy connections across the VPN are observed by users. Ideally it should be set to the same value on both sides of the VPN, but traffic will have MSS clamping applied in both directions.

Enable
When set, the **Maximum MSS** option is available and its value is used by the firewall configuration.

Note: For IPsec using VTI mode phase 2 entries, set the MSS value in the interface configuration for the assigned VTI interface under the **Interfaces** menu.

Maximum MSS
The maximum segment size set in TCP packets flowing across IPsec VPN tunnels. Defaults to `1400`. Must be low enough to account for the overhead of IPsec and the MTU of the link, but no so low that unnecessarily small segments are sent as that can be inefficient.

Advanced Options

Disable Firewall

When **Disable all packet filtering** is set, the firewall becomes a routing-only platform. This is accomplished by disabling `pf` entirely, and as a consequence, NAT is disabled since it is also handled by `pf`.

Tip: To disable *only* NAT, do not use this option. Consult *Disabling Outbound NAT* for more information on controlling outbound NAT behavior.

Firewall State Policy

Controls the default State Policy for states created by firewall rules. These policies fundamentally change how the firewall checks packets against existing state table entries to determine if a packet should be allowed. There are two options available, **Interface Bound States** and **Floating States**.

Note: There is no difference in the ability to view or kill states between either mode.

Tip: While this option controls the global default, there is a per-rule option to override this behavior as well. See *State Policy* for details.

Interface Bound States

Interface Bound States are more strict and secure. States are bound to specific interfaces by their OS/driver name (e.g. `igcX`). If a packet attempts to take a path through a different interface than the one to which it is bound, the packet is dropped.

As this is the most secure option, it is currently the default policy.

This policy is less likely to allow VPN or other traffic to "leak" or egress via unexpected paths (e.g. during interface events).

This policy has some drawbacks, however, as noted in the following subsections.

IPsec VTI Filtering

For firewalls utilizing IPsec VTI tunnels, due to the way the OS handles traffic on VTI interfaces in the default **IPsec Filter Mode** packets may appear to enter and exit on different interfaces (e.g. `ipsecX` vs `enc0`). This can cause issues with Interface Bound states but pass traffic OK with floating states.

This situation can be worked around a couple different ways:

Change IPsec Filter Mode
: The most secure option is only viable in certain cases. On installations which **only** contain VTI tunnels and **no** policy-based tunnels or mobile IPsec configurations, switch the **IPsec Filter Mode** option in the *Advanced IPsec Settings* to *Filter IPsec VTI and Transport on assigned interfaces, block all tunnel mode traffic*.

  When configured in this way, PF can track states and packets on VTI interfaces appropriately, but it is **not** compatible with tunnel mode or mobile IPsec.

Rules with Floating Policy Set
: The most compatible method is to add rules using the floating policy for IPsec VTI traffic:

  - Edit rules on the **IPsec** tab and change the per-rule *State Policy* in the **Advanced Options** to *Floating States* on each rule that matches inbound traffic from VTI peers.
  - Add new rule(s) on to the top of the **Floating** tab to match outbound traffic for VTI peers, for example:

    Action
    : *Pass*

    Quick
    : *Checked*

    Interface
    : *IPsec* (`enc0`)

    Direction
    : *Out*

    Advanced Options: State Policy
    : *Floating States*

    Set the other parameters to match the VTI peer traffic, or set the rule for *Any* protocol, source, and destination to match any outbound IPsec traffic.

Change Default State Policy
: Switching the default policy back to Floating states will allow it to work, but with the security implications mentioned previously.

High Availability State Synchronization

For High Availability configurations utilizing *state synchronization (pfsync)*, all nodes in the cluster must either be using identical hardware and physical interface assignments, or be using abstracted interfaces such as `laggX` that can mask hardware differences. Otherwise synchronized states will never match traffic on the secondary node, making state synchronization ineffective. See *pfsync and Physical Interfaces* for more information on this limitation.

Floating States

Floating States are less secure, more lenient in their checks, and are not strictly associated with any interface. The interface is tracked in state properties, but it is informational and not enforced.

This policy is more forgiving when it comes to multi-WAN and asymmetric routing scenarios. It also allows HA nodes with different hardware to utilize state synchronization.

The most significant drawback to this relaxed policy is that it might allow packets to be misdirected or take unexpected paths. This is especially the case if routing can be manipulated in some way (e.g. by a dynamic WAN). This can be especially problematic for secure traffic, such as between local systems on separate interfaces, or for VPN traffic.

State Policy History

The state policy behavior in PF has changed over time as it changed in the base OS, but the option to explicitly choose the default behavior did not exist until recently.

Very old versions of pfSense software (2.1.5 and before) behaved in the "floating" style.

From pfSense software version 2.2 until pfSense Plus software version 21.05.2/CE 2.5.2 the behavior was closer to "interface bound" but not identical.

From pfSense Plus software version 22.01/CE 2.6.0 until pfSense Plus software version 23.09.1/CE 2.7.2 the behavior was closer to "floating".

Starting with pfSense Plus software version 24.03/CE 2.8.0 the default is explicitly set to "interface bound" for increased security.

The ability to change the policy, as well as the change in default policy, will also be available to some previous releases via the recommended patches mechanism in the *System Patches* package.

Ethernet Filtering (Plus Only)

Enable experimental rule-based pass/block filtering of packets based on Ethernet (Layer 2) header attributes (e.g. MAC addresses). These rules are processed before other (L3) rules on the inbound direction, and after those rules outbound. When enabled, Ethernet rules are managed on their own tab at **Firewall > Rules**, **Ethernet tab**.

Note: This feature is exclusive to pfSense Plus version 23.05 and later.

See also:

- *Ethernet (Layer 2) Rules*
- *Ordering of NAT and Firewall Processing*

Static Route Filtering

The **Bypass firewall rules for traffic on the same interface** option applies if the firewall has one or more static routes defined. If this option is enabled, traffic that enters and leaves through the same interface will not be checked by the firewall. This may be required in situations where multiple subnets are connected to the same interface, to avoid blocking traffic that is passed through the firewall in one direction only due to asymmetric routing. See *Bypass Firewall Rules for Traffic on Same Interface* for a more in-depth discussion on that topic.

Disable Auto-added VPN rules

By default, when IPsec is enabled firewall rules are automatically added to the appropriate interface which will allow the tunnel to establish. When **Disable Auto-added VPN rules** is checked, the firewall will not automatically add these rules. By disabling these automatic rules, the firewall administrator has control over which addresses are allowed to connect to a VPN. Further information on these rules can be found at *VPNs and Firewall Rules*.

Disable Reply-To

In a Multi-WAN configuration the firewall has a beneficial default behavior that ensures traffic leaves the same interface through which it arrived. This is accomplished using the `pf` keyword `reply-to` which is added automatically to interface tab firewall rules for WAN-type interfaces. When a connection matches a rule with `reply-to`, the firewall remembers the path through which the connection was made and routes the reply traffic back to the gateway for that interface.

Tip: WAN-type interfaces are interfaces which have a gateway set on their **Interfaces** menu entry configuration, or interfaces which have a dynamic gateway such as DHCP, PPPoE, or assigned OpenVPN, GIF, or GRE interfaces.

In situations such as bridging, this behavior is undesirable if the WAN gateway IP address is different from the gateway IP address of the hosts behind the bridged interface. Disabling `reply-to` will allow clients to communicate with the proper gateway.

Another case that has issues with `reply-to` involves static routing to other systems in a larger WAN subnet. Disabling `reply-to` in this case would help ensure that replies return to the proper router instead of being routed back to the gateway.

This behavior can also be disabled on individual firewall rules rather than globally using this option.

Disable Negate rules

In a Multi-WAN configuration traffic for directly connected networks and VPN networks typically must still flow properly when using policy routing. The firewall will insert rules to pass this local and VPN traffic without a gateway specified, to maintain connectivity. In some cases these negation rules can over-match traffic and allow more than intended.

Tip: The best practice is to create manual negation rules at the top of internal interfaces such as LAN. These rules should pass to local and VPN destinations without a gateway set on the rule, to honor the system routing table. These rules do not have to be at the top of the interface rules, but they must be above rules that have a gateway set.

Allow APIPA

Automatic Private IP Addressing (APIPA), or IPv4 Link-Local addressing, uses a special subnet of `169.254.0.0/16`. This traffic is for local links only (same L2), it must not be routed or traverse a firewall. As such, inbound traffic from these addresses is automatically blocked by internal firewall rules by default.

When **Allow APIPA traffic** is checked, the default block rules are removed, and user firewall rules can control the traffic.

There are some use cases which utilize these addresses for private communication on an interface, such as AWS VPC BGP, and in those cases, the option can be enabled along with carefully crafted manual firewall rules.

> **Warning:** When this option is enabled, take care to never allow APIPA traffic to match policy routing rules. If APIPA traffic matches policy routing rules, behavior is unpredictable. There have been reports of such errors leading to packet loops and unexpectedly high resource usage. See Redmine Issue #2073 for more.

Aliases Hostnames Resolve Interval

This option controls how often hostnames in aliases are resolved and updated by the `filterdns` daemon. By default this is `300` seconds (5 minutes). In configurations with a small number of hostnames or a fast/low-load DNS server, decrease this value to pick up changes faster.

Check Certificate of Alias URLs

When **Verify HTTPS certificates when downloading alias URLs** is set, the firewall will require a valid HTTPS certificate for web servers used in URL table aliases. This behavior is more secure, but if the web server is private and uses a self-signed certificate, it can be more convenient to ignore the validity of the certificate and allow the data to be downloaded.

> **Warning:** The best practice is to always use a server certificate with a valid chain of trust for this type of role, rather than weakening security by allowing a self-signed certificate.

Bogon Networks

The **Update Frequency** drop-down for **Bogon Networks** controls how often these lists are updated. Further information on bogon networks may be found in *Block Bogon Networks*.

Network Address Translation

NAT Reflection mode for Port Forwards

The **NAT Reflection mode for port forwards** option controls how NAT reflection is handled by the firewall. These NAT redirect rules allow clients to access port forwards using the public IP addresses on the firewall from within local internal networks.

See also:

Refer to *NAT Reflection* for a discussion on the merits of NAT Reflection when compared to other techniques such as Split DNS.

There are three possible modes for NAT Reflection:

Disabled
: The default value. When disabled, port forwards are only accessible from WAN and not from inside local networks.

Pure NAT
: This mode uses a set of NAT rules to direct packets to the target of the port forward. It has better scalability, but it must be possible to accurately determine the interface and gateway IP address used for communication with the target at the time the rules are loaded. There are no inherent limits to the number of ports other than the limits of the protocols. All protocols available for port forwards are supported.

  When this option is enabled, **Automatic Outbound NAT for Reflection** must also be enabled if the clients and servers are in the same local network.

NAT + Proxy
: *NAT + proxy* mode uses a helper program to send packets to the target of the port forward. The connection is received by the reflection daemon and it acts as a proxy, creating a new connection to the local server. This behavior puts a larger burden on the firewall, but is useful in setups where the interface and/or gateway IP address used for communication with the target cannot be accurately determined at the time the rules are loaded. *NAT + Proxy* reflection rules are not created for ranges larger than 500 ports and will not be used for more than 1000 ports total between all port forwards. This feature only supports TCP port forwards.

Individual NAT rules have the option to override the global NAT reflection configuration, so they may have NAT reflection forced on or off on a case-by-case basis.

Reflection Timeout

The **Reflection Timeout** setting forces a timeout on connections made when performing NAT reflection for port forwards in *NAT + Proxy* mode. If connections are staying open and consuming resources, this option can mitigate that issue.

NAT Reflection for 1:1 NAT

When checked, this option adds additional reflection rules which enable access to 1:1 mappings of external IP addresses from internal networks. This gives the same functionality that already exists for port forwards, but for 1:1 NAT. There are complex routing scenarios that may render this option ineffective.

This option only affects the *inbound* path for 1:1 NAT, not outbound. The underlying rule style is similar to the *Pure NAT* mode for port forwards. As with port forwards, there are per-entry options to override this behavior.

Automatic Outbound NAT for Reflection

When checked, this option automatically creates outbound NAT rules which assist reflection rules that direct traffic back out to the same subnet from which it originated. These additional rules allow Pure NAT and 1:1 NAT Reflection to function fully when the clients and servers are in the same subnet. In most cases, this box must be checked for NAT Reflection to work.

Note: This behavior is necessary because when clients and servers are in the same subnet, the traffic source must be changed so that the connection appears to originate from the firewall. Otherwise, the return traffic will bypass the firewall and the connection will not succeed.

TFTP Proxy

The built-in TFTP proxy will proxy connections to TFTP servers outside the firewall, so that client connections may be made to remote TFTP servers. Ctrl-click or shift-click to select multiple entries from the list. If no interfaces are chosen, the TFTP proxy service is deactivated.

State Timeouts

The **State Timeout** section allows fine-tuning of the state timeouts for various protocols. These are typically handled automatically by the firewall and the values are dictated by the *Firewall Optimization Options* options. In rare cases, these timeouts may need adjusted up or down to account for irregularities in device behavior or site-specific needs.

All of the values are expressed in *seconds*, and control how long a connection in that state will be retained in the state table.

See also:

Descriptions in the following options reference firewall state conditions as described in *Interpreting States*.

TCP First
: The first packet of a TCP connection.

TCP Opening
: The state before the destination host has replied (e.g. `SYN_SENT:CLOSED`).

TCP Established
: An established TCP connection where the three-way handshake has been completed.

TCP Closing
: One side has sent a TCP FIN packet.

TCP FIN Wait
: Both sides have exchanged FIN packets and the connection is shutting down. Some servers may continue to send packets during this time.

TCP Closed
: One side has sent a connection reset (TCP RST) packet.

TCP Tsdiff
: The allowed TCP timestamp difference.

UDP First
: The first UDP packet of a connection has been received.

UDP Single
: The source host has sent a single packet but the destination has not replied (e.g. `SINGLE:NO_TRAFFIC`).

UDP Multiple
: Both sides have sent packets.

ICMP First
: An ICMP packet has been received.

ICMP Error
: An ICMP error was received in response to an ICMP packet.

Other First, Other Single, Other Multiple
: The same as **UDP**, but for other protocols.

8.6.3 Networking

DHCP Options

Server Backend

Selects the DHCP backend to use for allocating DHCP and DHCPv6 addresses to clients.

Kea DHCP
Activates the Kea DHCP backend. This is a modern and well-supported DHCP server but the implementation is still under development.

Note: The most notable missing feature is integration with the DNS Resolver to resolve DHCP hostnames in DNS.

ISC DHCP (Deprecated)
This is the legacy DHCP server which has been the default in the past. It is no longer supported by ISC and they will no longer release updates for security issues or bug fixes.

While it is deprecated, it contains functionality not yet implemented in the Kea backend, so for the time being it is still offered as a choice. It will eventually be removed from pfSense software once the Kea backend is feature complete.

Ignore Deprecation Warning
As ISC DHCP software is deprecated and potentially insecure, the GUI displays a warning when this backend is active. Checking this box suppresses that warning message.

RADVD Debug

When checked, all log levels for RADVD will be logged to **System > Routing** logs. Otherwise, only log levels of `LOG_ERR` and higher will be logged.

DHCP6 Debug

When checked, the DHCPv6 client is started in debug mode to aid in troubleshooting.

Do not Allow PD/Address Release

By default `dhcp6c` sends a `RELEASE` message to the ISP when it exits. Some ISPs then release the allocated address and/or prefix. This option prevents `dhcp6c` from sending that signal.

DHCP6 DUID

This option controls the DHCPv6 Unique Identifier (DUID) used by the firewall when requesting an IPv6 address. The firewall generates a DUID automatically, but in some cases, an administrator may want to use a different DUID. For example, if the operating system was reinstalled and the firewall should use the same DUID it had in the past, or if an upstream network administrator requires a specific DUID.

Note: Most users do not need to change this to any specific value, the default behavior is fine for nearly all environments. When in doubt, leave it alone unless directed to change it by an upstream network provider.

There are several possible DUID formats that this option can accept, chosen by the drop-down menu. When a format is chosen, the GUI displays a different set of input boxes specific to the selected format. The exact format depends upon the needs of the network administrator (e.g. ISP, datacenter, etc) and they would provide the format and values.

The available DUID formats are:

Raw DUID
DUID represented exactly as observed in a DUID file or in logs. Entered as:

Raw DUID
A single text area in which the DUID can be entered.

This option also includes a  **Copy DUID** button which copies the DUID from the placeholder (automatically generated by the firewall) into the text box so that the existing DUID can easily be placed into the configuration.

DUID-LLT
DUID format with Link-Layer Address Plus Time. Entered as:

Time
Time (in seconds) since January 1st, 2000 UTC

Link-Layer Address
The link-layer address (MAC) of an interface on the firewall in the format `xx:xx:xx:xx:xx:xx`.

DUID-EN
DUID assigned by a vendor based on Enterprise Number. Entered as:

Enterprise Number
IANA Private Enterprise Number of the vendor.

Identifier
Variable length identifier in the format `xx:xx:xx:xx`. The length depends upon the vendor.

DUID-LL
DUID based on only Link-Layer Address. Entered as:

Link-Layer Address
The link-layer address (MAC) of an interface on the firewall in the format `xx:xx:xx:xx:xx:xx`.

DUID-UUID
DUID based on the host Universally Unique Identifier (UUID). Entered as:

DUID-UUID
The UUID for this host in nnnnnnnn-nnnn-nnnn-nnnn-nnnnnnnnnnnn format

IPv6 Options

Allow IPv6

The **Allow IPv6** option controls a set of block rules which prevent IPv6 traffic from being handled by the firewall.

Note: This option **does not disable IPv6** functions or prevent it from being configured, it only controls traffic flow via firewall rules.

When the option is enabled, IPv6 traffic will be allowed when permitted by firewall rules and/or automatic rules, depending on the firewall configuration. This option is enabled by default on new configurations.

When the option is unchecked, all IPv6 traffic will be blocked. This behavior is similar to how IPv6 was treated before it was supported by pfSense® software. Configurations imported from or upgraded from versions older than 2.1 will have this option unchecked, so they behave consistently after upgrade.

IPv6 over IPv4 Tunneling

The **Enable IPv6 over IPv4 Tunneling** option enables forwarding for IP protocol 41/RFC 2893 to an IPv4 address specified in the **IPv4 address of Tunnel Peer** field.

When configured, this forwards all incoming protocol 41/IPv6 traffic to a host behind this firewall instead of handling it locally.

Tip: Enabling this option does not add firewall rules to allow the protocol 41 traffic. A rule must exist on the WAN interface to allow the traffic to pass through to the local receiving host.

Prefer IPv4 over IPv6

When set, this option causes the firewall *itself* to prefer sending traffic to IPv4 hosts instead of IPv6 hosts when a DNS query returns results for both.

In rare cases when the firewall has partially configured, but not fully routed, IPv6 this can allow the firewall to continue reaching Internet hosts over IPv4.

Note: This option controls the behavior of the firewall itself, such as when polling for updates, package installations, downloading rules, and fetching other data. It cannot influence the behavior of clients behind the firewall.

IPv6 DNS Entry

This option controls whether or not the firewall creates local DNS entries for the firewall itself with IPv6 addresses, when available.

By default (unchecked), the firewall automatically adds DNS entries for itself using its local IPv4 and IPv6 interface addresses. In some cases, such as with dynamic IPv6 addresses like tracked interfaces, the IPv6 address may disappear or change and clients may attempt to use an outdated address until their cached DNS response expires.

When the option is checked, the firewall only adds DNS entries for its IPv4 addresses.

Network Interfaces

Hardware Checksum Offloading

When checked, this option disables hardware checksum offloading on the network cards. Checksum offloading is usually beneficial as it allows the checksum to be calculated (outgoing) or verified (incoming) in hardware at a much faster rate than it could be handled in software.

Note: When checksum offloading is enabled, a packet capture will see empty (all zero) or flag incorrect packet checksums. These are normal when checksum handling is happening in hardware.

Checksum offloading is broken in some hardware, particularly Realtek cards and virtualized/emulated cards such as those on Xen/KVM. Typical symptoms of broken checksum offloading include corrupted packets and poor throughput performance.

Tip: In virtualization cases such as Xen/KVM it may be necessary to disable checksum offloading on the host as well as the VM. If performance is still poor or has errors on these types of VMs, switch the type of NIC if possible.

Hardware TCP Segmentation Offloading

Checking this option will disable hardware TCP segmentation offloading (TSO, TSO4, TSO6). TSO causes the NIC to handle splitting up packets into MTU-sized chunks rather than handling that at the OS level. This can be faster for servers and appliances as it allows the OS to offload that task to dedicated hardware, but when acting as a firewall or router this behavior is **highly undesirable** as it actually increases the load as this task has already been performed elsewhere on the network, thus breaking the end-to-end principle by modifying packets that did not originate on this host.

Warning: This option is not desirable for routers and firewalls, but can benefit workstations and appliances. It is disabled by default, and should remain disabled unless the firewall is acting primarily or solely in an appliance/endpoint role.

Do not uncheck this option unless directed to do so by a support representative. This offloading is broken in some hardware drivers, and can negatively impact performance on affected network cards and roles.

Hardware Large Receive Offloading

Checking this option will disable hardware large receive offloading (LRO). LRO is similar to TSO, but for the incoming path rather than outgoing. It allows the NIC to receive a large number of smaller packets before passing them up to the operating system as a larger chunk. This can be faster for servers and appliances as it offloads what would normally be a processing-heavy task to the network card. When acting as a firewall or router this is **highly undesirable** as it delays the reception and forwarding of packets that are not destined for this host, and they will have to be split back up again on the outbound path, increasing the workload significantly and breaking the end-to-end principle.

Warning: This option is not desirable for routers and firewalls, but can benefit workstations and appliances. It is disabled by default, and should remain disabled unless the firewall is acting primarily or solely in an appliance/endpoint role.

Do not uncheck this option unless directed to do so by a support representative. This offloading is broken in some hardware drivers, and can negatively impact performance on affected network cards and roles.

hn ALTQ Support

Checking this option will enable support for ALTQ traffic shaping on `hn(4)` network interfaces in Hyper-V.

For ALTQ to work on `hn(4)` interfaces, the operating system must disable the multi-queue API which may reduce the system capability to handle traffic. The administrator must decide if this reduction in performance is worth the benefit of traffic shaping.

The firewall must be rebooted for this setting to take effect.

Suppress ARP messages

The firewall makes a log entry in the main system log when an IP address appears to switch to a different MAC address. This log entry notes that the device has moved addresses, and records the IP address and the old and new MAC addresses.

This event can be completely benign behavior (e.g. NIC teaming on a Microsoft server, a device being replaced) or a legitimate client problem (e.g. IP conflict), and it could show up constantly or rarely if ever. It all depends on the network environment.

The best practice is to allow these ARP messages to be printed to log since there is a chance it will report a problem worth the attention of a network administrator. However, if the network environment contains systems which generate these messages while operating normally, suppressing the errors can make the system log more useful as it will not be cluttered with unneeded log messages.

Reset All States

When set, if an interface IP address changes, the firewall will reset the entire state table instead of only clearing states for the old interface IP address.

This behavior is potentially disruptive, and is off by default. In single WAN environments, this is not typically any more disruptive than the WAN address changing, since clients already have to reestablish all connections.

In most cases, this behavior is not necessary, but it can help in certain situations where WAN addresses change rapidly and the normal behavior misses states for former IP addresses.

Use `if_pppoe` Kernel Module

When set, pfSense software uses the kernel-based `if_pppoe` backend to handle PPPoE WAN interfaces and disables the MPD backend for PPPoE WANs. The `if_pppoe` backend is very fast and efficient, but it does not support some advanced features found in the older deprecated MPD backend, such as MLPPP. The `if_pppoe` backend for PPPoE interfaces conflicts with the MPD backend so the two cannot be used at the same time.

This option is disabled by default, but will be the default in future versions of pfSense Plus software.

8.6.4 Miscellaneous

Proxy Support

If this firewall resides in a network which requires a proxy for outbound Internet access, enter the proxy options in this section so that requests from the firewall for items such as packages and updates will be sent through the proxy.

Proxy URL
This option specifies the location of the proxy for making outside connections. It must be an IP address or a fully qualified domain name.

Proxy Port
The port to use when connecting to the proxy URL. By default the port is `8080` for HTTP proxy URLs, and `443` for SSL proxy URLs. The port is determined by the proxy, and may be a different value entirely (e.g. `3128`). Check with the proxy administrator to find the proper port value.

Proxy Username
If required, this is the username that is sent for proxy authentication.

Proxy Password
If required, this is the password associated with the username set in the previous option.

Load Balancing

When pfSense® software is directed to perform load balancing, successive connections will be redirected in a round-robin manner to a gateway, balancing the load across all available paths. The options in this section alter or fine-tune that behavior.

Sticky Connections
When active, connections from the same source are sent through the same gateway, rather than being sent in a purely round-robin manner.

This "sticky" association will exist as long as states are in the table for connections from a given source address (e.g. the IP address of a user). Once the states for that source expire, so will the sticky association. Further connections from that source host will be redirected to the next available gateway in the group.

This behavior can help with protocols such as HTTPS and FTP, where the server may be strict about all connections coming from the same source. The downside of this behavior is that balancing is not as efficient, a heavy user could dominate a single WAN rather than having their connections spread out.

Source Tracking Timeout
Controls how long the sticky association will be maintained for a host after the all of the states from that host expire. The value is specified in seconds.

By default, this value is not set, so the association is removed as soon as the states expire. If sticky connections appear to work initially but seem to stop partway through sessions, increase this value to hold an association longer. Web browsers often hold open connections for a while as users are on a site, but if there is a lot of idle time, connections may be closed and states may expire.

Power Savings

There are currently two different types of power configuration available, Speed Shift and SpeedStep (PowerD). Using Speed Shift is the best practice, but it is only supported on certain models of recent hardware.

Tip: The GUI displays options for Speed Shift only when the proper hardware is present. SpeedStep/PowerD settings are always available.

With either method of power management, if processes need the power, the CPU speed will be increased as needed and lowered when demand decreases. This lowers the amount of heat a CPU generates, and can also lower power consumption.

Warning: Speed Shift takes precedence over SpeedStep. If Speed Shift is enabled, SpeedStep support is disabled. Only one of the two should be enabled at a time.

Speed Shift

Speed Shift configures hardware-controlled performance states which enable the CPU itself to control changes in clock speed. This allows the system to respond much faster to changes in load. This method also does not rely on the BIOS passing useful values for power management since it is handled entirely at the CPU level.

Note: Speed Shift responds so fast to load that even the act of checking the current CPU frequency status raises the clock speed temporarily, making the results appear higher!

Enable Speed Shift
This checkbox enables or disables Speed Shift support.

The current status of Speed Shift is printed below the help text for this option.

Warning: Changing this setting requires a reboot.

Control Level
Chooses between per-core or per-package frequency control. Core-level control is the best practice in most cases, especially for hardware with only a single physical CPU.

The active control level is printed below the help text for this option.

Core Level Control
Each CPU core can run at a different frequency.

Package Level Control
All cores on the same physical CPU package are locked to the same speed, but each package may run at a different speed.

Warning: Changing this setting requires a reboot.

Power Preference
This option slider influences the bias of the hardware performance state toward performance (left, lower values) or energy efficiency (right, higher values).

A numerical representation of the preference level (from 0-100) is printed below the slider.

The default value is `80` to help keep heat and power usage down. For increased responsiveness to performance demands, move the slider farther to the left as needed.

PowerD

PowerD manages CPU frequency changes via SpeedStep. This daemon monitors the system and it lowers and raises the CPU frequency based on activity levels.

Note: The behavior of this option depends greatly on the hardware in use. In some cases, the CPU frequency may lower but have no measurable effect on power consumption and/or heat, where others will cool down and use considerably less power. It is considered safe to run, but is left off by default unless supported hardware is detected.

Enable PowerD
Checking this option enables the `powerd` daemon.

Modes
The mode for `powerd` may also be selected for three system states:

AC Power
Normal operation connected to AC power.

Battery Power
Mode to use when the firewall is running on battery. Support for battery power detection varies by hardware.

Unknown Power
Mode used when `powerd` cannot determine the power source.

Four modes choices exist for each of these states:

Maximum
Keeps the performance as high as possible at all times.

Minimum
Keeps performance at its lowest, to reduce power consumption.

Adaptive
Tries to balance savings by decreasing performance when the system is idle and increasing when busy.

Hiadaptive
Similar to adaptive but tuned to keep performance high at the cost of increased power consumption. It raises the CPU frequency faster and drops it slower. This is the default mode.

Note: Some hardware requires `powerd` running to operate at its maximum attainable CPU frequency. If the firewall device does not have `powerd` enabled but always runs at what appears to be a low CPU frequency, enable `powerd` and set it to *Maximum* for at least the **AC Power** state.

Watchdog

Certain firewall hardware includes a **Watchdog** feature which can reset the hardware when the watchdog daemon can no longer interface with the hardware after a specified timeout. This can increase reliability by resetting a unit when a hard lock is encountered that might otherwise require manual intervention.

The downside to any hardware watchdog is that any sufficiently busy system may be indistinguishable from one that has suffered a hard lock.

Enable Watchdog
: When checked, the `watchdogd` daemon is run which attempts to latch onto a supported hardware watchdog device.

Watchdog Timeout
: The time, in seconds, after which the device will be reset if it fails to respond to a watchdog request. If a firewall regularly has a high load and triggers the watchdog accidentally, increase the timeout.

Cryptographic & Thermal Hardware

On systems with configurable cryptographic and/or thermal hardware, this section provides options to control the hardware. On systems without configurable cryptographic modules, this section only displays options for thermal hardware.

IPsec-MB

The checkbox for **IPsec-MB** enables IPsec Multi-Buffer (IPsec-MB, IIMB) Cryptographic Acceleration.

IPsec-MB assists VPN performance by replacing the cryptographic functions provided by the kernel for AES-CBC, AES-GCM, and ChaCha20-Poly1305 with accelerated functions that utilize the optimal CPU SIMD instruction set.

This benefits any VPN utilizing the accelerated algorithms in the kernel which includes IPsec, OpenVPN DCO, and WireGuard.

IPsec-MB is faster than AES-NI and can even meet or exceed the performance of dedicated acceleration hardware such as QAT on current versions of pfSense software.

Note: If IPsec-MB and QAT are both enabled, IPsec-MB will take over handling of AES-GCM acceleration. Depending on the hardware, QAT may accelerate AES-GCM faster than IPsec-MB, but IPsec-MB can accelerate ChaCha20-Poly1305 which is not supported by QAT. Depending on the required performance of each algorithm it may be better to only enable QAT, or to enable both, but it depends on the environment and workload.

See also:

- *Cryptographic Accelerator Support*
- *Tuning IPsec-MB*

Cryptographic Hardware

There are a few options available for accelerating cryptographic operations via hardware. Some are built into the kernel, and others are loadable modules.

Note: Some modules and hardware are only supported by pfSense® Plus software.

See also:

Cryptographic Accelerator Support

The following choices are available, depending on hardware:

Intel QuickAssist (QAT) [Plus Only]
Loads the Intel QuickAssist (QAT) driver for supported hardware. QAT accelerates many types of AES and SHA operations and is ideal for use with IPsec and OpenVPN DCO.

BSD Crypto Device
Loads the BSD Crypto device module (`cryptodev`) so it can be used by other available acceleration devices. Most accelerator drivers hook into the `crypto(9)` framework in FreeBSD, so many aspects of the system will automatically use acceleration for supported ciphers when this module is loaded.

AES-NI CPU-based Acceleration
Loads the **AES-NI** (Advanced Encryption Standard, New Instructions) kernel module. Notably, the `aesni` module will accelerate operations for AES-GCM, available in IPsec.

Support for AES-NI is built into many recent Intel and some AMD CPUs. Check with the OEM for specific CPU or SoC support.

Speeds with AES-NI vary by support of the underlying software. IPsec speed will be greatly increased with AES-NI loaded provided that AES-GCM is used and properly configured.

AES-NI and BSD Crypto Device
Loads both the AES-NI and BSD Crypto Device modules together, which is the optimal configuration in most cases. Choose this unless a specific environment or configuration is found to work better without it.

SafeXcel and BSD Crypto Device [Plus Only]
Loads both the `safexcel` and the BSD Crypto Device modules. SafeXcel acceleration hardware is found on some ARM systems sold by Netgate, such as the SG-3100.

There are other supported cryptographic devices with drivers built into the kernel. One example is the driver for the Marvell Cryptographic Engine and Security Accelerator (CESA) chipset, which is found on some ARM systems sold by Netgate, such as the SG-1100 and SG-2100.

In most cases, if a supported accelerator chip is detected by the firewall, it will be shown in the **System Information** widget on the dashboard or in the system log at boot time.

Note: Certain special cases also exist where software can detect and use acceleration hardware directly, even without drivers loaded. One example is OpenSSL, which directly supports AES-NI. Thus, even without the driver loaded, software which utilizes encryption through OpenSSL can still take advantage of AES-NI acceleration.

Thermal Sensors

The firewall can read temperature data from a few sources to display on the dashboard. If the firewall has a supported CPU, selecting a thermal sensor will load the appropriate driver to read its temperature.

Note: Temperature data can be displayed by the **Thermal Sensors** *dashboard widget* or via `sysctl`.

The following sensor types are supported:

None/ACPI
: The firewall will attempt to read the temperature from an ACPI-compliant motherboard sensor if one is present, otherwise no sensor readings are available.

Intel Core
: Loads the `coretemp` module which supports reading thermal data from Intel core-series CPUs and other modern Intel CPUs using their on-die sensors, including Atom-based processors.

AMD K8, K10, and K11
: Loads the `amdtemp` module which supports reading thermal data from modern AMD CPUs using their on-die sensors.

If the firewall does not have a supported thermal sensor chip, this option will have no effect. To unload the selected module, set this option to *None/ACPI* and then reboot.

Note: The `coretemp` and `amdtemp` modules report thermal data directly from the CPU core. This may or may not be indicative of the temperature elsewhere in the system. Case temperatures can vary greatly from temperatures on the CPU die.

Kernel Page Table Isolation (PTI)

Kernel PTI is a method for working around CPU vulnerabilities such as Meltdown. By exploiting that vulnerability without Kernel PTI, kernel memory could be accessed by unprivileged users on affected CPUs.

Note: While more secure, this protection can incur a performance penalty. If untrusted users do not have access to run arbitrary code on the firewall, it can be disabled without significant security risk.

Kernel PTI is active by default only on CPUs affected by the vulnerability.

This option forces the workaround off, and requires a reboot to change.

If a vulnerable CPU is not detected, PTI is disabled by default and this option will have no effect.

The current state of Kernel PTI is printed below the option.

Microarchitectural Data Sampling (MDS) Mitigation

Microarchitectural Data Sampling (MDS) mitigation is a method for working around weaknesses in Intel CPUs which support hyperthreading. By exploiting MDS without mitigation in place, kernel memory could be accessed by unprivileged users on affected CPUs.

Note: While more secure, this protection can incur a performance penalty. If untrusted users do not have access to run arbitrary code on the firewall, it can be disabled without significant security risk.

This option controls which method of MDS mitigation is used, if any. Changing the option requires a reboot to activate. The following modes are available:

Default
: The default operating system behavior. As of this writing, the default behavior is to disable MDS mitigation.

Mitigation Disabled
: Forcefully disable MDS mitigation.

VERW instruction (microcode) mitigation enabled
: Use VERW instruction mitigation, implemented in CPU microcode, to mitigate MDS. This is the fastest and most optimal way to mitigate MDS, but it requires support in the CPU microcode for this instruction.

Software sequence mitigation enabled
: Mitigates MDS by using software sequences, which is much slower, but safer.

Automatic VERW or Software selection
: When set to Automatic, the operating system will attempt to use VERW instructions if they are available and software in all other cases.

The current state of MDS mitigation is printed below the option.

Schedules

The **Do not kill connections when schedule expires** option controls whether or not states are cleared when a scheduled rule transitions into a state that would block traffic. If unchecked, connections are terminated when the schedule time has expired. If checked, connections are left alone and will not be automatically closed by the firewall.

Gateway Monitoring

State Killing on Gateway Recovery

States from the firewall itself

Connections from the firewall itself can fail over to other gateways by setting a failover gateway group as the system's default gateway. By killing states on lower-priority gateways after a higher-priority gateway recovers, these connections can re-establish on the preferred gateway. This option overrides the failover gateway group's state-killing behavior by affecting all states, not only those created by policy routing rules.

Don't kill states from the firewall itself (default)
: States from the firewall itself are unaffected. The configured failover gateway group determines the state-killing behavior for states created by policy routing rules.

Kill all states for lower-priority gateways
All states on lower-priority gateways are killed when a higher-priority gateway returns to an online state.

Only kill states with the same Address Family as the gateway group
States of the same Address Family as the gateway group are killed for lower-priority gateways.

States from policy routing rules

The state-killing behavior on gateway recovery handles policy routing states separately. This allows for applying different behaviors to different types of traffic. For example, one gateway group can handle general internet traffic by killing states on both gateway failure and recovery. Separately, another group handling VOIP traffic would only kill states on gateway failure to avoid interrupting active calls.

Don't kill policy routing states for lower-priority gateways
Controls the default state-killing behavior for states created by policy routing rules using a failover gateway group. This behavior may also be controlled per gateway group. If unchecked (default), policy routing states on lower-priority gateways are killed when a higher-priority gateway recovers.

State Killing on Gateway Failure

When using Multi-WAN, clearing states on failed WANs can help redirect traffic for long-lived connections such as VoIP phone/trunk registrations to another WAN. However, clearing states can also disrupt ongoing connections if a lesser-used gateway is unstable or there is a gateway which is down long term but is not disabled, which would still states when it fails or is down during a filter reload.

There are several choices for this behavior, including:

Do not kill states on gateway failure (Default)
The monitoring process will not flush states when a gateway is in a down state during a filter reload. This is the default behavior and is the least disruptive, though clients may have to wait for connections to timeout after a WAN failure.

Kill states for all gateways which are down
Selectively kill states using gateways that fail or are down during a filter reload, so long as those states were created by policy routing rules.

This function can only kill states which contain gateway information populated by policy routing rules (e.g. gateways or gateway groups on firewall rules, or even `reply-to`.). It cannot kill states created by default gateway switching as in that case the gateway in the state is `0.0.0.0/::` and not a specific gateway.

Flush all states on gateway failure
Clears **all** states for existing connections when **any** gateway fails or is in a down state during a filter reload.

> **Warning:** When this is triggered the firewall clears the **entire** state table if any gateway is down, which can be highly disruptive.

More information on how this impacts Multi-WAN can be found in *State Killing/Forced Switch*.

Skip Rules When Gateway is Down

By default, when a rule has a specific gateway set and this gateway is down, the gateway is omitted from the rule and traffic is sent via the default gateway.

The **Do not create rules when gateway is down** option overrides that behavior and the entire rule is omitted from the ruleset when the gateway is down. Instead of flowing via the default gateway, the traffic will match a different rule instead. This is useful if traffic must only ever use one specific WAN and never flow over any other WAN.

Tip: When utilizing this option, create a reject or block rule underneath the policy routing rule with the same matching criteria. This will prevent the traffic from potentially matching other rules below it in the ruleset and taking an unintended path.

Static Routes

By default the firewall adds static routes for gateway monitor IP addresses to ensure traffic to the monitor IP address leaves via the correct interface. Enabling this checkbox overrides that behavior. When this option is set, the user will have to ensure the traffic exits the correct interface in some other way.

RAM Disk Settings

The `/tmp` and `/var` directories are used for writing files and holding data that is temporary and/or volatile. Using a RAM disk can reduce the amount of writing that happens on disks in the firewall. Modern SSDs do not have disk write concerns as older drives once did, but it can still be a concern when running from lower quality flash storage such as USB thumb drives.

This behavior has the benefit of keeping most of the writes off of the disk in the base system, but packages may yet write frequently to the drive. It also requires additional handling to ensure data such as RRD graphs and DHCP leases are retained across reboots. Data for both is saved during a proper shutdown or reboot, and also periodically if configured.

Use RAM Disks
When checked, a memory disk is created at boot time for `/tmp` and `/var/` and the associated structure is initialized. When this setting is toggled, a reboot is required and forced on save.

> **Warning:** The size of RAM disks is limited by the amount of available kernel memory. The actual limit is calculated and printed in the GUI underneath the size options.

/tmp RAM Disk Size
The size of the `/tmp` RAM disk, in MiB. The default value is `40`, but should be set higher if there is available RAM and kernel memory.

/var RAM Disk Size
The size of the `/var` RAM disk, in MiB. The default value is `60`, but should be set much higher, especially if packages will be used. `512-1024` is a better starting point, depending on the available firewall RAM and kernel memory.

Periodic RAM Disk Data Backups
These options control how frequently data in RAM disks is backed up. If the firewall is rebooted unexpectedly, the last backup is restored when the firewall boots. The lower the value, the less data that will be lost in such an event, but more frequent backups write more to the disk.

RRD Data
The time, in hours, between periodic backups of RRD files containing graph data.

DHCP Leases
The time, in hours, between periodic backups of the DHCP lease databases.

Log Directory
The time, in hours, between periodic backups of the system log directory.

Warning: Aside from the points mentioned above, there are several items to be cautious about when choosing whether or not to use the RAM disk option. Used improperly, this option can lead to data loss or other unexpected failures.

Utilize remote syslog to send the logs to another device on the network rather than risking losing data from unexpected outages.

Packages may not properly account for the use of RAM disks, and may not function properly at boot time or in other ways. Test each package, including whether or not it works immediately after a reboot.

These are RAM disks, so the amount of RAM available to other programs will be reduced by the amount of space used by the RAM disks. For example if the firewall has 2GB of RAM, and has 512MB for `/var` and 512MB for `/tmp`, then only 1GB of RAM will be available to the OS for general use.

Special care must be taken when choosing a RAM disk size, which is discussed in the following section.

RAM Disk Sizes

Setting a size too small for `/tmp` and `/var` can backfire, especially when it comes to packages. The suggested sizes on the page are an **absolute minimum** and often much larger sizes are required. The most common failure is that when a package is installed, and parts of the package touch places in both `/tmp` and `/var` and it can ultimately fill up the RAM disk and cause other data to be lost.

For `/tmp`, a minimum of `40` MiB is required. For `/var` a minimum of `60` MiB is required. To determine the proper size, check the current usage of the `/tmp` and `/var` directories before making a switch. Check the usage several times over the course of a few days so it is not caught at a low point. Watching the usage during a package installation adds another useful data point.

Hard Disk Standby

The **Hard disk standby time** option activates power management for disk drives in the firewall. The drop-down field sets the number of minutes that the disk can be idle before going into standby mode.

Using standby mode is not necessary for SSD or flash media. For traditional spinning platter hard disks, it may result in power savings and can potentially lengthen the disk lifetime by saving wear, at a cost of slower disk access when resuming from an idle state. Actual results entirely depend on the hardware involved.

The default behavior is *Always On* which prevents the disk from entering standby mode.

Installation Feedback

When this option is set, the firewall will not send its Netgate Device ID when making requests to Netgate servers.

8.6.5 System Tunables

The **System Tunables** tab under **System > Advanced** provides a means to set runtime FreeBSD system tunables, also known as sysctl object identifiers (OIDs).

Tip: In most cases, the best practice is to leave these tunables at their default values.

Firewall administrators familiar with FreeBSD, or users acting under the direction of a developer or support representative, may want to adjust or add values on this page so that they will be set as the system starts.

Kernel State and Tunables

The `sysctl` facility on FreeBSD allows managing certain aspects of the kernel state through a "Management Information Base" (MIB) style tree composed of individual object identifiers (OIDs) containing components separated by periods. These individual `sysctl` OIDs are often referred to as "tunables" but not all of them can be changed.

See also:

This is a simplified description. The sysctl manual page contains more detail.

The most common types of operating system tunables on FreeBSD are:

Runtime Tunables
: The values of runtime tunables can be changed at any time while the system is running.

Loader Tunables
: The values of loader tunables can only be changed at boot in the loader and they are read only afterward when the system is running.

Read Only Tunables
: The values of read only tunables can never be changed manually, they are typically for reference or statistical purposes.

Tunable OIDs and Values

There are many OIDs available from `sysctl`. The full list of OIDs and their possible values is outside the scope of this documentation, but for those interested in digging a little deeper, The sysctl manual page from FreeBSD contains detailed instructions and information.

To see the current values of all visible OIDs, run:

```
# sysctl -a
```

Managing Runtime Tunables

Persistent values for runtime tunables can be managed from within the GUI.

To create a new tunable:

- Navigate to **System > Advanced**, **System Tunables** tab
- Click  **New** at the top right of the list

To edit an existing tunable:

- Navigate to **System > Advanced**, **System Tunables** tab
- Locate the entry to edit
- Click  on its row

---

Note: The tunables on this page are different from **Loader Tunables**. For details on loader tunables, see *Managing Loader Tunables*.

When editing or creating a tunable, the following fields are available:

Tunable
The `sysctl` OID to set.

Value
The value to which the **Tunable** will be set.

Note: Some values have formatting requirements. Due to the vast number of sysctl OIDs, the GUI does not validate that the given **Value** will work for the chosen **Tunable**.

Description
An optional description for reference.

Click **Save** when the form is complete.

Managing Loader Tunables

Loader tunable values must be set before the kernel boots and user-defined loader tunables belong in `/boot/loader.conf.local`, which can be created or edited in several ways.

To determine loader tuneable values at boot the operating system first reads `/boot/defaults/loader.conf`, then `/boot/loader.conf`, and finally `/boot/loader.conf.local`. After the kernel boots, loader tunable values become read only.

These files each have a distinct purpose:

`/boot/defaults/loader.conf`
This file contains default values from FreeBSD and **must not be changed** as it will be rewritten during any upgrade.

`/boot/loader.conf`
This file contains loader values managed by pfSense software internally and **must not be changed**. It is rewritten

each boot and when certain options are changed, and any manual modifications are discarded. Values in this file can override the operating system defaults.

`/boot/loader.conf.local`
: Administrators can use this file to define custom loader tunable values. Since it is read last, it can override values from the OS default values as well as values set by pfSense internally.

  This file does not exist by default, but can be created at any time.

  This file is not backed up in `config.xml`, make a separate manual backup of its contents.

Note: Loader tunable values can also be defined for a single boot by setting them at the loader prompt from the boot menu.

Loader tunables are not currently manageable in the GUI in an integrated way, they must be manually managed by creating or editing the `/boot/loader.conf.local` file.

Users can create and edit that file in a variety of ways in the GUI or in the shell.

GUI File Editor

The file editor in the GUI can make changes to this file:

- Navigate to **Diagnostics > Edit File**
- Enter `/boot/loader.conf.local` in the **Path to file to be edited** box
- Click **Load** to load the existing content in the file if any exists

  If the file does not exist, the editor will print an error. This error can be ignored.
- Enter the loader tunable OIDs and values in the file, one per line.

  Comments can also be added by starting a line with #

  Example:

```
# Disable flow control on all ix interfaces
hw.ix.flow_control="0"
```

- Click **Save**

Reboot the firewall to activate the new tunable values.

Shell Editors

Similar to the above process, any text editor available in the shell can make changes to `/boot/loader.conf.local`. Available editors include `vi` and `ee` in the base system, along with `vim` and `nano` which are available to install via `pkg`. These changes must be made as the `admin` or `root` user, or by a user given sufficient access using the `sudo` package.

8.6.6 Notifications

The firewall can notify administrators of important events and errors by displaying an alert in the menu bar, indicated by the  icon.

In addition to GUI notifications, the firewall also supports the following notification methods:

- Local via LED indicators on supported hardware (not configurable)
- Local via Sounds using a PC speaker
- Remote via E-mail using SMTP
- Remote via Telegram notification API
- Remote via Pushover notification API
- Remote via Slack notification API

General Settings

Certificate Expiration
When set, the firewall will issue notifications as CA and certificate entries approach their expiration date so that administrators can take corrective action to renew or replace them. Notifications are also sent for expired entries.

Expiration times are checked daily, and notifications are displayed in the GUI and sent remotely.

Ignore Revoked
When set, the firewall will not send notifications for expired certificate entries which have been revoked in at least one CRL.

Certificate Expiration Threshold
The value, in days, at which CA and certificate entries are considered to be approaching their expiration date.

The default value is currently 27 days. Certificates from Let's Encrypt (*ACME package*) typically renew when they have around 30 days before they expire. The default value is long enough that it does not notify unnecessarily, but with enough time left that problems can be corrected.

Tip: If certificates are imported into the firewall from third party sources which take longer to process, increase this value sufficiently to give administrators enough notice to obtain an updated replacement certificate before the expiration date.

SMTP E-mail

E-mail notifications are delivered by a direct SMTP connection to a mail server. The server must be configured to allow relaying from the firewall or accept authenticated SMTP connections.

Disable SMTP
When checked, the firewall will not send SMTP notifications. This is useful to silence notifications while keeping SMTP settings in place for use by other purposes such as packages that utilize e-mail.

E-mail server
The hostname or IP address of the e-mail server through which the firewall will send notifications.

SMTP Port of E-mail server
The port to use when communicating with the SMTP server. The most common ports are `25` and `587`.

In many cases, `25` will not work unless it is to a local or internal mail server. Providers frequently block outbound connections to port `25`, so use `587` (the Submission port) when possible.

Connection Timeout to E-Mail Server
The length of time, in seconds, that the firewall will wait for an SMTP connection to complete.

Secure SMTP Connection
When set, the firewall will attempt a direct SSL/TLS connection when sending e-mail. The server must accept SSL/TLS connections on the configured port.

> **Warning:** This option is not compatible with ports that utilize plain text and switch to TLS after using STARTTLS (e.g. 25, 587).

Note: When this option is **not** checked, the firewall will still automatically attempt to use START-TLS to setup a secure TLS communications channel on ports 25 and 587 when authentication is configured.

Validate SSL/TLS
When set, the certificate presented by the mail server is checked for validity against the root certificate authorities trusted by the firewall. Ensuring this validity is the best practice.

In some rare cases a mail server may have a self-signed certificate or a certificate that otherwise fails validation. Unchecking this option will allow notifications to be sent to these servers using SSL/TLS. In this case, communication is still encrypted, but the identity of the server cannot be validated.

From e-mail address
The e-mail address for the `From:` header in notification messages, which specifies the source. Some SMTP servers attempt to validate this address so the best practice is to use a real address in this field. This is commonly set to the same address as **Notification E-mail address**.

Notification E-mail address
The e-mail address(es) for the `To:` header of the message, which is the destination where the notification e-mails will be delivered by the firewall.

Note: This field supports multiple addresses separated by a comma, for example: `me@example.com,otheradmin@example.com`.

Notification E-Mail Auth Username
Optional. If the mail server requires a username and password for authentication, enter the username here.

Notification E-Mail Auth Password
Optional. If the mail server requires a username and password for authentication, enter the password here and in the confirmation field.

Notification E-mail Auth Mechanism
This field specifies the authentication mechanism required by the mail server. The majority of e-mail servers work with *PLAIN* authentication, others such as MS Exchange may require *LOGIN* style authentication.

Note: In 2022 Google phased out access to SMTP Submission and other similar services using the account username and password directly. To access these services Google has deemed "less secure", the user must enable 2-Step Verification for their Google account and then create an App Password which can authenticate with these services.

Click  **Save** at the bottom of the page to store the settings before proceeding.

Click  **Test SMTP Settings** to generate a test notification and send it via SMTP using the previously stored settings. Save settings before clicking this button.

Sounds

Console Bell

When checked, emergency log messages, such as from a GUI login, will trigger a bell in connected consoles including serial terminals. On devices with a speaker, such messages can trigger an audible beep.

Startup/Shutdown Sound

If the firewall hardware has a PC speaker, it will play a sound when startup finishes and again when a shutdown is initiated.

Check **Disable the startup/shutdown beep** to prevent the firewall from playing these sounds.

Telegram

The notification system supports the Telegram API which can send notifications to desktops and mobile devices, among others.

Note: Using the Telegram API requires a Telegram Bot and its associated API key.

Enable Telegram
When set, the firewall will attempt to send remote notifications using the Telegram API and the settings in this section.

API Key
Required. The Telegram Bot API key the firewall will use to authenticate with the Telegram API server.

Chat ID
The destination for the notifications. This can be a chat ID number for private notifications, or a channel `@username` for public notifications.

Click  **Save** at the bottom of the page to store the settings before proceeding.

Click  **Test Telegram Settings** to generate a test notification and send it using the Telegram API with the previously stored settings. Save settings before clicking this button.

Pushover

The notification system supports the Pushover API which can send notifications to desktops and mobile devices, among others.

Note: Using the Pushover API requires a Pushover account user key and API key (Pushover Registration).

Enable Pushover
When set, the firewall will attempt to send remote notifications using the Pushover API and the settings in this section.

API Key
Required. The Pushover API Key (Pushover Registration) the firewall will use to authenticate with the Pushover API server.

User Key
Required. The User Key (Pushover Registration) of the Pushover account to which the **API Key** belongs.

Notification Sound
The notification sound that the end user device (Phone, etc) will play when notification messages are sent by the firewall.

See also:

For a list of sounds and audio, see the Pushover API Notification Sounds Documentation.

Message Priority
The message priority for firewall notifications.

Note: For more information about the priorities and their meanings, see the Pushover API Priority Documentation.

The following priorities are available:

Normal
Default setting. May trigger sound, vibration, and notification display depending on the user settings and client platform.

Lowest
No sound or vibration, but increases the notification count on some platforms.

Low
No sound or vibration. May trigger a notification display depending on the user settings and client platform.

High
Always play sound and vibrate. Bypasses pre-set quiet hours. Notification display is highlighted in red.

Emergency
Similar to *High* priority, but the notification is repeated until acknowledged by the user.

Emergency Priority Notification Retry Interval
The amount of time, in seconds, the Pushover servers will send the same notification for *Emergency* priority notifications until the notification is acknowledged.

This parameter must have a value of at least `30` seconds between retries. Default is `60` seconds (1 minute).

Emergency Priority Notification Expiration
The duration, in seconds, for which *Emergency* priority notifications will be retried until the notification is acknowledged. Notifications will be resent at intervals determined by the value of **Emergency Priority Notification Retry Interval**.

This parameter must have a maximum value of at most `10800` seconds (3 hours). Default is `300` seconds (5 minutes).

Click  **Save** at the bottom of the page to store the settings before proceeding.

Click  **Test Pushover Settings** to generate a test notification and send it using the Pushover API with the previously stored settings. Save settings before clicking this button.

Slack

The notification system supports the Slack API which can send notifications to Slack channels.

Note: Using the Slack API requires a Slack API key (Slack API Registration).

Enable Slack
When set, the firewall will attempt to send remote notifications using the Slack API and the settings in this section.

API Key
Required. The Slack API Key (Slack API Registration) the firewall will use to authenticate with Slack servers.

Slack Channel
The name of the Slack channel to which the firewall will send notifications (e.g. `#firewall`).

Click  **Save** at the bottom of the page to store the settings before proceeding.

Click  **Test Slack Settings** to generate a test notification and send it using the Slack API with the previously stored settings. Save settings before clicking this button.

8.7 Console Menu Basics

Basic configuration and maintenance tasks can be performed from the pfSense® system console. The console is available using a keyboard and monitor, serial console, or by using SSH. Access methods vary depending on hardware. Below is an example of what the console menu will look like, but it may vary slightly depending on the version and platform:

```
WAN (wan)       -> vmx0       -> v4/DHCP4: 198.51.100.6/24
                                 v6/DHCP6: 2001:db8::20c:29ff:fe78:6e4e/64
LAN (lan)       -> vmx1       -> v4: 10.6.0.1/24
                                 v6/t6: 2001:db8:1:eea0:20c:29ff:fe78:6e58/64
```

(continues on next page)

(continued from previous page)

```
0) Logout (SSH only)                  9) pfTop
1) Assign Interfaces                 10) Filter Logs
2) Set interface(s) IP address       11) Restart GUI
3) Reset admin account and password  12) PHP shell + pfSense tools
4) Reset to factory defaults         13) Update from console
5) Reboot system                     14) Disable Secure Shell (sshd)
6) Halt system                       15) Restore recent configuration
7) Ping host                         16) Restart PHP-FPM
8) Shell
```

Page Contents

8.7.1 First Connection Behavior

On pfSense Plus software version 24.03 and later, during the first connection to the console or SSH after installation or resetting to factory defaults, the user is prompted to set a new password for the `admin` account.

This change is mandatory, however, it can also be performed in the GUI using the *Setup Wizard*, the *User Password Manager*, or the *User Manager*.

If the password has been changed in the GUI, press `Ctrl-C` to cancel the console password change prompt. The script will check the password again and if it has been changed, it will display the menu. If the password is still the default value, however, the user will be logged out.

8.7.2 1) Assign Interfaces

This option restarts the **Interface Assignment** task, which is covered in detail in *Assign Interfaces* and *Manually Assigning Interfaces*. This menu option can create VLAN interfaces, reassign existing interfaces, or assign new ones.

8.7.3 2) Set interface(s) IP address

The script to set an interface IP address can set WAN, LAN, or OPT interface IP addresses, but there are also other useful features of this script:

- The firewall prompts to enable or disable DHCP service for an interface, and to set the DHCP IP address range if it is enabled.
- If the firewall GUI is configured for HTTPS, the menu prompts to switch to HTTP. This helps in cases when the SSL configuration is not functioning properly.
- If the anti-lockout rule on LAN has been disabled, the script enables the anti-lockout rule in case the user has been locked out of the GUI.

8.7.4 3) Reset admin account and password

This menu option invokes a script to reset the `admin` account and password.

The script takes a few actions to help regain access to the `admin` account:

- If the authentication source is set to a remote server such as RADIUS or LDAP, the script prompts to return the authentication source to the Local Database (User Manager).
- If the `admin` account has been removed, the script re-creates the account.
- If the `admin` account is disabled or expired, the script re-enables the account.

Once the `admin` account has been restored to a working state the script prompts to set and confirm a new password. This new password can then be used to login to the `admin` account in the GUI, console, or SSH (if enabled).

Tip: This option can be used to change the password for the `admin` from the console instead of using the GUI.

Note: On previous versions of pfSense software this option reset the password to a default value (*Default Username and Password*). This is no longer the case as the best practice is to avoid using default passwords.

8.7.5 4) Reset to factory defaults

This menu choice restores the system configuration to factory defaults. It will also attempt to remove any installed packages.

This action is also available in WebGUI at **Diagnostics > Factory Defaults**.

See *Resetting to Factory Defaults* for more details about how this process works.

8.7.6 5) Reboot system

This menu choice cleanly shuts down the firewall and restarts the operating system. There are several options which control what the firewall will do when rebooting. The choices offered by the reboot option are explained in *Reboot Methods*.

See also:

This action is also available in WebGUI at **Diagnostics > Reboot**, see *Rebooting the Firewall* for details.

8.7.7 6) Halt system

This menu choice cleanly shuts down the firewall and either halts or powers off, depending on hardware support.

Warning: The best practice is to **never** cut power from a running system. Halting before removing power is always the safest choice.

See also:

This action is also available in WebGUI at **Diagnostics > Halt System**. See *Halting and Powering Off the Firewall* for additional details.

8.7.8 7) Ping host

This menu option runs a script which attempts to contact a host to confirm if it is reachable by the firewall through a connected network. The script prompts the user for an IP address, and then the script sends that target host three ICMP echo requests.

The script displays output from the test, including the number of packets received, sequence numbers, response times, and packet loss percentage.

The script uses `ping` when given an IPv4 address or a hostname, and `ping6` when given an IPv6 address.

This is only a basic ping test. For more options, see *Ping Host* to run a similar test from the GUI.

8.7.9 8) Shell

This menu choice starts a command line shell.

Warning: A shell is very useful and very powerful, but also has the potential to be very dangerous.

Note: The majority of users do not need to touch the shell, or even know it exists.

Complex configuration tasks may require working in the shell, and some troubleshooting tasks are easier to accomplish from the shell, but there is always a chance of causing irreparable harm to the system.

Veteran FreeBSD users may feel slightly at home there, but there are many commands which are not present on pfSense software installations since unnecessary parts of the OS are removed for security and size constraints.

A shell started in this manner uses `tcsh`, and the only other shell available is `sh` . While it is possible to install other shells for the convenience of users, Netgate neither recommends nor supports using other shells.

8.7.10 9) pfTop

This menu option invokes `pftop` which displays a real-time view of the firewall states, and the amount of data they have sent and received. It can help pinpoint sessions currently using large amounts of bandwidth, and may also help diagnose other network connection issues.

See also:

See *pfTop* for more information on how to use pfTop.

8.7.11 10) Filter Logs

The **Filter Logs** menu option displays firewall log entries in real-time, in their raw form. The raw logs contain much more information per line than the log view in the WebGUI (**Status > System Logs**, **Firewall tab**), but not all of this information is easy to read.

Tip: For a simplified console view of the firewall logs in real time with low detail, use the following shell command:

```
tail -F /var/log/filter.log | filterparser.php
```

8.7.12 11) Restart GUI

Restarting the webConfigurator will restart the system process that runs the GUI (`nginx`). In extremely rare cases the process may have stopped, and restarting it will restore access to the GUI.

If the GUI is not responding and this option does not restore access, invoke menu option 16 to **Restart PHP-FPM** after using this menu option.

8.7.13 12) PHP shell + pfSense tools

The PHP shell is a powerful utility that executes PHP code in the context of the running system. As with the normal shell, it is also potentially dangerous to use. This is primarily used by developers and experienced users who are intimately familiar with both PHP and the pfSense software code base.

See also:

See *Using the PHP Shell* for additional details and a list of available playback scripts.

8.7.14 13) Upgrade from console

This menu option runs the `pfSense-upgrade` script to upgrade the firewall to the latest available version. This is operationally identical to running an upgrade from the GUI and requires a working network connection to reach the update server.

This method of upgrading is covered with more detail in *Upgrading using the Console*.

8.7.15 14) Enable/Disable Secure Shell (sshd)

This option toggles the status of the Secure Shell Daemon, `sshd`. This option works the same as the option in the WebGUI to enable or disable SSH.

8.7.16 15) Restore recent configuration

This menu option starts a script that lists and restores backups from the configuration history. This is similar to accessing the configuration history from the GUI at **Diagnostics > Backup/Restore** on the **Config History** tab (*Configuration History*).

This script can display the last few configuration files, along with a timestamp and description of the change made in the configuration, the user and IP address that made the change, and the config revision. This is especially useful if a recent configuration error accidentally prevented access to the GUI.

8.7.17 16) Restart PHP-FPM

This menu option stops and restarts the daemon which handles PHP processes for `nginx`. If the GUI web server process is running but unable to execute PHP scripts, invoke this option. Run this option in conjunction with **Restart webConfigurator** for the best result.

8.8 Resetting to Factory Defaults

The firewall configuration can be reset back to defaults, a process which also attempts to remove any installed packages. This reset can be performed in the GUI from **Diagnostics > Factory Defaults**, by using the console menu, or in some cases by using a hardware button.

In each case, the firewall will automatically reboot with a default configuration after the reset, which may require console access to resolve.

Note: This process does not remove any changes made to the file system, it only resets the configuration.

If system files have been corrupted or altered in an undesirable way, the best practice is to make a backup and reinstall from installation media.

8.8.1 Factory Default from the GUI

To reset the configuration to factory defaults using the GUI:

- Navigate to **Diagnostics > Factory Defaults**
- Review the items on the page which will be affected by the reset
- Click  **Factory Reset**
- Click **OK** to confirm the action and start the reset process

8.8.2 Factory Default from the Console

To reset the configuration to factory defaults using the console:

- Access the console menu locally or via SSH with an admin-level account (`admin`, `root`, or another privileged account using `sudo`).
- Enter the menu option which corresponds with **Reset to factory defaults** (e.g. `4`)
- Press `Enter`
- Enter the `y` to confirm the action
- Press `Enter` to start the reset process

8.8.3 Factory Default using a Hardware Button

On some appliances from Netgate, the reset button may be depressed with a paperclip or other similar object during the boot sequence.

> **Warning:** Reset button behavior varies by hardware. Check the appropriate product manual to confirm support and button behavior before attempting this procedure.

For most hardware which supports this feature, the procedure is similar:

- Apply power to the unit
- Depress the reset button after the initial POST sequence completes
- Hold the reset button in until the system LEDs turn off or the system reboots

The unit will reset the configuration to factory defaults and reboot again with that default configuration.

8.9 XML Configuration File

pfSense® software stores its settings in an XML format configuration file. All configuration settings including settings for packages are held in this one file. Run-time configuration files for services and firewall behavior are generated dynamically based on the settings held within this XML configuration file.

Those familiar with FreeBSD and related operating systems have found this out the hard way, when their changes to system configuration files were repeatedly overwritten by the firewall before they came to understand that pfSense software handles everything automatically.

The configuration file is stored at `/conf/config.xml` on the firewall.

8.9.1 Manually editing the configuration

A handful of configuration options are only available by manually editing the configuration file, though this isn't required in the vast majority of deployments. Some of these options are covered in other parts of this documentation where they are relevant. Additionally, for advanced administrators in rare cases large-scale or tricky changes may be easier to make by directly editing the configuration file.

Warning: Even for seasoned administrators it is easy to incorrectly edit the configuration file. Always keep backups and be aware that breaking the configuration will result in unintended consequences.

Edit a Backup

The safest and easiest method of editing the configuration file is to make a backup, edit the backup, and then restore:

- Navigate to **Diagnostics > Backup/Restore** in the GUI
- Download and save backup file
- Open the file in a text editor that properly understands UNIX line endings, and preferably an editor that has special handling for XML such as syntax highlighting. Do not use `notepad.exe` on Windows.
- Make changes to the configuration and save
- Navigate to **Diagnostics > Backup/Restore** in the GUI
- Restore the edited configuration

The firewall will automatically reboot as a part of the restoration process, and the new settings will be active afterward.

Edit In Place

Editing the configuration in-place is also possible in a variety of ways. The general procedure is:

- Edit `/conf/config.xml`
- Run `rm /tmp/config.cache` to clear the configuration cache
- Reboot, or use the GUI to save/reload whichever part of the firewall utilizes the edited settings

From the console or ssh, administrators familiar with the vi editor can use the `viconfig` command to edit the running configuration, and this command automatically clears the cache file after saving and exiting.

Other editors are available on the firewall, such as `ee` or in the GUI under **Diagnostics > Edit File** (*Editing Files on the Firewall*). Clear the cache file manually after using one of these other methods, either using the shell or **Diagnostics > Command Prompt** (*Command Prompt*).

8.10 pfSense® Plus Software Registration

The pfSense Plus Software Registration page is located at **System > Register**. This page activates features in pfSense Plus software installations on hardware and virtual machines not purchased from Netgate. The page also activates older Netgate® hardware purchased with Factory Edition (FE) pfSense software before the Netgate Device ID (NDI) was introduced.

The registration process requires an activation token supplied by Netgate. This token is generated when purchasing pfSense Plus software or via Netgate TAC for older Netgate hardware.

For more information about pfSense Plus software, or to purchase pfSense Plus software, visit Netgate Store.

Note: Registration is free for hardware purchased from Netgate with pfSense Plus software or the older Factory Edition of pfSense software. Most hardware is pre-registered and does not require activation. To activate hardware which is not automatically recognized, submit a request to Netgate TAC along with the serial number and NDI for the device at https://go.netgate.com. The serial number and NDI are displayed on the dashboard in the **System Information** widget, and may also be on a sticker located on the bottom of the device.

The current registration status is shown on the dashboard in the **Netgate Services and Support** widget, and is also indicated on **System > Register**.

The text on the registration page varies depending on the current registration status and availability. The page also displays errors encountered during the activation process, such as not being able to contact the registration server.

8.10.1 Registration Process

To register an installation of pfSense Plus software with Netgate:

- Obtain a pfSense Plus software activation token from Netgate
- Navigate to **System > Register** on the firewall
- Enter the **Activation Token**
- Click **Register**

See also:

- *Basic Firewall Configuration Example*
- *Troubleshooting Clock Issues*
- *Troubleshooting*
- *Troubleshooting Access when Locked Out of the Firewall*
- *Troubleshooting Time Zone Configuration*

Most pfSense® software configuration is performed using the web-based GUI. There are a few tasks that may also be performed from the console, whether it be a monitor and keyboard, over a serial port, or via SSH.

8.11 Connecting to the GUI

To reach the GUI, follow this basic procedure:

- Connect a client computer to the same network as the LAN interface of the firewall. This computer may be directly connected with a network cable or connected to the same switch as the LAN interface of the firewall.

  By default, the LAN IP address of a new installation of pfSense software is `192.168.1.1` with a `/24` mask (`255.255.255.0`), and there is also a DHCP server running. If a client computer is set to use DHCP, it should obtain an address in the LAN subnet automatically.

- On the client computer, open a web browser such as Firefox, Safari, or Chrome and navigate to https://192.168.1.1.

  The GUI listens on HTTPS by default, but if the browser attempts to connect using HTTP, it will be redirect by the firewall to the HTTPS port instead.

- Enter the default credentials in the login page:

username
`admin`

password
`pfsense`

In some cases additional steps may be necessary before the client computer can reach the GUI.

Warning: If the default LAN subnet conflicts with the WAN subnet, the LAN subnet must be changed before connecting it to the rest of the network. Attempting to access the GUI in this situation is unpredictable and unlikely to work until the conflict is resolved.

The LAN IP address may be changed and DHCP may be disabled using the console:

- Open the console (VGA, serial, or using SSH from another interface)
- Choose option `2` from the console menu
- Enter the new LAN IP address, subnet mask, and specify whether or not to enable DHCP.
- Enter the starting and ending address of the DHCP pool if DHCP is enabled. This can be any range inside the given subnet.

Note: When assigning a new LAN IP address, it cannot be in the same subnet as the WAN or any other active interface. If there are other devices already present on the LAN subnet, it also cannot be set to the same IP address as an existing host.

If the DHCP server on the firewall is disabled, client computers on LAN must have a statically configured IP address in the LAN subnet, such as `192.168.1.5`, with a subnet mask that matches the one given to the firewall, such as `255.255.255.0`.

CHAPTER

NINE

NETGATE® NEXUS

Netgate Nexus is the multi-instance management (MIM) system for pfSense Plus software. Designed to address the growing complexity of managing multiple firewall instances across distributed environments, Netgate Nexus empowers network operators to securely manage hundreds of pfSense Plus instances through a unified, intuitive GUI and REST API.

The Netgate Nexus controller is included in pfSense Plus software versions 25.07 and later.

9.1 Netgate Nexus Controller Setup

Before instances of pfSense Plus software can be registered to the Netgate Nexus controller for tasks such as multi-instance management (MIM), there are several setup tasks to complete.

9.1.1 Enable Netgate Nexus Controller

The Netgate Nexus controller must be enabled and running before registering instances.

- Open the pfSense Plus software WebGUI on the designated controller
- Navigate to **System > Advanced**, **Netgate Nexus** tab
- Check **Enable**
- Configure any other options as needed (*Netgate Nexus Controller Configuration Options*)
- Click **Save**

9.1.2 Firewall rules for Netgate Nexus

The Netgate Nexus controller **does not** automatically add firewall rules for the Netgate Nexus GUI or external controller VPN connectivity. Firewall rules are necessary for instances to connect the VPN itself and for administrators to reach the Netgate Nexus GUI. Configure these firewall rules on the controller host in the pfSense Plus software WebGUI.

Note: The Netgate Nexus controller automatically passes traffic tunneled through its VPN between the instances and the controller. There is no need to manage rules for that internal communication.

Allowing Incoming Netgate Nexus VPN Connections

Add a rule on WAN to pass connections to the Netgate Nexus VPN port.

- Open the pfSense Plus software WebGUI on the designated controller
- Navigate to **Firewall > Rules**, **WAN** tab

> **Note:** WAN is used as an example. This could also be any other interface to which instances will connect.

- Click  to add a new rule at the top of the list:
- Configure the rule with the following options:

Action
Pass

Protocol
UDP

Source
Any

> **Note:** This is acceptable if instances have dynamic addresses. If all instances are static, consider creating an alias to allow only those addresses.

Destination
This Firewall (self)

> **Note:** This could also be the specific interface or IP address instances use when connecting.

Destination Port

From
(Other)

Custom
`_nexus_vpn_port_`

> **Note:** This is a built-in alias which automatically contains the random port the controller selected to use for incoming VPN connections.

- Click **Save**
- Click **Apply Changes**

Allowing Netgate Nexus GUI Access

Access to the Netgate Nexus GUI is also restricted by firewall rules. If local interfaces or VPNs are restricted, rules must be added there as well. The ports for those rules are configured in the Netgate Nexus options (*General Options*).

> **Danger:** **Do not expose this port to the Internet**. Limit access as much as possible. Use a VPN for remote access.
>
> As with the pfSense Plus software WebGUI, the best practice is to restrict access to specific management hosts, networks, or VPN clients.

9.1.3 Accessing the Netgate Nexus GUI

To access the Netgate Nexus GUI, follow the links in the Netgate Nexus status under **System > Advanced**, **Netgate Nexus** tab (*Viewing Netgate Nexus Status*).

Use the HTTPS link to securely access the Netgate Nexus controller.

Note: If the Netgate Nexus controller is using a self-signed TLS certificate, then it may be necessary to click through an error in the browser warning about the validity of the self-signed certificate.

9.1.4 Netgate Nexus Authentication

After following the link, the controller will display a login screen.

Tip: Bookmark this page for faster access.

The Netgate Nexus controller uses the pfSense Plus software *User Manager*, so the same credentials will work for the Netgate Nexus controller that work for the pfSense Plus software WebGUI.

Enter valid credentials and click **Sign In** to access the Netgate Nexus GUI.

9.2 Netgate Nexus Options in the pfSense Plus WebGUI

The pfSense Plus software WebGUI contains options to manage the Netgate Nexus controller itself. These options are at **System > Advanced** on the **Netgate Nexus** tab.

9.2.1 Enabling Netgate Nexus

The Netgate Nexus controller must be *enabled and running* before it can be accessed by browsers or other instances.

- Open the pfSense Plus software WebGUI
- Navigate to **System > Advanced**, **Netgate Nexus** tab
- Check **Enable**
- Configure any other options as needed (*Netgate Nexus Controller Configuration Options*)
- Click **Save**

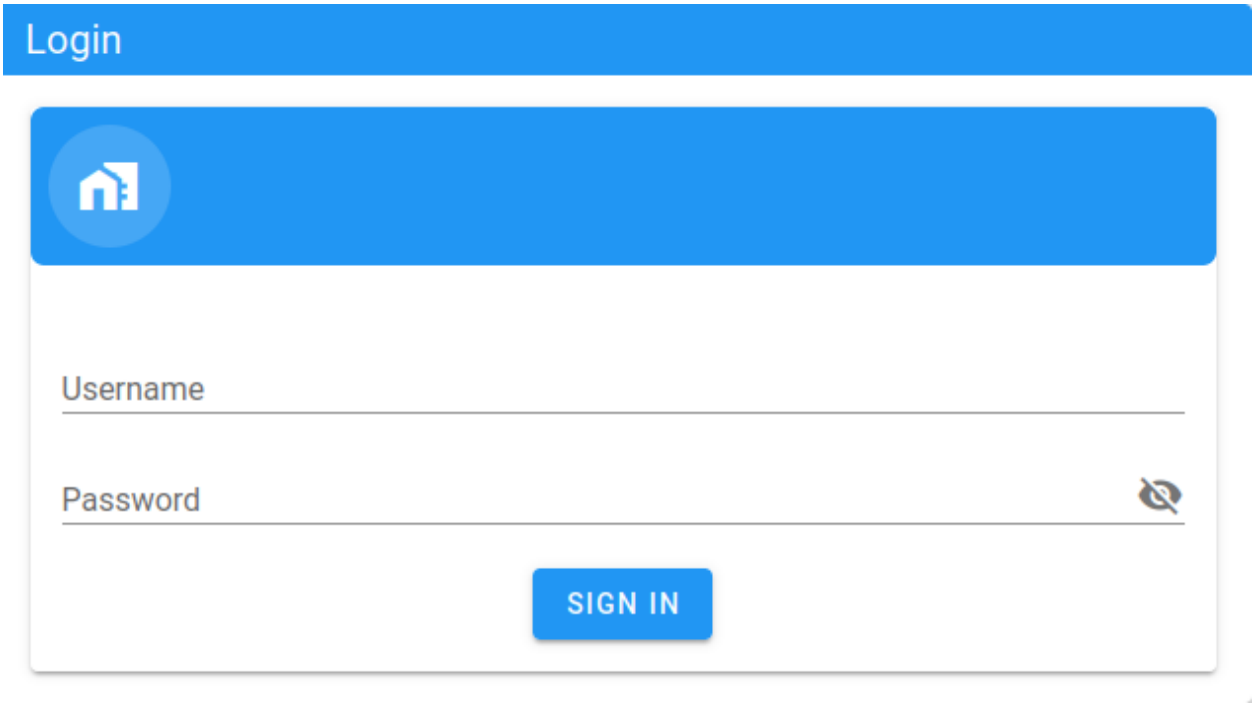

Fig. 1: Netgate Nexus Controller Login Screen

9.2.2 Netgate Nexus Controller Configuration Options

The default options are acceptable for most environments, but the behavior of the Netgate Nexus controller daemon can be fine-tuned by the options on the page at **System > Advanced**, **Netgate Nexus** tab.

These options are broken into two sections, **General Options** and **Advanced Options**.

General Options

Enable
Controls whether or not the Netgate Nexus controller daemon is enabled or disabled.

TLS Certificate
The TLS certificate the Netgate Nexus controller will use when acting as a TLS server (e.g. HTTPS).

This is typically the same certificate used by the pfSense Plus software WebGUI, but it can be a different certificate. This can be a local self-signed certificate, a globally trusted certificate imported into the WebGUI, or even a certificate managed by the *ACME package*.

Service Ports
The Netgate Nexus controller daemon uses multiple ports to accept connections:

API HTTP Port
The port used for unencrypted communication from browsers and API clients.

> **Danger:** Communication on this port is not encrypted. The best practice is to only use encrypted communication, so avoid using this port outside of local testing and development.

API HTTPS Port
The port used for encrypted communication from browsers and API clients.

Note: The controller picks a random port to use for the VPN. This port is available for use in firewall rules through the built-in alias named `_nexus_vpn_port_`. This port may be set to a specific value by setting **Listening Port** in the *Advanced Options*.

Advanced Options

Logging
Controls the behavior of messages logged by the Netgate Nexus controller daemon.

Level
The type of messages to log. Each level also includes messages from levels below it in the list.

Verbose
When checked, increases the verboseness of log messages.

Listening Address
A specific address the Netgate Nexus controller daemon will use to listen for incoming VPN connections from remote instances.

When set to *Any* (default), the controller listens on all available addresses.

Note: This does not control binding of the Netgate Nexus GUI service, only the VPN used for communication between instances and the controller.

Listening Port
A specific port the Netgate Nexus controller daemon will use to listen for incoming VPN connections from remote instances.

Advertised Addresses
One or more IP addresses or fully qualified domain names (FQDNs), optionally with a port number, which the controller will advertise to instances. When blank (default), the controller advertises all of its IP addresses for auto-discovery.

Tip: Using an FQDN here in combination with some form of Dynamic DNS can enable instances to reach the controller in cases where the controller host does not have a static IP address on any WAN interface.

JWT Session Expiry
Sets the expiration time of session tokens. Lower values are more secure, but require more frequent requests for new tokens.

Custom Options
Custom controller options. Each option must be on a separate line.

Warning: Do not use this section unless requested to do so by developers or TAC.

9.2.3 Viewing Netgate Nexus Status

The Netgate Nexus settings tab also includes status information for the controller daemon while the daemon is running. This includes links to the Netgate Nexus GUI as well as an entry indicating the VPN port upon which the controller is listening.

To view this status information:

- Open the pfSense Plus software WebGUI on the designated controller device
- Navigate to **System > Advanced**, **Netgate Nexus** tab
- Look in the bottom section of the **General Options** area

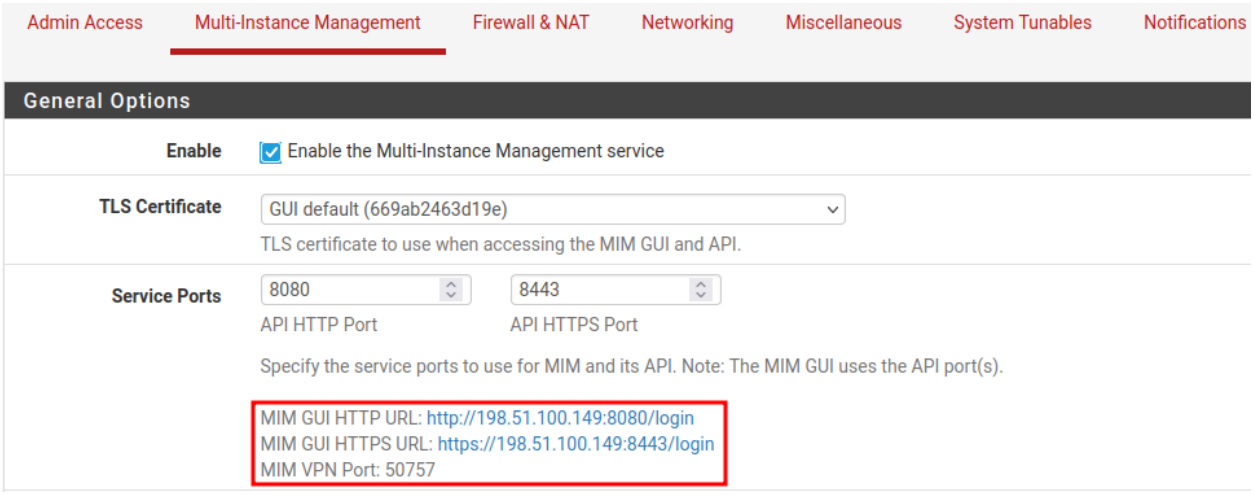

Fig. 2: Netgate Nexus Controller Daemon Status

9.3 Netgate Nexus Licensing

A Netgate Nexus license resides on the instance which performs the role of the controller. Customers can purchase entitlements from the Netgate Store which they can then apply to this license. At any given time, there will only be **one** active license (with its various entitlements) in use on the controller.

This document explains how to obtain an initial license, as well as how to apply tokens to update the entitlements of the license.

Note: This guide assumes the user has already enabled Multi-Instance Management as described in *Netgate Nexus Controller Setup*.

9.3.1 Licensing Requirements

Netgate Nexus requires pfSense Plus 25.07 or later running on Netgate® appliances, or on AWS and Azure virtual instances. While Netgate Nexus may work on third-party enterprise class hardware, Netgate cannot guarantee it will function and strongly cautions customers against using such hardware.

To check device eligibility, enable Netgate Nexus and visit the **License** menu on the devices. If Netgate Nexus cannot support the hardware, it will display an error message.

Controlled instances must be able to access the Controller. Air-gapped, offline, virtual and some hardware systems without serial numbers or other identifiers are not capable of participating in Netgate Nexus and cannot be managed.

9.3.2 Initializing the License

To start using the licensing system, the first step is to initialize a license.

To initialize a license:

- *Open the |nexus| GUI* on the designated controller and login
- Click the **License** menu item on the left side to open the license system

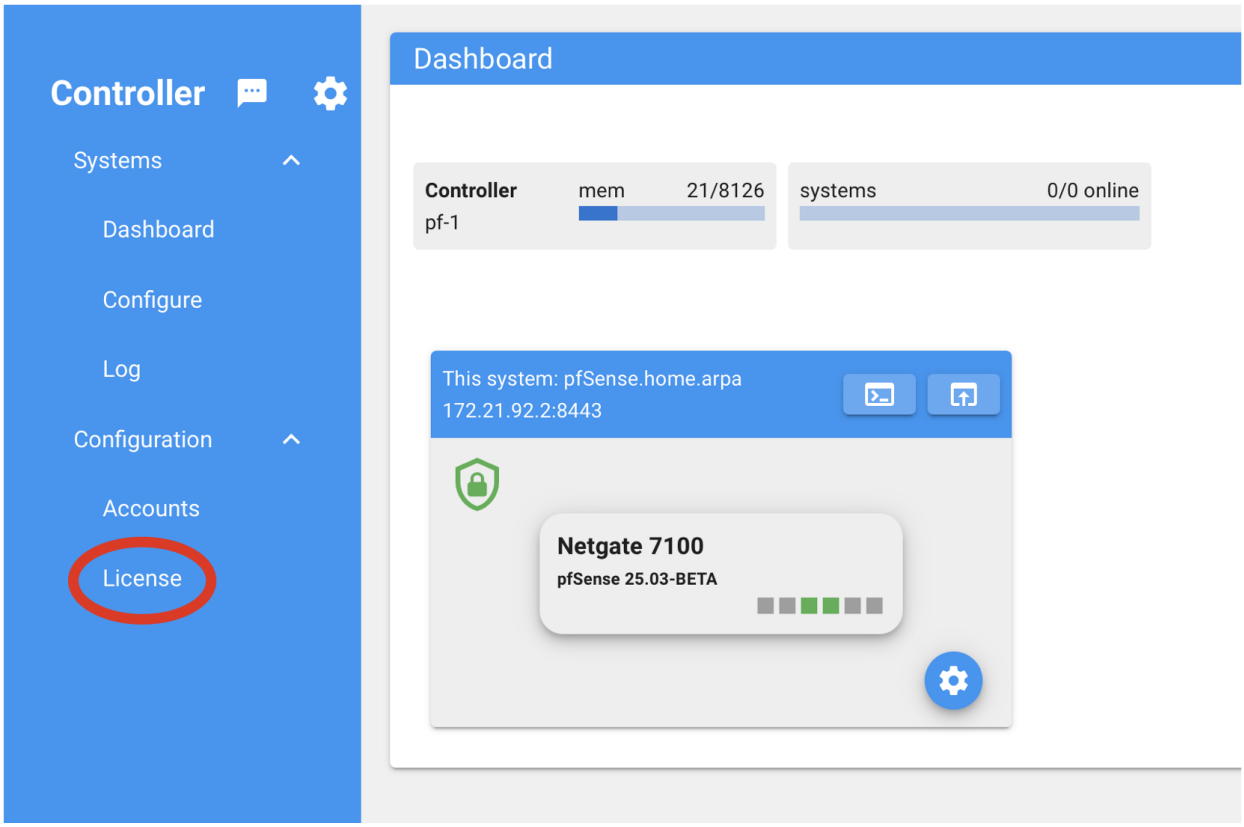

Fig. 3: Netgate Nexus License Menu Entry

- Inspect the **Current License** area of the screen to ensure the table is empty, as depicted in *Netgate Nexus License System with Add button marked*

Note: An empty table indicates no license has been initialized on this controller.

- Click  to create a license request, which initializes the license

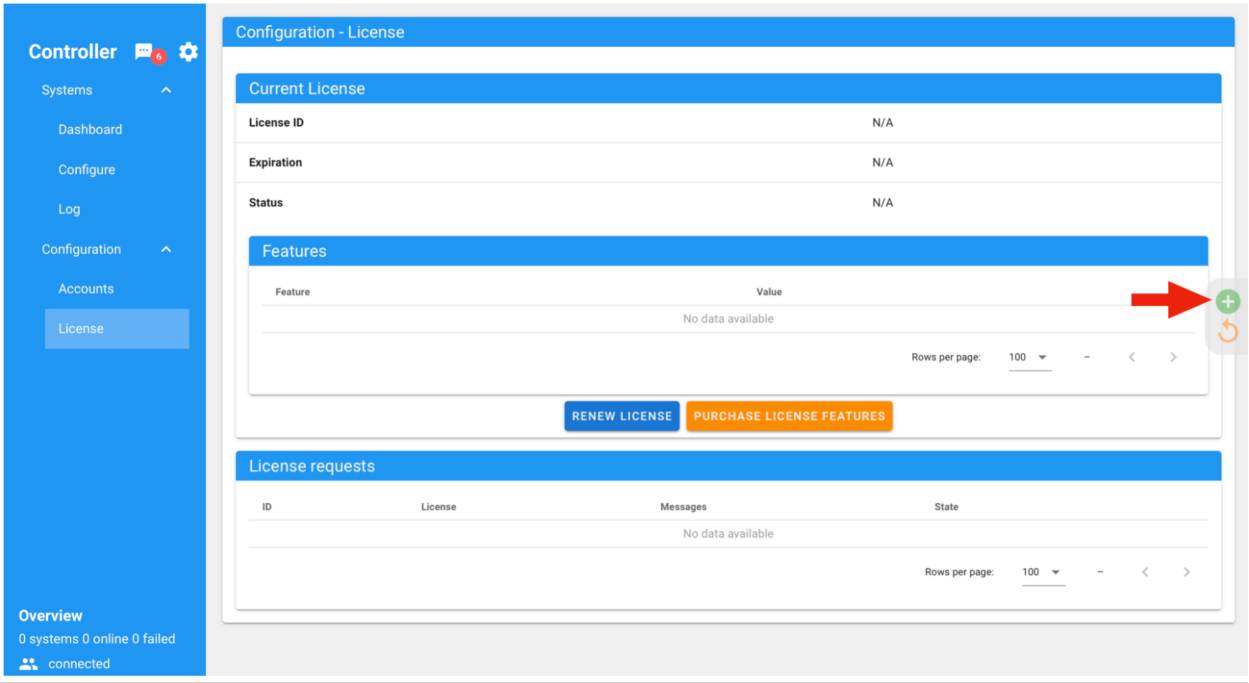

Fig. 4: Netgate Nexus License System with Add button marked

- Fill in the **Name** and **Email** fields on the **Create License Request** form

Note: Leave the **License Request Type** set to **License Signing Request**.

- Click **OK**

This initializes the license, which the GUI then displays in the license system screen.

9.3.3 License Details

When viewing the license, the License System displays the following details on the screen:

License ID
: A four-part phrase (e.g. `word1-word2-word3-word4`) which uniquely identifies the license.

Expiration
: The expiration date of the license, typically a one year period.

Status
: The current status of the license, e.g. **Valid**.

Features
: A list of entitlements applied to this license.

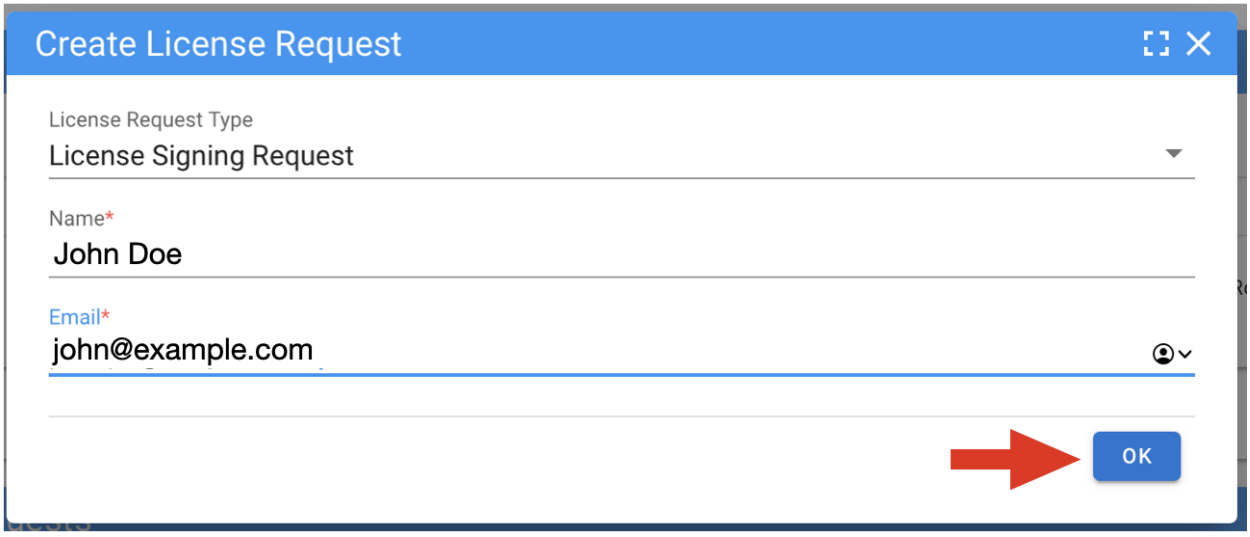

Fig. 5: Netgate Nexus License

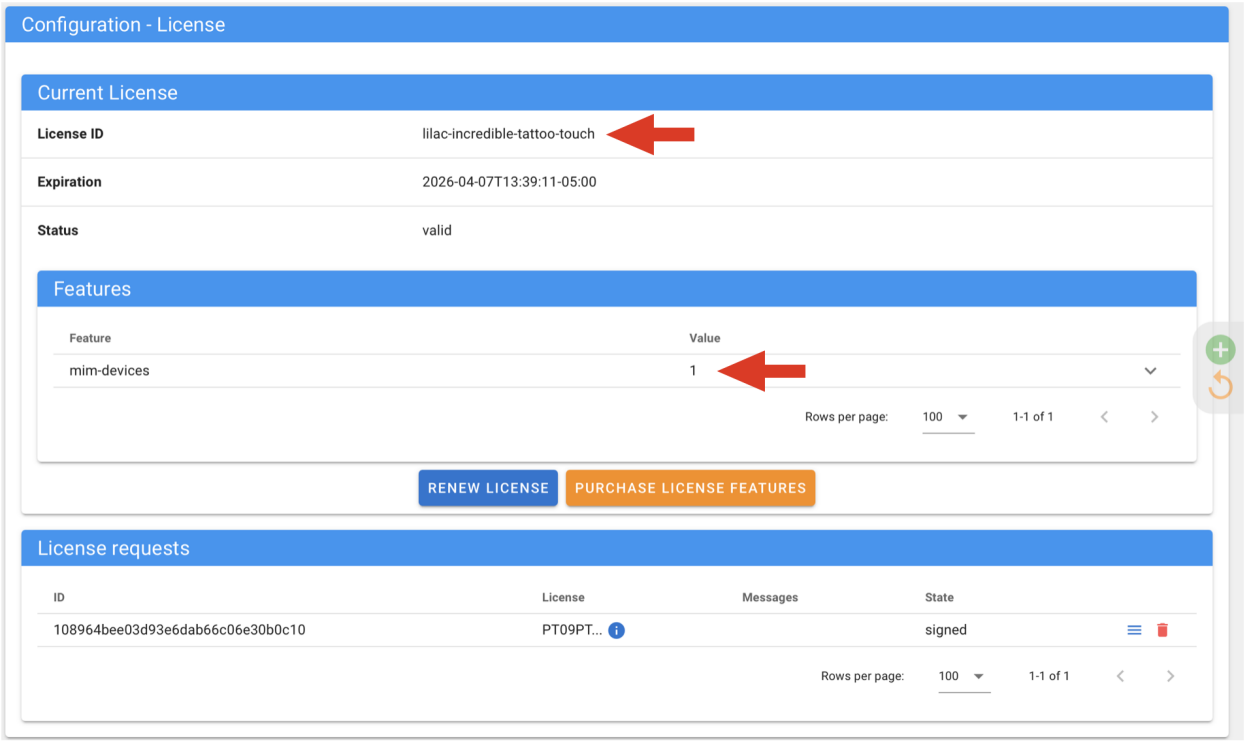

Fig. 6: Netgate Nexus License Details

mim-devices
The number of devices which can be controlled by multi-instance management from this device. The initial value is 1 by default, which means the current license may control **one** instance of pfSense Plus software, which is the instance upon which the controller itself is running.

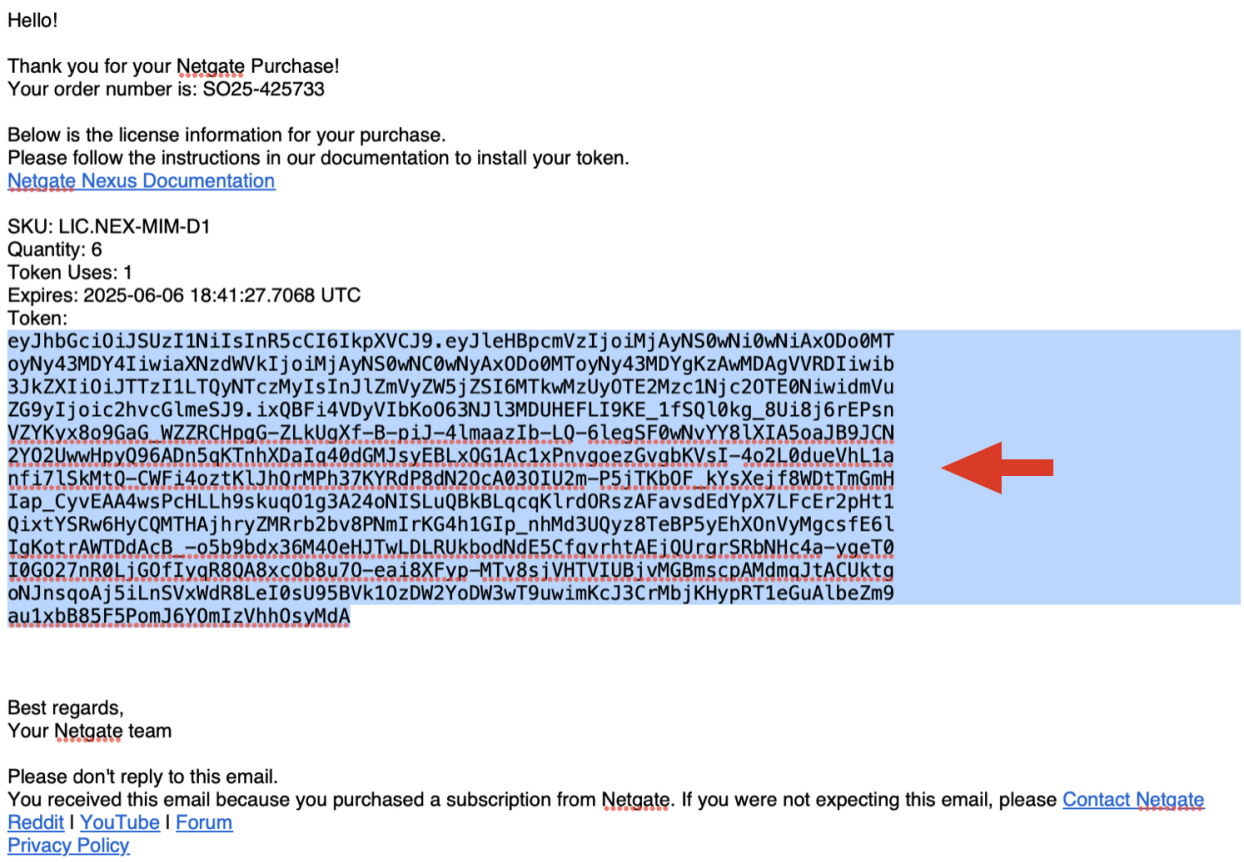
License Requests
A list of license requests associated with the current license and entitlements.

9.3.4 Increasing the Managed Instances

To increase the number of instances which can be managed by this controller, customers can purchase entitlements from the Netgate Store.

On the Multi-Instance Management product page, choose the quantity of additional instances to control, then complete the purchase.

The store sends several email messages after a purchase. One of these email messages contains the title "Netgate License Tokens" and looks like *Netgate Nexus License Token Text*:



Hello!

Thank you for your Netgate Purchase!
Your order number is: SO25-425733

Below is the license information for your purchase.
Please follow the instructions in our documentation to install your token.
Netgate Nexus Documentation

SKU: LIC.NEX-MIM-D1
Quantity: 6
Token Uses: 1
Expires: 2025-06-06 18:41:27.7068 UTC

Fig. 7: Netgate Nexus License Token Text

The example purchase depicted in *Netgate Nexus License Token Text* contains entitlements for **six** additional managed devices.

To add this entitlement to the license:

- Select the token text in the email message, as depicted in *Netgate Nexus License Token Text*
- Copy the text to the clipboard
- *Open the |nexus| GUI* on the designated controller and login
- Click the **License** menu item on the left side to open the license system
- Click  to create a license request
- Paste the token text into the **License Token** field

Fig. 8: Adding a Netgate Nexus License Token

- Click **OK**

The license details now contain the new **License Request** in the list at the bottom of the screen and the **mim-devices** count reflects the new total of device entitlements: 7:

Customers can add more managed instances to a license at any time by following the above procedure again.

See also:

Customers with questions can reach out to Netgate Sales or Netgate TAC.

9.4 Netgate Nexus GUI

The web-based Netgate Nexus graphical user interface (GUI) has multi-instance management (MIM) functionality which allows administrators to manage pfSense Plus software installations registered with the controller.

From within the Netgate Nexus GUI, administrators can view status information, configure instances, use remote consoles, and more.

Note: This document assumes the Netgate Nexus controller is enabled (*Netgate Nexus Options in the pfSense Plus WebGUI*), configured (*Netgate Nexus Controller Setup*), and has instances registered (*Instance Registration*).

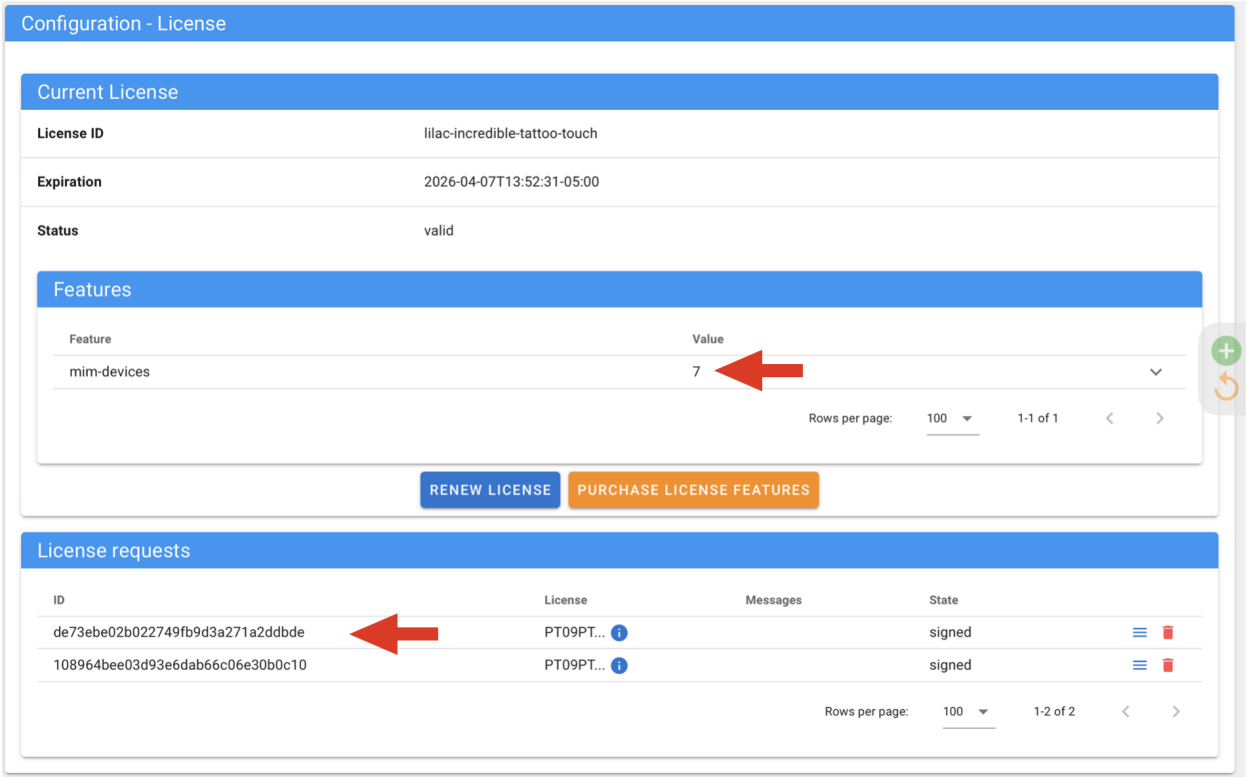

Fig. 9: Netgate Nexus License with Entitlements

9.4.1 Netgate Nexus Dashboard

The Netgate Nexus GUI dashboard contains an overview of all instances managed by this controller (*Multi-Instance Management*).

Access the Netgate Nexus GUI

Before proceeding, open the Netgate Nexus GUI as described in *Accessing the Netgate Nexus GUI* and login.

Tip: Accessing the Netgate Nexus GUI on the controller will allow administrators to manage any instance registered with the controller. The Netgate Nexus GUI on instances can only manage the local instance.

After logging in, the Netgate Nexus GUI displays its dashboard.

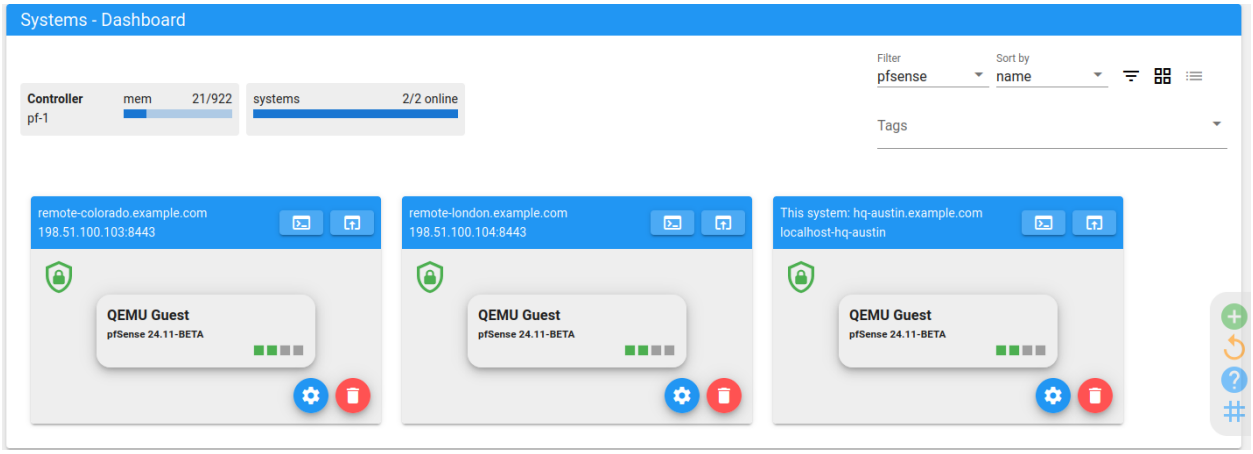

Fig. 10: Netgate Nexus Controller Dashboard

Status Summary

The dashboard contains status summary items in the upper left.

The first status item reports the current controller memory usage, both in text form and as a gauge.

The second status item reports the total number of registered instances and their online status.

Note: The controller host itself is not included in the systems summary as it would be redundant – if the controller was offline, the dashboard could not be loaded.

Instance List Entries

The instance list in the dashboard contains an entry for every instance registered with the controller, plus the controller itself.

Each list entry contains several items indicating the status of the instance, management controls, and options.

Hostname
: The hostname of the instance is printed in the bar at the top of the instance entry at the upper left.

Address
: The IP address and Netgate Nexus GUI port is printed in the bar at the top of the instance entry under the hostname.

Management Controls
: The upper right area of the bar at the top of the instance entry contains two icons to manage the instance:

Opens a *Remote Console* on the instance.

Enters the *Remote Configuration* interface for the instance.

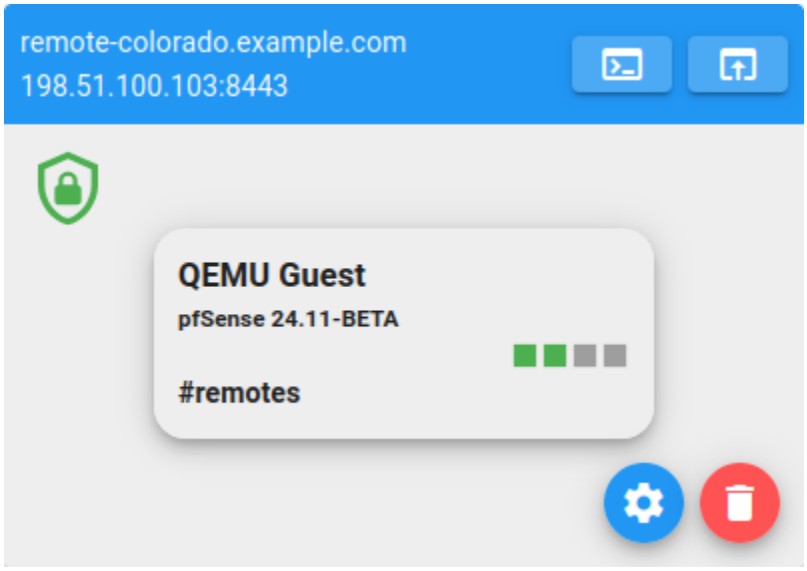

Fig. 11: Instance List Entry

Status Icon
In the upper left of the main area of the instance entry is an icon indicating its status. Possible states include:

- Online: 
- Error: 

Device Type
The first line of text in the instance body is the type of device. This can be a hardware model, hypervisor type, cloud provider, etc.

Version Information
The current software version is printed under the device type.

Interface Status
The instance entry contains a row of squares indicating network interface status for the device. Connected interfaces are green, disconnected or disabled interfaces are gray. Hover the mouse cursor over a square to see its name and link speed.

Tags (If present)
Entries can be classified via tags (*Tag Manager*). If an instance has assigned tags, they are printed here.

Entry Options
The  icon opens a modal dialog window with general options for this instance entry.

Remove Entry
The  icon deregisters (removes) this entry from the controller.

Instance List Filter & Sort

The list of instances on the dashboard can be filtered and sorted to locate and manage items easier. The options to filter and sort the list are in the upper right area of the dashboard.

Fig. 12: Instance List Filter & Sort Controls

In that area, the following options are available:

Filter
: This drop-down menu allows filtering the list by item type.

Sort By
: This drop-down menu sorts the items on the dashboard by a specific attribute.

  The current sort options are:

  Name
  : Sorts by instance hostname.

  State
  : Sorts by online/error status.

  Address
  : Sorts by IP address.

  Type
  : Sorts by device type.

Tags
: Enter a tag name to filter the list so it only shows items matching a specific tag or multiple tags.

Sort Order

: The sort order icon toggles between ascending ( ) and descending ( ) sort order.

Tile View

: Clicking the icon switches the dashboard to tile view, which is the default.

Detail View

: Clicking the icon switches the dashboard to a detailed list view.

Dashboard ToolBox

The Netgate Nexus Dashboard ToolBox is located on the right side of the dashboard screen and contains several options to manage dashboard items.

This ToolBox can appear in two different ways as determined by the *Controller Options*.

- It can be a floating bar pinned to the right side of the screen:

Fig. 13: Dashboard ToolBox - Right Side Style

- It can be collapsed behind a  hamburger menu button:

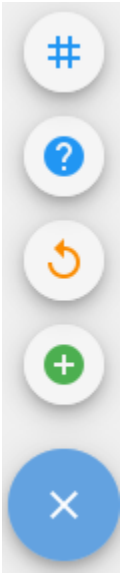

Fig. 14: Dashboard ToolBox - FAB Style

The available actions are the same in both styles.

The actions available in the ToolBox are:

Register an instance with the controller (*Instance Registration*).

Reload dashboard data.

Open the Help menu which also contains the current controller data for use in the registration process (*Instance Registration*).

Opens the tag manager which assigns tags to dashboard list entries (*Tag Manager*).

Tag Manager

Dashboard items can be tagged to allow filtering entries based on custom keywords. To assign tags to instances, open the Tag Manager from the *Dashboard ToolBox*.

The Tag Manager can add or remove tags from one or more instances as follows:

- Click **Select Devices**
- Pick devices from the list, or click **Select All**
- Click in the **Tags** field
- Enter a tag name
- Press `Tab`, press `Enter`, or click out of the **Tags** field
- Click the desired action:  to add the tag to the selected instances, or  to remove the tag from the selected instances.

9.4.2 Nexus Controller

The topics in this section cover areas of the Netgate Nexus GUI which apply to the controller itself.

Nexus Menu

The Nexus Menu is on the left side of the Netgate Nexus GUI.

At the top right of the menu are icons for *controller messages* () and *controller options* ().

At the bottom of the menu is an **Overview** area with a text summary of instances and their status, along with a count of users currently logged into the controller.

The main body of the menu consists of several areas of interest, including:

Dashboard
: The Netgate Nexus dashboard (*Netgate Nexus Dashboard*)

Configure
: Configure an instance (*Remote Configuration*).

  While configuring an instance, the menu lists its address in the menu.

Log
: View Netgate Nexus controller logs.

Software
: Netgate Nexus image and package management.

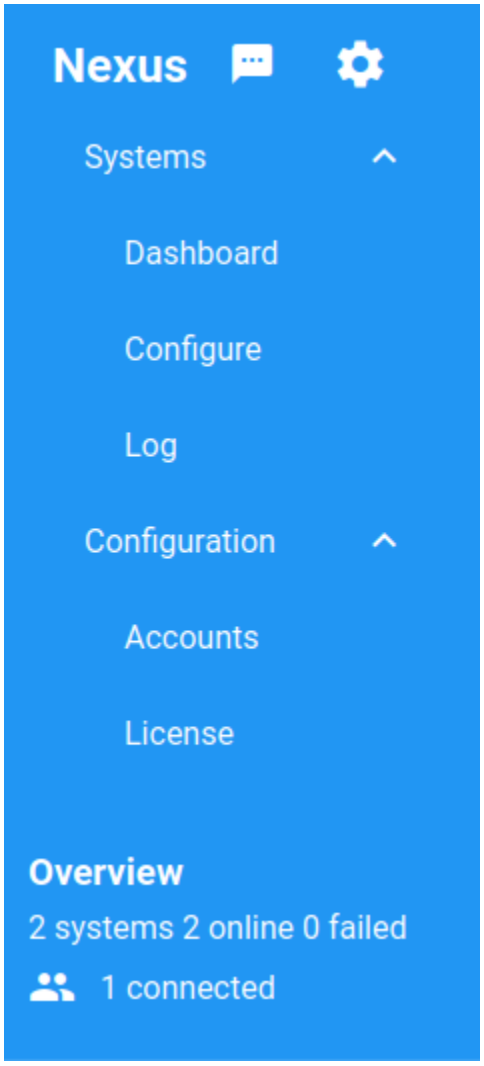

Fig. 15: Nexus Menu

Accounts
User authentication configuration. This configuration is linked to the pfSense Plus software User Manager on the controller host.

Controller Messages

Click  in the *Nexus Menu* to view messages and alerts from the Netgate Nexus controller.

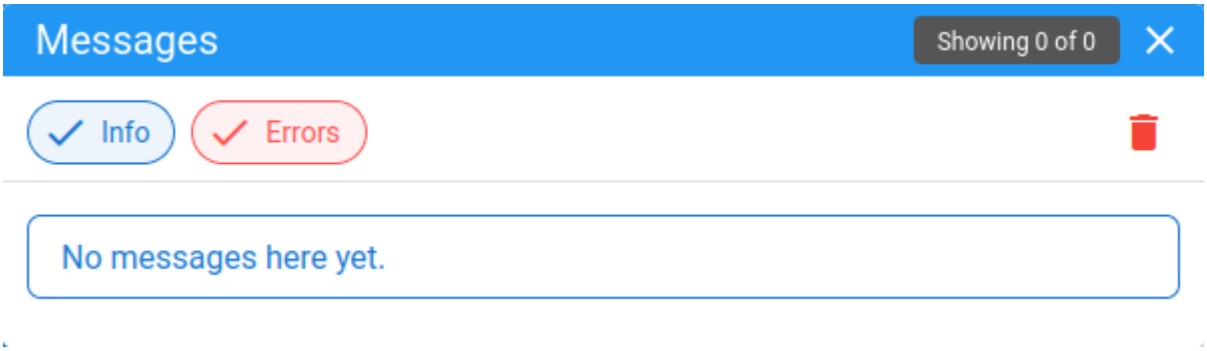

Fig. 16: Messages List

The messages can be filtered by type. Click **Info** or **Errors** to hide/show that particular type of message. If the type has a check mark icon, messages of that type will be included in the list. The window title bar contains a count of messages displayed in the current view, plus a total.

Click  at the top right of the window to clear all messages.

Controller Options

Click  in the *Nexus Menu* to configure options which affect the behavior of the controller itself and the GUI. This dialog window also contains some status information.

Options

The top area of the dialog contains options which affect the appearance of the controller GUI.

Theme Color
Select one of the colors to change the GUI theme to a scheme based on the chosen color.

Dark Mode
Toggles the GUI theme between light and dark mode.

ToolBox View
Changes the appearance of the *ToolBox* on the right side of the page.

Right-side ToolBox
Presents the ToolBox as a free-floating menu always visible on the right side of the page (*Dashboard ToolBox - Right Side Style*).

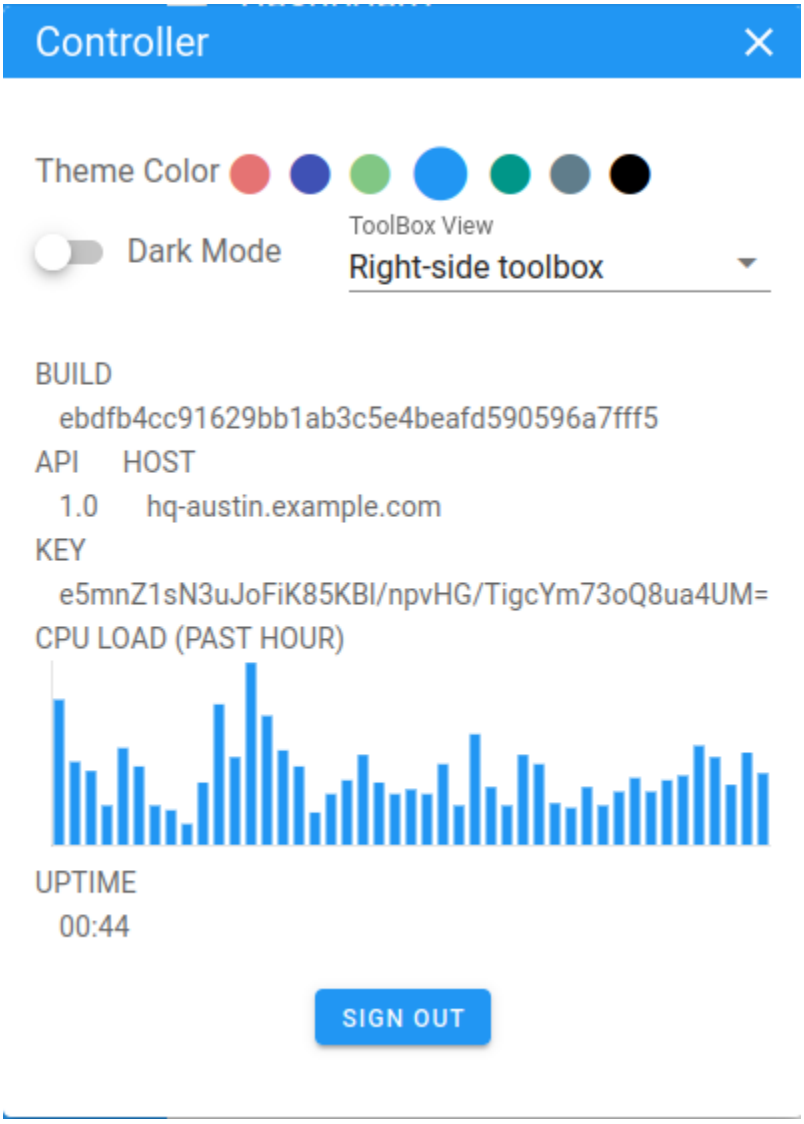

Fig. 17: Controller Options Dialog

FAB Toolbox

Hides the ToolBox behind a  hamburger menu button which must be clicked to see the individual menu entries (*Dashboard ToolBox - FAB Style*).

Status Information

The middle portion of the window contains status information about the controller.

Build
The current build of the controller software.

API Version
The current API version used by the controller.

Host
The hostname of the device running the controller.

Key
The API key used by the controller.

CPU Load
A graph of CPU load on the device running the controller from the last hour.

Uptime
The amount of time the controller has been running.

Actions

At the bottom of the window are buttons to perform actions on the controller.

Sign Out
Logs the current user out of the controller and returns to the login screen.

Restart Controller
Restarts the controller software.

9.4.3 General Netgate Nexus GUI Usage

Window Controls

Certain functions in the Netgate Nexus GUI present modal dialog windows which have window controls.

Fig. 18: Modal Window Controls

These functions include:

Expand the current window so it fills the browser window.

Close the current window and return to the previous page.

Managing Lists of Items

Some areas in the Netgate Nexus GUI contain lists of items. For example, when configuring the controller itself or instances. Lists of items are managed in a similar manner no matter where they are located, though some lists have more options than others.

Per-item Actions

List entries may contain icons to act on individual rows.

Create a new entry and add it to the list immediately below this row.

Create a new separator bar below this row.

Create a new item using the settings from this item as starting values.

Edit this list item.

Click and drag using this icon to move an item. Drop it in the new location.

View settings which control this list entry.

Selecting List Items

Some lists allow selecting one or more items to perform actions. Certain lists also have a “Select All” toggle to change the selection status of all entries.

This item is not selected. Click the icon to select the item.

This item is selected. Click the icon to deselect the item.

Some items in this list are selected, and some are deselected. Click the icon to select all items.

ToolBox List Actions

Fig. 19: List Management - ToolBox for Firewall Rules

When managing lists, the ToolBox may show one or more of the following icons.

Create a new item and add it to the list.

Reload data for this list from the controller or instance.

Add a new separator row.

Remove the selected item(s).

Toggle the state of the selected item(s). For example, disable or enable the item.

Copy the selected item(s) to another location. For example, copy firewall rules to another interface.

View help information for the page or items.

Open the tag manager.

9.5 Multi-Instance Management

A core feature of Netgate Nexus is multi-instance management (MIM). The Netgate Nexus controller is capable of managing multiple installations of pfSense Plus software from a single host. The Netgate Nexus controller includes a web-based graphical user interface (GUI) and an API.

Using the Netgate Nexus GUI MIM functionality, administrators can:

- See quick at-a-glance status of local and remote pfSense Plus software installations.
- Configure the local pfSense Plus software installation using a new single page application interface.
- Configure multiple remote pfSense Plus software installations paired with the controller using a new single page application interface.
- Open remote interactive consoles similar to an SSH connection.

9.5.1 Designing a Multi-Instance Management Configuration

The Netgate Nexus controller host has a critical role at the center of a Multi-Instance Management (MIM) configuration, so choosing the most appropriate place to host the controller is an important decision.

MIM Behavior Overview

Instances of pfSense Plus software are registered with the controller *using a manual process*. After registration, instances connect a special-purpose VPN back to the controller host which allows them to communicate privately and securely. All communication between the controller and instances is encrypted using this VPN. The only port on the controller which needs exposed to the Internet is the port for inbound VPN connections from registered instances.

Note: This VPN is **only** for use by the Netgate Nexus controller, it **does not** enable connectivity between networks behind the other instances and the controller.

Designate a Controller Host

Selecting a controller host typically involves a few factors:

- The controller works best with a static IP address, but can also advertise a hostname which can be used in combination with Dynamic DNS if necessary. Instances can have dynamic addresses.
- Instances must be able to make connections back to the controller.
- The controller host requires increased CPU and memory resources to handle its additional duties.
- The controller should reside in a location with stable power and connectivity.

Considering these factors, designate one host as the Netgate Nexus controller and the remaining devices will be instances.

9.5.2 Instance Registration

After setting up the Netgate Nexus controller as described in *Netgate Nexus Controller Setup*, it is possible to start registering instances of pfSense Plus software with the controller for multi-instance management (MIM).

This is a two way process: Instances must be registered with the Netgate Nexus controller and the controller must be activated on instances.

Repeat the process in this document for each instance of pfSense Plus software to be registered with the controller.

Register Instance with Controller

The first task is to register the instance with the Netgate Nexus controller.

First, enable Netgate Nexus on the instance and copy the registration data:

- Open the pfSense software WebGUI on the instance
- Navigate to **System > Advanced**, **|product_name|** tab
- Check **Enable**
- Click **Save**
- Click **Copy** to the right of the **Registration Data** field

Next, use that registration data to add the device to the controller

- Open the pfSense Plus GUI on the designated controller (*Accessing the Netgate Nexus GUI*)
- Click **Systems > Dashboard** in left menu
- Click  in the toolbox on the right side of the page to add a new item

---

Note: Depending on the controller configuration, this may first require a click on the  (hamburger menu) button to expand the right menu.

- Set **Create Method** to **Quick**

  This is the default option.
- Click in the **Device info JSON** text field
- Paste the clipboard contents
- Click **OK**

The device will now appear on the Netgate Nexus GUI dashboard, but with incomplete information since the registration is not yet complete.

Activate MIM on pfSense Plus Software Instance

To complete the registration, the controller must also be activated on the instance.

First, copy the activation data from the Netgate Nexus controller:

- Open the Netgate Nexus GUI on the designated controller (*Accessing the Netgate Nexus GUI*)
- Click  (Help) in the toolbox on right

---

Note: Depending on the controller configuration, this may first require a click on the  (hamburger menu) button to expand the right menu.

- Click the **JSON** tab
- Click  **Copy**
- Click  to close the window

Next, enter that activation data on the instance:

- Open the pfSense Plus WebGUI on the instance
- Navigate to **System > Advanced**, **Netgate Nexus** tab
- Click in the **Activation Data** field
- Paste the clipboard contents
- Click **Save**

Now the registration is complete and the instance can be managed from the controller.

9.5.3 Managing pfSense Plus Software Instances

The web-based Multi-Instance Management (MIM) graphical user interface (GUI) enables administrators to manage individual instances of pfSense Plus in multiple ways.

Note: This document assumes the controller is already enabled (*Netgate Nexus Options in the pfSense Plus WebGUI*), configured (*Netgate Nexus Controller Setup*), and has instances registered (*Instance Registration*).

Before proceeding, open the MIM GUI as described in *Accessing the Netgate Nexus GUI* and log in, after which the browser will be on the *Netgate Nexus Dashboard*.

Remote Configuration

Click the  icon on an instance entry from the *Netgate Nexus Dashboard* to open the remote configuration view.

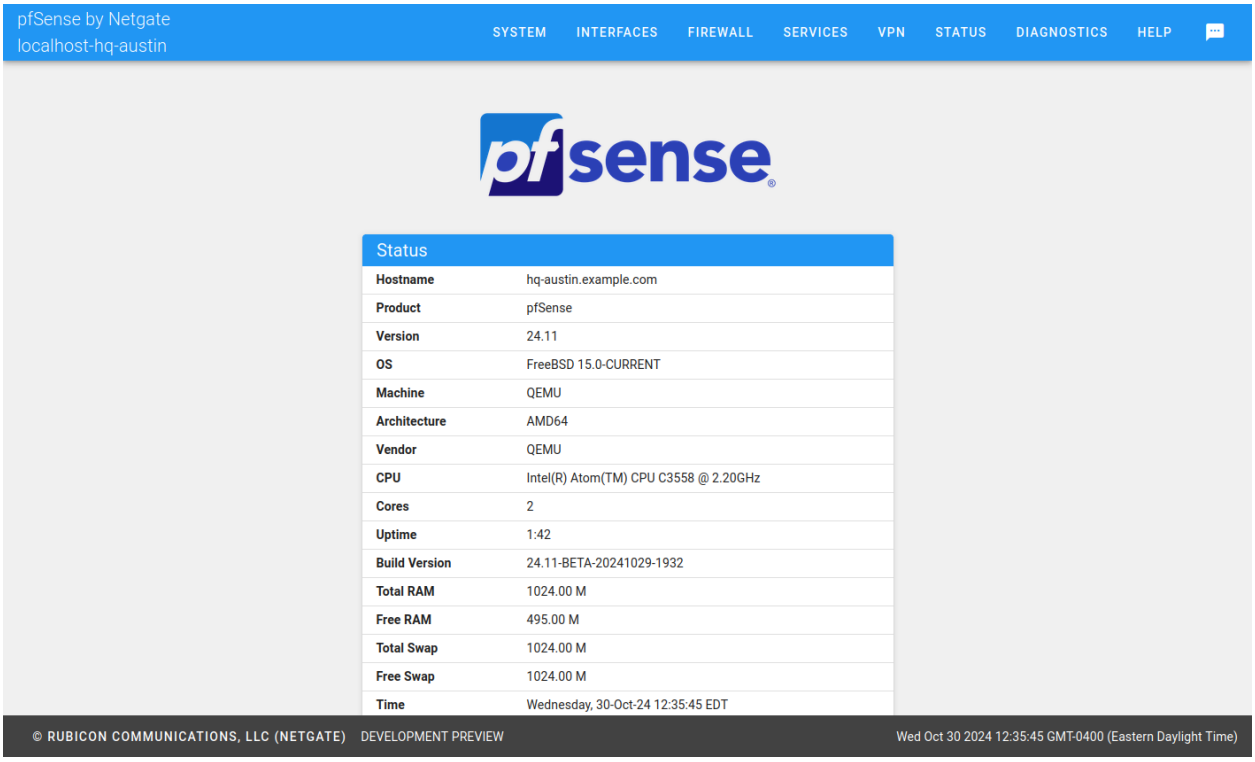

Fig. 20: Remote Configuration View

Managing individual instances of pfSense Plus software using the MIM GUI works in a similar manner to managing those instances using their *pfSense software WebGUI* directly. The look and feel of the MIM GUI configuration screens are different, but functions in both GUIs are under the same menu locations and offer the same options.

Areas where the behavior of the MIM GUI differs from the pfSense software WebGUI are noted in this document.

Instance Status / pfSense Software Dashboard

When opening the configuration view for an instance, the MIM GUI presents a status page for the instance. Though this page shares some similarity with the pfSense Software WebGUI dashboard, the instance status page in the MIM GUI does not yet have the same functionality or widgets available.

Managing Interfaces

Managing interfaces via the MIM GUI is different than using the pfSense software WebGUI. Rather than having individual menu entries, interfaces are managed from the assignment list.

To edit interface settings:

- Open the remote device management view for an instance
- Navigate to **Interfaces > Assignments**
- Find the interface in list
- Click  at the end of its row to edit the interface settings

Remote Console

Click the  icon on an instance entry from the *Netgate Nexus Dashboard* to open the remote console.

The remote console appears in a *modal window* which has the same features and functionality as the *console menu on pfSense software* as if it were accessed directly via serial console, video console, or SSH.

CHAPTER

TEN

BACKUP AND RECOVERY

10.1 Making Backups in the GUI

Making a backup in the GUI is simple:

- Navigate to **Diagnostics > Backup & Restore**
- Set any desired options, or leave the options at their default values.
- Click **Download Configuration as XML** (Figure *GUI Backup*).

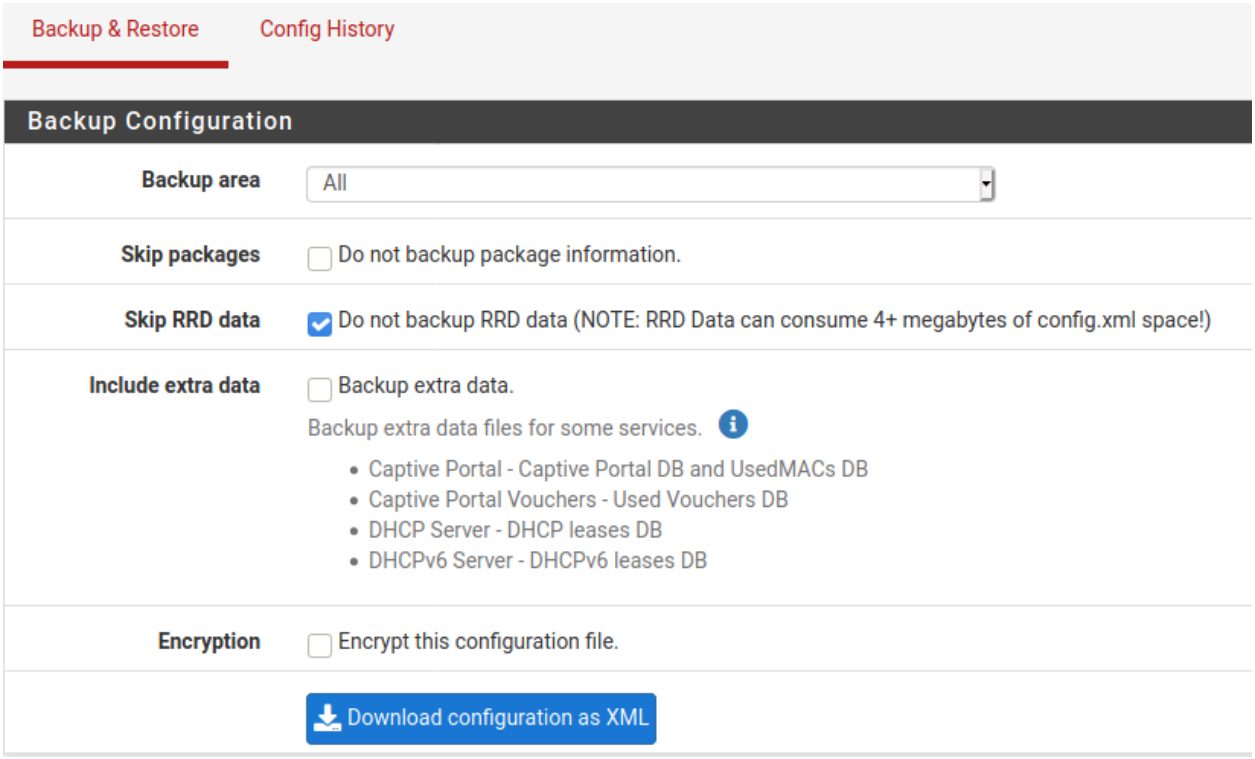

Fig. 1: GUI Backup

The web browser will then prompt to save the file somewhere on the PC being used to view the GUI. It will be named `config-<hostname>-<timestamp>.xml`, but that may be changed before saving the file.

10.1.1 Backup Options

When performing a backup, GUI options are available to control what is contained within the backup file.

Backup Area
Limits the backup contents to a single configuration area, rather than a complete configuration backup.

The default behavior is to inclue all areas in the backup.

Note: When restoring a configuration containing only a single area, the **Restore area** value must be set to match.

Skip Packages
Controls whether or not the backup will contain installation data and settings for packages. Omitting this data from a backup can be a useful way to quickly remove all traces of packages from a configuration when troubleshooting.

> **Warning:** After restoring a configuration without package data all packages must be reinstalled and reconfigured.

The default is *unchecked* so that all package data is included in the backup.

Skip RRD Data
Controls whether or not the backup will contain an exported copy of data used to generate *monitoring graphs*. When restoring a backup containing RRD data, the graph data is also restored.

The default is *checked* which omits the RRD data from the backup as it significantly increases the size of backup files.

Include Extra Data
Controls whether or not the backup file will include additional optional data. This includes Captive Portal databases and DHCP lease databases. These databases are volatile. While the data can be useful for transferring to new hosts or for frequent backups, it is not as useful for long-term backups.

The default is *unchecked* which omits this extra data from the backup as it can significantly increase the size of backup files.

Backup SSH Keys
Controls whether or not the backup file will include a copy of the SSH host keys.

Clients use these keys to uniquely identify the firewall, so preserving the keys when restoring makes it easier for clients to recognize the firewall after reinstalling or restoring to new hardware. Additionally, AutoConfigBackup uses the SSH host keys to identify the firewall when creating and restoring backups, so preserving the keys allows the firewall to maintain a consistent backup history after a reinstallation.

Encryption
Controls whether or not the backup file is encrypted before download.

When set, the GUI presents **Password** and confirmation fields, the contents of which are used by pfSense® software to encrypt the backup file with AES-256.

The default behavior is *unchecked* which creates clear text XML backup files.

10.2 Automatic Configuration Backup Service

Automatic Configuration Backup, also called AutoConfigBackup or ACB for short, is an encrypted remote backup service. AutoConfigBackup provides secure off-site backups for devices running pfSense® software without user intervention beyond the initial configuration.

Netgate® provides the AutoConfigBackup service free of charge for all users of pfSense software, both Plus and CE. This functionality is available as a core component of pfSense software included in the base installation.

This feature is located in the pfSense software GUI at **Services > Auto Config Backup**.

Tip: Read this entire section thoroughly before enabling the service.

10.2.1 How AutoConfigBackup Works

AutoConfigBackup performs several actions for each backup:

- AutoConfigBackup is triggered by configuration change (default), scheduled backup, or manual entry (*Backup Frequency*).
- AutoConfigBackup encrypts a backup copy of the pfSense® software configuration with *a user-supplied password*.
- AutoConfigBackup prepares to upload the backup by placing the encrypted backup and its metadata in a staging area.
- Once per minute, AutoConfigBackup checks for staged backups pending upload.
- AutoConfigBackup uploads each staged backup entry over HTTPS to the AutoConfigBackup service at Netgate® which stores it using *a device-specific key* to identify the owner of the backup.

Note: The AutoConfigBackup service retains the most recent **100** encrypted configuration backups for each device key. The server removes any backups beyond this number when AutoConfigBackup uploads new entries for a device key.

10.2.2 AutoConfigBackup Configuration

To configure the *Automatic Configuration Backup Service*, navigate to **Services > Auto Config Backup**, **Settings** tab in the pfSense® software GUI.

This document describes each option available on the **Settings** tab.

Enable ACB

When checked, AutoConfigBackup is active and will make automatic configuration backups as determined by the other settings on this page.

Backup Frequency

This option controls when AutoConfigBackup creates backups.

On Every Configuration Change
When selected, AutoConfigBackup will create a backup on every significant configuration change.

Note: Some minor configuration changes are safely ignored if they do not impact functionality.

On a Regular Schedule
Enables *Schedule* controls to create periodic backups at specific times instead of creating a backup on every change. This can be more efficient on systems with many frequent changes.

Tip: The default schedule creates a backup once per day. In most cases it should not be set more frequently than that, or at most a 2-4 times per day. If a device requires more frequent backups, backing up each change is likely a better practice.

Note: If the configuration has not changed since the previous scheduled backup time, AutoConfigBackup will not make a new backup.

Schedule

Controls the **Minute** of the hour, **Hours** of the day, **Day** of the month, **Month** of the year, and **Day of the week** on which backups are performed using standard cron format.

The value of **Minute** is randomized until the page is saved. The default value of **Hours** is `0`. The default for **Day**, **Month**, and **Day of Week** are all `*`. This results in a default schedule of a backup taken each day during the midnight hour at a random minute.

Note: This control is only visible when **Backup Frequency** is set to *On a Regular Schedule*.

Device Key

The AutoConfigBackup service requires a unique identifier for each device, this is called the **Device Key**. AutoConfigBackup uses the device key to identify entries belonging to a specific device when uploading or retrieving backups, similar to a username.

AutoConfigBackup displays the device key on each AutoConfigBackup tab for reference.

Warning: Treat this key as a secret!

Anyone who has this key can manipulate the backups for this key.

The device key value defaults to a randomly generated string for new configurations as well as upgraded configurations with AutoConfigBackup disabled. This randomized device key is stored in the configuration. Previous versions of AutoConfigBackup used the SHA256 hash of the SSH public key on the device to generate the device key, these older style keys are now called “legacy keys”.

Note: Upgraded AutoConfigBackup configurations which are enabled and using a legacy key will continue using the legacy key until the key is changed manually or AutoConfigBackup is disabled.

Next to the **Device Key** reference field there is a  **Change Key** button. This button navigates to the *Change Device Key* page which allows administrators to generate or enter a new **Device Key**.

Warning: Keep a careful record of this Device Key!

Each AutoConfigBackup tab has a download icon to save a local copy of the device key (). Store this key in a safe and secure location.

If an administrator loses the **Device Key**, there is a chance Netgate TAC can help recover the key if AutoConfigBackup has a unique *Hint/Identifier*. If the hint is distinct, Netgate TAC *may* be able to use it to recover the device key. Do not count on this though!

Encryption Password

AutoConfigBackup encrypts the backup using the AES-256-CBC algorithm and this **Encryption Password** before it transmits the configuration to the AutoConfigBackup servers hosted by Netgate®.

Warning: This password is an encryption key, so the best practice is to use a long and complex string to ensure the backup contents are securely encrypted.

AutoConfigBackup **only** uses this password locally for encryption and decryption, it does not use or transmit the password as a login/credential.

When an administrator restores, views, or downloads an entry from the list of available remote backups, AutoConfigBackup fetches the remote backup entry and decrypts it with this password.

Danger: Keep a careful record of the encryption password! The encryption password is private and only known to the local device.

If the administrator loses the Encryption Password the backup contents cannot be recovered.

Danger: Changing this password will make AutoConfigBackup encrypt new backups using the new password, but old backups using a different password will no longer be readable by AutoConfigBackup.

Hint/Identifier

AutoConfigBackup sends the contents of the optional **Hint/Identifier** field as plain text metadata along with the encrypted configuration. This value is not visible to users, it is only visible to Netgate TAC.

If this hint is unique, it may allow Netgate TAC to locate a missing device key.

Manual Backup Limit

This setting controls the number of manual backups AutoConfigBackup will retain.

AutoConfigBackup can retain up to `50` manual backups, which it will not overwrite with automatic backups. Manual backups still count against the `100` backup limit. When the amount of manual backups exceeds this limit, AutoConfigBackup will remove older manual backups.

Descending Date Order

When set, AutoConfigBackup will sort the list of backup entries on the *Restore tab* in descending order by date (newest first) instead of the default order, which is oldest first.

10.2.3 Changing the AutoConfigBackup Device Key

The *Device Key* for the *Automatic Configuration Backup Service* can be changed at any time.

Changing the device key involves invoking the **Change Key** function from *AutoConfigBackup settings* and then completing the process using this *Change Device Key Page*.

> **Danger:** Changing the **Device Key** disconnects AutoConfigBackup from all previous backups stored using the old key.
>
> Administrators can still access the old backups so long as they know the old device key and encryption password. Securely store a backup copy of the current device key(s) before changing the device key.

Device Key Change Procedure

To change the *Device Key*:

- Open the pfSense® software GUI in a web browser
- Navigate to **Services > Auto Config Backup**, **Settings** tab
- Click  **Change Key**
- Use the  icons in each section to download and securely store copies of the **Current Device Key** and, if present, the **Legacy Device Key**
- Click  **Generate New Key** or manually enter a **New Device Key**
- Read the **Warning** section
- Check the confirmation box

- Click  **Update Key**
- Click **OK** on the confirmation dialog

For an explanation of each field on this page, refer to the next section, *Change Device Key Page*.

Change Device Key Page

The **Change Device Key** page allows administrators to change the AutoConfigBackup device key. It contains numerous warnings and explanations which guide users through the process.

> **Danger:** Changing the **Device Key** disconnects AutoConfigBackup from all previous backups stored using the old key.
>
> Administrators can still access the old backups so long as they know the old device key and encryption password. Securely store a backup copy of the current device key(s) before changing the device key.

Current Device Key

The **Current Device Key** section displays the current randomized device key stored in the device configuration.

The GUI will not display this section if AutoConfigBackup is enabled and using a legacy device key.

The section also includes a count of backup entries on the AutoConfigBackup service associated with the current device key.

Tip: Use the  icon in this section to download a copy of the current device key, then store it in a safe and secure location.

If there are **zero** hosted backups for the current device key, then it may not be necessary to store this key as there isn't anything left to access using this device key.

Legacy Device Key

The **Legacy Device Key** section displays the legacy style device key. This older key style is based on the SHA256 hash of the SSH public key on the device.

The GUI will not display this section if the device does not contain any SSH host keys. For example, on a fresh installation where SSH has never been enabled.

The section also includes a count of backup entries on the AutoConfigBackup service associated with the legacy device key.

Tip: Use the  icon in this section to download a copy of the legacy device key, then store it in a safe and secure location.

If there are **zero** hosted backups for the legacy device key, then it may not be necessary to store this key as there isn't anything left to access using this device key.

New Device Key

This field sets a new AutoConfigBackup device key. The key must be exactly `64` hexadecimal characters in length (`0` through `9`, `a` through `f`).

Use the  **Generate New Key** button next to the text field to generate a new randomized key in the correct format.

It is also possible to enter an existing device key in this field to make AutoConfigBackup use a device key from a previous installation.

> **Warning: Treat this key as a secret!**
>
> Anyone who has this key can manipulate the backups for this key.

Warning

This checkbox serves as a confirmation that the administrator has read the warnings and acknowledges the consequence that changing the device key will disconnect AutoConfigBackup from backups stored under the old device key.

After reading and understanding the warnings and saving the old keys, check the box in this section to enable the **Update Key** button.

Update Key

Clicking the  **Update Key** button will store the new device key in the configuration, replacing the current device key in the process.

Note: This button is disabled by default. Check the *Warning* checkbox to enable this button.

After clicking the button the GUI presents one more confirmation box using a JavaScript alert. Click **OK** to the confirmation dialog to complete the process.

If the **New Device Key** is not valid, the page will display an error without taking any action.

10.2.4 Restoring from AutoConfigBackup

Restoring a backup entry from the *Automatic Configuration Backup Service* is a straightforward process, but there are several other actions and techniques which may be useful as well.

The AutoConfigBackup **Restore** tab contains a list of backups and controls to act on those backups as well as showing backups for other devices.

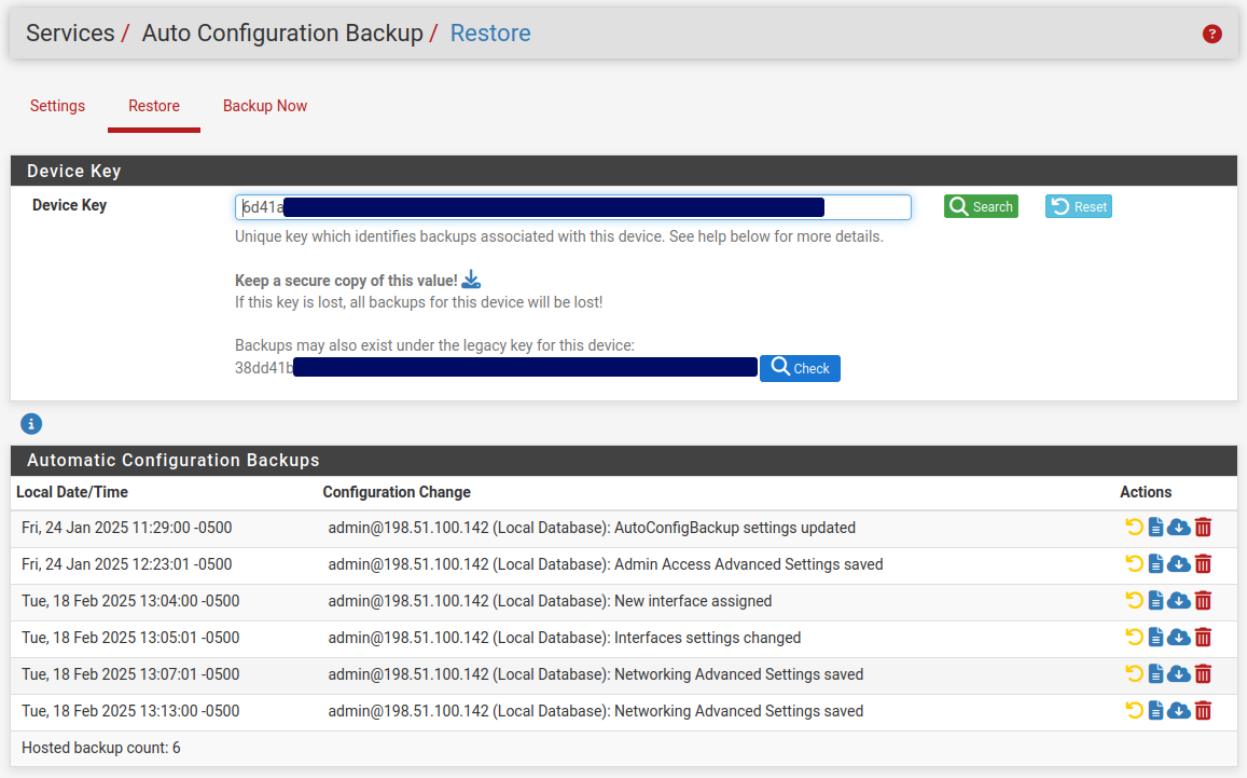

Fig. 2: AutoConfigBackup **Restore** tab, with Device Key and backup list visible

Restoring an AutoConfigBackup Entry

This procedure is a brief overview of how to restore a remote configuration backup from the AutoConfigBackup service using the GUI:

- Navigate to **Services > Auto Config Backup**
- Click the **Restore** tab at the top
- Locate the desired entry in the *Backup List*
- Click  to the right of the configuration row
- Click OK to confirm the restore action

AutoConfigBackup will download the configuration specified from the AutoConfigBackup service, decrypt it with the *Encryption Password*, and restore the configuration.

> **Warning:** By default the restore process **will not** initiate a reboot. Depending on the configuration items restored, a reboot may not be necessary. For example, firewall and NAT rules are automatically reloaded after restoring a configuration, but interface configurations are not.

After restoring, the GUI presents a prompt offering to reboot. If the restored configuration changes anything other than the NAT and firewall rules, the device requires a reboot to fully activate the changes:

- Click **Yes** in the save message, which navigates to the *Reboot page*

- Click  **Submit** to reboot the device

For more details about other capabilities of the **Restore** tab, continue reading this document.

Device Key

This section displays the *Device Key* AutoConfigBackup used to retrieve the backups on the page. This could be a randomized device key stored in the configuration or a *legacy device key*.

Tip: Click  to save a copy of this device key.

To see backups stored using another key, paste the key into the **Device Key** field and click  **Search**.

When viewing another key, use the  **Reset** button to return the page to the original device key.

The lower section contains a  **Check** button to easily swap to another known key. This button behavior changes depending on the current view:

- When viewing a current device key, if the device contains a legacy device key, this button will show backups stored under the legacy key.
- When viewing backups from the legacy key, it changes to a button which displays backups from the current device key.
- If there is no alternate key, the button does not display.

Backup List

The section of the page titled **Automatic Configuration Backups** displays a list of remote backup entries stored on the AutoConfigBackup service for a given *Device Key*.

The list contains the following columns for each backup entry:

Local Date/Time
The date and time the backup was created, with the time zone adjusted to be local to this device.

Note: The AutoConfigBackup service stores entries with a UTC timestamp.

Configuration Change
A brief description of the configuration change. This is typically an automatic string containing who made a change and what change they made, but may also contain a *manual backup reason*.

Actions
A list of actions which can be taken on a backup entry:

-  : Restore this AutoConfigBackup backup entry. Prompts for confirmation. Read *Restoring an AutoConfigBackup Entry* for additional details and warnings.

- : *Views the details of the AutoConfigBackup backup entry*, including the configuration itself.
- : Downloads the AutoConfigBackup backup entry as an XML file.
- : Deletes the AutoConfigBackup backup entry. Prompts for confirmation.

At the bottom of the list are two lines:

- A current count of hosted backups for this device key on the AutoConfigBackup service.
- A count of configuration backups staged for upload which have not yet been processed. The page only includes this line when there are staged entries waiting. Staged configuration backup entries are uploaded once per minute. See *How AutoConfigBackup Works* for details.

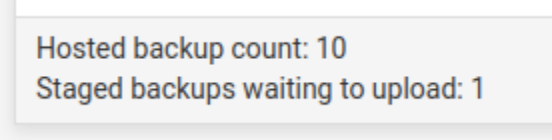

Fig. 3: Bottom of AutoConfigBackup **Restore** tab backup list showing backup count and number of backups staged waiting to upload.

Viewing AutoConfigBackup Entry Details

Clicking the icon for an entry on the *Backup List* opens up the **Revision** tab for the AutoConfigBackup backup entry.

This page contains the following fields:

Service Date/Time
The date and time in UTC when this backup revision was stored on the AutoConfigBackup service.

Local Date/Time
The same timestamp converted to the local time zone of the device.

Revision Reason
A brief description of the configuration change. This is typically an automatic string containing who made a change and what change they made, but may also contain a *manual backup reason*.

SHA256 Summary
A SHA256 hash of the configuration data, used to confirm that the contents are correct.

Encrypted config.xml
The encrypted blob containing the configuration data. This can be copied and pasted and decrypted manually as described in *Encrypted Configuration files*.

Decrypted config.xml
The decrypted contents of the configuration. This can be copied and pasted to a file and saved, similar to downloading the entry.

Tip: The  **Download this revision** button accomplishes this much easier, but some users may wish to copy/paste the contents for other purposes.

Restore Button

Clicking the  **Restore** button restores this AutoConfigBackup backup entry. Prompts for confirmation. Read *Restoring an AutoConfigBackup Entry* for additional details and warnings.

Download this revision Button

Clicking the  **Download this revision** button Downloads the AutoConfigBackup backup entry as an XML file.

Bare Metal Restoration from AutoConfigBackup

If the disk in the firewall fails or if the device key changes, the AutoConfigBackup service can restore a backup from the previous installation as long as the *Device Key* and the *Encryption Password* of the previous installation are both known.

- Install pfSense® software on the device
- Connect to the GUI and login
- Click the logo at the top left to skip the wizard

  If the WAN requires special configuration, use the wizard or configure it manually.
- Navigate to **Services > Auto Config Backup**, **Settings** tab
- Set the **Encryption Password** to match the previous installation
- Navigate to the **Restore** tab
- Paste the old device key into the **Device Key** field
- Click the  **Search** button

  This temporarily displays a list of backups for an alternate *Device Key*.
- Locate the desired entry in the *Backup List*
- Click  to the right of the configuration row
- Click **OK** to confirm the restore action
- Click **Yes** in the save message, which navigates to the *Reboot page*
- Click  **Submit** to reboot the device

When the device boots back up it will be running the restored configuration.

10.2.5 Manual AutoConfigBackup Entry

Manual backups using the *Automatic Configuration Backup Service* are a best practice before and after an upgrade or a series of significant changes.

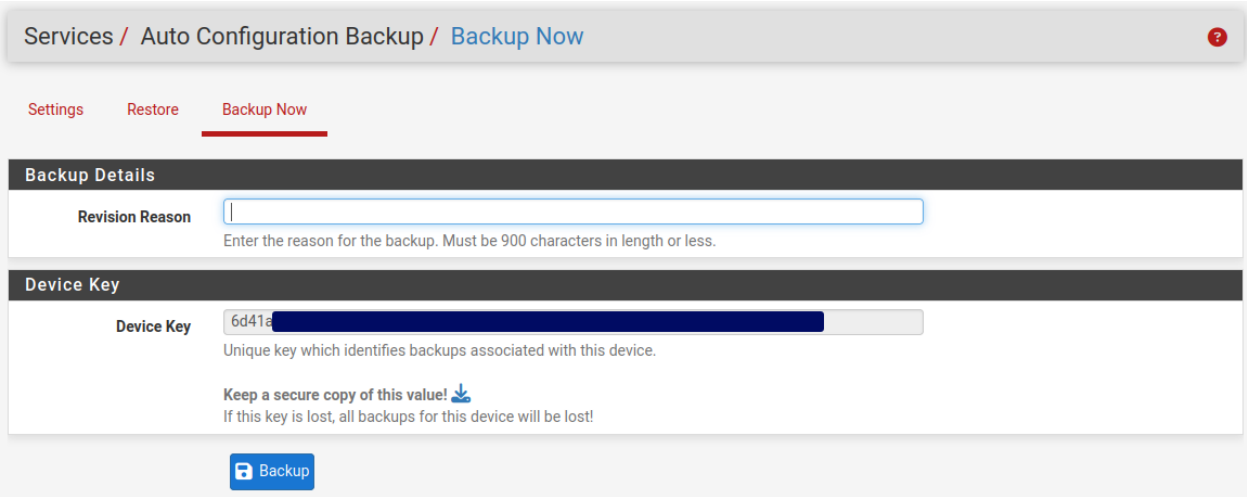

Fig. 4: **Backup Now** tab which creates manual AutoConfigBackup backup entries

This page creates manual AutoConfigBackup entries using a custom backup description provided by the administrator. The custom backup description makes it easy to identify and restore the manual backup entry.

Note: This page is not available when AutoConfigBackup is in a disabled state.

When AutoConfigBackup creates backups on every configuration change, a series of changes can make it difficult to know where the process started or ended. When using scheduled backups, the time of the scheduled backup may not have happened at a key point in the process. In either case, having manual entries at the start and end provides important remote backup entries which otherwise may not exist.

To create a manual backup of the configuration using AutoConfigBackup:

- Navigate to **Services > Auto Config Backup**
- Click the **Backup Now** tab at the top
- Enter a **Revision Reason**
- Confirm the **Device Key** is correct as it is the key AutoConfigBackup will use when uploading the backup
- Click **Backup**
- Wait *at least one minute* before *checking if the backup succeeded*

10.2.6 AutoConfigBackup Testing and Status

After *configuring* the *Automatic Configuration Backup Service*, the best practice is to perform tests to confirm backups are working properly.

Testing AutoConfigBackup

Testing backups is a vital part of every backup strategy. Without testing the entire backup and restore process, administrators can never know if a backup is viable. As such, it is crucial to test creating backups and restoring backups when first configuring AutoConfigBackup and periodically after.

Danger: Do not skip backup testing!

Without knowing if the entire backup and restore process works, any problems in the process may not be discovered until it is too late during a critical moment.

The only good backup is a tested backup!

Test Manual Backup

The following steps cover the general tasks involved in testing a *manual backup*. For specifics on each step, follow the cross-reference links.

- *Configure and enable* AutoConfigBackup
- Create a *Manual AutoConfigBackup Entry* entry
- Wait *at least one minute*
- *Check if the backup succeeded*
- Make a change, such as editing and saving a firewall or NAT rule
- *Restore the manual backup* and reboot
- Check if the change made after the manual backup is present

The restored configuration should not contain the change made after the manual backup.

Test Configuration Change Backup

The following steps cover the general tasks involved in testing AutoConfigBackup when it is configured to make a new backup on each configuration change. For specifics on each step, follow the cross-reference links.

- *Configure and enable* AutoConfigBackup using a **Backup Frequency** of *Automatically backup on every configuration change*
- Make a change to trigger a configuration backup, such as editing and saving a firewall or NAT rule
- Wait *at least one minute*
- *Check if the backup succeeded*
- Make a second change, such as editing and saving a **different** firewall or NAT rule
- *Restore the first backup* and reboot
- Check if the second change is present

The restored configuration should not contain the second change.

Test Scheduled Backups

The following steps cover the general tasks involved in testing AutoConfigBackup when it is configured to create backups on a schedule. For specifics on each step, follow the cross-reference links.

- *Configure and enable* AutoConfigBackup using a **Backup Frequency** of *Automatically backup on a regular schedule* with an appropriate schedule

  Tip: For ease of testing, configure the schedule to backup every 5 or 10 minutes, then configure a more reasonable schedule after testing, such as once per day.

- Make a change to trigger a configuration backup, such as editing and saving a firewall or NAT rule
- Wait until after the scheduled backup time passes, plus *at least one additional minute*
- *Check if the backup succeeded*
- Make a second change, such as editing and saving a **different** firewall or NAT rule
- *Restore the scheduled backup* and reboot
- Check if the second change is present

The restored configuration should not contain the second change.

Check Restore Tab

Administrators can check the status of an AutoConfigBackup run by reviewing the *Backup List* on the *Restore tab*.

AutoConfigBackup fetches its list of backup entries from the AutoConfigBackup service. If the backup is in the list on the **Restore** tab, the backup was successful and is present on the server.

Depending on the *Backup Frequency*, a backup may not appear right away. For example, a scheduled backup won't appear until after the scheduled time passes. For manual backups or backups on each configuration change, new backups may not appear for *at least one minute* as the uploads are queued and then processed out of that queue.

If there are backups pending upload, the backup list will contain a note with a count of staged backup entries.

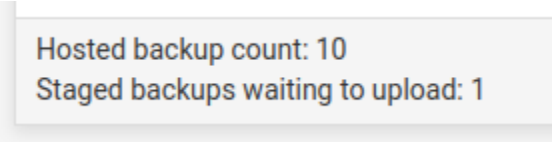

Fig. 5: Bottom of AutoConfigBackup **Restore** tab backup list showing backup count and number of backups staged waiting to upload.

If a backup fails, AutoConfigBackup logs an alert and displays a notice in the GUI.

View and/or download a backup then confirm it has the expected content.

AutoConfigBackup Logs

AutoConfigBackup creates log entries which describe its successes and failures. These can be found in the **System/General** sub-tab of the *System Logs*.

This is a sample of log entries created when creating a *Manual AutoConfigBackup Entry*:

```
/services_acb_backup.php: Staging AutoConfigBackup encrypted configuration backup for␣
↪deferred
          upload to https://acb.netgate.com
/usr/local/sbin/acbupload.php: Starting upload of staged AutoConfigBackup encrypted␣
↪configuration
          backups to https://acb.netgate.com
/usr/local/sbin/acbupload.php: Completed AutoConfigBackup encrypted configuration backup␣
↪upload
          to https://acb.netgate.com (success)
```

Check the logs when creating backups to ensure there are no errors which were not also printed in notices in the GUI.

Some AutoConfigBackup logs are informational and do not indicate a problem. For example, AutoConfigBackup skips certain redundant or frequent and not critical configuration changes. When AutoConfigBackup ignores a change, it logs the following message:

```
Skipping staging AutoConfigBackup entry for ignored reason: <reason>
```

10.3 ZFS Boot Environments (Plus Only)

ZFS Boot Environments make upgrades and major changes safer by taking snapshots of key filesystem areas, allowing the firewall to be rolled back to an earlier known good state if the user encounters problems with an upgrade, configuration change, or other potentially problematic situation.

The upgrade process automatically creates a new ZFS Boot Environment and administrators can create them manually as well. Administrators can then select a previous ZFS Boot Environments using the GUI or even the boot loader menu which makes quickly recovering from unforeseen issues a breeze.

Warning: ZFS Boot Environments are available only in pfSense Plus software version 22.05 and later. They are not available on pfSense® CE software.

10.3.1 How Boot Environments Work

A ZFS Boot Environment is a snapshot of the filesystem at a specific point in time, plus a clone of that snapshot. Snapshots are read only views of the filesystem at a given point, whereas clones are read/write.

Each snapshot and clone consumes some disk space but the exact amount varies based on how much the current contents of the filesystem have diverged from the contents when the entries were created.

Note: For most users tracking periodic updates or creating occasional ZFS boot environments the disk usage will be moderate over time. Users tracking development snapshots with frequent updates may see much larger amounts of space consumed by ZFS Boot Environments from snapshots. See *Boot Environment Disk Space Usage* for details.

When an administrator triggers the upgrade process the firewall creates a new ZFS Boot Environment before the upgrade begins. This preserves the current state of the firewall as it was before the upgrade.

What happens next has changed over time. From pfSense Plus software version 22.05 until 23.09.1, the upgrade process then activates the new ZFS Boot Environment so that when the upgrade proceeds and reboots, it reboots into the new environment to complete the upgrade.

Starting with pfSense Plus software version 24.03, this changed to a more efficient and robust procedure: The upgrade process creates a new Boot Environment and performs the upgrade inside that entry before rebooting. It makes sure the upgrade succeeded and then reboots into the newly upgraded environment. It detects any errors during boot and if there is a problem it can automatically roll back to the previous Boot Environment.

Either way, if there is a problem, an administrator can manually activate a pre-upgrade ZFS Boot Environment and reboot the firewall and it will return to its state before the upgrade happened.

See also:

For an overview of the upgrade process, see *Upgrade Process Overview*.

10.3.2 Boot Environment Requirements

- pfSense Plus software version 22.05 or later
- The firewall must be using ZFS

> **Note:** If the firewall is using UFS, it must be reinstalled with ZFS.

- ZFS requires 64-bit hardware (amd64, arm64)
- Certain ZFS dataset layout changes may require a fresh install, though many existing ZFS installations will work

10.3.3 Managing Boot Environments in the GUI

The GUI page to manage ZFS Boot Environments is **System > Boot Environments**.

> **Note:** If the **Boot Environment** menu entry is missing, the firewall does not support ZFS Boot Environments.

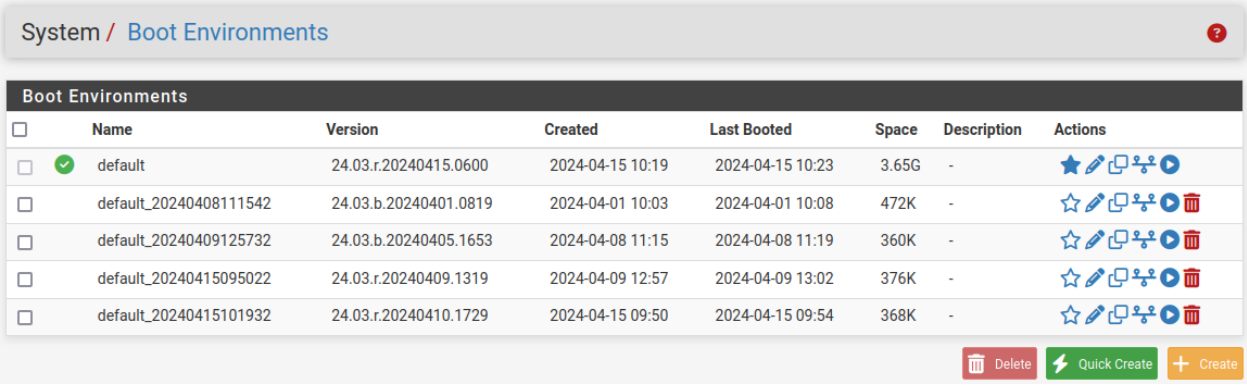

Fig. 6: ZFS Boot Environment list in the GUI

The Boot Environments page lists all existing ZFS Boot Environments with the following fields, as shown in *ZFS Boot Environment list in the GUI*:

Checkbox
Selection checkbox for batch actions which affect multiple Boot Environment entries.

Name
The name of the ZFS Boot Environment.

Automatic entries, such as those created by the upgrade process, are prefixed by `auto-` and include the timestamp at which they were created.

Base Version
The version of pfSense® software contained within the ZFS Boot Environment.

Created
The time at which the ZFS Boot Environment was created.

Last Booted
The time at which the firewall last booted into the ZFS Boot Environment.

Space
The amount of disk space consumed by the ZFS Boot Environment.

Description
The longer text description of the ZFS Boot Environment.

Actions
Actions the administrator can take on the ZFS Boot Environment.

-  : Indicates the ZFS Boot Environment the firewall will use for the next boot
-  : Persistently activate the entry as the next ZFS Boot Environment
-  : Edit the ZFS Boot Environment
-  : Clone the ZFS Boot Environment
-  : View the configuration history within this Boot Environment (*Configuration History*)
-  : Temporarily activate the ZFS Boot Environment one time and reboot

  There is an additional confirmation prompt to reboot after selecting this option.

-  : Delete the ZFS Boot Environment

Creating a new Boot Environment

Administrators can create new ZFS Boot Environments in several different ways.

> **Warning:** While boot environments are helpful, they do not remove the need for off-device backups. Take separate *configuration backups* before starting any potentially disruptive set of changes, including upgrades.

Automatic During Upgrade

By default the firewall automatically creates a new ZFS Boot Environment before performing an upgrade. The upgrade is performed inside the new Boot Environment and the firewall automatically reboots and verifies that the Boot Environment is working properly. This behavior can be altered using the options under *Boot Environments*.

Quick Create

Clicking **Quick Create** from the ZFS Boot Environment list will clone the current default ZFS Boot Environment. The resulting entry will be named `quick-` followed by the current timestamp.

Create / Clone

Clicking **Create** from the ZFS Boot Environment list opens a form to create a new ZFS Boot Environment with custom options, including:

Name
: Short name to briefly indicate purpose, must only contain characters from the set `a-z`, `A-Z`, `0-9` and `_`.

Clone From
: The existing ZFS Boot Environment to use as the basis for this new entry.

Description
: A longer description for the ZFS Boot Environment without formatting restrictions.

Click **Save** to create the new ZFS Boot Environment.

The  entry from the ZFS Boot Environment list works identically but it pre-selects the chosen entry in the **Clone From** field.

Editing an existing Boot Environment

Clicking  on the row for a ZFS Boot Environment opens a form to edit the **Name** and **Description** of the entry. The clone source cannot be changed after the entry has been created.

Selecting Boot Environments in the GUI

There are multiple ways in the GUI to select which ZFS Boot Environment the firewall will use next.

From the ZFS Boot Environment at **System > Boot Environments** there are two methods:

- Click  to select the ZFS Boot Environment persistently
- Click  to select the ZFS Boot Environment for a single boot only and reboot. This is not persistent and the next boot after will return to the default.

From **Diagnostics > Reboot**, select a **Boot Environment** from the list and reboot. This is not persistent and the next boot after will return to the default.

Removing Boot Environments

ZFS Boot Environments can be removed individually or in batches.

Note: The current Boot Environment cannot be removed!

To remove individual ZFS Boot Environments:

- Navigate to **System > Boot Environments**
- Locate the entry to remove in the list
- Click the  icon at the end of the row
- Click **OK** on the confirmation dialog to remove the Boot Environment

To remove multiple Boot Environments:

- Navigate to **System > Boot Environments**
- Select each entry to remove by clicking the checkbox to the left of each entry or by clicking anywhere in the row *except* the icons in the **Actions** column.

  Note: To quickly select all entries except the current Boot Environment, use the checkbox in the header row of the list.

- Click the  **Delete** button below the list
- Click **OK** on the confirmation dialog to remove all of the selected Boot Environment entries.

10.3.4 Selecting Boot Environments in the Loader Menu

At boot, pfSense® software briefly displays the loader menu with a logo and several options to control the boot behavior.

This loader menu will contain an option for ZFS **Boot Environments**, typically option `8` but may vary depending on the platform.

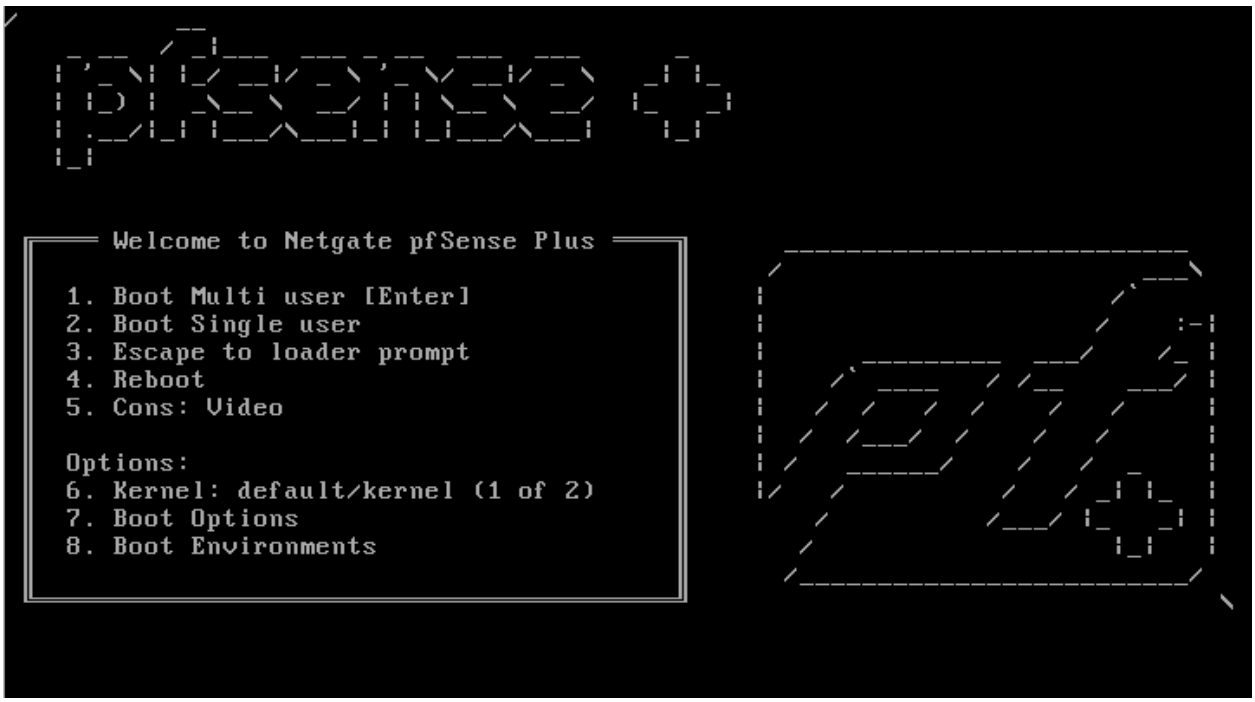

Fig. 7: Loader Menu - Enter the number for the Boot Environments option

Press the option for **Boot Environments** and the loader will display a new menu with ZFS Boot Environment options.

From this menu:

- Press option `2` to cycle through all available boot environments. Stop when the desired ZFS Boot Environment name is shown.
- Press option `3` to change the `bootfs` location if it is not correct

  This is unnecessary in the vast majority of cases as it likely only has one option.
- Press the `Enter` key to boot the selected Boot Environment or press `1` to return to the previous menu and change other options.

Note: This change is not persistent and the next boot after will return to the default ZFS Boot Environment. To make this change persist, select the entry in the GUI using  .

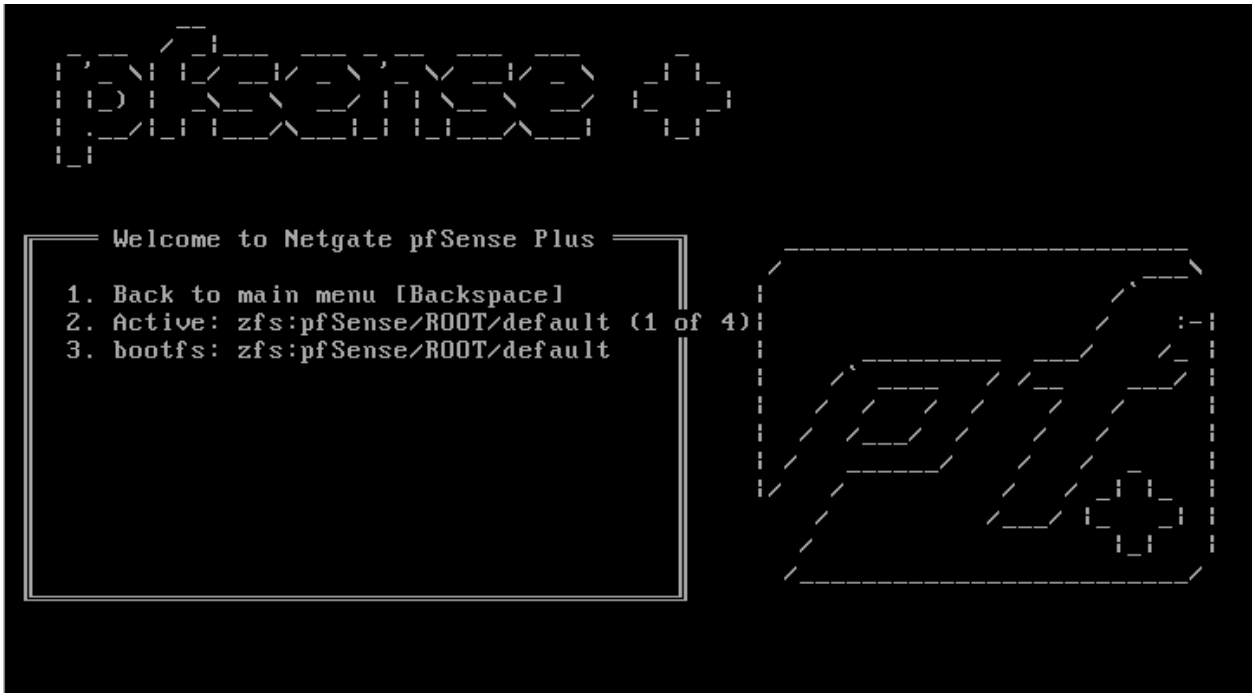

Fig. 8: Boot Environment Selection Menu

10.3.5 Boot Environment Status

The System Information widget on the Dashboard contains a **Boot Environment** section which prints the current ZFS Boot Environment and what the next ZFS Boot Environment will be.

Note: If the **Boot Environment** section of the widget is missing, the firewall does not support ZFS Boot Environments.

On **System > Boot Environments** the list of environments has an icon at the start of the row indicating the active and next ZFS Boot Environment.

- : The firewall booted from this entry.
- : The firewall will boot from this entry next.

  If this icon is not present the firewall will boot from the entry indicated by .

10.3.6 Boot Environment Disk Space Usage

ZFS Boot Environment snapshots consume an increasing amount of disk space over time as the contents of the disk diverge from when it was created compared to the current state of the disk.

A ZFS Boot Environment snapshot taken before upgrading to a new version of pfSense® Plus software can consume several gigabytes of space as those updates will rewrite the entire base system and all of the other components including packages as they are all reinstalled. Updating between development snapshots will cause a ZFS Boot Environment to consume about 500MB of disk space, give or take, based on what changed in the snapshot.

Warning: Frequent upgrades between development snapshots can cause ZFS Boot Environments to consume a lot of disk space!

The operating system reflects this usage as a change in the capacity of the disk. The size of a disk will appear to decrease proportionate to the snapshot usage, and this change is reflected on the dashboard **Disks** widget and in utilities such as `df`.

Removing older ZFS Boot Environments that are no longer necessary will free the space and make it available again. While the system will attempt to clean up older automatically created ZFS Boot Environments, ultimately it is up to the administrator to decide which ZFS Boot Environments are necessary.

Examples

The following are examples of space usage for numerous ZFS Boot Environments.

GUI

This figure shows the Dashboard **Disks** and **ZFS** widgets on a firewall with a 12GB disk and 12 ZFS Boot Environments from snapshot upgrades.

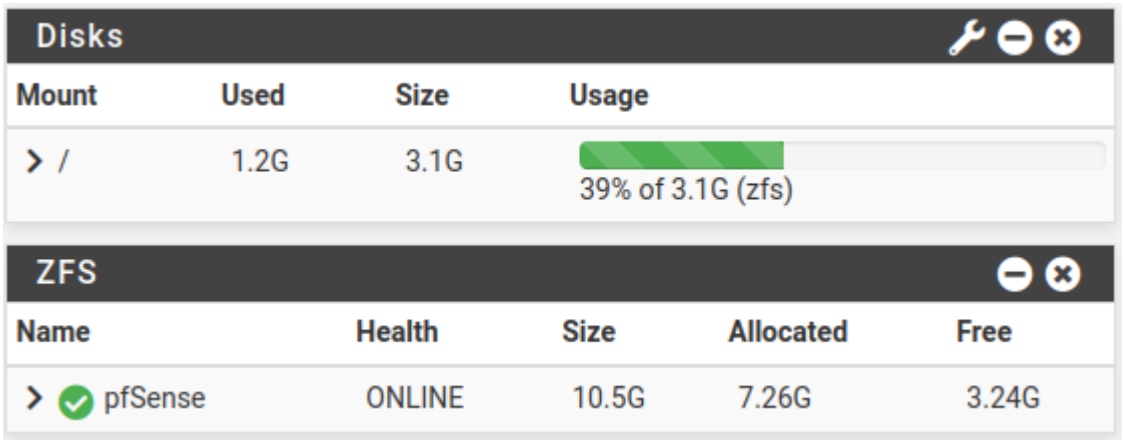

Fig. 9: Dashboard Disk Usage with 12 Boot Environments

Note that the disk size is listed as being only about 3GB when it should be significantly larger.

The next figure is the same system with the older Boot Environments removed so that only the default and one previous entry remain:

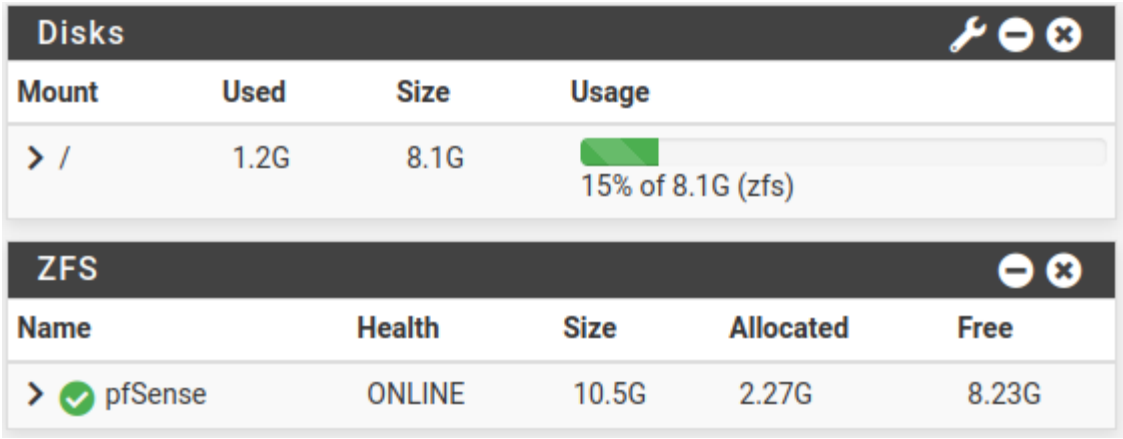

Fig. 10: Dashboard Disk Usage with 1 Boot Environment

Shell

Similar to the above example, this is the same firewall but with the disk usage checked at the shell instead of the GUI.

With 12 Boot Environments:

```
: df -h /
Filesystem              Size    Used   Avail Capacity  Mounted on
pfSense/ROOT/default    3.1G    1.2G    1.9G    39%    /

: zfs list /
NAME                   USED  AVAIL  REFER  MOUNTPOINT
pfSense/ROOT/default  6.93G  1.90G  1.20G  /
```

With the default plus one automatic Boot Environment:

```
: df -h /
Filesystem              Size    Used   Avail Capacity  Mounted on
pfSense/ROOT/default    8.1G    1.2G    6.9G    15%    /

: zfs list /
NAME                   USED  AVAIL  REFER  MOUNTPOINT
pfSense/ROOT/default  1.96G  6.89G  1.20G  /
```

10.3.7 Boot Environment Tips & Tricks

Reboot to Roll Back

- Create a new ZFS Boot Environment before making potentially disruptive changes to the firewall. This represents the current known-good state of the firewall.

> **Warning:** While boot environments are helpful, they do not remove the need for off-device backups. Take separate *configuration backups* before starting any potentially disruptive set of changes.

- Activate the new ZFS Boot Environment persistently with 
- Proceed to make the changes and monitor the firewall state.

If the changes caused a problem:

- Reboot and the firewall will restart from the ZFS Boot Environment with the known-good state.

If the changes are OK:

- Activate the default ZFS Boot Environment to continue using the new changes on future reboots.

10.4 Alternate Remote Backup Techniques

The easiest method to make secure and encrypted remote backups of the pfSense® software configuration is the free *Automatic Configuration Backup Service*. Rest easy knowing it is taking care of handling remote backups automatically without needing to worry. Sit back, have a cup of coffee, and read on for alternate techniques.

The other techniques in this document perform backups remotely, but each method has its own security issues which may rule out their use. For starters, several of these techniques do not encrypt the configuration, which may contain sensitive information. This can result in the raw configuration being transmitted over an unencrypted, untrusted link. If one of these techniques must be used, it is best to do so from a non-WAN link (LAN, DMZ, etc.) or across a VPN. Access to the storage media holding the backup must also be controlled, if not encrypted.

10.4.1 Pull

Pulling the configuration means to use a remote client to "pull" the configuration off of the firewall. The methods in this section accomplish the same goal using different utilities.

Pull with wget

The `wget` utility can retrieve the configuration from a remote firewall. This process can be scripted with `cron` or by other means to automate the process.

Warning: Even when using HTTPS, this is not a truly secure transport mode since certificate checking is disabled to accommodate self-signed certificates, enabling man-in-the-middle attacks. When running backups with `wget` across untrusted networks, use HTTPS with a certificate that can be verified by `wget`.

The `wget` command must be split into multiple steps to handle the login procedure and backup download while also accounting for CSRF verification.

For a firewall running HTTPS with a self-signed certificate, the commands are as follows:

- Fetch the login form and save the cookies and CSRF token:

```
$ wget -qO- --keep-session-cookies \
  --save-cookies cookies.txt \
  --no-check-certificate \
  https://192.168.1.1/diag_backup.php \
  | grep "name='__csrf_magic'" \
  | sed 's/.*value="\(.*\)".*/\1/' > csrf.txt
```

- Submit the login form along with the first CSRF token and save the second CSRF token (can't reuse the same file) – now the script is logged in and can take action:

```
$ wget -qO- --keep-session-cookies --load-cookies cookies.txt \
  --save-cookies cookies.txt --no-check-certificate \
  --post-data "login=Login&usernamefld=admin&passwordfld=pfsense&__csrf_magic=$(cat␣
↪csrf.txt)" \
  https://192.168.1.1/diag_backup.php \
  | grep "name='__csrf_magic'" \
  | sed 's/.*value="\(.*\)".*/\1/' > csrf2.txt
```

- Submit the download form along with the second CSRF token to save a copy of `config.xml`:

```
$ wget --keep-session-cookies --load-cookies cookies.txt --no-check-certificate \
  --post-data "download=download&donotbackuprrd=yes&__csrf_magic=$(head -n 1 csrf2.
↪txt)" \
  https://192.168.1.1/diag_backup.php -O config-router-`date +%Y%m%d%H%M%S`.xml
```

Note: The behavior of variable expansion and other aspects of the commands may vary by shell. This example uses `bash` for the client shell.

Replace the username and password with the credentials for the firewall, and the IP address is whichever IP address is reachable from the client performing the backup, and using HTTP or HTTPS to match the firewall GUI.

There are additional parameters which can control the contents of the backup in several ways:

- To backup the RRD files, remove the `&donotbackuprrd=yes` parameter from the post data string on the last command.
- To include extra data such as DHCP leases and captive portal databases, add `&backupdata=yes` to the post data string on the last command.
- To include the SSH keys for the firewall, add `&backupssh=yes` to the post data string on the last command.

The client performing the backup will also need access to the GUI, so adjust the firewall rules accordingly. Performing this type of backup over an Internet-connected WAN is not secure. At a minimum, use HTTPS and restrict access to the GUI to a trusted set of public IP addresses. A better practice is to do this locally or over a VPN.

Using cURL

The same task can be accomplished using cURL instead of `wget`:

- Fetch the login form and save the cookies and CSRF token:

```
$ curl -L -k --cookie-jar cookies.txt \
    https://192.168.1.1/ \
    | grep "name='__csrf_magic'" \
    | sed 's/.*value="\(.*\)".*/\1/' > csrf.txt
```

- Submit the login form to complete the login procedure:

```
$ curl -L -k --cookie cookies.txt --cookie-jar cookies.txt \
    --data-urlencode "login=Login" \
    --data-urlencode "usernamefld=admin" \
    --data-urlencode "passwordfld=pfsense" \
```

(continues on next page)

(continued from previous page)

```
    --data-urlencode "__csrf_magic=$(cat csrf.txt)" \
    https://192.168.1.1/ > /dev/null
```

Now the script is logged in and can perform actions!

- Fetch the target page to obtain a new CSRF token:

```
$ curl -L -k --cookie cookies.txt --cookie-jar cookies.txt \
    https://192.168.1.1/diag_backup.php  \
    | grep "name='__csrf_magic'"   \
    | sed 's/.*value="\(.*\)".*/\1/' > csrf.txt
```

- Download the backup:

```
$ curl -L -k --cookie cookies.txt --cookie-jar cookies.txt \
    --data-urlencode "download=download" \
    --data-urlencode "donotbackuprrd=yes" \
    --data-urlencode "__csrf_magic=$(head -n 1 csrf.txt)" \
    https://192.168.1.1/diag_backup.php > config-router-`date +%Y%m%d%H%M%S`.xml
```

Note: The behavior of variable expansion and other aspects of the commands may vary by shell. This example uses `bash` for the client shell.

There are additional parameters which can control the contents of the backup in several ways:

- To backup the RRD files, remove the `--data-urlencode "donotbackuprrd=yes" \` parameter from the last command.
- To include extra data such as DHCP leases and captive portal databases, add `--data-urlencode "backupdata=yes" \` to the last command.
- To include the SSH keys for the firewall, add `--data-urlencode "backupssh=yes" \` to the last command.

10.4.2 Push with SCP

The `scp` command can push the configuration file from the firewall to another host. Using `scp` to push a one-time backup by hand can be useful, but using it in an automated fashion carries risks. The command line for `scp` varies depending on the system configuration, but will be close to the following:

```
$ scp /cf/conf/config.xml \
   user@backuphost:backups/config-`hostname`-`date +%Y%m%d%H%M%S`.xml
```

Pushing the configuration in an automated manner requires the firewall administrator to generate an SSH key without a passphrase. Due to the insecure nature of a key without a passphrase, generating such a key is left as an exercise for the reader. This adds risk due to the fact that anyone with access to that file has access to the designated account, though because the key is kept on the firewall where access is restricted, it isn't a considerable risk in most scenarios. Ensure the remote user is isolated and has little to no privileges on the destination system.

A chrooted `scp` environment may be desirable in this case. The `scponly` shell is available for most UNIX platforms which allows SCP file copies but denies interactive login capabilities. Some versions of OpenSSH have chroot support built in for sftp (Secure FTP). These steps greatly limit the risk of compromise with respect to the remote server, but still leave the backed up data at risk. Once access is configured, a cron entry could be added to the firewall to invoke `scp`.

A summary of the setup is as follows:

- Generate an ssh key for the root user on the firewall *without a passphrase*. (Warning: dangerous!)
- Add a user to a remote system, and add the new public key to its `~/.ssh/authorized_keys` file
- Create a cron job on the firewall that would copy `/cf/conf/config.xml` to the remote system with `scp`

10.4.3 Basic SSH backup

Similar to the `scp` backup, there is another method that will work from one UNIX system to another. This method does not invoke the SCP/SFTP layer, which in some cases may not function properly if a system is already in a failing state:

```
$ ssh root@192.168.1.1 cat /cf/conf/config.xml > backup.xml
```

When executed, that command will yield a file called `backup.xml` in the current working directory that contains the remote firewall configuration. Automating this method using cron is also possible, but this method requires an SSH key without as passphrase on the host performing the backup. This key will enable administrative access to the firewall, so it must be tightly controlled. (See *Secure Shell (SSH)* for details.)

10.5 Restoring from Backups

Backups are not useful without a means to restore them, and by extension, test them. Several means for restoring configurations are available in pfSense® software. Each method has the same end result: a running firewall identical to when the backup was made.

10.5.1 Backup Compatibility

The version of pfSense Plus or pfSense CE software is not as important as the **Configuration Revision** number when determining backup compatibility. Differences in the configuration revision number indicate changes in the format of the configuration data which makes them not directly compatible.

See also:

There is a list of software versions and their corresponding configuration revision numbers at *Versions of pfSense software and FreeBSD*.

Backups using the same configuration revision can be restored as-is, both for complete configuration backups and partial (section-based) backups.

Complete backups with a lower configuration revision **can** be restored to a current version. The upgrade code will adjust the values in the configuration to convert it into a current format.

Partial (section-based) backups **cannot** be restored if they were taken on a version with a different configuration revision, as there is no mechanism for the upgrade code to handle partial backups.

Backups with a higher configuration revision **cannot** be restored to an older version. There is no mechanism to downgrade a configuration as the older version will have no knowledge of changes which happened in future versions of the software.

Restoring between pfSense CE and pfSense Plus or vice versa may work in many cases, but results depend upon the target hardware and version. For example, restoring to pfSense Plus on hardware with an integrated Ethernet switch may require manual adjustments. Contact Netgate TAC for specific guidance.

10.5.2 Restoring with the GUI

The easiest way for most users to restore a configuration is by using the GUI:

- Navigate to **Diagnostics > Backup & Restore**
- Locate the **Restore Backup** section (Figure *GUI Restore*).
- Select the area to restore, or leave at the default selection for a complete backup.

Note: This value must match the **Backup area** chosen when creating the backup.

- Click **Browse**
- Locate the backup file on the local PC
- Click **Restore Configuration**

The firewall will then apply the configuration and reboot with the settings obtained from the backup file.

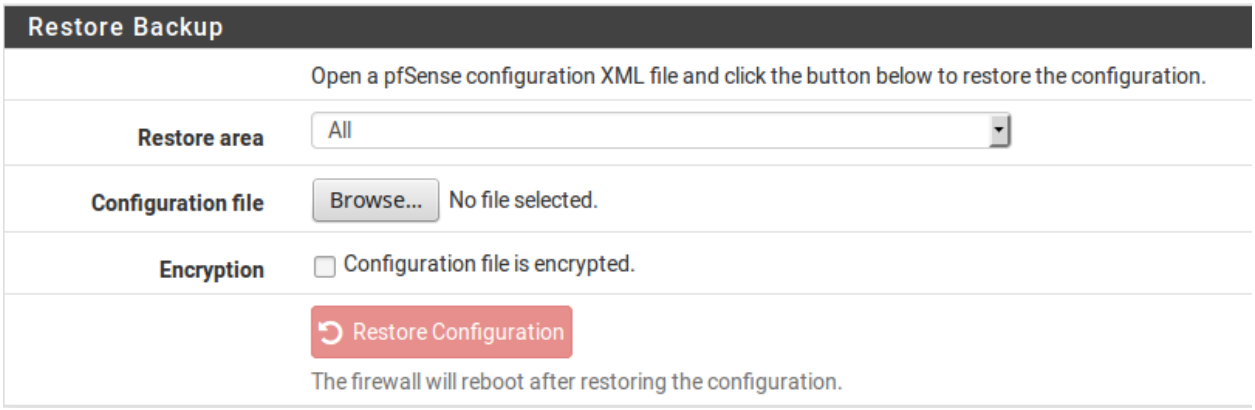

Fig. 11: GUI Restore

While easy to work with, this method has prerequisites when dealing with a full restore to a new installation. First, it would need to be done after the new target system is fully installed and running. Second, it requires an additional PC connected to a working network or crossover cable behind the firewall being restored.

Restore Options

Restore Area
Restores a backup containing only a single configuration area, rather than a complete configuration backup.

> **Warning:** Restoring a single area does not trigger a reboot nor does it cause any part of the configuration to be reapplied. To ensure the restored configuration area is active, issue a reboot or manually refresh the configuration for the relevant area after restore (e.g. edit/save/apply on a page, issue a filter reload, etc).

> **Warning:** When restoring a single area, the area being restored must be from the **same** version. Single areas do not support running upgrade code on the configuration, and thus cannot be adjusted if the format of the area changed from a previous version.

> **Warning:** This does not restore one area from a full backup, the backup file must only contain the area to restore.

Note: This value must match the **Backup area** chosen when creating the backup.

Configuration File
A **Browse** button to select a backup file to upload and restore.

Preserve Switch Configuration
This option is available on Netgate hardware with integrated switches. When set, the current active switch configuration will be copied into the restored configuration, preserving it for later use. This makes it easier to restore a configuration from hardware without an integrated switch.

Note: This only copies the integrated switch configuration, and does not copy VLAN or LAGG interface entries which may be relevant to using the switch. This behavior is safer, as the configuration being restored may also contain important configuration data in those areas.

Encryption
When set, a **Password** field is presented, the contents of which is used by the firewall to decrypt the contents of the backup file before restoring the configuration.

10.5.3 Configuration History

For minor problems, using one of the internal backups on the firewall is the easiest way to back out a change. By default the previous `30` configurations are stored in the **Configuration History**, along with the current running configuration. The configuration history is found at **Diagnostics > Backup & Restore** on the **Config History** tab. The amount of entries available in the configuration history is configurable (*Configuration Backup Cache Settings*).

Configuration History List

Each row in the configuration history contains the following items:

Diff Selectors
Two columns of radio selectors which pick entries for viewing the differences between them. See *Config History Diff* for details.

Checkbox (Plus Only)
Selection checkbox for deleting multiple entries from the history. Select one or more entries and then click the  **Delete** button under the list.

Date
The date and time at which the configuration file was made.

Configuration Change
An identifier declaring which system or user made a configuration change along with a brief description of what changed in the configuration.

Version/Revision
The configuration revision of the entry, as described earlier in this document in *Backup Compatibility*.

See also:

- *Versions of pfSense software and FreeBSD*

Size
The amount of disk space consumed by this backup.

Actions
Icons which take action on each entry individually, including:

-  : Restore this configuration from the history.
-  : Download this configuration file from the history.
-  : Delete this configuration file from the history.

Note: There is no need to delete entries by hand to save space; the firewall automatically deletes old configuration backups when it creates new entries.

However, it is a good practice to remove known-bad configuration changes to ensure that they are not accidentally restored.

Note: The order of these columns differs between pfSense Plus and pfSense CE software.

Restoring from Configuration History

To restore a configuration from the history:

- Navigate to **Diagnostics > Backup & Restore**
- Click the **Config History** tab (Figure *Configuration History on pfSense Plus Software*)
- Locate the desired backup in the list
- Click  to restore that configuration file

Warning: Restoring a configuration with this method does not initiate an automatic reboot. Minor changes do not require a reboot, though reverting some major changes will.

If a change was only made in one specific section, such as firewall rules, trigger a refresh in that area of the GUI to apply the changes. For firewall rules, a filter reload would be sufficient. For OpenVPN, edit and save the VPN instance. The necessary actions to take depend on the changes in the restored configuration, but the best way ensure that the full configuration is active is to reboot.

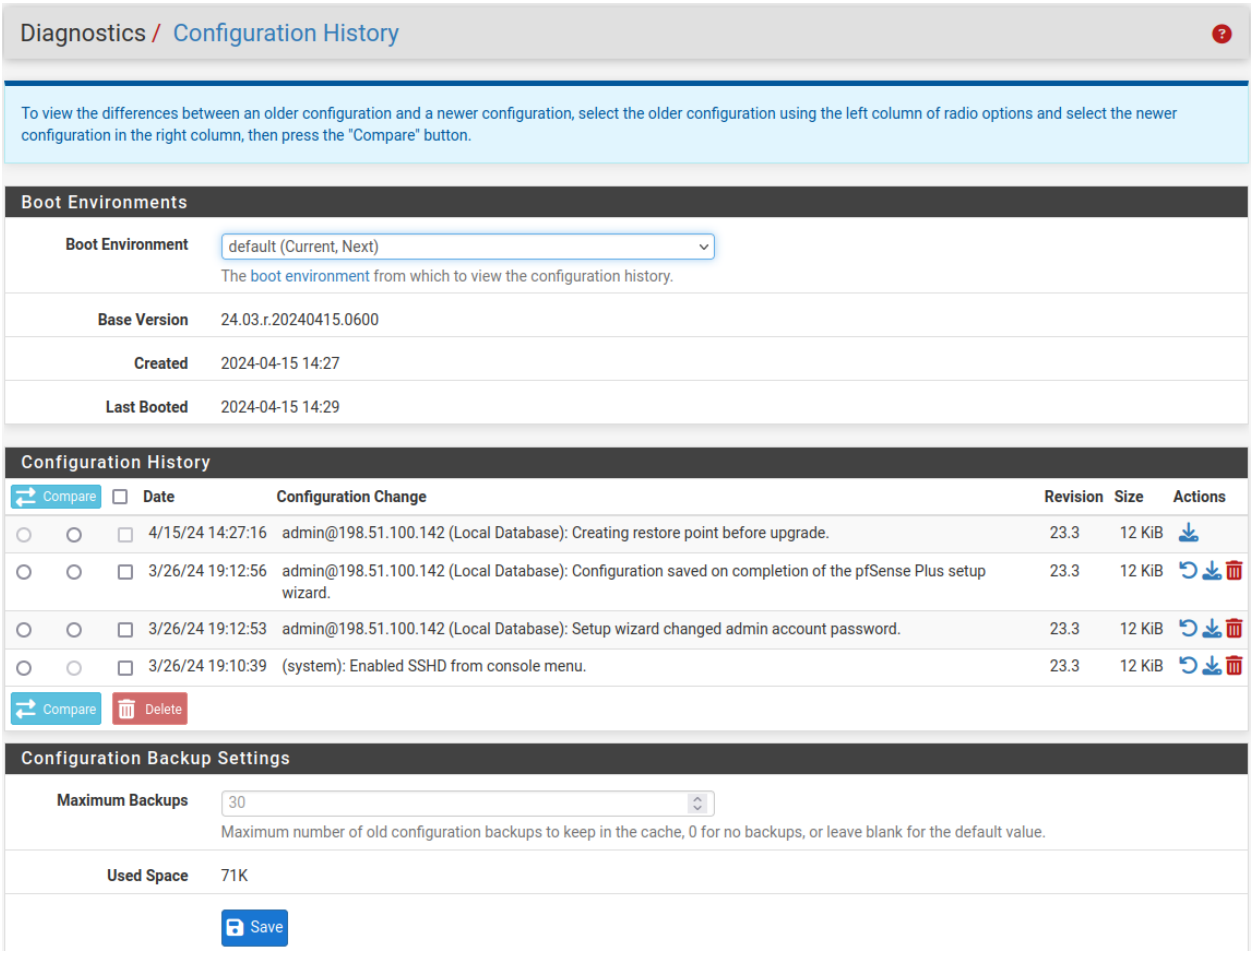

Fig. 12: Configuration History on pfSense Plus Software

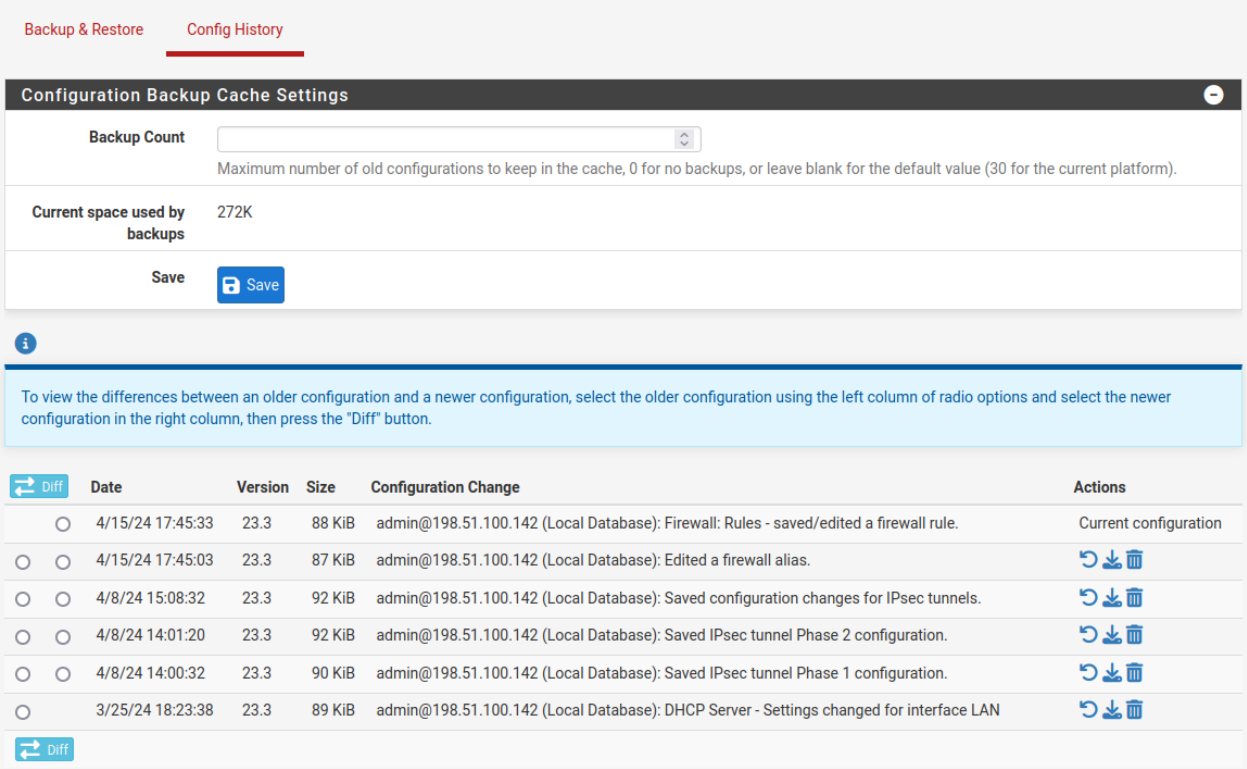

Fig. 13: Configuration History on pfSense CE Software

If necessary, reboot the firewall with the new configuration by going to **Diagnostics > Reboot System** and click **Yes**.

ZFS Boot Environments (Plus Only)

On pfSense Plus software installations utilizing *ZFS Boot Environments*, this page contains an additional **Boot Environments** section. Each Boot Environment contains its own Configuration History, and the option in this section controls which set of Configuration History entries the page displays.

The **Boot Environments** section contains the following fields:

Boot Environments
: A drop-down selection list containing all of the available ZFS Boot Environments. Selecting a different entry refreshes the page to display Configuration History entries from that Boot Environment.

Base Version
: Read-only field indicating the version of pfSense software installed in the selected Boot Environment.

Created
: Read-only field indicating the date that the selected Boot Environment was created.

Last Booted
: Read-only field indicating the date that the selected Boot Environment was last booted.

Configuration Backup Cache Settings

The amount of backups stored in the configuration history may be changed if needed.

- Navigate to **Diagnostics > Backup & Restore**
- Click the **Config History** tab
- Click  at the right end of the **Configuration Backup Cache Settings** bar to expand the settings (If present)
- Enter the new number of configurations to retain in the **Backup Count** field
- Click **Save**

Note: On pfSense Plus software the settings are at the bottom of the page and always visible. On pfSense CE software the settings are above the list, but collapsed by default.

Along with the configuration count, the page also displays the amount of space consumed by the backup cache.

Config History Diff

The differences between any two configuration files may be viewed in the **Config History** tab.

On the left side of the configuration history list there are two columns of radio buttons. Use the leftmost column to select the *older* of the two configuration entries, and then use the right column to select the *newer* of the two entries. Once both entries have been selected, click **Compare** (Plus) or **Diff** (CE) at either the top or bottom of the column.

Console Configuration History

The configuration history is also available from the console menu as option `15`, **Restore Recent Configuration**. The menu selection will list recent configuration files and offer to restore one. This is useful if a recent change has locked administrators out of the GUI or taken the firewall off the network.

10.5.4 Restoring by Mounting the Disk

Attaching the disk from an installation of pfSense software to a computer running FreeBSD enables the drive to be mounted by the FreeBSD host and a new configuration may be copied directly onto the installed system, or a configuration file from a failed system may be copied off.

Note: This can also be performed on a separate installation of pfSense in place of a computer running FreeBSD, but do not use an active production firewall for this purpose. Instead, use a spare or test firewall.

The `config.xml` file is kept in `/cf/conf/`, but the difference is in the location where this directory resides. This is part of the root slice (typically `da0p2`). The drive and partition name will vary depending on disk type and position in the host.

10.5.5 Encrypted Configuration files

The GUI can automatically determine the correct decryption method when restoring an encrypted configuration backup file, whether it's from a current version or an older version. When restoring an encrypted configuration file, check **Configuration file is encrypted** then enter the password in the **Password** field, and restore as usual from there.

Encrypted configuration files can be manually decrypted using the correct password for offline inspection.

The method used to encrypt configuration files has changed in recent versions, so use the method appropriate for the version which generated the encrypted configuration file.

In any of the following cases, replace <PASSWORD> with the appropriate password string, and change the filenames as needed.

Plus 22.05 and CE 2.7.0 and later

These versions use secure options with high iterations for increased security:

```
$ openssl enc -d -a -aes-256-cbc \
  -in config-encrypted.xml -out dencryptedfile.xml \
  -pass pass:<PASSWORD> -salt -md sha256 -pbkdf2 -iter 500000
```

Warning: If the password contains any non-shell-safe characters such as `!`, `` `,\ ``, `;` or similar, escape the characters or quote the string.

These versions also include a *PHP shell script* which can encrypt and decrypt configurations from a shell on the firewall itself:

```
$ pfSsh.php playback cryptconfig \
  decrypt /root/config-encrypted.xml /root/dencryptedfile.xml
```

The script will prompt for the decryption password.

Plus 21.02 through 22.01 / CE 2.5.x through CE 2.6.x

These versions used more secure parameters than the older options, but with the default iteration count:

```
$ openssl enc -d -a -aes-256-cbc \
  -in config-encrypted.xml -out dencryptedfile.xml \
  -pass pass:<PASSWORD> -salt -md sha256 -pbkdf2
```

Warning: If the password contains any non-shell-safe characters such as `!`, `` `,\ ``, `;` or similar, escape the characters or quote the string.

Older versions

Versions before the ones stated previously used older legacy options:

```
$ openssl enc -d -a -aes-256-cbc \
  -in config-encrypted.xml -out dencryptedfile.xml \
  -pass pass:<PASSWORD> -salt -md md5
```

Warning: If the password contains any non-shell-safe characters such as `!`, `` `,\ ``, `;` or similar, escape the characters or quote the string.

10.6 Automatically Restore Configuration During Installation

In addition to restoring through the GUI, pfSense® software supports methods which restore a configuration to a new setup without going through all the trouble of setting up a client and restoring using a web browser.

These methods are significantly easier than reconfiguring the LAN and restoring via the network, especially in complex environments. The firewall will start up using the restored configuration immediately without needing intermediate steps.

10.6.1 Recover config.xml From Existing Installation

The installer has a *Configuration Restore* option which can read configuration files and other key data (SSH host keys, DHCP leases) from an existing installation before starting the install process and then it restores those files to the new installation when it completes.

This is useful for upgrades, filesystem changes, loader changes, or any other situation requiring a reinstallation on the same disk.

Note: The **Configuration Restore** option works on installations using either UFS or ZFS.

See *Configuration Restore* for information on how to utilize this feature during installation.

The firewall will boot off the target disk with the configuration restored by the installer already in place. The firewall will reinstall packages automatically in the background.

10.6.2 Restore Configuration from Media During Install

The *Configuration Restore* feature will look for files named `config.xml` anywhere on a FAT or FAT32 partition. Selecting one of these files will copy it into the target installation automatically during the install process.

The configuration may include additional data from options on the backup page, such as RRD, SSH keys, DHCP lease databases, and captive portal data. The configuration may also be encrypted, the installer will prompt for the password to decrypt the configuration if necessary.

> **Warning:** This feature does not support drives formatted with exFAT, only FAT or FAT32.
>
> For this feature to work correctly, the USB drive must contain a partition table and it must not be formatted as a raw device.

Tip: The pfSense software memstick installation image contains a FAT partition which the installer can use for this purpose. If the partition is not visible on the workstation which wrote the memstick image, remove and reinsert the USB drive.

This feature works with any FAT or FAT32 partition the installer can mount during the install process. This can be a USB thumb drive/memory stick or an optical disk/virtual drive.

- Connect a USB drive formatted with a FAT or FAT32 partition
- Copy a backup configuration file to the drive
- Rename the backup to `config.xml`

  Example: If the USB drive is `E:`, the full path would be `E:\config.xml`

  Note: The installer looks for `config.xml` in any directory on the drive, there are no restrictions on where the file must be located.

- Unmount/eject the USB drive, remove it, then plug it into the firewall

See *Configuration Restore* for information on how to utilize this feature during installation.

10.6.3 Restore using the External Configuration Locator (ECL)

pfSense software also includes a feature called the External Configuration Locator, or ECL for short. The ECL process runs at boot time to, as the name implies, locate configuration files on external storage. If the ECL finds a configuration file, it copies that file to the firewall disk, replacing any existing configuration.

Note: The ECL runs on every boot, so its use is not limited to fresh installations.

This procedure is nearly identical to the method in *Restore Configuration from Media During Install*, but the USB disk containing the configuration does not need to be present during the installation. The same warnings from that procedure also apply here.

- On a FAT, FAT32, or UFS formatted USB drive, make a directory called `config`
- Copy a backup configuration file to the `config` directory
- Rename the backup to `config.xml`

Example: If the USB drive is `E:`, the full path would be `E:\config\config.xml`.

Note: The ECL also looks for `config.xml` in the root directory of the drive, but the best practice is to place the file in the `config` directory.

- Unmount/eject and remove the USB drive
- Install pfSense software as usual

  This is optional, since the ECL runs on existing installations.
- Reboot the firewall
- Insert the USB drive containing the configuration while the firewall boots and the ECL will read in the configuration file from there

---

Note: USB drives which only contain files can be inserted before the firewall boots. Bootable USB drives, such as the installation memstick, should not be inserted until after the firewall has started to boot from its own disk. This behavior will vary by target device and its boot preferences. Monitor the console to find the appropriate timing.

Timing is also affected by the speed of the device. Slower systems may not mount the USB drive before the ECL runs.

- Wait for the firewall to complete the boot process
- Check that the configuration was loaded properly

  If the configuration did not load as expected, check the file location and name on the USB drive, and check the timing of when the USB drive was present during the boot process, then start over. Monitor the console for details.
- Remove the USB drive once the correct configuration file is in place

If this is the first boot post-installation, then this process also triggers reinstallation of packages listed in the restored configuration.

Warning: This procedure will copy the `config.xml` file from the USB drive to the target drive at **every** boot. However, the running firewall **will not** copy its own configuration back to the USB drive. Thus, leaving the drive inserted in the firewall will result in losing **all** configuration changes not present in the configuration file on the USB drive.

10.7 Restoring a Configuration File to a Different Version

Configurations are specific to a given version of pfSense® software. The configuration is the same on all platforms and architectures using the same version of pfSense software. The version of FreeBSD used is not relevant.

Generally speaking, a complete older configuration version can always be restored to a newer release of pfSense software. The firewall will upgrade the configuration as needed provided that has the **entire** configuration and not a partial copy.

A newer configuration **cannot** be restored to an older release that had a different configuration version. Certain releases of pfSense software had the same configuration version, and restoring between those is possible, but still not recom-

mended. See *Versions of pfSense software and FreeBSD* to see which configuration versions were used on specific releases.

A configuration **section** or partial configuration cannot be restored between different configuration versions. It may work by pure luck, but often there are configuration format differences that require changes to be made to the older configuration. These changes are automatic if a complete configuration is restored. If a partial restore is required, perform a full upgrade in a test VM or lab and then copy the needed section out of the resulting `config.xml` post-upgrade.

10.8 Caveats and Gotchas

While the configuration XML file kept by pfSense® software includes all of the settings, it does not include any changes that may have been made to the system by hand, such as manual modifications of source code. Additionally some packages require extra backup methods for their data.

The configuration file may contain sensitive information such as VPN keys or certificates, and passwords (other than the admin password) in plain text. Some passwords must be available in plain text during run time, making secure hashing of those passwords impossible (*Password Storage Security Policies*). Hence backup copies of these files must also be protected in some way. If they are stored on removable media, take care with physical security of that media and/or encrypt the drive.

If the GUI must be used over the WAN without a VPN connection, at least use HTTPS. Otherwise, a backup is transmitted in the clear, including any sensitive information inside that backup file. We strongly recommend using a trusted network or encrypted connection.

10.9 Password Storage Security Policies

Sensitive data such as PPPoE/PPTP client, PPTP VPN, DynDNS passwords as well as remote authentication servers RADIUS (shared secret), LDAP (bind user password), and IPsec shared secrets, among others, appear in plain text or with reversible Base64 encoding in the pfSense® software configuration file, `config.xml`. This is a deliberate design decision in m0n0wall that has been carried over here.

Since the firewall cannot prompt the user for a password each time it is required, the implementations of affected areas require plain text passwords to operate. pfSense software could, of course, use some snake oil encryption on those passwords, but that would only create a false sense of security. Any encryption applied to the passwords could be reversed by anyone with access to the source code (i.e. everybody). Hashes like SHA256 cannot be used where the plain text password is needed at a later stage, unlike for the system password, which is only stored as a hash.

By leaving the passwords in plain text, it is very clear that `config.xml` deserves to be stored in a secure location (and/or encrypted with one of the countless programs out there). Any sort of hashing used would not be secure, and would be dangerous because it would give the impression of security where none exists.

See also:

- *Backup Files and Directories with the Backup Package*

Thanks to the XML-based configuration file used by pfSense® software, backups are a breeze. All of the settings for the system are held in one single file (see *XML Configuration File*). In the vast majority of cases, this one file can be used to restore a system to a fully working state identical to what was running previously. There is no need to make an entire system backup, as the base system files are not modified by a normal, running, system.

Note: In rare cases, packages may store files outside of config.xml, check the package documentation for additional information and backup suggestions.

10.10 Backup Strategies

The optimal backup strategy can be summarized in the following points:

- Take frequent backups
- Keep multiple copies of backups in a safe location off the firewall
- Periodically test backups

The remainder of this section expands on these points.

The best practice is to make a backup after each minor change, and both before and after each major change or series of changes. Typically, an initial backup is taken in case the change being made has undesirable effects. An after-the-fact backup is taken after evaluating the change and ensuring it had the intended outcome. Periodic backups are also helpful, regardless of changes, especially in cases where a manual backup may be missed.

pfSense software makes an internal backup upon each change, and the best practice is to download a manual backup as well. The automatic backups made on each change are useful for reverting to prior configurations after changes have proven detrimental, but are not good for disaster recovery as they are on the system itself and not kept externally. As it is a fairly simple and painless process, administrators should make a habit of downloading a backup now and then and keeping it in a safe place. Backups may be handled easily and automatically using the free **AutoConfigBackup** service.

Tip: Backup files can contain sensitive information, so carefully consider security measures for backups kept off the firewall. If they are on other network file shares, ensure access is restricted. For offline backups, consider physical security measures such as keeping media containing backups in a fire safe and at a remote secure location such as a second office or bank safety deposit box.

If changes have been made to system files, such as custom patches or code alterations, those changes must be backed up manually or with the backup package described in *Backup Files and Directories with the Backup Package*, as they will not be backed up or restored by the built-in backup system. This includes alterations to system files mentioned elsewhere in the documentation, such as `/boot/device.hints`, `/boot/loader.conf.local`, and others.

Note: Custom patches should be handled using the **System Patches** package, which is backed up with `config.xml`, rather than saving manually patched files.

In addition to making backups, **backups must also be tested**. Before placing a system into production, backup the configuration, wipe the disk, and then attempt some of the different restoration techniques in this chapter. The best practice is to periodically test backups on a non-production machine or virtual machine. The only thing worse than a missing backup is an unusable backup!

RRD graph data can optionally be held in the XML configuration file backup. This behavior is disabled by default due to the resulting size of the backup file. There are also other ways to ensure this data is backed up safely. See *Backup Files and Directories with the Backup Package* later in this chapter.

CHAPTER

ELEVEN

INTERFACE TYPES AND CONFIGURATION

11.1 WAN vs LAN Interfaces

pfSense® software treats interfaces differently based on whether or not they act as a WAN type interface (e.g. connection to an upstream network) or a LAN type interface (e.g. connection to an internal network). Most traditional interfaces will fall into one of the two categories, with VPN interfaces being more of a gray area.

Note: The NAT portions of this document only refer to IPv4 behavior, not IPv6.

11.1.1 Choosing between WAN and LAN Types

The **IPv4 Upstream Gateway** and **IPv6 Upstream Gateway** options on the *interface configuration* control whether the firewall considers an assigned interface as a WAN or LAN type interface.

If an interface has a gateway selected the firewall treats it as a WAN type interface. If an interface **does not** have a gateway selected the firewall treats as a LAN type interface.

There is no way to change the default behavior of dynamic interface types such as DHCP, PPP, and most assigned VPN interfaces. The GUI hides the gateway options on the interface configuration for these types of interfaces. The behavior of these interfaces is noted in the remainder of this document where relevant.

No matter how the firewall treats an interface by default the firewall behavior can almost always be adjusted through the use of options in the GUI.

11.1.2 WAN Type Interface

A WAN type interface is an interface through which the Internet can be reached, directly or indirectly. The firewall treats any interface with a gateway selected on its *interface configuration* as a WAN type interface. Dynamic IP address interfaces such as DHCP and PPP receive a dynamic gateway automatically and the firewall always considers them WAN interfaces.

For example, a static IP address WAN (e.g. **Interfaces > WAN**) would typically have a gateway selected such as *WAN_GW*. If this gateway selection is **not** present the firewall will treat the interface as a LAN type interface instead.

The firewall behavior changes in several ways for WAN type interfaces:

- The firewall performs outbound NAT on traffic **exiting** a WAN type interface when using *Automatic* or *Hybrid* outbound NAT modes.
- The firewall **will not** perform outbound NAT for traffic **originating** from the subnet(s) directly attached to a WAN type interface when using *Automatic* or *Hybrid* outbound NAT modes.

- The firewall includes a WAN type interface in the count of WAN interfaces for Multi-WAN features. Some functions are hidden unless the firewall has more than one WAN type interface.
- The firewall adds `reply-to` to firewall rules on a WAN type interface which returns packets for connections coming in through that WAN back out via the same WAN where possible.

Note: This behavior can be overridden on a per-rule basis using the option on firewall rules or it can be disabled globally on **System > Advanced**, **Firewall & NAT** tab.

- The firewall adds `route-to` to automatic firewall rules for outbound traffic on a WAN type interface which ensures outbound traffic on the interface is sent to the configured gateway.
- The traffic shaper wizard treats a WAN type interface as a WAN.
- The DNS Resolver will not allow queries from the subnet(s) on a WAN type interface without a manual ACL entry.

11.1.3 LAN Type Interface

A LAN type interface is an interface which connects to a local network, for example a LAN, DMZ, management network, guest network, and so on. Typically this also includes site-to-site links used to reach other local or internal networks, such as VPNs and private or dedicated circuits.

The firewall treats any assigned interface **without** a gateway selected on its *interface configuration* as a LAN type interface.

Warning: Do not select a gateway on the **Interfaces** menu entry for local interfaces such as LAN or for site-to-site VPNs.

Local and other interfaces may have a gateway defined under **System > Routing** so long as that gateway **is not** selected on its interface configuration.

The firewall behavior changes in several ways for LAN type interfaces:

- The firewall will perform outbound NAT for traffic **originating** from the subnet(s) directly attached to a LAN type interface when that traffic exits a WAN type interface and *Automatic* or *Hybrid* outbound NAT mode is active.
- If NAT reflection is active the firewall will create NAT reflection rules which allow clients on LAN type interfaces to access port forwards from behind the firewall.

Note: This behavior can be changed on a per-rule basis using the option on NAT rules or it can be controlled globally on **System > Advanced**, **Firewall & NAT** tab.

- The firewall **will not** perform outbound NAT on traffic **exiting** a LAN type interface when using *Automatic* or *Hybrid* outbound NAT mode.
- The firewall **does not** add `reply-to` or `route-to` to firewall rules on a LAN type interface.
- The traffic shaper wizard treats a LAN type interface as a LAN.
- The DNS Resolver automatically **allows** queries from the subnet(s) on a LAN type interface.

11.1.4 VPN Interfaces

Assigned IPsec VTI and OpenVPN interfaces are treated differently than traditional interfaces. Most, but not all, of these points also apply to assigned GRE and GIF tunnel interfaces.

VPNs have numerous use cases which are similar to both LAN and WAN type interfaces, and in some cases both. For example a VPN could be for site-to-site links, remote access for mobile clients, or for connecting to the Internet through a VPN provider. The default behavior of the firewall attempts to balance the most common user needs and expectations when handling assigned VPN interfaces.

Note: Currently WireGuard interfaces act similar to traditional interfaces when assigned, so their behavior primarily depends upon whether or not a gateway is selected in their interface configuration.

- The firewall treats an assigned VPN interface as a LAN type interface for NAT, which means that it lists the subnets on these interfaces as traffic sources for outbound NAT and it does not perform outbound NAT on traffic exiting these interfaces.

  In most cases a user does not expect the firewall to perform NAT on VPN traffic by default. Outbound NAT rules in *Hybrid* or *Manual* outbound NAT modes can make the firewall perform outbound NAT if a use case requires NAT.
- The firewall treats an assigned VPN interface as a WAN type interface for traffic shaping if a VPN interface is capable of using ALTQ traffic shaping.
- The firewall treats an assigned VPN interface as a WAN interface for firewall rule attributes such as `reply-to` and `route-to`. This ensures that traffic entering the firewall over a specific VPN connection returns back through the same VPN.
- The DNS Resolver treats an assigned VPN interface as a LAN interface and allows queries from subnet(s) configured on the VPN.

Note: Firewall features such as per-interface rules, NAT, and `reply-to` do not work with IPsec VTI interfaces by default. The **IPsec Filter Mode** setting can allow IPsec VTI interfaces to utilize these features. See *Advanced IPsec Settings*.

11.1.5 Verifying an Interface Type

There are a couple ways to confirm if the firewall is treating an interface as a WAN or a LAN.

The interface status page (**Status > Interfaces**) is useful for determining the interface type. For non-VPN interfaces the presence of the **Gateway IPv4** and/or **Gateway IPv6** attribute on an interface indicates that the firewall considers it as a WAN type interface.

The next easiest method is to check the outbound NAT settings at **Firewall > NAT**, **Outbound** tab. Check the **Automatic Rules** section if the mode is set to *Automatic* or *Hybrid*. WAN type interfaces will have rules in the list with their name in the **Interface** column. LAN type interfaces have their subnets listed in the **Source** column of each rule.

Note: If the outbound NAT mode is *Automatic* or *Hybrid* and there are **no** entries in the **Automatic Rules** list, that generally indicates that the firewall has either no WAN type interfaces or no LAN type interfaces. Check the gateway settings on each assigned interface and ensure that **all** WAN interfaces have a gateway selected and that **no** LAN interfaces have a gateway selected.

Another method is to start a traffic shaper wizard (**Firewall > Traffic Shaper**, **Wizards** tab) and step through until the wizard lists the interfaces. From there, check if an interface is present in either the LAN or WAN interface selection lists.

Note: This method will not work for interface types which do not support ALTQ traffic shaping.

11.2 Interface Configuration

To assign a new interface:

- Navigate to **Interfaces > Assignments**
- Pick the new interface from the **Available network ports** list
- Click  **Add**

The newly assigned interface will be shown in the list. The new interface will have a default name allocated by the firewall such as OPT1 or OPT2, with the number increasing based on its assignment order. The first two interfaces default to the names WAN and LAN but they can be renamed. These OPTx names appear under the **Interfaces** menu, such as **Interfaces > OPT1**. Selecting the menu option for the interface will open the configuration page for that interface.

11.2.1 General Configuration

The following options are available for all interface types.

Description
The name of the interface. Interface names may only contain letters, numbers and the only special character that is allowed is an underscore (_).

This changes the name of the interface on the **Interfaces** menu, on the tabs under **Firewall > Rules**, under **Services > DHCP**, and elsewhere throughout the GUI. Using a custom name makes it easier to remember the purpose of an interface and to identify an interface for adding firewall rules or choosing other per-interface functionality.

IPv4 Configuration Type
Configures the IPv4 settings for the interface. Details for this option are in the next section, *IPv4 Configuration Types*.

IPv6 Configuration Type
Configures the IPv6 settings for the interface. Details for this option are in *IPv6 Configuration Types*.

MAC address
The MAC address of an interface can be changed ("spoofed") to mimic a previous piece of equipment, depending on the type of interface.

> **Warning:** The best practice is to not force a specific MAC address. The old MAC address will generally be cleared out by resetting the equipment to which this firewall connects, or by clearing the ARP table, or waiting for the old ARP entries to expire. Changing the MAC address is a long-term solution to a temporary problem.

Spoofing the MAC address of the previous firewall can allow for a smooth transition from an old router to a new router, so that ARP caches on devices and upstream routers are not a concern. It can also be used to fool a piece of equipment into believing that it's talking to the same device that it was talking to before, as in cases where a certain network router is using static ARP or otherwise filters based on MAC address. This is common on cable modems, where they may require the MAC address to be registered if it changes.

Note: ARP cache problems tend to be very temporary, resolving automatically within minutes or by power cycling other equipment.

One downside to spoofing the MAC address is that unless the old piece of equipment is permanently retired, there is a risk of later having a MAC address conflict on the network, which can lead to connectivity problems.

If the old MAC address must be restored, this option must be emptied out and then the firewall *must* be rebooted. Alternately, enter the original MAC address of the network card and save/apply, then empty the value again.

MTU (Maximum Transmission Unit)
The Maximum Transmission Unit (**MTU**) size field can typically be left blank, but can be changed when required. Some situations may call for a lower MTU to ensure packets are sized appropriately for an Internet connection. In most cases, the default assumed values for the WAN connection type will work properly. It can be increased for those using jumbo frames on their network.

On a typical Ethernet style network, the default value is `1500`, but the actual value can vary depending on the interface configuration.

MSS (Maximum Segment Size)
Similar to the MTU field, the **MSS** field "clamps" the Maximum Segment Size (MSS) of TCP connections to the specified size in order to work around issues with Path MTU Discovery.

Speed and Duplex
The default value for link speed and duplex is to let the firewall decide what is best. That option typically defaults to *Autoselect*, which negotiates the best possible speed and duplex settings with the peer, typically a switch.

The speed and duplex setting on an interface must match the device to which it is connected. For example, when the firewall is set to *Autoselect*, the switch must also be configured for *Autoselect*. If the switch or other device has a specific speed and duplex forced, it must be matched by the firewall.

Switch Port
Netgate Appliances with an integrated switch have an option on this page which controls the link state for this interface by having it mirror the state of a switch port. In this way, a firewall interface configured as a VLAN which maps to a switch port can be set to follow the status of the physical switch port. Otherwise, since it is a VLAN attached to an internal uplink, the status would always show as up.

Consult the Netgate Product Manuals for more information on switch configuration.

11.2.2 Reserved Networks

Block Private Networks
When **Block private networks** is active, the firewall inserts a rule automatically which prevents any RFC 1918 networks (`10.0.0.0/8`, `172.16.0.0/12`, `192.168.0.0/16`) and loopback (`127.0.0.0/8`) from communicating on that interface.

This option is typically only desirable on WAN type interfaces to prevent the possibility of privately numbered traffic coming in over a public interface.

Block bogon networks
When **Block bogon networks** is active, the firewall will block traffic from a list of unallocated and reserved networks. This list is periodically updated by the firewall automatically.

> **Warning:** This option should only be used on external interfaces (WANs), it is not necessary on local interfaces and it can potentially block required local traffic.

See *Block Bogon Networks* for more details on how this feature works.

11.3 IPv4 Configuration Types

Once an interface has been assigned, in most cases it will require an IP address. For IPv4 connections, the following choices are available in the **IPv4 Configuration Type** selector on an interface page (e.g. **Interfaces > WAN**):

- None
- Static IPv4
- DHCP
- PPP
- PPPoE
- PPTP
- L2TP

Each of these is described in this document.

11.3.1 None

When **IPv4 Configuration Type** is set to *None*, IPv4 is disabled on the interface. This is useful if the interface has no IPv4 connectivity or if the IPv4 address on the interface is being managed in some other way, such as for a VPN or tunnel interface.

11.3.2 Static IPv4

With **Static IPv4**, the interface contains a manually configured IPv4 address. When chosen, three additional fields are available on the interface configuration screen:

IPv4 Address
The IPv4 address for the interface (e.g. `192.168.1.1`).

CIDR Subnet Mask
The CIDR Subnet Mask determines the size of the subnet to which the **IPv4 Address** belongs. This must match the value used by other hosts in the same subnet.

IPv4 Upstream Gateway
An upstream gateway for IPv4 traffic, if any. Selecting a gateway here will cause the firewall to treat this interface as a WAN-type interface for NAT and related functions. See *WAN vs LAN Interfaces* for more information.

> **Warning:** Do not set a gateway for internal interfaces such as a LAN or DMZ. Only select a gateway on externally-connected interfaces such as a WAN or a private site-to-site link which the firewall should consider a WAN.
>
> Gateways may still be used on internal interfaces for the purpose of static routes without selecting an **IPv4 Upstream Gateway** here.

The **IPv4 Upstream Gateway** field is pre-populated with existing IPv4 gateways defined under **System > Routing** (*Gateways*).

The  **Add a new gateway** button is a shortcut to create a new gateway if one does not already exist. Clicking that button displays a modal form to add the gateway without leaving this page. Fill in the details requested on the new form:

Default Gateway
If this is the only WAN or will be a new default WAN, check this box. The default IPv4 and IPv6 gateways work independently of one another. The two need not be on the same interface. Changing the default IPv4 gateway has no effect on the IPv6 gateway, and vice versa.

Gateway Name
The name used to refer to the gateway internally, as well as in places like Gateway Groups, quality graphs, and elsewhere.

Gateway IPv4
The IPv4 address of the gateway. This address must be inside the same subnet as the Static IPv4 address when using this form.

Description
A bit of text to indicate the purpose of the gateway.

11.3.3 DHCP

When an interface is set to **DHCP**, the operating system will attempt automatic IPv4 configuration of this interface via DHCP. This option also activates several additional fields on the page. Under most circumstances these additional fields may be left blank.

Hostname
Some ISPs require the **Hostname** for client identification. The value in the **Hostname** field is sent as the DHCP client identifier and hostname when requesting a DHCP lease.

Alias IPv4 Address
This value used as a fixed IPv4 alias address by the DHCP client since a typical IP Alias VIP cannot be used with DHCP. This can be useful for accessing a piece of gear on a separate, statically numbered network outside of the DHCP scope. One example would be for reaching a cable modem management IP address.

Reject Leases From
An IPv4 address for a DHCP server that should be ignored. For example, a cable modem that hands out private IP addresses when the cable sync has been lost. Enter the private IP address of the modem here, e.g. `192.168.100.1` and the firewall will never pick up or attempt to use an IP address supplied by the specified server.

DHCP VLAN Priority
Optionally sets a VLAN Priority tag (802.1p) on DHCP client traffic. Should only be enabled when required by an ISP and with the settings they provide.

Advanced Configuration
Enables options to control the protocol timing. In the vast majority of cases this must be left unchecked and the options inside unchanged.

Protocol Timing
The fields in this area give fine-grained control over the timing used by `dhclient` when managing an address on this interface. These options are almost always left at their default values. For more details on what each field controls, see the dhclient man page

Presets
Has several options for preset protocol timing values. These are useful as a starting point for custom adjustments or for use when the values need to be reset back to default values.

Configuration Override
Enables a field to use a custom `dhclient` configuration file. The full path must be given. Using a custom file is rarely needed, but some ISPs require DHCP fields or options that are not supported by the GUI.

11.3.4 PPP Types

The various PPP-based connection types such as PPP, PPPoE, PPTP, and L2TP are all covered in detail at *PPPs*. When one of these types is selected here on the interfaces screen, their basic options can be changed as described. To access the advanced options, follow the link on this page or navigate to **Interfaces > Assignments** on the **PPPs** tab, find the entry, and edit it there.

11.4 IPv6 Configuration Types

Similar to IPv4, the **IPv6 Configuration Type** controls if and how an IPv6 address is assigned to an interface. There are several different ways to configure IPv6 and the exact method depends on the network to which this firewall is connected and how the ISP has deployed IPv6.

> **Warning:** Every ISP is different and large providers can even vary by region.
>
> The ISP determines IPv6 settings for a circuit, and they are the only valid source for that information. As such, this documentation does not include examples for specific providers. Contact the ISP for information about their IPv6 client settings and requirements.
>
> The ISP should provide instructions and specific values for configuring IPv6 on their service. For example, on a circuit with a static IPv6 configuration the ISP should supply the subnet addresses and prefix values for the WAN itself, as well as for routed prefixes. Providers who require DHCPv6 should supply values for settings such as the prefix delegation size, along with any requirements they have for client behavior.

See also:

For more information on IPv6, including a basic introduction, see *IPv6*.

11.4.1 None

When **IPv6 Configuration Type** is set to *None*, IPv6 is disabled on the interface. This is useful if the interface has no IPv6 connectivity or if the IPv6 address on the interface is being managed in some other way, such as for a VPN or tunnel interface.

11.4.2 Static IPv6

The Static IPv6 controls work identically to the Static IPv4 settings. See *Static IPv4* for details.

With **Static IPv6**, the interface contains a manually configured IPv6 address. When chosen, three additional fields are available on the interface configuration screen: **IPv6 Address**, a prefix length selector, and the **IPv6 Upstream Gateway** field.

Note: Do not set a gateway for internal interfaces such as a LAN or DMZ. Only select a gateway on externally-connected interfaces such as a WAN or a private site-to-site link which the firewall should consider a WAN.

Gateways may still be used on internal interfaces for the purpose of static routes without selecting an **IPv6 Upstream Gateway** here.

See *WAN vs LAN Interfaces* for more information.

The default IPv4 and IPv6 gateways work independently of one another. The two need not be on the same interface. Changing the default IPv4 gateway has no effect on the IPv6 gateway, and vice versa.

11.4.3 DHCP6

DHCP6 configures automatic IPv6 configuration of this interface via DHCPv6. DHCPv6 will configure the interface with an IPv6 address, prefix length, DNS servers, etc. but not a gateway. The gateway is obtained via router advertisements, so this interface will be set to accept router advertisements. This is a design choice as part of the IPv6 specification, not a limitation of this implementation. For more information on router advertisements, see *Router Advertisements*.

Several additional fields are available for IPv6 DHCP that do not exist for IPv4 DHCP:

Use IPv4 Connectivity as Parent Interface
When set, the IPv6 DHCP request is sent using IPv4 on this interface, rather than using native IPv6. This is only required in special cases when the ISP requires this type of configuration.

Request only an IPv6 Prefix
When set, the DHCPv6 client does not request an address for the interface itself, it only requests a delegated prefix.

DHCPv6 Prefix Delegation Size
If the ISP supplies a routed IPv6 network via prefix delegation, they will publish the delegation size, which can be selected here. It is typically a value somewhere between *48* and *64*. For more information on how DHCPv6 prefix delegation works, see *DHCP6 Prefix Delegation*.

Note: To use this delegation, another internal interface must be set to an **IPv6 Configuration Type** of *Track Interface* (*Track Interface*) so that it can use the addresses delegated by the upstream DHCPv6 server.

Send IPv6 Prefix Hint
When set, the **DHCPv6 Prefix Delegation Size** is sent along with the request to inform the upstream server how large of a delegation is desired by this firewall. If an ISP allows the choice, and the chosen size is within their allowed range, the requested size will be given instead of the default size.

Debug
When set, the DHCPv6 client is started in debug mode.

Do not wait for a RA
Informs the operating system not to wait for a router advertisement when configuring the interface. This is required by some ISPs.

Do not allow PD/Address release
Prevents the operating system from sending a DHCPv6 release message on exit.

Some ISPs will release the allocated address or prefix when a client sends this message. With this option set, the client is more likely to receive the same allocation with subsequent requests.

DHCPv6 VLAN Priority
Optionally sets a VLAN Priority tag (802.1p) on DHCPv6 client traffic. Should only be enabled when required by an ISP and with the settings they provide.

Advanced Configuration
Enables a wide array of advanced tuning parameters for the DHCPv6 client. These options are rarely used, and when they are required, the values are dictated by the ISP or network administrator. See the dhcp6c.conf man page for details.

Configuration Override
Enables a field to use a custom configuration file. The full path must be given. Using a custom file is rarely needed, but some ISPs require DHCP fields or options that are not supported in the pfSense GUI.

11.4.4 SLAAC

Stateless address autoconfiguration (*SLAAC*) as the IPv6 type makes the operating system attempt to configure the IPv6 address for the interface from router advertisements (RA) that advertise the prefix and related information.

Note: DNS is not typically provided via RA, so the firewall will still attempt to get DNS servers via DHCPv6 when using SLAAC. The RDNSS extensions to the RA process may allow DNS servers to be obtained from RA in some cases. For more information on router advertisements, see *Router Advertisements*.

This selection has one additional option:

Use IPv4 connectivity as parent interface
When set, IPv6 requests are sent over the IPv4 connectivity layer used by this interface (e.g. PPPoE) rather than the parent interface directly. May be required by certain ISPs.

11.4.5 6RD Tunnel

6RD is an IPv6 tunneling technology employed by ISPs to quickly enable IPv6 support for their networks, passing IPv6 traffic inside specially crafted IPv4 packets between and end user router and the ISP relay. It is related to 6to4 but is intended to be used within the ISP network, using the IPv6 addresses from the ISP for client traffic. To use 6RD, the ISP must supply three pieces of information: The 6RD prefix, the 6RD Border Relay, and the 6RD IPv4 Prefix length.

6RD Prefix
The 6RD IPv6 prefix assigned by the ISP, such as `2001:db8::/32`.

6RD Border Relay
The IPv4 address of the ISP 6RD relay.

6RD IPv4 Prefix Length
Controls how much of the end user IPv4 address is encoded inside of the 6RD prefix. This is normally supplied by the ISP. A value of `0` means the entire IPv4 address will be embedded inside the 6RD prefix. This value allows ISPs to effectively route more IPv6 addresses to customers by removing redundant IPv4 information if an ISP allocation is entirely within the same larger subnet.

11.4.6 6to4 Tunnel

Similar to 6RD, *6to4* is another method of tunneling IPv6 traffic inside IPv4. Unlike 6RD, however, 6to4 uses constant prefixes and relays. As such there are no user-adjustable settings for using the *6to4* option. The 6to4 prefix is always `2002::/16`. Any address inside of the `2002::/16` prefix is considered a 6to4 address rather than a native IPv6 address. Also unlike 6RD, a 6to4 tunnel can be terminated anywhere on the Internet, not only at the end user ISP, so the quality of the connection between the user and the 6to4 relay can vary widely.

6to4 tunnels are always terminated at the IPv4 address of `192.88.99.1`. This IPv4 address is anycasted, meaning that although the IPv4 address is the same everywhere, it can be routed regionally toward a node close to the user.

Another deficiency of 6to4 is that it relies upon other routers to relay traffic between the 6to4 network and the remainder of the IPv6 network. There is a possibility that some IPv6 peers may not have connectivity to the 6to4 network, and thus these would be unreachable by clients connecting to 6to4 relays, and this could also vary depending upon the 6to4 node to which the user is actually connected.

11.4.7 Track Interface

The *Track Interface* choice works in concert with another IPv6 interface using DHCPv6 Prefix Delegation. When a delegation is received from the ISP, this option designates which interface will be assigned the IPv6 addresses delegated by the ISP and in cases where a larger delegation is obtained, which prefix inside the delegation is used.

IPv6 Interface
A list of all interfaces on the system currently set for dynamic IPv6 WAN types offering prefix delegation (DHCPv6, PPPoE, 6rd, etc.). Select the interface from the list which will receive the delegated subnet information from the ISP.

IPv6 Prefix ID
If the ISP has delegated more than one prefix via DHCPv6, the IPv6 Prefix ID controls which of the delegated `/64` subnets will be used on this interface. This value is specified in hexadecimal.

For example, If a `/60` delegation is supplied by the ISP that means 16 `/64` networks are available, so prefix IDs from `0` through `f` may be used.

For more information on how prefix delegation works, see *DHCP6 Prefix Delegation*.

11.5 Interface Groups

Unlike the other interfaces in this chapter, an **Interface Group** is not a type of interface that can be assigned. Interface groups are used to apply firewall or NAT rules to a set of interfaces on a common tab. If this concept is unfamiliar, consider how the firewall rules for OpenVPN, the PPPoE server, or L2TP server work. There are multiple interfaces in the underlying OS, but the rules for all of them are managed on a single tab for each type.

If many interfaces of a similar function are present on the firewall that need practically identical rules, an interface group may be created to add rules to all of the interfaces at the same time. Interfaces can still have their own individual rules, which are processed after the group rules.

11.5.1 Interface Group Options

When creating or editing an Interface Group, the following options are available:

Group Name
The name of the interface group. Has the same restrictions as the name of an interface. The name may only contain upper and lowercase letters, no numbers, spaces, or special characters.

Group Description
An optional text description for reference.

Group Members
A multi-select list of assigned interfaces on the firewall from which group members can be added. Add interfaces to the group by selecting them with ctrl-click (PC) or cmd-click (MAC).

11.5.2 Creating an Interface Group

To create an interface group:

- Navigate to **Interfaces > Assignments**, **Interface Groups** tab
- Click  **Add** to create a new group
- Fill in the options as described in *Interface Group Options*
- Click **Save**

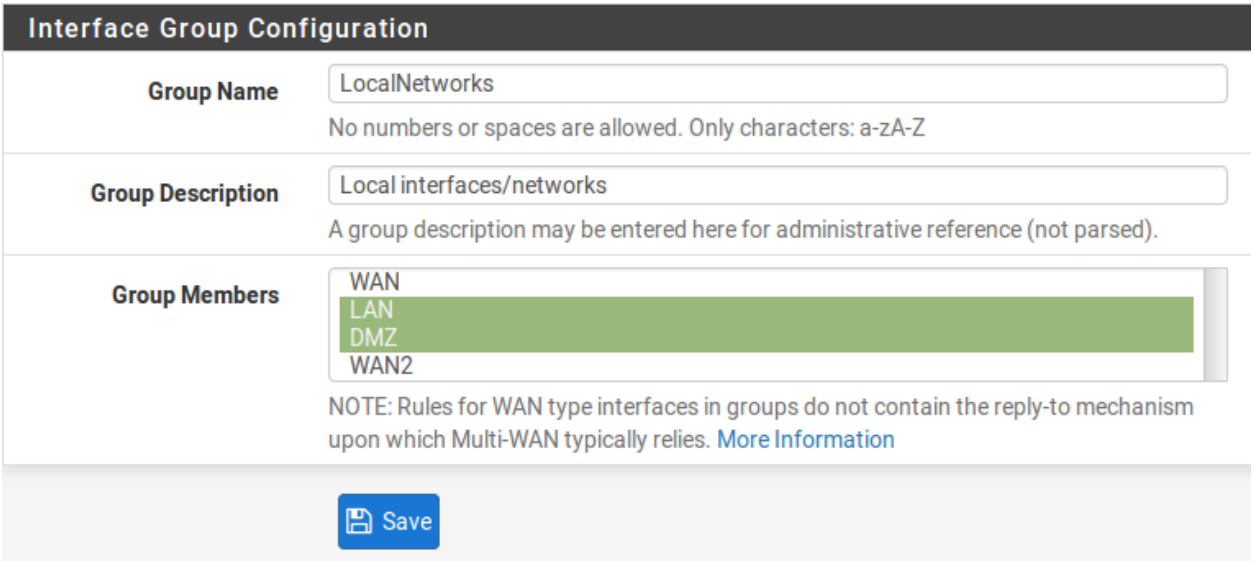

Fig. 1: Add Interface Group

11.5.3 Using an Interface Group

Interface groups each have an individual tab under **Firewall > Rules** to manage their rules. Figure *Interface Group Firewall Rules Tab* shows the firewall rule tab for the group defined in figure *Add Interface Group*

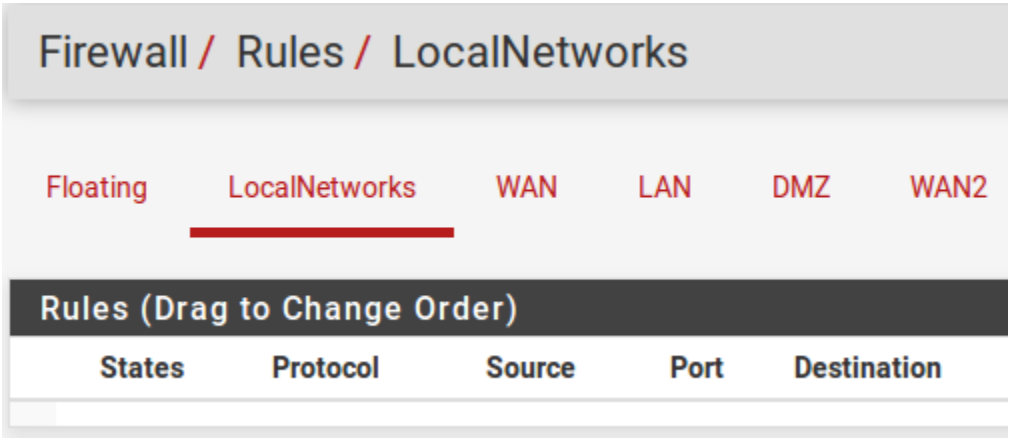

Fig. 2: Interface Group Firewall Rules Tab

See also:

Configuring Firewall Rules for information on managing firewall rules.

11.5.4 Group Rule Processing Order

The rule processing order for user rules is:

- Floating rules
- Interface group rules
- Rules on the interface directly

For example, if a rule on the group tab matches a connection, the interface tab rules will not be consulted. Similarly, if a floating rule with **Quick** set matched a connection, the interface group rules will not be consulted.

The processing order prevents some combination of rules that otherwise might be a good fit. For example, if a general blocking rule is present on the group, it cannot be overriden by a rule on a specific interface. Same with a pass rule, a specific interface rule cannot block traffic passed on a group tab rule.

11.5.5 Use with WAN Interfaces

The best practice is to not use interface groups with multiple WANs. Doing so may appear to be convenient, but the group rules do not receive the same treatment as actual WAN tab rules. For example, rules on a tab for a WAN-type interface will receive `reply-to` which allows pf to return traffic back via the interface from which it entered. Group tab rules do not receive `reply-to` which effectively means that the group rules only function as expected on the WAN with the default gateway.

11.6 PPPs

There are four types of PPP interfaces:

- **PPP** for cellular and modem devices
- **PPPoE** for DSL or similar connections
- **PPTP** and **L2TP** for ISPs that require them for authentication

In most cases these are managed by the interface settings directly, but the settings are also available under **Interfaces > Assignments** on the **PPPs** tab.

See also:

- *PPP Logs*

11.6.1 Multi-Link PPP (MLPPP)

Multi-Link PPP (MLPPP) is available for any type of PPP instance by selecting multiple **Link Interface** entries at the same time.

> **Warning:** MLPPP only works on multiple circuits from the same provider where the provider supports MLPPP.
>
> MLPPP is not compatible with the `if_pppoe` backend for PPPoE WANs (*Use if_pppoe Kernel Module*).

MLPPP bonds multiple PPP links into a single larger aggregate channel. Unlike other multi-WAN techniques MLPPP can utilize the full bandwidth of all links for a single connection. MLPPP also does not have the usual concerns about load balancing and failover. The MLPPP link is presented as one interface with one IP address. If one link fails the connection functions the same but with reduced capacity.

For more information on MLPPP, see *Multiple WAN Connections*.

11.6.2 PPP (Point-to-Point Protocol) Interface Types

Add or edit a PPP entry as follows:

- Navigate to **Interfaces > Assignments** on the **PPPs** tab
- Click  to edit an existing entry or  to add a new entry
- Set the **Link Type**

The **Link Type** determines the remaining options on the page. The available link types are explained throughout the remainder of this document.

PPP (Cellular Modem)

The **PPP** link type is used for talking to a modem over a serial device. This can be anything from a USB modem dongle for accessing a cellular network down to an old hardware modem for dial-up access.

Note: Some cellular modems appear as Ethernet devices and not serial devices. Those are configured as regular interfaces, not as PPP devices.

See also:

- *Cellular Wireless*

When configuring a PPP device, the following options are available:

Link Interface
A list of serial devices that the firewall can use to communicate with a modem. Click on a specific entry to select it for use by the firewall.

Note: The firewall does not automatically detect the serial device for a modem. Some modems present themselves as several devices and the subdevice for the PPP line may be any of the available choices. Start with the last device, then try the first, and then others in between if none of those function.

Description
A text description of this PPP instance, for reference (e.g. `VZW Modem`).

Country
The country in which this modem resides (e.g. *United States*).

The firewall populates the **Provider** list based on the value of this field.

Provider
The cellular service provider for this modem (e.g. *Verizon*).

The firewall populates the **Plan** list based on the value of this field.

Plan
The type of cellular service this modem uses from **Provider**.

This populates the remaining fields where possible with values specific to the **Plan**.

The remaining options can be configured manually if other values are needed, or when using an unlisted provider:

Username and Password
The credentials used for the PPP login, if any.

Phone Number
The number to dial at the ISP to gain access. For cellular providers this tends to be a number such as `*99#` or `#777`. For dial-up this is usually a traditional telephone phone number.

Access Point Name (APN)
Some ISPs require this value to identify the service to which the client connects. Some providers use this to distinguish between consumer and business plans or legacy networks.

APN Number
Optional setting. Defaults to `1` if the APN is set, and ignored when APN is unset.

SIM PIN
Security code on the SIM to prevent unauthorized use of the card.

> **Warning:** Do not enter anything here if the SIM does not have a PIN.

SIM PIN Wait
Number of seconds the firewall will wait for the SIM to discover network after the PIN is sent to the SIM. If the delay is not long enough the SIM may not have time to initialize properly after unlocking.

Init String
The modem initialization string, if necessary. Most modern modems do not require a custom initialization string.

Note: Do not include `AT` at the beginning of the command.

Connection Timeout
Time the firewall will wait for a connection attempt to succeed, in seconds. Default is `45` seconds.

Uptime Logging
When checked, the firewall tracks the uptime for the connection and displays it on **Status > Interfaces**.

PPPoE (Point-to-Point Protocol over Ethernet)

PPPoE is a popular method of authenticating and gaining access to an ISP network. It is commonly found on DSL and some fiber networks in certain regions, but may also be used on other link types.

Tip: For the best performance on PPPoE WANs, use the kernel-based `if_pppoe` backend. For details, see *Use if_pppoe Kernel Module*.

Due to limitations in the way PPPoE frames are processed by network cards when using MPD, incoming PPPoE traffic is limited to a single network interface queue. As such, performance may be limited or otherwise lower than expected. See *PPPoE with Multi-Queue NICs* for details.

To configure a PPPoE link, start by setting **Link Type** to *PPPoE* and complete the remainder of the settings as follows:

Link Interface(s)
A list of network interfaces the firewall can use for PPPoE. These are typically physical interfaces but PPPoE can also work over some other interface types such as VLANs. Select one entry for normal PPPoE or multiple entries for MLPPP.

Description
An optional text description of the PPP entry.

Username and Password
The credentials for this PPPoE connection. The credentials will be provided by the ISP and the username is typically in the form of an e-mail address, such as `mycompany@ispexample.com`.

Service Name
Left blank for most ISPs but some ISPs require this to be set to a specific value.

Contact the ISP to confirm the value if the connection does not function when left blank.

Configure NULL Service Name
Some ISPs require clients to send a `NULL` value instead of a blank service name. Check this option when the ISP requires this behavior.

Periodic Reset
Configures a pre-set time when the firewall will drop the connection and reconnect. This is rarely needed, but in certain cases it can better handle reconnections when an ISP has forced daily reconnections or similar quirky behavior.

PPTP (Point-to-Point Tunneling Protocol)

Not to be confused with a PPTP VPN, this type of PPTP interface is meant to connect to an ISP and authenticate, much the same as PPPoE. The options for a PPTP WAN are identical to the PPPoE options of the same name. Refer to the previous section for configuration information.

L2TP (Layer 2 Tunneling Protocol)

L2TP, as it is configured here, is used for connecting to an ISP that requires it for authentication as a type of WAN. L2TP works nearly identically to PPTP. Refer to the previous sections for configuration information.

L2TP has one additional option not found on other types:

Shared Secret
A shared secret the firewall will use to authenticate the tunnel connection and encrypt control L2TP control packets. May be left blank if the server does not support a shared secret.

> **Warning:** This **must** match the shared secret set on the L2TP server.

11.6.3 Advanced PPP Options

All PPP types have several advanced options in common. In most cases these settings can remain at their default values.

Click  **Display Advanced** to display these options.

Dial On Demand
The default behavior for a PPP link is to immediately connect and immediately attempt to reconnect when a link is lost. This behavior is described as **Always On**. **Dial-on-Demand** delays this connection attempt. When set, the firewall waits until a packet attempts to leave the via this interface to make a connection attempt. Once the firewall connects it will not automatically disconnect.

Idle Timeout
The firewall will hold a PPP connection open indefinitely by default. A value in **Idle Timeout**, specified in seconds, will cause the firewall to monitor the line for activity. If there is no traffic on the link for the given amount of time, the firewall will disconnect the link. If **Dial-on-Demand** has also been set, the firewall will return to dial-on-demand mode.

Note: The firewall performs gateway monitoring by default which generates two ICMP pings per second on the interface. **Idle Timeout** will not function in this case. This can be worked around by editing the gateway for this PPP link and checking **Disable Gateway Monitoring**.

Compression (vjcomp)
This option controls whether or not the firewall will use Van Jacobson TCP header compression for this connection. By default the firewall will negotiate this with the peer during login and enable it if both sides support the feature. Checking **Disable vjcomp** will disable support for this feature. This feature is beneficial because it saves several bytes per TCP data packet when possible. The best practice is to keep the option enabled unless the remote requires it to be disabled.

Note: This compression is ineffective for TCP connections with enabled modern extensions like time stamping or SACK, which modify TCP options between sequential packets.

TCP MSS Fix
This option causes the PPP daemon to adjust incoming and outgoing TCP SYN segments so that the requested maximum segment size (MSS) is not greater than the amount allowed by the interface MTU.

This is necessary in most cases to avoid problems caused by routers which drop ICMP "Datagram Too Big" messages. Without these messages, peers cannot detect a when packets attempt to cross a link which cannot carry frames of the required size. Consider this scenario. The originating machine sends data which passes a rogue router then arrives at a host that has an MTU that is not big enough for the data. Because the IP "Don't Fragment" option is set, this machine sends an ICMP "Datagram Too Big" message back to the originator and drops the packet. The rogue router drops the ICMP message and the originator never gets to discover that it must reduce the fragment size or drop the IP "Don't Fragment" option from its outgoing data. If this behavior is undesirable, check **Disable tcpmssfix**.

Note: The MTU and MSS values for the interface may also be adjusted on the configuration page for the interface under the **Interfaces** menu, such as **Interfaces > WAN** (*Interface Configuration*).

Short Sequence (ShortSeq)

This option is only meaningful when the firewall is negotiating MLPPP with the provider. It proscribes shorter multi-link fragment headers, saving two bytes on every frame. It is not necessary to disable this for connections that are not multi-link. If MLPPP is active and this feature must be disabled, check **Disable shortseq**.

Address Control Field Compression (ACFComp)
This option only applies to asynchronous link types. It saves two bytes per frame. To disable this, check **Disable ACF Compression**.

Protocol Field Compression (ProtoComp)
This option saves one byte per frame for most frames. To disable this, check **Disable Protocol Compression**.

PPPoE has two additional advanced options:

Multilink over single link
When set, the firewall will use LCP multi-link extensions over a single link. This ignores the MTU/MRU settings. Only enable if supported by the ISP.

Force MTU
When set, overrides the MTU negotiated with the ISP with a higher value known to work on the link.

> **Warning:** This option violates RFC 1661 and can break connectivity. While it may result in faster speed as larger packets can be transferred, there is no guarantee that it will function in the future if the provider makes changes.

11.7 GRE (Generic Routing Encapsulation)

Generic Routing Encapsulation (GRE) is a method of tunneling traffic between two endpoints without encryption. It can be used to route packets between two locations that are not directly connected, which do not require encryption. It can also be combined with a method of encryption that does not perform its own tunneling.

Note: The GRE protocol was originally designed by Cisco, and it is the default tunneling mode on many of their devices.

GRE tunnels can carry either IPv4, IPv6, or both types of traffic at the same time.

11.7.1 GRE Interface Settings

Parent interface
The interface upon which the GRE tunnel will terminate. Often this will be WAN or a WAN-type connection.

Remote Address
The address of the remote peer. This is the address where the GRE packets will be sent by this firewall; The routable external address at the other end of the tunnel.

Local IPv4/IPv6 Tunnel Address
The **internal** IPv4 and IPv6 address for the end of the tunnel on this firewall. The firewall will use this address for its own traffic in the tunnel, and tunneled remote traffic would be sent to this address by the remote peer.

Remote IPv4/IPv6 Tunnel Address
The IPv4 and IPv6 address used by the firewall **inside** the tunnel to reach the far side. Traffic destined for the other end of the tunnel must use this address as a gateway for routing purposes.

IPv4/IPv6 Tunnel Subnet
The subnet mask for the GRE interface address.

Add Static Route
When set, the firewall adds an explicit static route for the remote inner tunnel address/subnet via the local tunnel address. This can help with reaching the remote subnet in cases where other route table entries may select the wrong path to that destination.

Description
A short description of this GRE tunnel for documentation purposes.

11.7.2 GRE Interface Management

To create or manage a GRE interface:

- Navigate to **Interfaces > Assignments**, **GRE** tab

Note: The items in this list are managed in the usual way. See *Managing Lists in the GUI*.

- Click  **Add** to create a new GRE instance
- Complete the settings as described in *GRE Interface Settings*
- Click **Save**
- Navigate to **Interfaces > Assignments**
- Select the new GRE interface in the **Available network ports** list
- Click  **Add**
- Note the name given to the new interface (e.g. OPT1)
- Navigate to **Interfaces > <name>** where <name> corresponds to the name of the GRE interface (e.g. OPT1)
- Check **Enable interface**
- Enter a new name for the interface in **Description** (optional)
- Click **Save**

Then use the interface as any other WAN-type interface. The firewall automatically creates a dynamic gateway for routing purposes. Depending on the use case, the interface may need NAT or firewall rules, static routes, and so on.

11.8 GIF (Generic tunnel InterFace)

A Generic Tunneling Interface (GIF) is similar to *GRE*; Both protocols are a means to tunnel traffic between two hosts without encryption. In addition to tunneling IPv4 or IPv6 directly, GIF may be used to tunnel IPv6 over IPv4 networks and vice versa. GIF tunnels are commonly used to obtain IPv6 connectivity to a tunnel broker such as Hurricane Electric in locations where IPv6 connectivity is unavailable.

See also:

See *Configuring IPv6 Through A Tunnel Broker Service* for information about connecting to a tunnel broker service.

GIF interfaces carry more information across the tunnel than can be done with GRE, but GIF is not as widely supported. For example, a GIF tunnel is capable of bridging layer 2 between two locations while GRE cannot.

GIF interfaces can carry IPv4 or IPv6 traffic, but not both at the same time.

Note: Support for GIF varies by vendor, but is not as common as others like GRE.

11.8.1 GIF Interface Settings

Parent interface
The interface upon which the GIF tunnel will terminate. Often this will be WAN or a WAN-type connection.

GIF Remote Address
The address of the remote peer. This is the address where the GIF packets will be sent by this firewall; The routable external address at the other end of the tunnel. For example, in a IPv6-in-IPv4 tunnel to Hurricane Electric, this would be the **IPv4 address** of the tunnel server, such as `209.51.181.2`.

GIF tunnel local address
The **internal address** for the end of the tunnel on this firewall. The firewall will use this address for its own traffic in the tunnel, and tunneled remote traffic would be sent to this address by the remote peer. For example, when tunneling IPv6-in-IPv4 via Hurricane Electric, they refer to this as the **Client IPv6 Address**.

GIF tunnel remote address
The address used by the firewall **inside** the tunnel to reach the far side. Traffic destined for the other end of the tunnel must use this address as a gateway for routing purposes. For example, when tunneling IPv6-in-IPv4 via Hurricane Electric, they refer to this as the **Server IPv6 Address**.

GIF Tunnel Subnet
The subnet mask or prefix length for the interface address. Typically `64`. This option is ignored with IPv6 and a `128` prefix is enforced by the kernel instead.

ECN Friendly Behavior
The ECN friendly behavior option controls whether or not the Explicit Congestion Notification (ECN)-friendly practice of copying the TOS bit into/out of the tunnel traffic is performed by the firewall. By default the firewall clears the TOS bit on the packets or sets it to `0`, depending on the direction of the traffic. With this option set, the bit is copied as needed between the inner and outer packets to be more friendly with intermediate routers that can perform traffic shaping. This behavior breaks RFC 2893 so it must only be used when both peers agree to enable the option.

Outer Source Filtering
When set, the firewall will not automatic filter based on the outer GIF source. This is normally desirable as it ensures a match with the configured remote peer, which is more secure. When disabled,

martian and inbound filtering is not performed which allows asymmetric routing of the outer traffic. This is less secure, but some GIF peers may source traffic in this manner.

Description
A short description of this GIF tunnel for documentation purposes.

11.8.2 GIF Interface Configuration

To create or manage a GIF interface:

- Navigate to **Interfaces > Assignments**, **GIF** tab

Note: The items in this list are managed in the usual way. See *Managing Lists in the GUI*.

- Click  **Add** to create a new GIF instance
- Complete the settings as described in *GIF Interface Settings*
- Click **Save**
- Navigate to **Interfaces > Assignments**
- Select the new GIF interface in the **Available network ports** list
- Click  **Add**
- Note the name given to the new interface (e.g. OPT1)
- Navigate to **Interfaces > <name>** where <name> corresponds to the name of the GIF interface (e.g. OPT1)
- Check **Enable interface**
- Enter a new name for the interface in **Description** (optional)
- Click **Save**

Then use the interface as any other WAN-type interface. The firewall automatically creates a dynamic gateway for routing purposes. Depending on the use case, the interface may need NAT or firewall rules, static routes, and so on.

11.9 LAGG (Link Aggregation)

Link aggregation is handled by `lagg(4)` type interfaces (LAGG) on pfSense® software. LAGG combines multiple physical interfaces together as one logical interface. There are several ways this can work, either for gaining extra bandwidth, redundancy, or some combination of the two.

Note: LACP will only work across multiple switches if the switches are Stackable.

11.9.1 LAGG Interface Settings

When creating or editing a LAGG interface, the following settings are available:

Parent Interfaces
This list contains all currently unassigned interfaces, plus members of the current LAGG interface when editing an existing instance.

To add interfaces to this LAGG, select one or more interfaces in this list.

Note: An interface may only be added to a LAGG group if it is not assigned. If an interface is not present in the list, it is likely already assigned as an interface.

LAGG Protocol
The operating modes for LAGG interfaces are: LACP, Failover, Load Balance, Round Robin, and None.

LACP
The most commonly used LAGG protocol. This mode supports IEEE 802.3ad Link Aggregation Control Protocol (LACP) and the Marker Protocol. In LACP mode, negotiation is performed with the switch – which must also support LACP – to form a group of ports that are all active at the same time. This is known as a Link Aggregation Group, or LAG. The speed and MTU of each port in a LAG must be identical and the ports must also run at full- duplex. If link is lost to a port on the LAG, the LAG continues to function but at reduced capacity. In this way, an LACP LAGG bundle can gain both redundancy and increased bandwidth.

Traffic is balanced between all ports using the selected **Hash Algorithm**.

In addition to configuring this option on the firewall, the switch must enable LACP on these ports or have the ports bundled into a LAG group. Both sides must agree on the configuration in order for it to work properly.

LACP Timeout Mode controls how often the firewall sends LACP PDUs. An LACP timeout occurs when three consecutive PDUs are missed.

Slow
Default. LACP PDUs are sent every `30` seconds. A timeout occurs after `90` seconds.

Fast
LACP PDUs are sent every second. A timeout occurs after `3` seconds.

Failover
When using the Failover LAGG protocol traffic will only be sent on the *primary* interface of the group. If the primary interface fails, then traffic will use the next available interface.

Note: By default, traffic may only be received by the active interface. Create a system tunable for `net.link.lagg.failover_rx_all` with a value of `1` to allow traffic to be received on every member interface.

Failover mode has one additional option:

Failover Primary Interface
This option sets the primary interface for failover mode, or **auto** to allow the

firewall to select the primary interface automatically. In auto mode, the first selected interface in the list is primary.

Each non-primary interface is eligible for use in failover if the primary fails.

Load Balance
Load Balance mode accepts inbound traffic on any port of the LAGG group and balances outgoing traffic on any active ports in the LAGG group. It is a static setup that does not monitor the link state nor does it negotiate with the switch. Outbound traffic is load balanced based on all active ports in the LAGG using the chosen **Hash Algorithm**.

Round Robin
This mode accepts inbound traffic on any port of the LAGG group and sends outbound traffic using a round robin scheduling algorithm. Typically this means that traffic will be sent out in sequence, using each interface in the group in turn.

None
This mode disables traffic on the LAGG interface without disabling the interface itself. The OS will still believe the interface is up and usable, but no traffic will be sent or received on the group.

Hash Algorithm
The *LACP* and *Load Balance* protocols choose how to balance traffic between their interfaces when transmitting data using details from packets checked against the chosen **Hash Algorithm**.

Note: This can only affect traffic transmitted from this system, it has no influence over how the peer sends data or how data received from the peer is processed by the LAGG. That behavior must be configured on the peer.

For a packet to egress via a different interface, it must differ in some way from other packets. This option allows the user to choose which packet properties are checked when differentiating between packets for determining the egress interface.

The options are based on combinations of properties on different *Layers of the OSI model*:

Layer 2
Source/Destination MAC Address and optional VLAN number.

Layer 3
Source/Destination IPv4/IPv6 Address.

Layer 4
Source/Destination port.

When the selected **Hash Algorithm** includes a given layer, packets are checked for any difference in values at that layer.

The default `Layer 2/3/4` selection means that any difference in the VLAN, MAC address, source or destination IP address, or source/destination port on a packet is eligible to flow out a different interface.

Note: In some equipment the default is Layer 2 only meaning that any traffic for a single MAC address would only utilize one interface, which primarily affects links between routers, essentially turning them into failover only LAGGs. If possible, choose additional layers for the hash algorithm to better balance the load.

Description
A short note about the purpose of this LAGG instance.

11.9.2 LAGG Interface Configuration

To create or manage LAGG interfaces:

- Navigate to **Interfaces > Assignments**, **LAGGs** tab
- Click  **Add** to create a new LAGG, or click  to edit an existing instance.
- Complete the settings as described in *LAGG Interface Settings*
- Click **Save**

After creating a LAGG interface, it works like any other physical interface. Assign the lagg interface under **Interfaces > Assignments** and give it an IP address, or build other things on top of it such as VLANs.

Note: If the only purpose of the LAGG interface is to carry VLANs, it does not need to be assigned.

11.9.3 LAGG and Traffic Shaping

Due to limitations in FreeBSD, `lagg(4)` does not support `altq(4)` so it is not possible to use the traffic shaper on LAGG interfaces directly. `vlan(4)` interfaces support `altq(4)` and VLANs can be used on top of LAGG interfaces, so using VLANs can work around the problem. As an alternate workaround, Limiters can control bandwidth usage on LAGG interfaces.

11.9.4 LAGG Throughput

Using a LAGG does not necessarily guarantee full throughput equal to the sum of all interfaces. In particular, a single flow will not exceed the throughput of a LAGG member interface. Traffic on a LAGG is hashed in such a way that flows between two hosts, such as this firewall and an upstream gateway, would only use a single link since the flow is between a single MAC address on each side.

In networks where many hosts communicate with different MAC addresses, the usage can approach the sum of all interfaces in the LAGG.

11.10 QinQ Configuration

QinQ, also known as IEEE 802.1ad or stacked VLANs, is a means of nesting VLAN tagged traffic inside of packets that are already VLAN tagged, or "double tagging" the traffic.

See also:

- *Virtual LANs (VLANs)*

QinQ is used to move groups of VLANs over a single link containing one outer tag, as can be found on some links between locations from ISPs or datacenters. QinQ can be a quick and easy way of trunking VLANs across locations without having a trunking-capable connection between the sites, provided the infrastructure between the locations does not strip tags from the packets.

11.10.1 QinQ Interface Settings

When creating or editing a QinQ interface entry, the following options are available:

Parent Interface
The interface that will carry the QinQ traffic.

First level tag
The outer VLAN ID on the QinQ interface, or the VLAN ID given by the provider for the site-to-site link.

Adds interface to QinQ interface groups
When checked, a new interface group will be created called **QinQ** that can be used to filter all of the QinQ subinterfaces at once.

When hundreds or potentially thousands of QinQ tags are present, this greatly reduces the amount of work needed to use the QinQ interfaces

Description
Optional text for reference, used to identify the entry

Member(s)
Member VLAN IDs for QinQ tagging. These can be entered one per row or in ranges such as `100-150`.

Click **Add Tag** to add another line for more tags or ranges.

11.10.2 QinQ Interface Configuration

Setting up QinQ interfaces is fairly simple:

- Navigate to **Interfaces > Assignments**
- Click the **QinQ** tab
- Click **Add** to add a new QinQ entry
- Configure the QinQ entry as described in *QinQ Interface Settings*
- Click **Save** to complete the interface

11.10.3 QinQ Example

In the following example (Figure *QinQ Basic Example*), a QinQ interface is configured to carry tagged traffic for VLANs `10` and `20` across the link on `igb3` with a first level tag of `2000`.

In Figure *QinQ List*, this entry is shown on the QinQ tab summary list.

The automatic interface group, shown in Figure *QinQ Interface Group*, must not be manually edited. Because these interfaces are not assigned, it is not possible to make alterations to the group without breaking it. To re-create the group, delete it from this list and then edit and save the QinQ instance again to add it back.

Rules may be added to the **QinQ** tab under **Firewall > Rules** to pass traffic in both directions across the QinQ links.

From here, how the QinQ interfaces are used is mostly up to the needs of the network. Most likely, the resulting interfaces may be assigned and then configured in some way, or bridged to their local equivalent VLANs (e.g. bridge an assigned `igb2.10` to `igb3.2000.10` and so on).

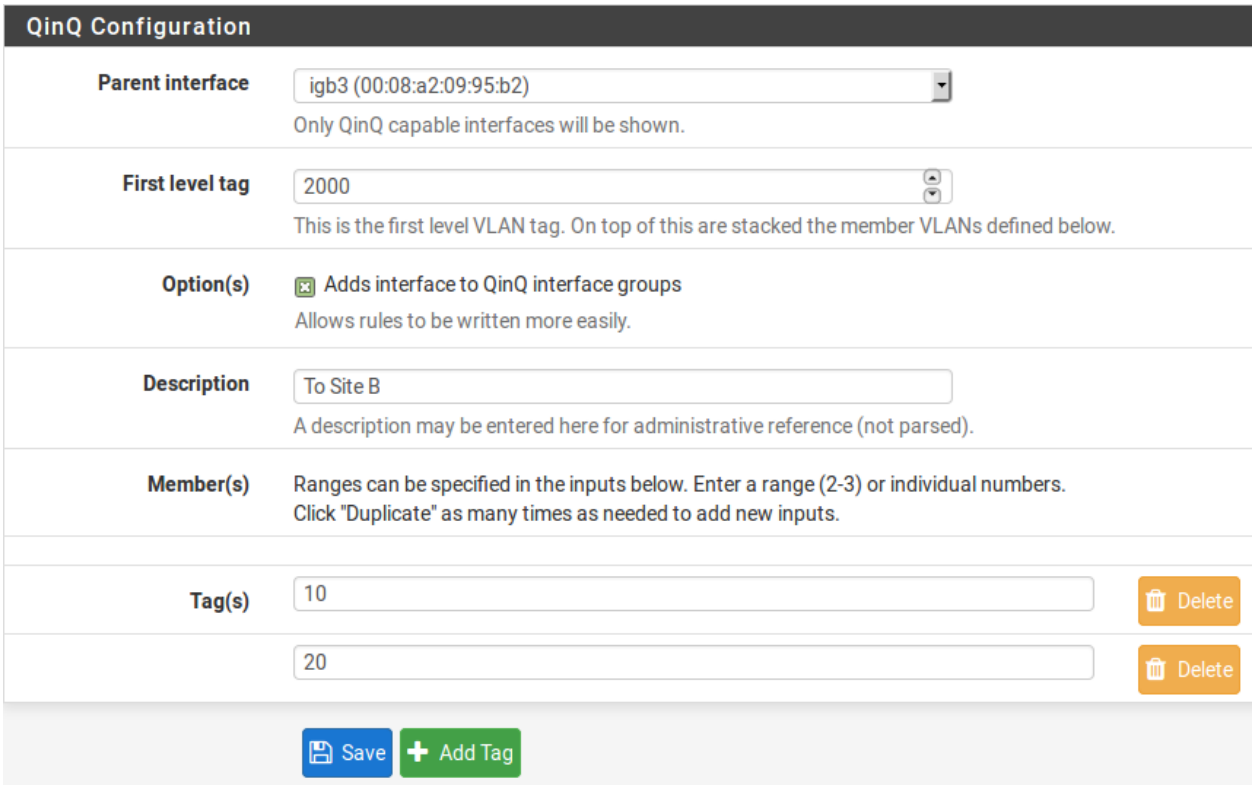

Fig. 3: QinQ Basic Example

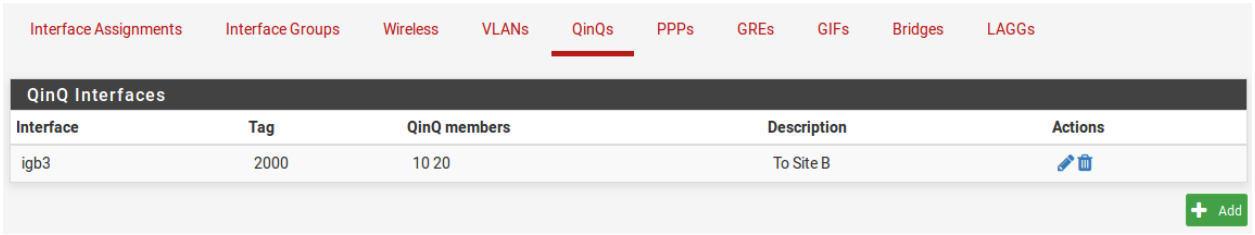

Fig. 4: QinQ List

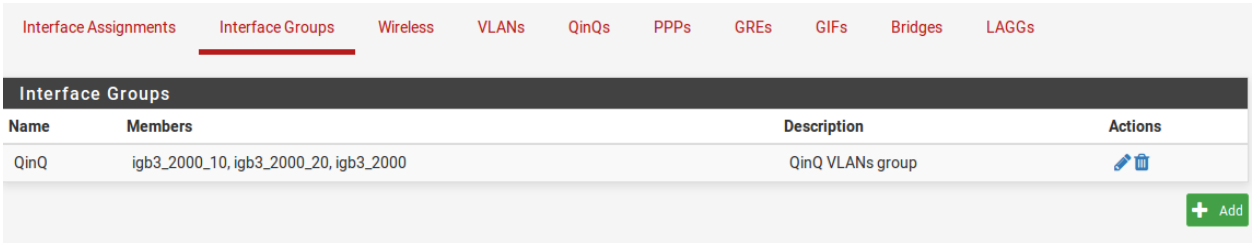

Fig. 5: QinQ Interface Group

The QinQ configuration will be roughly the same on both ends of the setup. For example, if both sides use identical interface configurations, then traffic that leaves Site A out on `igb3.2000.10` will go through VLAN `2000` on `igb3`, come out the other side on VLAN `2000` on `igb3` at Site B, and then in `igb3.2000.10` at Site B.

11.11 Integrated Switches

Certain models of hardware sold by Netgate have integrated switches. These switches can be configured in a variety of ways, with multiple ports on the same network or with each port on a separate network. The default configuration of the switch and the procedure to change that configuration varies by model.

Models with integrated switches include:

- Netgate 7100
- Netgate 3100
- Netgate 2100
- Netgate 1100

See also:

- *Virtual LANs (VLANs)*
- *Bridging*
- *Wireless*

pfSense® software supports numerous types of network interfaces, either using physical interfaces directly or by employing other protocols such as PPP or VLANs.

Interface assignments and the creation of new virtual interfaces are all handled under **Interfaces > Assignments**.

11.12 Physical and Virtual Interfaces

Most interfaces discussed in this chapter can be assigned as WAN, LAN, or an OPT interface under **Interfaces > Assignments**. All currently-defined and detected interfaces are listed directly on **Interfaces > Assignments** or in the list of interfaces available for assignment. By default, this list includes only the physical interfaces, but the other tabs under **Interfaces > Assignments** can create virtual interfaces which can then be assigned.

Interfaces support various combinations of options. They can also support multiple networks and protocols on a single interface, or multiple interfaces can be bound together into a larger capacity or redundant virtual interface.

All interfaces are treated equally; Every interface can be configured for any type of connectivity or role. The default WAN and LAN interfaces can be renamed and used in other ways.

Physical interfaces and virtual interfaces are treated the same once assigned, and have the same capabilities. For example, a VLAN interface can have the same type of configuration that a physical interface can have. Some interface types receive special handling once assigned, which are covered in their respective sections of this chapter.

This section covers the various types of interfaces that can be created, assigned, and managed.

11.13 Switches

Some Netgate Appliances sold in the Netgate Store contain built-in switches which can be configured in the GUI under **Interfaces > Switches**. Documentation for the switch configuration can vary by model, and may be found in the Netgate Product Manuals which match a given product.

11.14 Limitations

While the firewall does not impose any limits on the number of interfaces, large numbers of interfaces may function in suboptimal ways. For example, the firewall may take much longer to configure interfaces and the GUI may have rendering issues with large numbers of tabs or menu entries.

Most hardware will accommodate as many physical interfaces as can fit into the case. Issues may vary from driver to driver but generally are hardware-related and not the result of the operating system or pfSense software.

Note: With a large number of physical interfaces, the number of mbufs will likely need to be increased. See *Hardware Tuning and Troubleshooting*.

Physical limitations aside, significant numbers of virtual interfaces such as VLANs, LAGGs, VPNs, and more may be added to the firewall. These types interfaces tend to outnumber physical interfaces, especially VLANs.

Issues reported by users with large numbers of interfaces (physical and virtual) vary by hardware, configuration, and browser. These issues tend to increase as the number of interfaces approaches 200. Should a particular environment require more than 128 interfaces, consider alternate designs that do not involve using all of the interfaces on the firewall directly. If the firewall must handle large numbers of interfaces, be wary of potential performance and GUI concerns.

CHAPTER

TWELVE

USER MANAGEMENT AND AUTHENTICATION

12.1 Default Username and Password

The factory default credentials for a pfSense® software installation are:

Username
`admin`

Password
`pfsense`

Warning: Change the password to a secure value as soon as possible. Do not leave the password at the default value, even in a lab or test environment.

Note: On pfSense Plus software version 24.03 and later, administrators are required to change this password to a custom non-default value the first time they login.

12.2 Privileges

Managing privileges for users and groups is done similarly, so both will be covered here rather than duplicating the effort. Whether a user or group is managed, the entry must be created and saved first before privileges can be added to the account or group.

To add privileges, edit an existing user or group and click  **Add** in the **Assigned Privileges** or **Effective Privileges** section.

The GUI presents a list of all available privileges. Privileges may be added one at a time by selecting a single entry, or by multi-select using ctrl-click or cmd-click. If other privileges are already present on the user or group, they are hidden from this list so they cannot be added twice. To search for a specific privilege by name, enter the search term in the **Filter** box and click  **Filter**.

Selecting a privilege will show a short description of its purpose in the information block area under the permission list and action buttons. Most of the privileges are self-explanatory based on their names, but a few notable permissions are:

WebCfg - All Pages
Grants the user access to any page in the GUI

WebCfg - Dashboard (all)
Grants the user access to the dashboard page and all of its associated functions (widgets, graphs, etc.)

WebCfg - System: User Password Manager Page
If the user has access to only this page, they can login to the GUI to set their own password but do nothing else.

User - VPN - IPsec xauth Dialin
Allows the user to connect and authenticate for IPsec xauth

User - Config - Deny Config Write
Prevents the user from making changes to the firewall configuration (`config.xml`).

> **Warning:** This does not prevent the user from taking other actions that do not involve writing to the configuration.

User - System - Shell account access
Grants the user the ability to login over SSH, though the user will not have root-level access so functionality is limited. A package for *sudo* is available to enhance this feature.

After login, the firewall will attempt to display the dashboard. If the user does not have access to the dashboard, the GUI will forward the user to the first page in their privilege list to which they have access.

Menus on the firewall only contain entries for which privileges exist on a user account. For example, if the only Diagnostics page that a user has access to is **Diagnostics > Ping** then no other items will be displayed in the **Diagnostics** menu.

12.3 Manage Local Users

The **Users** tab under **System > User Manager** is where individual users are managed.

Note: The admin user cannot be deleted and its username may not be changed.

12.3.1 Creating and Editing Users

The first step is always to add the user and save. Privileges can only be added to existing users, they cannot be added when creating a new user.

Tip: If multiple users need the same privileges, the most efficient method is to add a *group* and then add users to the group.

To add a new user:

- Navigate to **System > User Manager**
- Click  **Add**

To edit an existing user:

- Navigate to **System > User Manager**
- Click  on the row containing the user

12.3.2 User Settings

When creating or editing a user, the following options are available:

Disabled
This checkbox controls whether this user will be active. To deactivate this account, check the option.

Username
Sets the login name for the user. This field is required, must be 16 characters or less and may only contain letters, numbers, and a period, hyphen, or underscore.

Password / Confirm Password
The password for this user. Ensure the two fields match to confirm the password.

This password cannot be set to the same value as the username. Additionally, on pfSense Plus software version 24.03 and later, the password cannot be set to the default value (*Default Username and Password*).

Note: Passwords are stored in the configuration as salted hashes, not plain text.

Tip: GUI users can also change their own password using the *User Password Manager* page.

Full Name
Optional field which can be used to enter a longer name or a description for this user account.

Expiration Date
Optional date at which the firewall will automatically deactivate this user account. The date must be entered in `MM/DD/YYYY` format.

Custom Settings
Enables options for per-user custom GUI settings. See *Per-user GUI Options and Dashboard Layout* for details.

Group Memberships
If one or more groups exist on the firewall (*Manage Local Groups*), this control can add the user as a member.

To add a group for this user:

- Click the group name in the **Not Member Of** column
- Click  to move it to the **Member Of** column

To remove a group from the user:

- Click the group name in the **Member Of** column
- Click  to move it to the **Not Member Of** column

Effective Privileges

A list of privileges this user has, either directly assigned or inherited by group membership.

Appears only when editing an existing user, not when creating a user.

Privilges assigned to the user may be edited by these controls, but group privileges cannot. Group privileges must be managed on the *group*.

See also:

See *Privileges* for information on managing privileges.

Certificate

Certificates associated with this user account.

The behavior of this section changes depending on whether the page is creating a new user or editing an existing user. This section is disabled if there are no internal certificate authorities defined on the firewall capable of signing a certificate.

To create a certificate while adding a user:

- Check **Click to create a user certificate**
- Fill in the **Descriptive name**
- Choose a **Certificate Authority**
- Select a **Key Type** and **Key Length**
- Select a **Digest Algorithm**
- Enter a **Lifetime**

See also:

For more information on these parameters, see *Create an Internal Certificate*.

When editing a user, this section of the page instead becomes a list of certificates associated with this user account.

To create a certificate for an existing user:

- Click  **Add**
- Fill in the settings on the page as described in *Create an Internal Certificate* (some data is pre-filled)

To associate an existing certificate with this user:

- Set **Method** to *Choose an Existing Certificate*
- Select an entry from the **Existing Certificate** list
- Click **Save**

Authorized SSH keys

Public keys for SSH and SCP authentication.

To add a key, paste or enter in the key data. Multiple keys are allowed, one per line.

> **Warning:** Only enter authorized keys into this field. Do not add them to files in user home directories. Those files will be overwritten by the GUI the next time account information is synchronized to disk (e.g. at boot time).

IPsec Pre-Shared Key
Pre-Shared Key (PSK) for this user to connect to a non-xauth Pre-Shared Key mobile IPsec setup.

If a PSK is entered here, the username is used as the identifier. The PSK is also displayed under **VPN > IPsec** on the **Pre-Shared Keys** tab.

Note: This field has no effect for IKEv2 or xauth mobile IPsec.

Keep Command History
If this user has shell access, this option preserves the last 1000 unique commands entered at a shell prompt between login sessions. The user can access history using the up and down arrows at an SSH or console shell prompt and search the history by typing a partial command and then using the up or down arrows.

Per-user GUI Options and Dashboard Layout

Each user can have their own settings for various GUI options and their dashboard layout. To enable this for a user, check the **Custom Settings** box when adding or editing the user.

When that option is active, additional GUI options for the user are present on the user account page. Additionally, the user can have their own personal dashboard layout, starting from the system-wide layout.

Choose the other GUI options desired for the user such as theme, top navigation, host name in menu, dashboard columns, show/hide associated panels, left column labels and browser tab text.

Tip: Users with the **WebCfg - System: User Settings** privilege may adjust their own GUI options.

Users in the `admin` group already have this privilege.

A user with **Custom Settings** enabled and the **User Settings** privilege will have menu option **System > User Settings**. The user can select this to change the GUI options for their account.

When a user with **Custom Settings** adds, moves or removes dashboard widgets, the custom dashboard layout is saved in the preferences for only that user.

12.4 Manage Local Groups

Groups manage sets of user privileges so they do not need to be maintained individually on every user account. For example, a group can be used for IPsec xauth users, or a group that can access the firewall dashboard, a group of firewall administrators, or many other possible scenarios using any combination of privileges.

Groups are managed under **System > User Manager** on the **Groups** tab.

Note: The `all` and `admins` groups cannot be deleted.

12.4.1 Groups and Remote Authentication

When working with group privileges while authenticating against LDAP and RADIUS (*Authentication Servers*), local groups must exist with names that exactly match groups from the server. For example, if an LDAP group named `firewall_admins` exists then the firewall must also contain a identically named group, `firewall_admins`, with the desired privileges.

If a user attempts to authenticate against a remote authentication server and there are no matching groups, the user will not have any privileges from groups, and cannot access resources which require privileges.

12.4.2 Creating and Editing Groups

As with users, the first step is to add the group and save. Privileges can only be added to existing groups, they cannot be added when creating a new group.

To add a new group:

- Navigate to **System > User Manager**, **Groups** tab
- Click  **Add**

To edit an existing group:

- Navigate to **System > User Manager**, **Groups** tab
- Click  on the row containing the group

12.4.3 Group Settings

Group name
The name of the group.

For groups in the *Local* scope, this setting has the same restrictions as a username: It must be 16 characters or less and may only contain letters, numbers, and a period, hyphen, or underscore.

Groups in the *Remote* scope do not have strict name restrictions, for example they may have longer names.

Scope
The scope in which this group is available for use.

Note: LDAP and RADIUS groups can match names in both local and remote scopes.

Local
Groups on the firewall itself, such as those for use in the shell, filesystem, and other local uses. These groups are added to the operating system, so they are subject to naming restrictions imposed there.

Remote
Groups from remote sources, such as authentication servers (RADIUS or LDAP). These groups are not exposed to the operating system, and thus are only available for use in the GUI and other similar uses not involving the operating system layer. This scope has relaxed name restrictions, for example, group names may be longer and may contain spaces.

Description
Optional free-form text for reference and to better identify the purpose of the group in case the **Group name** is not sufficient.

Group Memberships
This set of controls defines which existing users will be members of the new group. Firewall users are listed in the **Not Members** column by default.

To add a user to this group:

- Click the user name in the **Not Members** column
- Click  to move it to the **Members** column

To remove a user from this group:

- Click the user name in the **Members** column
- Click  to move it to the **Not Members** column

Assigned Privileges
A list of privileges assigned to this group. Appears only when editing an existing group.

See also:

See *Privileges* earlier in this for information on managing privileges.

12.5 Settings

The **Settings** tab in the User Manager controls how the firewall authenticates users for the GUI and SSH.

Session Timeout
This field specifies how long a GUI login session will last when *idle*. This value is specified in **minutes**, and the default is four hours (`240` minutes). A value of `0` may be entered to disable session expiration, making the login sessions valid forever. A shorter timeout is better, though it should be long enough that an active administrator would not be logged out unintentionally while making changes.

> **Warning:** Allowing a session to stay valid when idle for long periods of time is insecure. If an administrator leaves a terminal unattended with a browser window open and logged in, someone or something else could take advantage of the open session.

Authentication Server
This selector chooses the primary authentication source for users logging into the GUI. This can be a RADIUS or LDAP server, or the default *Local Database*.

Note: Authentication falls back to *Local Database* if the RADIUS or LDAP server is unreachable, returns an authentication failure, or otherwise results in an error, even if another method is chosen.

This ensures that an administrator can always access the device, even if the authentication server is broken.

Password Hash Algorithm
Selects which algorithm the firewall will use when creating hashes for passwords in user manager accounts.

May be one of the following choices:

bcrypt - Blowfish-based crypt
Secure password hashing with a crypt algorithm based on Blowfish. The most secure option currently available.

Note: This hashing algorithm is restricted to a maximum password length of 72 characters.

SHA-512 - SHA-512-based crypt
Secure password hashing with a crypt algorithm based on SHA-512. Weaker than bcrypt but still has an acceptable level of security in many environments.

Some users may prefer SHA-512-based crypt hashes for compatibility or compliance purposes.

Shell Authentication
When set, the selected **Authentication Server** will also be configured as the authentication source for SSH access to the firewall. By default, only accounts in the *User Manager* with shell privileges can login over SSH.

This works with both RADIUS and LDAP servers, with some caveats:

RADIUS Servers
When used with a RADIUS server, accounts must exist on the firewall with the same names and the expected privileges. They will authenticate against RADIUS but use the local accounts settings otherwise.

LDAP Servers
When used with an LDAP server, the **Shell Authentication Group DN** must be set on the *LDAP Authentication Server* entry. Users must be a member of that group and have valid `posixAccount` attributes in their LDAP account.

Auth Refresh Time
Time in seconds for which the firewall cache authentication results. The default is `30` seconds, maximum `3600` (one hour). Shorter times result in more frequent queries to authentication servers.

The firewall periodically re-authenticates users against the remote server to ensure the account is still valid and has the expected privileges. Checking frequently is more secure, but puts a larger burden on the authentication server and can increase page load times on the firewall.

12.5.1 Remote Authentication Servers and Privileges

When using a RADIUS or LDAP server to authentication for the GUI, the *users* and/or *group memberships* must be defined in the firewall in order to properly allocate permissions, as there is no method to obtain permissions dynamically from an authentication server.

For group membership to work properly, the firewall must be able to recognize the groups as presented by the authentication server. This requires two things:

- The local groups must exist with identical names (*Manage Local Groups*).
- The firewall must be able to locate or receive a list of groups from the authentication server.

See *Authentication Servers* for details specific to each type of authentication server.

12.6 User Password Manager

The self-service user password manager page (**System > User Password Manager** or **System > User Manager**, **Change Password** tab) allows a user to change their own password in the User Manager Local Database.

This page is separate from the User Manager so that privileges can be granted to access this page without giving a user access to the user manager as a whole. The privilege governing this page is labeled "WebCfg - System: User Password Manager".

The page prompts the user to enter and confirm a new password. Saving the settings changes the password.

Warning: This password cannot be set to the same value as the username. Additionally, on pfSense Plus software version 24.03 and later, the password cannot be set to the default value (*Default Username and Password*).

Note: Passwords are stored in the configuration as salted hashes, not plain text.

12.7 Authentication Servers

The firewall can use RADIUS and LDAP servers to authenticate users from remote sources.

User Manager Support contains information on which areas of the firewall support these servers

To add a new server:

- Navigate to **System > User Manager**, **Authentication Servers** tab
- Click  **Add**

To edit an existing server, click  next to its entry on the same page.

Each type of authentication server is covered in the following documents

12.7.1 RADIUS Authentication Servers

Remote Authentication Dial-In User Service (RADIUS) is a protocol commonly supported by a wide variety of networking equipment for user authentication, authorization, and accounting (AAA).

Servers are commonly available as well, including *FreeRADIUS* and *Active Directory via NPS*.

Though most areas on pfSense® software which support RADIUS now integrate their RADIUS settings via the user manager, a few remain which use separate settings, such as the PPPoE and L2TP servers.

See also:

- *Controlling Client Parameters via RADIUS*

Warning: Secure the link between the firewall and the RADIUS server. If the server is local, use a trusted management network. If the server is remote, communicate only over VPN tunnels.

Some RADIUS protocols transmit passwords in plain text, and though others attempt to protect the password in other ways, other aspects of the protocol are not encrypted and may contain sensitive information.

RADIUS Configuration

Descriptive name
The name for this RADIUS server. This name will be used to identify the server throughout the GUI.

Protocol
The protocol used by the firewall when performing RADIUS requests. May be one of:

PAP
Password Authentication Protocol. Sends passwords unencrypted, and is considered weak. It is more widely supported than other methods, and may be required by specific features (e.g. mOTP).

Warning: Due to its security deficiencies, avoid using PAP where possible.

MD5-CHAP
Challenge-Handshake Authentication Protocol using MD5 hashing. The RADIUS server sends a challenge value and the client responds with a hash of the challenge value and the password together. More secure than PAP as it does not transmit passwords in the clear, but both parties must know the plain text of the password.

MS-CHAPv1
A Microsoft variation of CHAP where neither side needs to know the plain text of the password. Though it is generally more secure, it has other known weaknesses which make it vulnerable to attack.

MS-CHAPv2
An updated variation of MS-CHAPv1. It is used in EAP as well as 802.1x/WPA Enterprise for wireless. However, it also has known weaknesses.

Note: Certain RADIUS features may require specific modes. For example, mOTP typically requires PAP since it reads the password in the clear to separate the PIN and OTP code. Services utilizing EAP typically use MS-CHAPv2.

Hostname or IP address
The address of the RADIUS server. This can be a fully qualified domain name or an IPv4 IP address.

Shared Secret
The password established for this firewall *on the RADIUS server* software.

Services offered
This selector sets which services are offered by this RADIUS server.

Authentication
The firewall will use this RADIUS server to authenticate users.

Accounting
The firewall will send RADIUS start/stop accounting packet data for login sessions if supported in the area where it is used.

Authentication and Accounting
The server will be used for both types of actions.

Authentication port
Only appears if an Authentication mode is chosen. Sets the UDP port where RADIUS authentication will occur. The default RADIUS authentication port is `1812`.

Accounting port
Only appears if an Accounting mode is chosen. Sets the UDP port where RADIUS accounting will occur. The default RADIUS accounting port is `1813`.

Authentication Timeout
Controls how long, in seconds, that the RADIUS server may take to respond to an authentication request. If left blank, the default value is `5` seconds. If an interactive two-factor authentication system is in use, increase this timeout to account for how long it will take the user to receive and enter a token, which can be 60-120 seconds or more if it must wait for an external action such as a phone call, SMS message, etc.

Note: The system will retry authentication **three** times before giving up, and the timeout applies to each attempt individually. Thus, authentication may take up to 3x this value to terminate if the server is unreachable.

RADIUS NAS IP Attribute
Sets the value the firewall will send in the RADIUS request `NAS-IP-Address` attribute. This value is used by the RADIUS server to identify this firewall. The server can use this value to make authentication decisions, or to denote which node users were authenticated by in accounting data.

In most cases, the `NAS-IP-Address` value does not matter so long as it is unique to this firewall. However, more complicated RADIUS environments may use this attribute to let the server make more informed decisions about users logging into different services. For example, if there are multiple Captive Portal instances on the firewall, multiple RADIUS server entries can be created, each using the specific interface address for a given portal. The RADIUS server could then choose to only let certain sets of users login to each portal.

Adding a RADIUS Server

To add a new RADIUS server:

- Add the firewall as a client on the RADIUS server
- Navigate to **System > User Manager**, **Authentication Servers** tab
- Click  Add
- Set the **Type** selector to *RADIUS*

  The GUI will change the form to display RADIUS Server Settings
- Fill in the fields as described in *RADIUS Configuration*
- Click **Save** to create the server
- Navigate to **Diagnostics > Authentication** to test the RADIUS server using a valid account.

RADIUS Groups

There are two requirements for RADIUS groups to function properly:

- The RADIUS server must return a list of groups in the `Class` RADIUS reply attribute as a string.
- The same groups must exist locally (*Manage Local Groups*)

Multiple groups returned by the RADIUS server in the `Class` attribute must be separated by a semicolon. For example, in FreeRADIUS, to return the `admins` and `VPNUsers` groups, use the following Reply-Item RADIUS Attribute:

```
Class := "admins;VPNUsers"
```

If the RADIUS server returns the group list properly for a user, and the groups exist locally, then the groups will be listed on the results when using the **Diagnostics > Authentication** page to test an account.

If the groups do not show up when testing, ensure the groups exist in the *Group Manager* with matching names and that the server is returning the `Class` attribute as a string, not binary.

12.7.2 LDAP Authentication Servers

Though Lightweight Directory Access Protocol (LDAP) is technically a repository for user information, it also supports mechanisms for user authentication via bind operations.

There are many popular user directory implementations which use LDAP, including Active Directory, OpenLDAP, FreeIPA, and more.

Note: LDAP server implementations and schemas vary widely. As such, there are no complete and specific examples in this document.

LDAP Configuration

Hostname or IP address
The address of the LDAP server. This can be a fully qualified domain name, an IPv4 IP address, or an IPv6 IP address.

Note: If this LDAP server uses SSL, the value of this field **must** match the certificate presented by the LDAP server. Typically this means it must be a hostname which resolves to the IP address of the LDAP server, but the specific requirements depend on the contents of the server certificate.

For example, with a value of `ldap.example.com` in this field, the server certificate must include an FQDN value of `ldap.example.com`, and `ldap.example.com` must resolve to `192.168.1.5`. One exception to this is if the IP address of the server also happens to be the listed in the server certificate.

This can be worked around in some cases by creating a DNS host override to make the server certificate hostname resolve to the correct IP address if they do not match in this network infrastructure and they cannot be easily fixed.

Port value
This setting specifies the port on which the LDAP server is listening for LDAP queries. The default port is `389` for Standard TCP and STARTTLS, and `636` for SSL. This field is updated automatically with the proper default value based on the selected **Transport**.

Note: When using port `636` for SSL, the firewall uses an `ldaps://` URL, not STARTTLS. Ensure that the LDAP server is listening on the correct port with the correct mode.

Transport
This setting controls which transport method will be used by the firewall to communicate with the LDAP server.

Warning: LDAP queries will contain sensitive data, such as usernames, passwords, and other information about the user. The best practice is for the firewall to use encryption when communicating with the LDAP server, if the LDAP server supports it. Both SSL/TLS and STARTTLS will encrypt traffic between the firewall and the LDAP server.

Standard TCP
(Default) Plain unencrypted TCP connections on port `389`. This is not secure, but is widely supported and also useful for debugging with packet captures. Do not use this protocol across untrusted networks.

STARTTLS Encrypted
Connects using TCP port `389` but negotiates encryption with the server using STARTTLS.

Note: Not all LDAP servers support STARTTLS, check the LDAP server documentation and configuration.

SSL/TLS Encrypted
Connects using SSL/TLS on TCP port `636` to encrypt LDAP queries.

Note: Not all LDAP servers support SSL/TLS, check the LDAP server documentation and configuration.

Peer Certificate Authority
The CA chosen with this selector is used by the firewall to validate the LDAP server certificate when **Transport** is set to **SSL/TLS Encrypted** or **STARTTLS Encrypted** mode.

The selected CA must match the CA which signed the LDAP server certificate, otherwise validation will fail. If the LDAP server is using a globally trusted certificate (e.g. Let's Encrypt or another public CA), choose *Global Root CA List*.

See *Certificate Authority Management* for more information on creating or importing CAs.

Client Certificate
(Plus only) This certificate is sent to the LDAP server to identify this client when using an encrypted transport mode. If the LDAP server requires a client certificate, the server will use this certificate to ensure that the firewall is authorized to make LDAP queries.

This certificate must be issued by the CA used by the LDAP server to validate connecting clients.

Protocol version
Chooses which version of the LDAP protocol is employed by the LDAP server, either *2* or *3*, typically *3*.

Server Timeout
The time, in seconds, after which LDAP operations are considered as failed. Using a lower value will

allow the GUI to try other authentication sources faster when the server fails. If the LDAP server is slow or overloaded, a larger value can help the firewall accept delayed responses.

Search scope
Determines where, and how deep, an LDAP search will be performed to locate a match.

Level
Controls the depth of the LDAP search.

One Level
Search only one level, defined by the **Authentication Containers**.

Entire Subtree
Search the entire subtree of the directory, starting with the **Authentication Containers**.

Tip: This is typically the best choice, and is nearly always required for Active Directory configurations.

Base DN
Controls where the search will start. Typically set to the root of the LDAP structure, e.g. `DC=example,DC=com`

Authentication containers
A list of potential account locations or containers, separated by semicolons. These containers will be prepended to the **Base DN** above when the firewall crafts LDAP queries. Alternately, specify a full container path here and leave the **Base DN** blank.

Tip: If the LDAP server supports it, and the bind settings are correct, click  **Select a container** to browse the LDAP server and select containers from a list.

Some examples of containers are:

- `CN=Users;DC=example;DC=com` This searches for users inside of the domain component `example.com`, a common syntax for Active Directory
- `CN=Users,DC=example,DC=com;OU=OtherUsers,DC=example,DC=com` This searches in two different locations, the second of which is restricted to the `OtherUsers` organizational unit.

Extended Query
Specifies an extra restriction to query after the username, which allows group membership to be used as a filter. This must include both the item to search as well as the method of searching. For example, a restriction based on group membership would use `memberOf`. Check the LDAP server documentation for information on forming such queries.

To set an extended query, check the box and fill in the **Query** value with a filter such as:

```
memberOf=CN=VPNUsers,CN=Users,DC=example,DC=com
```

For users of RFC2307 groups, such as with OpenLDAP, an extended filter might look more like the following:

```
&(objectClass=posixGroup)(cn=VPNUsers)(memberUid=*)
```

Bind credentials
Controls how this LDAP client will attempt to bind to the server.

Note: Active Directory typically requires the use of bind credentials and may need a service account or administrator-equivalent depending on the server configuration. Consult Windows documentation to determine which is necessary in a specific environment.

Bind Anonymous
(Default) When checked the firewall will use anonymous binds. When unchecked the GUI presents the **Bind Credentials** fields.

Bind Credentials (User DN/Password)
When **Bind Anonymous** is unchecked, the credentials in these fields are used by the firewall to make authenticated binds when performing a query.

The **User DN** may be a username or a full DN, depending on what the LDAP server requires.

Attributes

Initial Template
This option only appears when initially creating an LDAP server entry. It pre-fills the remaining options on the page with common defaults for a given type of LDAP server. The choices include *OpenLDAP*, *Microsoft AD*, and *Novell eDirectory*.

User naming attribute
The attribute used to identify the name of a user, most commonly `cn` or `samAccountName`.

Group naming attribute
The attribute used to identify a group, such as `cn`.

Group member attribute
The attribute of a user that signifies it is the member of a group, such as `member`, `memberUid`, `memberOf`, or `uniqueMember`.

RFC2307 Groups
Specifies how group membership is organized on the LDAP server. When unset (default), the queries assume the server uses Active Directory style group membership (RFC 2307bis) where groups are listed as an attribute of the user object. When checked, queries use RFC 2307 style group membership where the users are listed as members on the group object.

Note: In this mode the `Group member attribute` will typically be set to `memberUid`, but may vary by LDAP schema.

RFC2307 User DN
When set, queries include the user DN when searching for groups.

Group Object Class
Specifies the object class of RFC 2307 style groups. Typically `posixGroup` but it may vary by LDAP schema. Not necessary for Active Directory style groups.

Shell Authentication Group DN
The LDAP group DN for users allowed to login via SSH. This is used with the **Shell Authentication** option on the *Settings* tab to allow LDAP users to login via SSH.

To login via SSH, users must be a member of this group and have valid `posixAccount` attributes in their LDAP account.

UTF8 Encode
When checked, queries to the LDAP server are encoded for UTF-8 and the responses are decoded from UTF-8. Support varies depending on the LDAP server. Generally only necessary if user names, groups, passwords, and other attributes contain UTF-8 or international style accented characters.

Username Alterations
When unchecked, a username given as `user@hostname` will have the `@hostname` portion stripped so only the username is sent in the LDAP bind request. When checked, the username is sent in full.

Allow Unauthenticated Bind
When set, bind requests with empty passwords will be rejected locally. Some LDAP servers, specifically Microsoft Active Directory, will accept unauthenticated bind requests and treat them as successful.

> **Warning:** This behavior must be disabled on the LDAP server where possible. Allowing requests to succeed with an empty password is a significant security risk and it affects any device or service authenticating against an LDAP server.
>
> Though this option allows the firewall to reject such authentication attempts, other LDAP clients may not offer the same choice. Disabling the feature on the server is the most secure means of correcting the problem. Consult the LDAP server documentation for information on disabling this behavior.

Adding an LDAP Server

To add a new LDAP server:

- Make sure that the LDAP server can be reached by the firewall
- Import the Certificate Authority used by the LDAP server before proceeding if using SSL/TLS or STARTTLS encryption

  See *Certificate Authority Management* for more information on creating or importing CAs.
- Navigate to **System > User Manager**, **Authentication Servers** tab
- Click  **Add**
- Set the **Type** selector to *LDAP*

  The GUI will change the form to display LDAP server settings
- Fill in the fields as described previously in *LDAP Configuration*
- Click **Save** to create the server
- Visit **Diagnostics > Authentication** to test the LDAP server using a valid account

Tip: The debug option on **Diagnostics > Authentication** writes messages to the system log containing a lot of information about LDAP queries and results, which can be of great assistance when testing LDAP server entries.

Multiple Entries to the Same Server

It's not only possible, but useful, to have multiple entries defined for the same LDAP server with different filtering for separate purposes. For example:

- An entry without any filtering for general authentication with areas that recognize groups and the privilege system or where groups do not matter (e.g. GUI administrative access, Captive Portal)
- An entry with an extended query limiting to a single group for VPN access (e.g. OpenVPN for employees) – This way the VPN does not need to check group membership, the authentication will only succeed for members of the LDAP group.
- An entry with an extended query limiting to a different single group for a special purpose VPN (e.g. Remote vendor access, Management VPN)

Name the entries appropriately and choose them for their respective intended purposes.

LDAP Groups

There are two requirements for LDAP groups to function properly:

- The LDAP authentication settings must match the group membership style used by the LDAP server
- The same groups must exist locally (*Manage Local Groups*)

If the LDAP query returns the group list properly for a user, and the groups exist locally, then the groups will be listed on the results when using the **Diagnostics > Authentication** page to test an account.

If the groups do not show up, ensure they exist in the *Group Manager* with matching names and that the proper group structure is present on the LDAP authentication server entry (e.g. RFC 2703 options.)

12.8 User Manager Shell Commands

There are two commands available in a shell (console or SSH) to interact with the User Manager:

usermgrwhoami
: Prints information about the current user from the User Manager database.

usermgrpasswd
: Allows `admin` or `root` to change the password for accounts in the User Manager database.

  When run without any parameters, the script changes the password for the current user (`admin`).

  Other parameters include:

  -c, --check
  : Checks the password for the user to see if it matches known problematic values (e.g. the default value or the username).

  -u <name>, --username <name>
  : Passes a specific username to use when checking or changing the password.

Note: Users other than `admin` and `root` cannot use this shell command because they do not have direct write access to the firewall configuration. Those users can visit the *User Password Manager* page to change their own password.

12.9 Logging Out of the GUI

To end a GUI login session navigate to **System > Logout** or close the browser window.

Sessions will automatically expire if they are idle for longer than the **Session Timeout** defined on **System > User Manager**, **Settings** tab. The default session timeout is 4 hours (240 minutes) of idle time.

- *Authenticating Users with Google Cloud Identity*
- *Troubleshooting Authentication*
- *Troubleshooting Access when Locked Out of the Firewall*

The User Manager in pfSense® software provides the ability to create and manage multiple user accounts. These accounts can be used to access the GUI, use VPN services like IPsec and OpenVPN, and use the Captive Portal.

The User Manager is located at **System > User Manager**. From there users, groups, servers may be managed, and settings that govern the behavior of the User Manager may be changed.

The User Manager can also be used to define external authentication sources such as RADIUS and LDAP.

See also:

Hangouts Archive to view the February 2015 Hangout on User Management and Privileges, and the August 2015 Hangout on RADIUS and LDAP.

12.10 User Manager Support

As of this writing, not all areas of the firewall hook back into the User Manager.

GUI
: Supports users in the User Manager, and via RADIUS or LDAP. Groups or Users from RADIUS or LDAP require definitions in the local User Manager to manage their access permissions.

XMLRPC Configuration Synchronization
: Supports users from the User Manager, and via RADIUS or LDAP. Requires special privilege granted to users or groups.

SSH/SCP
: Supports users from the User Manager, and via RADIUS or LDAP. Requires special privilege granted to users or groups.

IPsec
: Supports users in the User Manager, RADIUS or LDAP via User Manager for Xauth, and RADIUS for IKEv2 with EAP-RADIUS.

OpenVPN
: Supports users in the User Manager, RADIUS or LDAP via User Manager.

Captive Portal
: Support local users, RADIUS, or LDAP via User Manager.

L2TP
: Supports users in the L2TP settings, and via RADIUS in the L2TP settings.

PPPoE Server
: Supports users in the PPPoE settings, and via RADIUS in the PPPoE settings.

CHAPTER

THIRTEEN

CERTIFICATE MANAGEMENT

13.1 Certificate Properties

Certificate authority and certificate entries have several properties in common. The common properties of both types are covered here.

13.1.1 Keys

The public and private keys of the certificate are used for cryptographic operations.

Key Type
Certificate key type can be either **RSA** or **ECDSA** (Elliptic Curve Digital Signature Algorithm).

RSA
RSA keys are more common and well-supported than ECDSA, as well as having some performance benefits.

Key Length
When using RSA keys, the security is proportional to the key size. Larger keys are more secure, but they also take longer to generate and are slower to use. RSA performance decreases rapidly as the key size increases.

The best practice is to not use keys smaller than `2048` bits where possible. Legacy and embedded systems may not support larger keys.

ECDSA
ECDSA is a newer method, and is not as widely adopted. Its main advantage is that is can use smaller keys to provide equivalent levels of security to RSA. ECDSA is slower at verifying signatures than RSA, but scales better.

Curve Name
There are a variety of ECDSA curves available, but only a few have been confirmed to work with various services on the firewall. The services which support each curve are noted in the list. Pick the curve based on which services will use this certificate authority or certificate.

13.1.2 Digest Algorithm

Digest Algorithms, also known as Message Digest Algorithms and Hash Algorithms, are used to create a fixed-length hash of content for signing.

The larger the hash, the stronger it is and the less likely it is to be susceptible to collisions which compromise the integrity of the hash. The current best practice is to use a minimum of SHA-256.

Warning: Though the GUI still contains support for SHA-1, it is considered weak and should not be used. Rare exceptions can be made for legacy systems which do not support stronger hashes.

13.1.3 Lifetime

The Lifetime of a certificate authority or certificate determines the length, in days, for which the certificate is valid. Shorter lifetimes are more secure, but require more work as the certificates must be renewed or replaced more frequently.

See also:

Renew or Reissue a CA or Certificate.

For certificate authorities, a longer lifetime such as `3650` days (10 years) is acceptable.

Certificates for users typically also have a long lifetime, but specific values depend largely on the needs of an organization. The GUI defaults to `3650` days for User Certificates, but it a better practice is to use a lower value when practical.

Server certificates have stricter requirements for their lifetime. The current accepted maximum lifetime for server certificates is `398` days. Most browsers and other software will no longer accept new server certificates with longer lifetimes.

Note: Another special case is server certificates obtained using *ACME from Let's Encrypt*. These only have a lifetime of `90` days, but since they are automatically replaced well before they expire, there is little extra administrative overhead once the initial setup is complete.

13.1.4 Distinguished Name

The entity to which a certificate authority or certificate belongs, also known as the Subject, is identified by the unique components of the certificate. The primary component for this purpose is the Distinguished Name (DN). These are typically filled in with an organization's information, or in the case of an individual, personal information. This information is mostly cosmetic, and used to verify the accuracy of the CA, and to distinguish one CA from another.

A DN is composed of several fields which contain information about the subject.

Only the **Common Name** is required, the other fields may be left blank.

Warning: A DN with less unique information has the potential to be misidentified later when comparing certificate subjects. Always fill in enough information to uniquely identify the subject.

Common Name
: A short name, such as a username or hostname. Do not use spaces or punctuation, other than that which is typically found in a hostname.

Note: This name is not used directly for certificate validation on modern systems, which look at *Subject Alternative Name* values instead.

Country Code
The two letter ISO country code for the certificate subject location.

Note: The ISO country code is not the same as the hostname TLD code for a country.

State or Province
The geographical state or province name for the certificate subject location. This value should be spelled out, not using an abbreviation or code.

City
The city for the certificate subject location.

Organization
The name of the organization to which the subject belongs. For example, a company name, government agency name, or similar.

Organizational Unit
A division or department inside the organization, if any. For example, "IT Department" or "Accounting".

Note: When creating a certificate, the GUI populates most of these fields with the values from the certificate authority chosen for signing. The contents of the fields may be changed before performing the signing operation.

13.1.5 Subject Alternative Name

The Subject Alternative Name (SAN) list is only present on certificates. It contains information used to validate the identity of the certificate. For example, when connecting to a device on the network, a system may compare the hostname or IP address to which it connected with values in the certificate SAN list. This way, it can be sure it is communicating with the intended host and not an impostor.

Note: The **Common Name** value from a certificate is automatically added to the SAN list internally, as its inclusion is a requirement of current standards.

The following types of SAN entries can be added to a certificate:

FQDN or Hostname
A fully qualified domain name (e.g. `host.domain.tld`) or a hostname (`host`). In most cases this hostname would also exist in DNS. In the case of user certificates, this could also be a username.

IP Address
An IP address (e.g. `x.x.x.x`), typically an address found on a network device using this certificate. Necessary for clients to properly validate the certificate when connecting by IP address instead of by hostname.

URI
A Uniform Resource Identifier for the certificate subject. In practice, only used as an alternate way to determine the hostname when communicating with servers. It does not restrict certificate validity to specific URIs on a server.

E-mail Address
An e-mail address for the certificate subject.

13.1.6 Certificate Properties in Lists

When viewing the lists of CA and certificate entries, the properties of the entry are available in the **Distinguished Name** column. The DN is printed there and additional detailed information is available from the  icon.

Underneath that information, the GUI prints the start and end dates for the validity of the entry. The difference between the start and end date is the **Lifetime**. When an entry is nearing expiration, the GUI highlights the end date in yellow. When an entry is expired, it is red. The system also generates notifications for expiring certificates.

See also:

The certificate expiration warning threshold is `27` days by default, but can be customized. See *Notifications* for details.

13.2 Certificate Authority Management

Certificate Authority (CA) entries are managed from **System > Certificates**, on the **CAs** tab.

See also:

Renew or Reissue a CA or Certificate

13.2.1 Certificate Authority Settings

When creating or editing a CA entry, the following options are available:

Trust Store
Controls whether or not this CA is added to the certificate trust store on the firewall. When added to the trust store, a CA will be considered valid for all certificate operations performed by the operating system. If the firewall must contact a server using a certificate issued by a private CA, this allows such certificates to be trusted by client programs such as LDAP authentication, SMTP notifications, URL table connections, and many others.

Randomize Serial
Controls whether or not the CA will randomize serial numbers when it signs certificates or if it will use a sequential serial number.

The current best practice is to randomize serial numbers so they are unpredictable. This also reduces the chances of generating two certificates with the same serial number in circumstances where the CA is moved between different hosts or signs certificates in multiple places.

Common Properties
See *Certificate Properties* which covers the remaining fields on the page.

When importing or editing an existing CA entry, the following options are available:

Certificate Data
The PEM-encoded certificate data for the CA.

Certificate data is typically contained in a file ending with `.crt` or `.pem`. It would be plain text, and enclosed in a block such as:

```
-----BEGIN CERTIFICATE-----
[A bunch of random-looking base64-encoded data]
-----END CERTIFICATE-----
```

The format varies slightly for ECDSA certificates.

Certificate Private Key
The PEM-encoded private key for the CA. If this is omitted, the CA cannot sign certificates or CRLs, but it can be used for other purposes. When empty, the CA is marked as "External". They key can be filled in later to enable signing and to have the CA treated as "Internal".

The key data is typically in a file ending in `.key`. It would be plain text data enclosed in a block such as:

```
-----BEGIN RSA PRIVATE KEY-----
[A bunch of random-looking base64-encoded data]
-----END RSA PRIVATE KEY-----
```

The format varies slightly for ECDSA keys.

Next Certificate Serial
The serial number of the next certificate, used when the CA is not set to randomize serial numbers.

It is essential that each certificate have a unique serial, or there will be problems later with certificate revocation. If the next serial is unknown, attempt to estimate how many certificates have been made from the CA, and then set the number high enough a collision would be unlikely.

13.2.2 Create a new Certificate Authority Entry

To create a new CA entry, start the process as follows:

- Navigate to **System > Certificates**, **CAs** tab
- Click **Add** to create a new a CA
- Enter a **Descriptive name** for the CA

  This is used as a label for this CA throughout the GUI.
- Select the **Method** that best suits how the CA will be generated

  Create an Internal Certificate Authority
  Creates a new root CA. Fill in the settings as described in *Certificate Authority Settings*.

  Import an Existing Certificate Authority
  Exports a CA certificate created on another host, with or without a private key. This can be useful in two ways: One, for CAs made using another system, and two, for CAs made by others that must be trusted.

  Fill in the settings as described in *Certificate Authority Settings*.

  Note: If the CA has been signed by an intermediary and not directly by a root CA, then import each entry in the chain separately, starting with the root CA.

  Create an Intermediate Certificate Authority
  Creates a new intermediate CA, to be signed by another internal CA on this firewall.

Pick an existing internal CA for the **Signing Certificate Authority** and fill in the remaining settings as described in *Certificate Authority Settings*.

If errors are reported, such as invalid characters or other input problems, they will be described on the screen. Correct the errors, and attempt to Save again.

13.2.3 Edit a Certificate Authority

To edit an existing CA:

- Navigate to **System > Certificates**, **CAs** tab
- Locate the CA entry in the list
- Click the  icon at the end of its row

The edit screen presented by the GUI allows editing the fields as if the CA were being imported.

For information on the fields on this screen, see *Certificate Authority Settings*. In most cases the purpose of this screen would be to add the CA to the trust store, correct the **Serial** of the CA if needed, or to add a key to an imported CA so it can be used to create and sign certificates and CRLs.

13.2.4 Export a Certificate Authority

To export a CA:

- Navigate to **System > Certificates**, **CAs** tab
- Locate the CA entry in the list
- Click the  icon at the end of its row to export the CA certificate.

  The file will download with the descriptive name of the CA as the file name, with the extension `.crt`.
- Click the  icon to export the private key for the CA if necessary

  The file will download with the descriptive name of the CA as the file name, with the extension `.key`.

  In most cases the private key for a CA would not be exported unless the CA is being moved to a new location or a backup is being made. When using the CA for a VPN or most other purposes, only export the certificate for the CA and do not export the key.

  Warning: If the private key for a CA gets into the wrong hands, the other party could generate new certificates that would be considered valid against the CA.

13.2.5 Remove a Certificate Authority

To remove a CA, first it must be removed from active use.

- Check areas that can use a CA, such as OpenVPN, IPsec, and packages.

Note: In most cases, the areas using a CA are noted in the **In Use** column of the CA list. This does not necessarily include all areas, especially if the CA is used by a package.

- Remove entries utilizing the CA or select a different CA
- Navigate to **System > Certificates**, **CAs** tab
- Locate the CA entry in the list
- Click  at the end of the row for the CA

Note: This icon will only be present if the CA is not in use.

- Click OK on the confirmation dialog

13.2.6 Renew a Certificate Authority

To renew a CA entry:

- Navigate to **System > Certificates**, **CAs** tab
- Locate the CA entry in the list
- Click  at the end of the row for the CA
- Follow the rest of the renewal procedure as described in *Renew or Reissue a CA or Certificate*

13.3 Certificate Management

Certificates are managed from **System > Certificates**, on the **Certificates** tab.

When creating a certificate on any platform the process generally follows this flow:

- User creates a certificate signing request (CSR) and set of keys. The public key is a part of the CSR, but the private key is separate.
- The user transmits only the CSR to the CA, not the private key which remains private to the user.
- The CA signs the CSR, which results in a certificate.
- The CA transmits the certificate to the user.

The user now has a certificate trusted by the CA, and the private key for the certificate.

The GUI handles most this process automatically, but it also supports performing individual steps separately as well. For example, when creating an internal certificate, there is no need to create and sign a CSR in separate steps, the GUI automates that process and does them in one step. Aside from that, the GUI supports creating a CSR which can be sent to a separate CA and it also supports signing CSRs.

13.3.1 Certificate Settings

When creating a certificate entry or working with a CSR, the following common options are available:

Common Properties
See *Certificate Properties* which covers properties of most certificate entries.

Certificate Type
Sets the intended purpose of this certificate. This influences which key usage properties are set in the certificate and thus limits the ways in which the certificate can operate.

> **Warning:** The certificate can only be used for purposes which match the selected type. Attempting to use it in other ways will produce errors and fail, or prevent the certificate from being shown for selection.

User Certificate
Certificates for end users and clients. For example, IPsec and OpenVPN client certificates.

> **Note:** User type certificates include Extended Key Usage attributes indicating they may be used for client authentication. They also are marked with a constraint indicating that they are not a CA.

Server Certificate
Certificates for servers, services, daemons, etc. For example, HTTPS servers (GUI, Captive Portal, HAProxy, etc), IPsec IKEv2 mobile server, OpenVPN servers, and for packages such as FreeRADIUS.

> **Note:** Server type certificates include Extended Key Usage attributes indicating they may be used for server authentication as well as the OID `1.3.6.1.5.5.8.2.2` which is used by Microsoft to signifiy that a certificate may be used as an IKE intermediate. These are required for Windows 7 and later to trust the server certificate for use with certain types of VPNs. They also are marked with constraints indicating that they are not a CA, and they have `nsCertType` set to `server`.

Alternative Names
Identifiers for this certificate, such as a hostname. See *Subject Alternative Name* for details.

When importing an existing certificate entry, the following options are available:

Certificate Data
The PEM-encoded certificate data for the certificate.

Certificate data is typically contained in a file ending with `.crt` or `.pem`. It would be plain text, and enclosed in a block such as:

```
-----BEGIN CERTIFICATE-----
[A bunch of random-looking base64-encoded data]
-----END CERTIFICATE-----
```

The format varies slightly for ECDSA certificates.

Private Key Data
The PEM-encoded private key for the certificate.

The key data is typically in a file ending in `.key`. It would be plain text data enclosed in a block such as:

```
-----BEGIN RSA PRIVATE KEY-----
[A bunch of random-looking base64-encoded data]
-----END RSA PRIVATE KEY-----
```

The format varies slightly for ECDSA keys.

13.3.2 Create a new Certificate

To create a new certificate, start the process as follows:

- Navigate to **System > Certificates**, **Certificates** tab
- Click **Add** to create a new certificate
- Enter a **Descriptive name** for the certificate

  This is used as a label for this certificate throughout the GUI.
- Select the **Method** that best suits how the certificate will be generated

  These options and further instructions are in the corresponding sections below:

  - Create an Internal Certificate
  - Import an Existing Certificate
  - Create a Certificate Signing Request
  - Sign a Certificate Signing Request
- Complete the steps for the chosen method
- Click Save to finish the import process

Create an Internal Certificate

The most common **Method** is *Create an Internal Certificate*. This will make a new certificate using one of the existing certificate authorities.

- Select the **Certificate Authority** which will sign this certificate. Only a CA that has a private key present can be in this list, as the private key is required in order for the CA to sign a certificate.
- Set the properties of the certificate as described in *Certificate Settings*.
- Click **Save**.

Import an Existing Certificate

To import an existing certificate from an external source, set **Method** to *Import an Existing Certificate*. This can be useful for certificates made using another system or for certificates provided by a third party.

There are two ways to import a certificate, indicated by the **Certificate Type** option:

X.509 (PEM)
: Enter the **Certificate data** and **Private key data**, which are both required. See *Certificate Settings* for details on populating the contents of the fields.

The most common error is not pasting in the right portion of the certificate or private key. Make sure to include the entire block, including the beginning header and ending footer around the encoded data.

PKCS #12 (PFX)
This method reads the certificate data from a PKCS #12 file, commonly found with a `.p12` extension. If the `.p12` file contains a CA, it is also imported along with the certificate, provided it does not already exist locally.

PKCS #12 Certificate
Click **Browse** to locate the `.p12` file on the local client, it will be uploaded and read when saving.

PKCS #12 Certificate Password
Enter the password used to protect the contents of the `.p12` file

Intermediates
When set, if the PKCS #12 file contains multiple CA entries in a chain, this option will import all of them instead of only one.

Create a Certificate Signing Request

Choosing a **Method** of *Certificate Signing Request* creates a new request file that can signed by a CA at a later time, including by a third party CA not present on the firewall. This is commonly used to obtain a certificate from a trusted root certificate authority.

The parameters for creating this certificate are identical to those for creating a certificate and are covered in *Certificate Settings*.

Note: Though the GUI shows fields for **Certificate Type** and **Alternative Names** as described in *Certificate Settings*, they are only suggestions for the CA. The signing CA may ignore these options and replace them with values of its own.

Sign a Certificate Signing Request

Signing a certificate signing request (CSR) is a special process which uses an internal CA on the firewall to sign a CSR and turn it into a full-fledged certificate.

The following options are available when signing a CSR:

CA to sign with
The CA on the firewall which will sign this CSR. This must be an internal CA (private key present).

CSR to sign
This option chooses whether to sign a new CSR not present on the firewall or an existing CSR on the firewall.

New CSR
When chosen, the GUI presents fields in which the CSR data can be pasted.

CSR Data
The PEM-encoded CSR data. CSR data is typically contained in a file ending with `.req` or `.pem`. It would be plain text, and enclosed in a block such as:

```
-----BEGIN CERTIFICATE REQUEST-----
[A bunch of random-looking base64-encoded data]
-----END CERTIFICATE REQUEST-----
```

Key Data
The optional PEM-encoded private key for the certificate. This is not required to sign a CSR, but may be useful, or even necessary, if the resulting certificate will be used on the firewall. For example, a private key would be required for a local service or as a user certificate used with a VPN export package.

The key data is typically in a file ending in `.key`. It would be plain text data enclosed in a block such as:

```
-----BEGIN RSA PRIVATE KEY-----
[A bunch of random-looking base64-encoded data]
-----END RSA PRIVATE KEY-----
```

Existing CSR
The remaining items in the drop-down list are CSR entries which already exist on the firewall. Choose one to sign.

Certificate Lifetime
The lifetime of the new certificate. See *Lifetime* for details.

Digest Algorithm
The digest algorithm for the new certificate. See *Digest Algorithm* for details.

When signing a CSR, the signing CA may also give new values for **Certificate Type** and **Alternative Names** as described in *Certificate Settings*. The signing process in the GUI does not support automatically reading these values from a CSR, so set them again here.

When complete, the result is a certificate entry in the list, which can then be used or exported.

13.3.3 Edit a Certificate

To edit an existing certificate:

- Navigate to **System > Certificates**, **Certificates** tab
- Locate the Certificate entry in the list
- Click the  icon at the end of its row to reach the Edit page for the certificate.

The Edit page can modify some aspects of the certificate, such as:

- The **Descriptive Name** of the certificate.
- The **Certificate Data**, which may need to be replaced if the certificate was renewed by a CA off the firewall.
- The **Private key data**, which may need updated if the private key is regenerated (e.g. with a stronger key, or a different key type)

The Edit page also contains options for exporting entries with a password. See *Export Password-Protected Files or Use Different Encryption Options* for details.

13.3.4 Export a Certificate

There are multiple methods to export certificates. The primary differences are whether or not the files will have password protection and which type of encryption is used to protect the PKCS #12 archive. The certificate itself does not contain private information and thus does not require protection. The private key and PKCS #12 format files do contain private information and thus can be exported in a protected manner.

Export Unprotected Files

- Navigate to **System > Certificates**, **Certificates** tab
- Locate the Certificate entry in the list
- Click the  icon at the end of its row to export the certificate.

  The file will download with the descriptive name of the certificate as the file name, with the extension `.crt`.
- Click the  icon to export the private key for the certificate.

  The file will download with the descriptive name of the certificate as the file name, with the extension `.key`.
- Click the  icon to export a PCKS #12 file containing the CA, certificate, and private key together.

  The file will download with the descriptive name of the certificate as the file name, with the extension `.p12`.

Export Password-Protected Files or Use Different Encryption Options

The GUI can also export password-protected versions of the private key and PKCS #12 archives. This is more secure, but some systems may not support using password-protected keys. There is also an option to control the type of encryption used to protect the PKCS #12 archive because some platforms do not support certain types of algorithms when dealing with these files.

- Navigate to **System > Certificates**, **Certificates** tab
- Locate the Certificate entry in the list
- Click the  icon at the end of its row to reach the Edit page for the certificate.
- Fill in the desired **Export Password** (or leave it blank to export without a password)
- Choose an appropriate **PKCS #12 Encryption** option:

  High
  Uses AES-256 and SHA256 to encrypt the archive (default). This is the current strongest option and is supported by pfSense software, FreeBSD, Linux, and Windows 10/11. In most cases this is the most desirable option.

  Note: Use this level when exporting for platforms with OpenSSL 3.0.

  Low
  Uses 3DES and SHA1 to encrypt the archive. This algorithm is considered weak and deprecated by most modern operating systems, but it is required by the key management built into macOS (current versions, including Ventura 13.2) and older versions of Windows.

Legacy
Uses RC2-40 and SHA1 to encrypt the archive. Avoid using this level if at all possible as it is extremely weak by modern standards. This was the previous default on older versions of pfSense software (Plus 22.05, CE 2.6.0).

> **Warning:** OpenSSL 3.0 will not read PKCS #12 archives encrypted with this method as it has deprecated this type of weak encryption.

- Click the  **Export Private Key** button to export the private key for the certificate.

  The password-protected file will download with the descriptive name of the certificate as the file name, with the extension `.key`.

- Click the  **PCKS #12** button to export a PCKS #12 file containing the CA, certificate, and private key together.

  The password-protected file will download with the descriptive name of the certificate as the file name, with the extension `.p12`.

13.3.5 Export a Certificate Signing Request

- Navigate to **System > Certificates**, **Certificates** tab
- Locate the CSR entry in the list
- Click the  icon at the end of its row to export the CSR.

  The file will download with the descriptive name of the CSR as the file name, with the extension `.req`.

13.3.6 Remove a Certificate

To remove a certificate, first it must be removed from active use.

- Check areas that can use a certificate, such as the WebGUI options, OpenVPN, IPsec, and packages

> **Note:** In most cases, the areas using a certificate are noted in the **In Use** column of the certificate list. This does not necessarily include all areas, especially if the certificate is used by a package.

- Remove entries using the certificate, or choose another certificate
- Navigate to **System > Certificates**, **Certificates** tab
- Locate the certificate to delete in the list
- Click  at the end of the row for the certificate

> **Note:** This icon will only be present if the certificate is not in use.

- Click OK on the confirmation dialog

13.3.7 Renew a Certificate

To renew a certificate entry:

- Navigate to **System > Certificates**, **Certificates** tab
- Locate the certificate entry in the list
- Click  at the end of the row for the certificate
- Follow the rest of the renewal procedure as described in *Renew or Reissue a CA or Certificate*

13.3.8 User Certificates

If a VPN is being used that requires user certificates, they may be created in one of several ways. The exact method depends on where the authentication for the VPN is being performed and whether or not the certificate already exists.

No Authentication or External Authentication

If there is no user authentication, or if the user authentication is being performed on an external server (RADIUS, LDAP, etc) then make a user certificate like any other certificate described earlier. Ensure that *User Certificate* is selected for the **Certificate Type** and set the **Common Name** to match the username.

Local Authentication

If user authentication is being performed by this firewall, the user certificate can be made inside of the User Manager. The User Manager can create a certificate while creating a user or it can add certificates to existing users. These processes are documented at *Manage Local Users*.

13.4 Renew or Reissue a CA or Certificate

When a CA or certificate expires it must be replaced, renewed, or reissued. The GUI can Renew or Reissue a certificate using a semi-automatic process. This process can retain the existing properties of the CA or certificate, but results in a freshly signed copy. This process can also make changes to the lifetime, keys, and digest so they meet current security best practices.

The new copy of this certificate must be distributed to the intended target as it was originally.

13.4.1 Certificate Properties

The Renew or Reissue page displays information about the entry, including:

Subject
: The subject of the certificate, containing its Distinguished Name (DN)

Serial
: The serial number of the certificate.

Subject Key ID
: Fingerprint of the certificate key.

Certificate Type
Either **User** or **Server**, if known.

Issued By
The CA which signed the certificate (Name and DN)

13.4.2 Renew or Reissue Options

There are two options available which control what happens when the certificate is renewed:

Reuse Key
When set (default), the existing key on the certificate is retained. When unset, a fresh key will be created when the certificate is reissued.

Reuse Serial
Set this option to retain the existing serial number when reissuing. Uncheck to generate a new serial.

Retaining the serial when renewing a CA allows existing certificates to remain valid, though some clients may not respect the new CA if the serial does not change.

Similarly, certificates should have a new serial every time they are renewed or some peers will reject them.

The exact behavior depends on the service and clients, but generally speaking it is safe to reuse the serial on a CA but not safe to reuse the serial on a server or user certificate. For example, OpenVPN is OK with reusing the serial number on a CA when renewing, while web browsers will reject changing a server certificate, even self-signed, if the serial does not change when the contents of the certificate change.

Strict Security
When set, upgrades the security of the certificate to meet current standards.

The Renew or Reissue page performs a security analysis on the certificate, comparing its current values for Lifetime, Digest, and RSA Key size with current best security practices. This analysis is printed at the bottom of the page. If any of the values are weak, the **Would Change** column in the analysis indicates **Yes**.

13.4.3 Renew or Reissue Example

To start the renewal process, first locate the CA or certificate to renew:

- Navigate to **System > Certificates**
- Navigate to the **CAs** tab for CA entries, or the **Certificates** tab for certificates
- Locate the entry to renew in the list
- Click  at the end of the row for the certificate to load the Renew or Reissue page for the certificate

---

Note: The  icon only appears for entries which have been signed by an internal CA on the firewall.

- Review the contents of the page
- Set the *Renew or Reissue Options* as desired

- Click  **Renew/Reissue**
- Click **OK** to confirm the action

When the process completes, the certificate entry is updated in the configuration.

Note: If the certificate is in use by a service on the firewall, the associated service(s) are restarted automatically.

For user certificates, the updated certificate must be exported and transmitted to the user. If a new key was generated by the renewal process, it must also be transmitted to the user.

13.5 Certificate Revocation List Management

Certificate Revocation Lists (CRLs) are a part of the X.509 system that publish lists of certificates that must no longer be trusted. These certificates may have been compromised or otherwise need to be invalidated. An application using a CA, such as OpenVPN may optionally use a CRL so it can verify connecting client certificates. A CRL is generated and signed against a CA using its private key, so in order to create or add certificates to a CRL in the GUI, the private key of the CA must be present. If the CA is managed externally and the private key for the CA is not on the firewall, a CRL may still be generated outside of the firewall and imported.

The traditional way to use a CRL is to only have one CRL per CA and only add invalid certificates to that CRL. The GUI, however, supports multiple CRLs for a single CA. In OpenVPN, different CRLs may be chosen for separate VPN instances. This could be used, for example, to prevent a specific certificate from connecting to one instance while allowing it to connect to another. For IPsec, all CRLs are consulted and there is no selection as currently exists with OpenVPN.

Certificate Revocation Lists are managed from **System > Certificates**, on the **Certificate Revocation** tab.

From this screen CRL entries can be added, edited, exported, or deleted. The list shows all existing CRLs and an option to add a new CRL from a given CA. The screen also indicates whether the CRL is internal or external (imported), and it shows a count of how many certificates have been revoked on each CRL, and indicates if the CRL is in use.

13.5.1 Create a new Certificate Revocation List

To create a new CRL:

- Navigate to **System > Certificates**, **Certificate Revocation** tab
- Select a CA from the drop-down menu under the **Create or Import a New Certificate Revocation List**
- Click  **Add** at the end of the row to create a new CRL
- Set the **Method** to *Create an Internal Certificate Revocation List*
- Enter a **Descriptive Name** for the CRL

  This is used to identify this CRL in lists around the GUI. It's usually best to include a reference to the name of the CA and/or the purpose of the CRL.
- Enter the **Lifetime** value as a number of days for which the CRL should be valid

  The default value is `730` days (2 years).

Note: In practice, this limit would almost never be reached as the CRL is regenerated any time the CRL is edited or when a service which utilizes a CRL is reconfigured.

Note: The system attempts to prevent using too large a value for the lifetime to ensure the date doesn't overflow. On 32-bit platforms, the limit is before the UNIX time rollover in 2038. On other platforms, the limit is before UTCTime 2-digit dates roll over in 2050. See Redmine #13424 for details. Systems reporting an expired CRL can work around the error by making a new CRL with a lower lifetime or by applying a patch on that Redmine issue.

- Click **Save**

The browser will be return to the CRL list, and the new entry will be shown there.

13.5.2 Import an Existing Certificate Revocation List

To import a CRL from an external source:

- Navigate to **System > Certificates**, **Certificate Revocation** tab
- Select a CA from the drop-down menu under the **Create or Import a New Certificate Revocation List**
- Click  **Add** at the end of the row to create a new CRL
- Set the **Method** to *Import an Existing Certificate Revocation List*
- Enter a **Descriptive Name** for the CRL

  This is used to identify this CRL in lists around the GUI. It's usually best to include a reference to the name of the CA and/or the purpose of the CRL.
- Enter the **CRL data**

  This is typically in a file ending in `.crl`. It would be plain text data enclosed in a block such as:

```
-----BEGIN X509 CRL-----
[A bunch of random-looking base64-encoded data]
-----END X509 CRL-----
```

- Click **Save** to finish the import process.

If an error appears, follow the on-screen instructions to correct the problem and then try again. The most common error is not pasting in the right portion of the CRL data. Make sure to enter the entire block, including the beginning header and ending footer around the encoded data.

Warning: New entries cannot be added to imported CRLs. To update an imported CRL, see *Updating an Imported Certificate Revocation List*.

13.5.3 Export a Certificate Revocation List

- Navigate to **System > Certificates**, **Certificate Revocation** tab
- Locate the CRL to delete in the list
- Click the  icon

The file will download with the descriptive name of the CRL as the file name, and the extension `.crl`.

13.5.4 Delete a Certificate Revocation List

- Check areas that can use a CRL, such as IPsec and OpenVPN

Note: In most cases, the areas using a CRL are noted in the **In Use** column of the CRL list. This does not necessarily include all areas, especially if the CRL is used by a package.

- Remove entries using the CRL, or choose another CRL instead
- Navigate to **System > Certificates**, **Certificate Revocation** tab
- Locate the CRL to delete in the list
- Click the  icon at the end of the row for the CRL

Note: This icon will only be present if the CRL is not in use.

- Click OK on the confirmation dialog

If an error appears, follow the on-screen instructions to correct the problem and then try again.

13.5.5 Revoke a Certificate

A CRL isn't useful unless it contains revoked certificates. A certificate is revoked by adding the certificate to a CRL, or by entering its serial number.

- Navigate to **System > Certificates**, **Certificate Revocation** tab
- Locate the CRL to edit in the list
- Click the  icon at the end of the row for the CRL

  The GUI lists any revoked certificates on the CRL, and a control to add new ones.
- Select a **Reason** from the drop-down list to indicate why the certificate is being revoked

  This information doesn't affect the validity of the certificate it is merely informational in nature. This option may be left at the default value.
- To revoke by certificate, select the certificate(s) from the **Revoke Certificates** list

---

Note: Multiple certificates can be revoked at once by selecting all of them in the list.

- To revoke by serial number, enter one or more certificate serial numbers separated by spaces in the **Revoke by Serial** field
- Click  **Add** and the certificate(s) will be added to the CRL

Note: Certificates can be revoked by selection and by serial at the same time.

After adding a certificate, the CRL will be re-written if it is currently in use by any VPN instances so that the CRL changes will be immediately active.

13.5.6 Removing a Certificate from a CRL

Certificates can be removed from the CRL when editing a CRL:

- Navigate to **System > Certificates**, **Certificate Revocation** tab
- Locate the CRL to edit in the list
- Click the  icon at the end of the row for the CRL
- Find the certificate in the list and click the  icon to remove it from the CRL
- Click **OK** on the confirmation dialog

After removing a certificate, the CRL will be re-written if it is currently in use by any VPN instances so that the CRL changes will be immediately active.

13.5.7 Updating an Imported Certificate Revocation List

To update an imported CRL:

- Navigate to **System > Certificates**, **Certificate Revocation** tab.
- Locate the CRL to edit in the list
- Click the  icon at the end of the row for the CRL
- Enter a new copy of the **CRL Data**
- Click **Save**

After updating the imported CRL, it will be re-written if it is currently in use by any VPN instances so that the CRL changes will be immediately active.

13.6 DH Parameters

To put it simply, the DH parameters are extra bits of randomness that help out during the key exchange process. They do not have to match on both sides of the tunnel, and new DH parameters can be made at any time. DH parameters are not specific to a given setup in the way that certificates or keys are. There is no need to import an existing set of DH parameters because generating new parameters is a better practice.

pfSense® software ships with a default set of DH parameter files so that new firewalls do not have to spend significant CPU resources to build them when they are needed. These pre-generated parameters are stored in `/etc/dh-parameters`. Selecting a specific length in the GUI will use the DH parameter set from the corresponding file. These DH parameters are not stored in config.xml.

To generate a new set of DH parameters, which can take quite a long time depending on the hardware in use, run the following commands:

```
/usr/bin/openssl dhparam -out /etc/dh-parameters.1024 1024
/usr/bin/openssl dhparam -out /etc/dh-parameters.2048 2048
/usr/bin/openssl dhparam -out /etc/dh-parameters.4096 4096
```

CPU time used to generate the parameters increases significantly with length. For example, generating 1024-bit DH parameters only takes about 7 seconds on a C2758 CPU, but generating 2048-bit parameters takes 4 minutes, and generating 4096-bit parameters takes 10 minutes.

The GUI allows longer DH parameters to be selected if they exist in `/etc/` in the format specified above.

Supported lengths are: `1024`, `2048`, `3072`, `4096`, `7680`, `8192`, `15360`, and `16384`.

For example, to generate a new set of DH parameters of length `8192`, run:

```
/usr/bin/openssl dhparam -out /etc/dh-parameters.8192 8192
```

The **Certificate Manager** under **System > Certificates**, creates and maintains certificate authority (CA), certificate, and certificate revocation list (CRL) entries for use by the firewall.

Entries in the Certificate Manager are used by the firewall for purposes such as TLS for the GUI, VPNs, LDAP, various packages, and more.

13.7 Basic Introduction to X.509 Public Key Infrastructure

One authentication option for VPNs is to use X.509. An in depth discussion of X.509 and Public Key Infrastructure (PKI) is outside the scope of this documentation, and is the topic of a number of entire books for those interested in details. This chapter provides a basic understanding necessary for creating and managing certificates.

With PKI, a CA is the source of trust and is the first entity of a PKI structure. This CA then signs all of the individual certificates in a set. The certificate of the CA is used on VPN servers and clients to verify the authenticity of server and client certificates. The certificate for the CA can be used to verify signing on certificates, but not to sign certificates. Signing certificates requires the private key for the CA. The secrecy of the CA private key is what ensures the security of a PKI. Anyone with access to the CA private key can generate certificates to be used on a PKI, hence it must be kept secure. This key is never distributed to clients or servers.

Warning: Never copy more files to clients than are needed, as this may compromise the security of the PKI structure.

A certificate is considered valid if it has been trusted by a given CA. In the case of a VPN, this means that a certificate made from a specific CA would be considered valid for any VPN using that CA. For that reason the best practice is to create a unique CA for each VPN that has a different level of security. For instance, if there are two mobile access VPNs with the same security access, using the same CA for those VPNs is OK. However if one VPN is for users and another VPN is for remote management, each with different restrictions, then it is best for each VPN to have a unique CA.

Certificate revocation lists (CRLs) are lists of certificates that have been compromised or otherwise invalidated. Revoking a certificate will cause it to be considered untrusted so long as the application using the CA also uses a CRL. CRLs are generated and signed against a CA using its private key, so in order to create or add certificates to a CRL in the GUI the private key for a CA must be present.

CHAPTER

FOURTEEN

FIREWALL

One of the primary functions performed by pfSense® software is filtering traffic, deciding which traffic to pass or block between networks. This section covers fundamentals of firewalling, best practices, and required information necessary to configure firewall rules.

14.1 Managing Firewall Rules

Firewall rules control traffic passing through the firewall. These topics describe how to create and manage rules, plus settings related to rules.

14.1.1 Firewalling Fundamentals

This section deals primarily with introductory firewall concepts and lays the ground work for understanding how to configure firewall rules using pfSense® software.

Basic Terminology

Rule and *ruleset* are two terms used throughout this chapter:

Rule
: Refers to a single entry on the **Firewall > Rules** screen. A rule instructs the firewall how to match or handle network traffic.

Ruleset
: Refers to a group of rules collectively. Either *all* firewall rules as a whole, or a set of rules in a specific context such as the rules on an interface tab. The complete firewall ruleset is the sum of all user configured and automatically added rules, which are covered further throughout this section.

Rulesets on the **Interface** tabs are evaluated on a **first match** basis. This means that reading the ruleset for an interface from top to bottom, the first rule that matches will be the one used by the firewall. Evaluation stops after reaching this match and then the firewall takes the action specified by that rule. Always keep this in mind when creating new rules, especially when crafting rules to restrict traffic. The most permissive rules should be toward the bottom of the list, so that restrictions or exceptions can be made above them.

Note: The **Ethernet** and **Floating** tabs are exceptions to this rule processing logic. See *Ethernet (Layer 2) Rules* and *Floating Rules* for details.

Stateful Filtering

pfSense software is a stateful firewall, which means it remembers information about connections flowing through the firewall so that it can automatically allow reply traffic. This data is retained in the **State Table**. The connection information in the state table includes the source, destination, protocol, ports, and more: Enough to uniquely identify a specific connection.

Using this mechanism, traffic need only be permitted on the interface where it **enters** the firewall. When a connection matches a pass rule the firewall creates an entry in the state table. Reply traffic to connections is automatically allowed back through the firewall by matching it against the state table rather than having to check it against rules in both directions. This includes any related traffic using a different protocol, such as ICMP control messages that may be provided in response to a TCP, UDP, or other connection.

See also:

See *Firewall & NAT* and *State Type* for more information about state options and types.

Note: This does not apply to *Ethernet (Layer 2) Rules* which do not keep state, or to rules which have manually disabled the keep state option.

State Policy

The behavior of state matching can be fine-tuned by changing the State Policy to either strictly bind states to interfaces and only match on those interfaces ("Interface Bound States") or it can be more relaxed and ignore the interface when matching packets to states ("Floating States").

This behavior can be changed globally (*Firewall & NAT Advanced Options,*) and on a per-rule basis (*Firewall Rule Configuration, Advanced Options, State Policy*).

State table size

The firewall state table has a maximum size to prevent memory exhaustion. Each state takes approximately 1 KB of RAM. The default state table size in pfSense is calculated by taking about 10% of the RAM available in the firewall by default. On a firewall with 1GB of RAM, the default state table size can hold approximately 100,000 entries.

See also:

See *Large State Tables* for more information on state table sizing and RAM usage.

Each user connection typically consists of two states: One created as it enters the firewall, and one as it leaves the firewall. Therefore, with a state table size of 1,000,000, the firewall can handle approximately 500,000 user sessions actively traversing the firewall before any additional connections will be dropped. This limit can be increased as needed so long as it does not exceed the available amount of RAM in the firewall.

To increase the state table size:

- Navigate to **System > Advanced** on the **Firewall & NAT** tab
- Enter the desired number for **Firewall Maximum States**, or leave the box blank for the default calculated value. See Figure *Increased State Table Size to 2,000,000*
- Click **Save**

Historical state table usage is tracked by the firewall. To view the graph:

- Navigate to **Status > Monitoring**

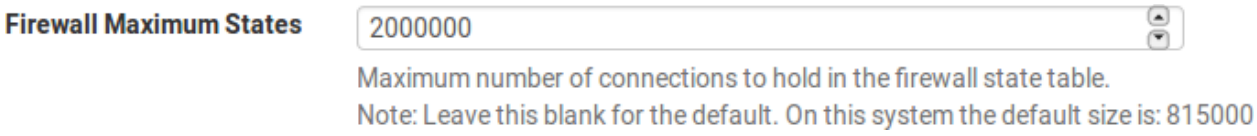

Fig. 1: Increased State Table Size to 2,000,000

- Click  to expand the graph options
- Set **Category** for the **Left Axis** to *System*
- Set the **Graph** for the **Left Axis** to *States*
- Click  **Update Graphs**

Block vs. Reject

There are two ways to disallow traffic using firewall rules on pfSense: **Block** and **reject**.

A rule set to **block** will silently drop traffic. A blocked client will not receive any response and thus will wait until its connection attempt times out. This is the behavior of the default deny rule in pfSense software.

A rule set to **reject** will respond back to the client for denied TCP and UDP traffic, letting the sender know that the connection was refused. Rejected TCP traffic receives a TCP RST (reset) in response, and rejected UDP traffic receives an ICMP unreachable message in response. Though reject is a valid choice for any firewall rule, IP protocols other than TCP and UDP are not capable of being rejected; These rules will silently drop other IP protocols because there is no standard for rejecting other protocols.

Deciding Between Block and Reject

There has been much debate amongst security professionals over the years as to the value of block vs. reject. Some argue that using block makes more sense, claiming it "slows down" attackers scanning the Internet. When a rule is set to reject, a response is sent back immediately that the port is closed, while block silently drops the traffic, causing the attacker's port scanner to wait for a response. That argument does not hold water because every good port scanner can scan hundreds or thousands of hosts simultaneously, and the scanner is not stalled waiting for a response from closed ports. There is a minimal difference in resource consumption and scanning speed, but so slight that it shouldn't be a consideration.

If the firewall blocks all traffic from the Internet, there is a notable difference between block and reject: Nobody knows the firewall is online. If even a single port is open, the value of that ability is minimal because the attacker can easily determine that the host is online and will also know what ports are open whether or not the blocked connections have been rejected by the firewall. While there isn't significant value in block over reject, the best practice is to use block on WAN rules. There is some value in not actively handing information to potential attackers, and it is also a bad practice to automatically respond to an external request unnecessarily.

For rules on internal interfaces the best practice is to use reject in most situations. When a host tries to access a resource that is not permitted by firewall rules, the application accessing it may hang until the connection times out or the client program stops trying to access the service. With reject the connection is immediately refused and the client avoids these hangs. This is usually nothing more than an annoyance, but it is still a good idea to use reject to avoid potential application problems induced by silently dropping traffic inside a network.

14.1.2 Introduction to the Firewall Rules screen

This section provides an introduction and overview of the Firewall Rules screen located at **Firewall > Rules**. This page lists the WAN ruleset to start with, which by default has no entries other than those for **Block private networks** and **Block bogon networks** if those options are active on the WAN interface, as shown in Figure *Default WAN Rules*.

Tip: Click the to the right of the **Block private networks** or **Block bogon networks** rules to reach the WAN interface configuration page where these options can be enabled or disabled. See *Block Private Networks* and *Block Bogon Networks* for more details.

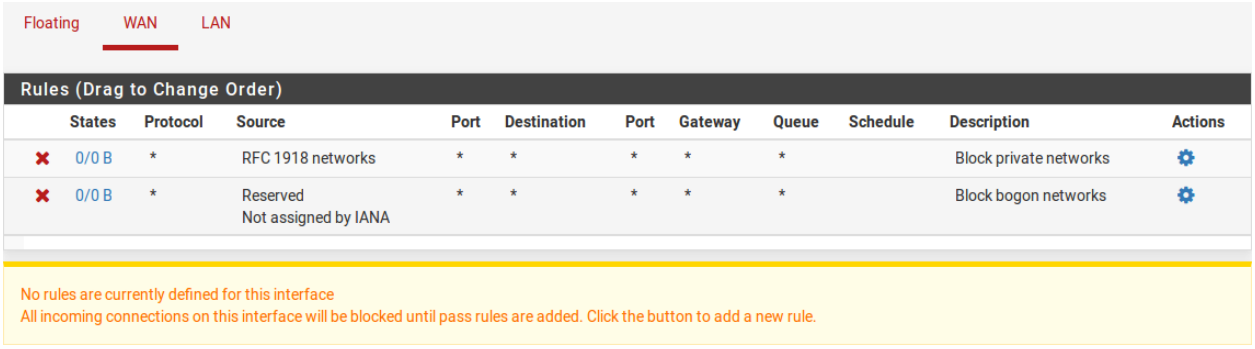

Fig. 2: Default WAN Rules

Click the **LAN** tab to view the LAN rules. By default, the only entries are the *Default allow LAN to any* rules for IPv4 and IPv6 as seen in Figure *Default LAN Rules*, and the **Anti-Lockout Rule** if it is active. The anti-lockout rule is designed to prevent administrators from accidentally locking themselves out of firewall management services. Click

next to the anti-lockout rule to reach the page where this rule can be disabled.

See also:

For more information on how the Anti-Lockout Rule works and how to disable the rule, see *Anti-lockout Rule* and *Anti-lockout*.

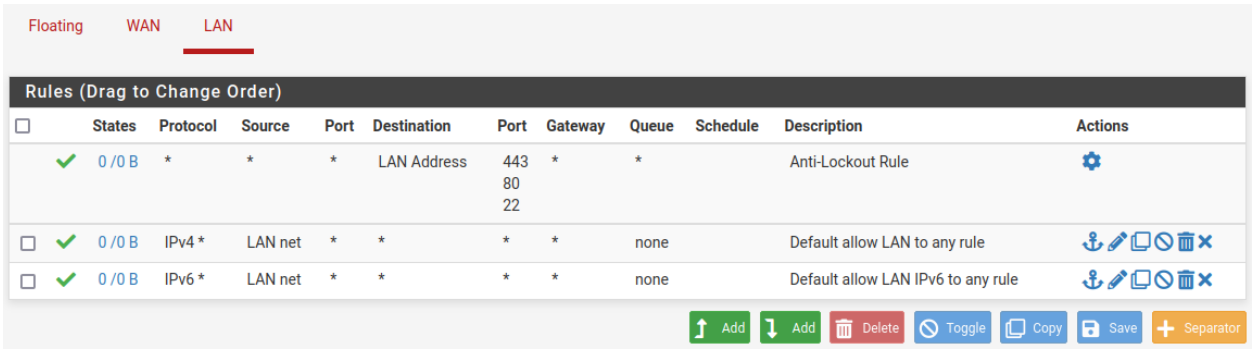

Fig. 3: Default LAN Rules

To display rules for other interfaces, click their respective tabs. OPT interfaces will appear with their descriptive names, so if the OPT1 interface was renamed `DMZ`, then the tab for its rules will also say **DMZ**.

To the left of each rule is a set of an indicator icons, including:

- The action of the rule: pass (), block (), or reject ().
- Logging status: If logging is enabled for the rule,  is present.
- Advanced options: If the rule has any advanced options enabled, an  icon is present.

Hovering the mouse cursor over any of these icons will display text explaining their meaning. The same icons are shown for disabled rules, except the icon and the rule are a lighter shade of their original color.

Adding a firewall rule

To add a rule to the top of the list, click  **Add**.

To add a rule to the bottom of the list, click  **Add**.

Editing Firewall Rules

To edit a firewall rule, click  to the right of the rule, or double click anywhere on the line.

The edit page for that rule will load, and from there adjustments are possible. See *Configuring Firewall Rules* for more information on the options available when editing a rule.

Reordering Firewall Rules

The order of the rules on an interface can be changed in two different ways: Drag-and-drop or select-and-click.

To reorder rules using the drag-and-drop method:

- Move the mouse over the firewall rule to move, the cursor will change to indicate movement is possible.
- Click and hold the mouse button down
- Drag the mouse to the desired location for the rule
- Release the mouse button
- Click  **Save** to store the new rule order

Warning: Attempting to navigate away from the page after moving a rule, but before saving the order, will result in the browser presenting an error confirming whether or not to exit the page. If the browser navigates away from the page without saving, the rule will still be in its original location.

To move rules in the list in groups or by selecting them first, use the select-and-click method:

- Select the rules to move

Note: Select rules by single clicking anywhere on their line or by checking the box at the start of the row.

- Click  on the row **below** where the rule should be moved.

Tip: Hold **Shift** before clicking the mouse on  to move the rule below the selected rule instead of above.

When moving rules using the select-and-click method, the new order is stored automatically.

Copying Firewall Rules

To make a new rule that is similar to an existing rule, click  to the right of the existing rule. The edit screen will appear with the existing rule's settings pre-filled, ready to be adjusted. When duplicating an existing rule, the new rule will be added directly *below* the original rule. For more information about how to configure the new rule, see *Configuring Firewall Rules*.

To copy multiple rules:

- Select the rules to copy

Note: Select rules by single clicking anywhere on their line or by checking the box at the start of the row.

- Click the  **Copy** button below the rule list

  The firewall will open a new modal dialog with options to set before copying.
- Select the **Destination Interface**
- Select **Convert interface definitions** to automatically adjust the source of the rule to match the target interface, if necessary
- Click  **Paste** to complete the operation

Warning: When copying rules to different interfaces, they may fall at the start or the end of the target interface rule list depending on the order of the interface rules in the configuration. Be prepared to reorder the rules on the target interface before applying changes.

Deleting Firewall Rules

To delete a single rule, click  to the right of the rule. The firewall will present a confirmation prompt before deleting the rule.

To delete multiple rules:

- Select the rows to remove

> **Note:** Select rules by single clicking anywhere on their line or by checking the box at the start of the row.

- Click the  **Delete** button below the rule list
- Confirm the action

Checking Rule Usage

The **States** column contains usage counters for each rule. It shows the number of active states created by a rule and the amount of traffic consumed by those states.

Hovering the mouse over these counters shows additional detailed statistics:

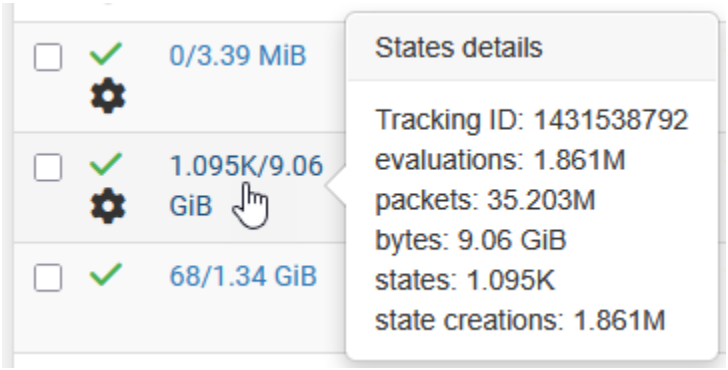

Fig. 4: Firewall Rule Usage Statistics

The statistics displayed by this view include:

Tracking ID
: The firewall *Rule Tracking ID* which uniquely identifies this rule.

Evaluations
: The number of times the firewall has evaluated this rule when processing packets.

Packets
: The number of packets passed by this rule.

Bytes
: The amount of traffic, in bytes, passed by this rule.

States
: The number of active state table entries created by this rule.

State Creations
The total number of state table entries created by this rule.

Note: Though the firewall makes an effort to maintain these statistics, the values can reset over time depending on firewall ruleset reloads and other similar actions.

Clicking the value in this column displays a list of states created by the rule.

See also:

Viewing Firewall States in the GUI

Clearing States Created by a Rule

Click the  icon to the right of a rule and then confirm the action to clear all active states created by that rule.

Note: This only affects states on this interface created by this rule directly. It does not clear states on other interfaces where traffic may have exited the firewall.

Disabling and Enabling Firewall Rules

To disable a rule, click  at the end of its row. The appearance of the rule will change to a lighter shade to indicate that it is disabled and the  icon changes to  .

To enable a rule which was previously disabled, click  at the end of its row. The appearance of the rule will return to normal and the enable/disable icon will return to the original  .

A rule may also be disabled or enabled by editing the rule and toggling the **Disabled** checkbox.

To disable or enable multiple rules at once:

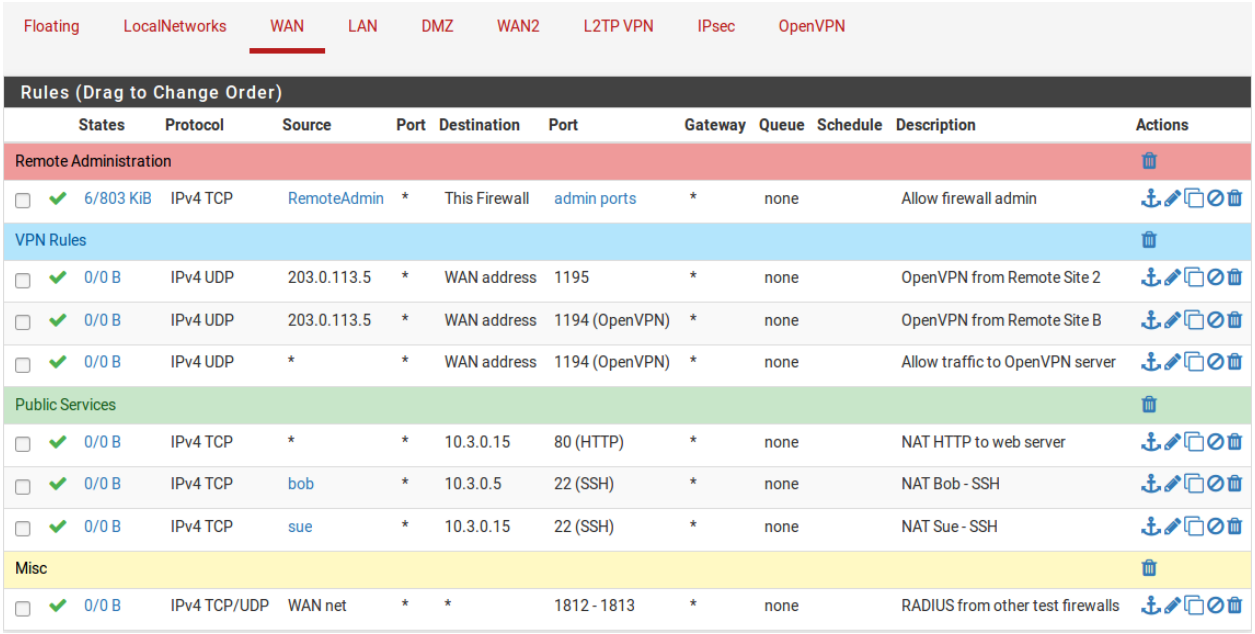
- Select the rules to disable

  Note: Select rules by single clicking anywhere on their line or by checking the box at the start of the row.

- Click the  **Toggle** button below the rule list

Rule Separators

Firewall Rule Separators are colored bars in the ruleset that contain a small bit of text, but do not take any action on traffic. They are useful for visually separating or adding notes to special parts of the ruleset. Figure *Firewall Rule Separators Example* shows how they can be utilize to group and document the ruleset.



Floating | LocalNetworks | WAN | LAN | DMZ | WAN2 | L2TP VPN | IPsec | OpenVPN

Rules (Drag to Change Order)

States	Protocol	Source	Port	Destination	Port	Gateway	Queue	Schedule	Description	Actions
Remote Administration										
6/803 KiB	IPv4 TCP	RemoteAdmin	*	This Firewall	admin ports	*	none		Allow firewall admin	
VPN Rules										
0/0 B	IPv4 UDP	203.0.113.5	*	WAN address	1195	*	none		OpenVPN from Remote Site 2	
0/0 B	IPv4 UDP	203.0.113.5	*	WAN address	1194 (OpenVPN)	*	none		OpenVPN from Remote Site B	
0/0 B	IPv4 UDP	*	*	WAN address	1194 (OpenVPN)	*	none		Allow traffic to OpenVPN server	
Public Services										
0/0 B	IPv4 TCP	*	*	10.3.0.15	80 (HTTP)	*	none		NAT HTTP to web server	
0/0 B	IPv4 TCP	bob	*	10.3.0.5	22 (SSH)	*	none		NAT Bob - SSH	
0/0 B	IPv4 TCP	sue	*	10.3.0.15	22 (SSH)	*	none		NAT Sue - SSH	
Misc										
0/0 B	IPv4 TCP/UDP	WAN net	*	*	1812 - 1813	*	none		RADIUS from other test firewalls	

Fig. 5: Firewall Rule Separators Example

To create a new Rule Separator:

- Open the firewall rule tab where the Rule Separator will reside
- Click  **Separator**
- Enter description text for the Rule Separator
- Choose the color for the Rule Separator by clicking the  icon of the desired color
- Click and drag the Rule Separator to its new location
- Click  **Save** inside the Rule Separator to store its contents
- Click  **Save** at the bottom of the rule list

To move a Rule Separator:

- Open the firewall rule tab containing the Rule Separator
- Click and drag the Rule Separator to its new location
- Click  **Save** at the bottom of the rule list

To delete a Rule Separator:

- Open the firewall rule tab containing the Rule Separator
- Click  inside the Rule Separator on the right side
- Click  **Save** at the bottom of the rule list

Rule Separators cannot be edited. If a change in text or color is required, create a new Rule Separator and delete the existing entry.

Tracking Firewall Rule Changes

The firewall tracks rule creation and changes with data stored on each rule. These timestamps are visible when editing an existing rule.

Rule Information

14.1.3 Ingress Filtering

Ingress filtering refers to the concept of firewalling traffic entering a network from an external source such as the Internet. In deployments with multi-WAN, the firewall has multiple ingress points. The default ingress policy on pfSense® software is to **block all traffic** as there are no allow rules on WAN in the default ruleset. Replies to traffic initiated from inside the local network are automatically allowed to return through the firewall by the state table.

14.1.4 Egress Filtering

Egress filtering refers to the concept of firewalling traffic initiated inside the local network, destined for a remote network such as the Internet. pfSense, like nearly all similar commercial and open source solutions, comes with a LAN rule allowing everything from the LAN out to the Internet. This isn't the best way to operate, however. It has become the de facto default in most firewall solutions because it is what most people expect. The common misperception is "Anything on the internal network is 'trustworthy', so why bother filtering"?

Why employ egress filtering?

From our experience in working with countless firewalls from numerous vendors across many different organizations, most small companies and home networks do not employ egress filtering. It can increase the administrative burden as each new application or service may require opening additional ports or protocols in the firewall. In some environments it is difficult because the administrators do not completely know what is happening on the network, and they are hesitant to break things. In other environments it is impossible for reasons of workplace politics. The best practice is for administrators to configure the firewall to allow only the minimum required traffic to leave a network where possible. Tight egress filtering is important for several reasons:

Limit the Impact of a Compromised System

Egress filtering limits the impact of a compromised system. Malware commonly uses ports and protocols that are not required on most business networks. Some bots rely on IRC connections to phone home and receive instructions. Some will use more common ports such as TCP port 80 (normally HTTP) to evade egress filtering, but many do not. If access to TCP port 6667, the usual IRC port, is not permitted by the firewall, bots that rely on IRC to function may be crippled by the filtering.

Another example is a case where the inside interface of a pfSense software installation was seeing 50-60 Mbps of traffic while the WAN had less than 1 Mbps of throughput. There were no other interfaces on the firewall. Some investigation showed the cause as a compromised system on the LAN running a bot participating in a distributed denial of service (DDoS) attack against a Chinese gambling web site. The attack used UDP port 80, and in this network UDP port 80 was not permitted by the egress ruleset so all the DDoS was accomplishing was stressing the inside interface of the firewall with traffic that was being dropped. In this situation, the firewall was happily chugging along with no performance degradation and the network's administrator did not know it was happening until it was discovered by accident.

The attack described in the above paragraph likely used UDP port 80 for two main reasons:

- UDP allows large packets to be sent by the client without completing a TCP handshake. With stateful firewalls being the norm, large TCP packets will not pass until the handshake is successfully completed, and this limits the effectiveness of the DDoS.
- Those who do employ egress filtering are commonly too permissive, allowing TCP and UDP where only TCP is required, as in the case of HTTP.

These types of attacks are commonly launched from compromised web servers. With a wide open egress ruleset, the traffic will go out to the Internet, and has the potential to overflow the state table on the firewall, cost money in bandwidth usage, and/or degrade performance for everything on the Internet connection.

Outbound SMTP is another example. Only allow SMTP (TCP port 25) to leave any network from a mail server. Or if a mail server is externally hosted, only allow internal systems to talk to that specific outside system on TCP port 25. This prevents every other system in the local network from being used as a spam bot, since their SMTP traffic will be dropped. Many mail providers have moved to using only authentication submission from clients using TCP port 587, so clients should not need access to port 25. This has the obvious benefit of limiting spam, and also prevents the network from being added to numerous black lists across the Internet that will prevent that site from sending legitimate e-mail to many mail servers. This may also prevent the ISP for that site from shutting off its Internet connection due to abuse.

The ideal solution is to prevent these types of things from happening in the first place, but egress filtering provides another layer that can help limit the impact if other measures fail.

Prevent a Compromise

Egress filtering can prevent a compromise in some circumstances. Some exploits and worms require outbound access to succeed. An older but good example of this is the Code Red worm from 2001. The exploit caused affected systems to pull an executable file via TFTP (Trivial File Transfer Protocol) and then execute it. A web server almost certainly does not need to use the TFTP protocol, and blocking TFTP via egress filtering prevented infection with Code Red even on unpatched servers. This is largely only useful for stopping completely automated attacks and worms as a real human attacker will find any holes that exist in egress filtering and use them to their advantage. Again, the correct solution to prevent such a compromise is to fix the network vulnerabilities used as an attack vector, however egress filtering can help.

Limit Unauthorized Application Usage

Many applications such as VPN clients, peer-to-peer software, instant messengers, and more rely on atypical ports or protocols to function. While a growing number of peer-to-peer and instant messenger applications will port hop until finding a port which is allowed out of the local network, many will be prevented from functioning by a restrictive egress ruleset, and this is an effective means of limiting many types of VPN connectivity.

Prevent IP Address Spoofing

This is a commonly cited reason for employing egress filtering, but pfSense software automatically blocks spoofed traffic via the *antispoof* functionality of `pf`, so it isn't applicable here. Preventing IP address spoofing means that malicious clients cannot send traffic with obviously falsified source addresses.

Prevent Information Leaks

Certain protocols should never be allowed to leave a local network. Specific examples of such protocols vary from one environment to another, but a few common examples are:

- Microsoft RPC (Remote Procedure Call) on TCP port 135
- NetBIOS on TCP and UDP ports 137 through 139
- SMB/CIFS (Server Message Block/Common Internet File System) on TCP and UDP port 445.

Stopping these protocols can prevent information about the internal network from leaking onto the Internet, and will prevent local systems from initiating authentication attempts with Internet hosts. These protocols also fall under *Limit the Impact of a Compromised System* as discussed previously since many worms have relied upon these protocols to function. Other protocols that may be relevant are syslog, SNMP, and SNMP traps. Restricting this traffic will prevent misconfigured network devices from sending logging and other potentially sensitive information out to the Internet. Rather than worry about what protocols can leak information out of a local network and need to be blocked, the best practice is to only allow the traffic that is required.

Approaches for implementing egress filtering

On a network that has historically not employed egress filtering, it can be difficult to know what traffic is absolutely necessary. This section describes some approaches for identifying traffic and implementing egress filtering.

Allow what is known, block the rest, and work through the fallout

One approach is to add firewall rules for known required traffic to be permitted. Start with making a list of things known to be required such as in Table *Egress Traffic Required*.

Table 1: Egress Traffic Required

Description	Source	Destination	Destination port
HTTP and HTTPS from all hosts	LAN Network	Any	TCP 80 and 443
SMTP from mail server	Mail Server	Any	TCP 25
DNS queries from internal DNS servers	DNS Servers	Any	TCP and UDP 53

After making the list, configure firewall rules to pass only that traffic and let everything else hit the default deny rule.

Log Traffic and Analyze Logs

Another alternative is to enable logging on all pass rules and send the logs to a syslog server. The logs can be analyzed by the syslog server to see what traffic is leaving the network. pfSense software uses a custom log format, so the logs typically need be parsed by a custom script unless the server has some knowledge of the pfSense software filter log format. Analysis of the logs will help build the required ruleset with less fallout as it will yield a better idea of what traffic is necessary on the local network.

14.1.5 Firewall Rule Best Practices

This section covers general best practices for firewall rule configuration.

Default Deny

There are two basic philosophies in computer security related to access control: default allow and default deny. A default deny strategy for firewall rules is the best practice. Firewall administrators should configure rules to permit only the bare minimum required traffic for the needs of a network, and let the remaining traffic drop with the default deny rule built into pfSense® software. In following this methodology, the number of deny rules in a ruleset will be minimal. They still have a place for some uses, but will be minimized in most environments by following a default deny strategy.

In a default two-interface LAN and WAN configuration, pfSense software utilizes default deny on the WAN and default allow on the LAN. Everything inbound from the Internet is denied, and everything out to the Internet from the LAN is permitted. All home grade routers use this methodology, as do all similar open source projects and most similar commercial offerings. It's what most people expect out of the box, therefore it is the default configuration. That said, while it is a convenient way to start, it is not the recommended means of long-term operation.

pfSense software users often ask "What bad things should I block?" but that is the wrong question as it applies to a default allow methodology. Noted security professional Marcus Ranum includes default permit in his "Six Dumbest Ideas in Computer Security" paper, which is recommended reading for any security professional. Permit only what a network requires and avoid leaving the default allow all rule on the LAN and adding block rules for "bad things" above the permit rule.

Keep it short

The shorter a ruleset, the easier it is to manage. Long rulesets are difficult to work with, increase the chances of human error, tend to become overly permissive, and are significantly more difficult to audit. Utilize aliases to keep the ruleset as short as possible.

Review Firewall Rules

The best practice is a manual review of the firewall rules and NAT configuration on a periodic basis to ensure they still match the minimum requirements of the current network environment. The recommended frequency of such reviews varies from one environment to another. In networks that do not change frequently, with a small number of firewall administrators and good change control procedures, quarterly or semi-annually is usually adequate. For fast changing environments or those with poor change control and several people with firewall access, review the configuration at least on a monthly basis.

Quite often when reviewing rules with customers, Netgate TAC asks about specific rules and they respond with "We removed that server six months ago." If something else would have taken over the same internal IP address as the previous server, then traffic would have been allowed to the new server that may not have been intended.

Document The Configuration

In all but the smallest networks, it can be hard to recall what is configured where and why. The best practice is to use the **Description** field in firewall and NAT rules to document the purpose of the rules. In larger or more complex deployments, create and maintain a more detailed configuration document describing the entire pfSense software configuration. When reviewing the firewall configuration in the future, this will help determine which rules are necessary and why they are there. This also applies to any other area of the configuration.

It is also important to keep this document up to date. When performing periodic configuration reviews, also review this document to ensure it remains up-to-date with the current configuration. Ensure this document is updated whenever configuration changes are made.

Reducing Log Noise

By default, pfSense software logs packets blocked by the default deny rule. This means all of the noise getting blocked from the Internet will be logged. Sometimes there will not be much noise in the logs, but in many environments there will inevitably be something incessantly spamming the logs.

On networks using large broadcast domains – a practice commonly employed by cable ISPs – this is most often NetBIOS broadcasts from clue-deficient individuals who connect Windows machines directly to their broadband connections. These machines will constantly pump out broadcast requests for network browsing, among other things. ISP routing protocol packets may also be visible, or router redundancy protocols such as VRRP or HSRP. In co-location environments such as data centers, a combination of all of those things may be present.

Because there is no value in knowing that the firewall blocked 14 million NetBIOS broadcasts in the past day, and that noise could be covering up logs that are important, it is a good idea to add a block rule on the WAN interface for repeated noise traffic. By adding a block rule *without logging enabled* on the WAN interface, this traffic will still be blocked, but no longer fill the logs.

The rule shown in Figure *Firewall Rule to Prevent Logging Broadcasts* is configured on a test system where the "WAN" is on an internal LAN behind an edge firewall. To get rid of the log noise to see the things of interest, we added this rule to block – but not log – anything with the destination of the broadcast address of that subnet.

Rules (Drag to Change Order)

		States	Protocol	Source	Port	Destination	Port	Gateway	Queue	Schedule	Description
☐	✖	0/0 B	IPv4 *	*	*	10.0.64.255	*	*	none		Do not log broadcasts

Fig. 6: Firewall Rule to Prevent Logging Broadcasts

The best practice is to add similar rules, matching the specifics of any log noise observed in an environment. Check the firewall logs under **Status > System Logs**, **Firewall** tab to see what kind of traffic the firewall is blocking, and review how often it appears in the log. If any particular traffic is consistently being logged more than 5 times a minute, and the traffic is not malicious or noteworthy, add a block rule for it to reduce log noise.

Logging Practices

Out of the box, pfSense software does not log any passed traffic and logs all dropped traffic. This is the typical default behavior of almost every open source and commercial firewall. It is the most practical, as logging all passed traffic is rarely desirable due to the load and log levels generated. This methodology is a bit backwards, however, from a security perspective. Blocked traffic cannot harm a network so its log value is limited, while traffic that gets passed could be very important log information to have if a system is compromised. After eliminating any useless block noise as described in the previous section, the remainder is of some value for trend analysis purposes. If significantly more or less log volume than usual is observed, it is probably good to investigate the nature of the logged traffic. OSSEC, an open source host-based intrusion detection system (IDS), is one system that can gather logs from a firewall via syslog and alert based on log volume abnormalities.

14.1.6 Rule Methodology

In pfSense® software, rules on interface tabs are applied on a per-interface basis, always in the inbound direction on that interface. This means traffic initiated from hosts connected to the LAN is filtered using the LAN interface rules. Traffic initiated from hosts on the Internet is filtered with the WAN interface rules. Because all rules in pfSense software are stateful by default, a state table entry is created when traffic matches an allow rule. All reply traffic is automatically permitted by this state table entry.

The exception to this is Floating rules (*Floating Rules*), which can act on any interface using the inbound, outbound, or both directions. Outbound rules are never required, because filtering is applied on the inbound direction of every interface. In some limited circumstances, such as a firewall with numerous internal interfaces, having them available can significantly reduce the number of required firewall rules. In such a case, apply egress rules for Internet traffic as outbound floating rules on the WAN interface to avoid having to duplicate them for every internal interface. The use of inbound and outbound filtering makes a configuration more complex and more prone to user error, but it can be desirable in specific applications.

Interface Groups

Interface groups, discussed in *Interface Groups*, are a method to place rules on multiple interfaces at the same time. This can simplify some rule configurations if similar rules are required on many interfaces in the same way. Interface group rules, like interface rules, are processed in the inbound direction only. The VPN tabs for OpenVPN, L2TP, and the PPPoE server are all special Interface groups that are automatically created behind the scenes.

For example, a group may be used for a collection of interfaces including all LAN or DMZ type interfaces, or for a group of VLANs.

Note: Interface groups are not effective with Multi-WAN because group rules cannot properly handle `reply-to`. Due to that deficiency, traffic matching a group rule on a WAN that does not have the default gateway will go back out the WAN with the default gateway, and not through the interface which it entered.

Rule Processing Order

There are three main classes of Layer 3 rules: Regular interface rules, Floating rules, and Interface Group rules (including VPN tab rules). The order of processing of these types is significant, and it works like so:

1. Floating Rules
2. Interface Group Rules
3. Interface Rules

The rules are ordered in that way in the actual ruleset, keep that in mind when crafting rules. For example, if an interface group contains a rule to block traffic, that rule cannot be overridden with an interface tab rule because the traffic has already been acted upon by the group rule, which was matched first in the ruleset.

The rules are processed until a match is found, however, so if a packet is *not* matched in the group rules, it can still be matched by an interface rule.

Another significant place this comes into play is with assigned OpenVPN interfaces. If an "allow all" rule is in place on the OpenVPN tab, it is matched with the group rules. This means the rules on the interface tab will not apply. This can be a problem if OpenVPN rules need to have `reply-to` in order to ensure certain traffic exits back via the VPN.

See also:

See *Ordering of NAT and Firewall Processing* for a more detailed analysis of rule processing and flow through the firewall, including how NAT rules come into play.

Automatically Added Firewall Rules

pfSense software automatically adds internal firewall rules for a variety of reasons. This section describes automatically added rules and their purpose.

Anti-lockout Rule

To prevent locking an administrator out of the web interface, pfSense enables an anti-lockout rule by default. This is configurable on the **System > Advanced** page under **Anti-lockout**. This automatically added rule allows traffic from any source inside the network containing the rule, to any firewall administration protocol listening on the LAN IP address. For example, it grants access to TCP port 443 for the WebGUI, TCP port 80 for the GUI redirect, and TCP port 22 if SSH is enabled. If the WebGUI port has been changed, the configured port is the one allowed by the anti-lockout rule.

In security-conscious environments, the best practice is to disable this rule and configure the LAN rules so only an alias of trusted hosts can access the administrative interfaces of the firewall. A better practice yet is to not allow access from the LAN but only from an isolated administrative management network.

Restricting access to the administrative interface from LAN

First, to configure the firewall rules as desired to restrict access to the required management interface(s). In this typical use case example, both SSH and HTTPS are used for management, so create a ManagementPorts alias containing these ports (Figure *Alias for Management Ports*).

Then create an alias for hosts and/or networks that will have access to the management interfaces (Figure *Alias For Management Hosts*).

The resulting aliases are shown in Figure *Alias List*.

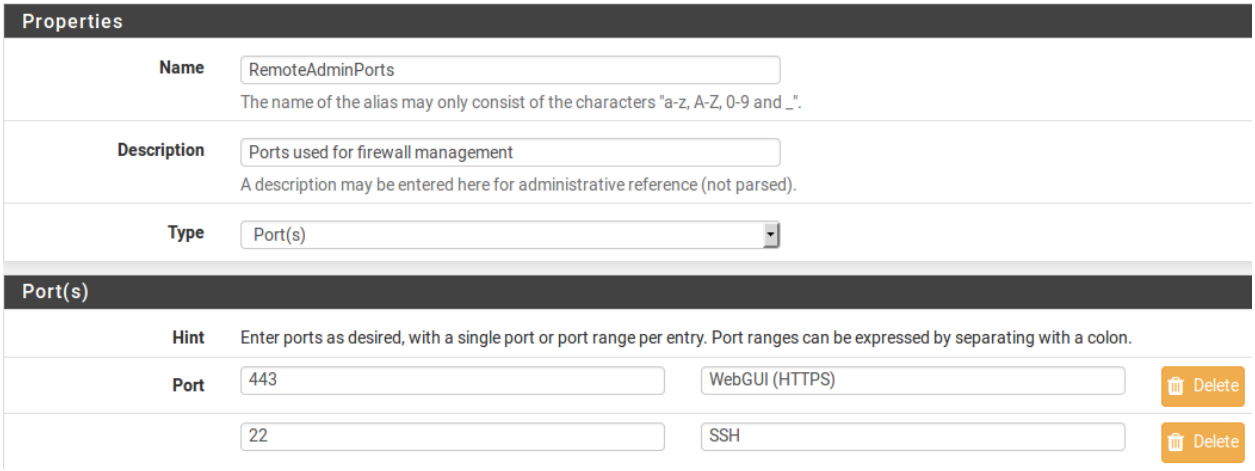

Fig. 7: Alias for Management Ports

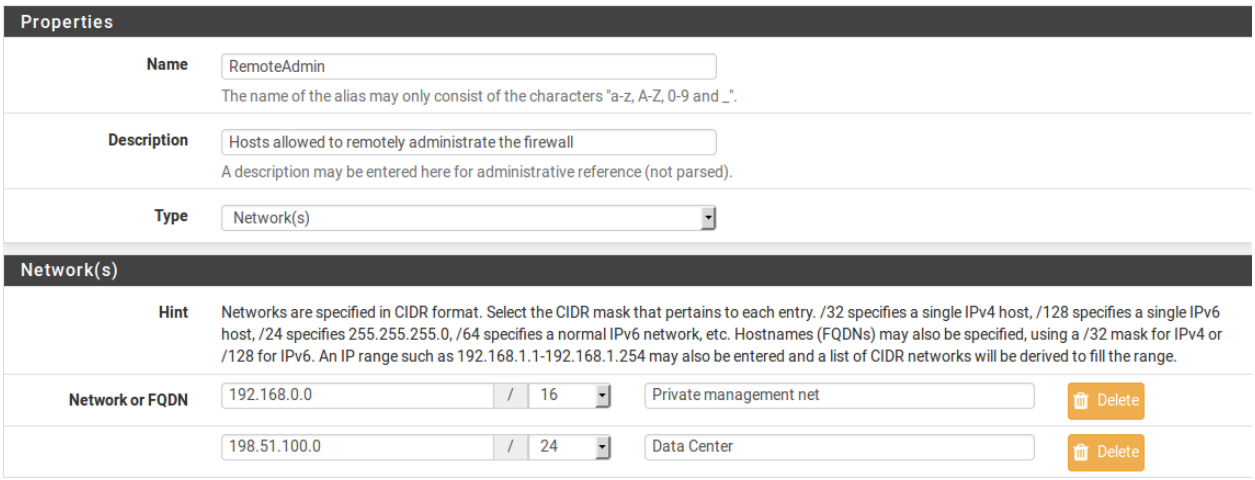

Fig. 8: Alias For Management Hosts

RemoteAdmin	192.168.0.0/16, 198.51.100.0/24	Hosts allowed to remote admin
RemoteAdminPorts	443, 22	Ports used for firewall management

Fig. 9: Alias List

Then the LAN firewall rules must be configured to allow access by the previously defined hosts, and deny access to all else. There are numerous ways to accomplish this, depending on specifics of the environment and how egress filtering is handled. Figure *Example Restricted Management LAN Rules* show two examples. The first allows DNS queries to the LAN IP address, which is needed if the DNS Resolver or DNS Forwarder are enabled, and also allows LAN hosts to ping the LAN IP address. It then rejects all other traffic. The second example allows access from the management hosts to the management ports, then rejects all other traffic to the management ports. Choose the methodology that works best for the network environment in question. Remember that the source port is not the same as the destination port.

	States	Protocol	Source	Port	Destination	Port	Gateway	Queue	Schedule	Description
☐	✔ 0/0 B	IPv4 TCP/UDP	10.0.0.0/8	*	LAN address	53 (DNS)	*	none		Allow internal network to query the DNS Resolver
☐	✔ 0/0 B	IPv4 ICMP echoreq	10.0.0.0/8	*	LAN address	*	*	none		Allow internal network to ping the LAN IP Address
☐	✔ 0/0 B	IPv4 TCP	RemoteAdmin	*	LAN address	RemoteAdminPorts	*	none		Allow access to firewall management
☐	0/0 B	IPv4 *	*	*	LAN address	*	*	none		Reject everything else to the LAN IP address
☐	✔ 0/2.59 MiB	IPv4 *	10.0.0.0/8	*	*	*	*	none		LAN Traffic

Fig. 10: Example Restricted Management LAN Rules

	States	Protocol	Source	Port	Destination	Port	Gateway	Queue	Schedule	Description
☐	✔ 0/0 B	IPv4 TCP	RemoteAdmin	*	LAN address	RemoteAdminPorts	*	none		Allow access to firewall management
☐	0/0 B	IPv4 TCP	*	*	LAN address	RemoteAdminPorts	*	none		Reject access to firewall management from other host
☐	✔ 0/2.59 MiB	IPv4 *	10.0.0.0/8	*	*	*	*	none		LAN Traffic

Fig. 11: Restricted Management LAN Rules Alternate Example

Once the firewall rules are configured, disable the webGUI anti-lockout rule on the **System > Advanced** page (Figure *Anti-Lockout Rule Disabled*). Check the box and click **Save**.

Note: If the management interface can no longer be accessed after disabling the anti-lockout rule, the firewall rules were not configured appropriately. Re-enable the anti-lockout rule by using the **Set Interface(s) IP address** option at the console menu, then choose to reset the LAN IP address. Set it to its current IP address, and the rule will automatically be re-enabled.

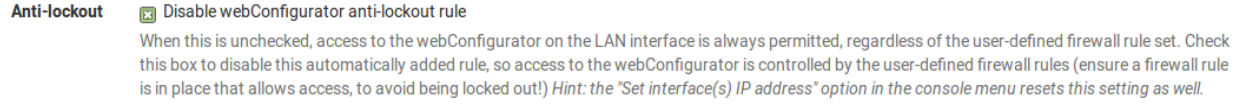

Fig. 12: Anti-Lockout Rule Disabled

Anti-spoofing Rules

pfSense software uses the antispoof feature in `pf` to block spoofed traffic. This provides Unicast Reverse Path Forwarding (uRPF) functionality as defined in RFC 3704. The firewall checks each packet against its routing table, and if a connection attempt comes from a source IP address on an interface where the firewall knows that network does not reside, it is dropped. For example, a packet coming in WAN with a source IP address of an internal network is dropped. Anything initiated on the internal network with a source IP address that does not reside on the internal network is dropped.

Block Private Networks

The **Block private networks** option on the WAN interface automatically puts in a block rule for RFC 1918 subnets. Unless private IP space is in use on the WAN, enable this option. This only applies to traffic initiated on the WAN side. Local clients may still reach hosts on private networks from the inside of the firewall. This option is available for any interface, but is generally only used on WAN type interfaces. A similar rule can be created manually to block private networks on interfaces by creating an alias containing the RFC 1918 subnets and adding a firewall rule to the top of the interface rules to block traffic with a source matching that alias. (See *Private IP Addresses* for more information about private IP addresses.)

Block Bogon Networks

Bogon networks are those which should never be seen on the Internet, including reserved and unassigned IP address space. The presence of traffic from these networks can indicate either spoofed traffic or an unused subnet that has been hijacked for malicious use. Bogon lists are intended to filter invalid traffic from the Internet (e.g. on WANs) coming to the firewall for cases where the source cannot be otherwise filtered or validated, such as for public services. If rules on an interface only allow from specific remote sources, bogon blocking does not offer any benefit. pfSense software provides two bogons lists that are updated as needed, one for IPv4 bogon networks and one for IPv6 bogon networks.

Warning: Blocking bogon networks is not suited for use on local/private interfaces such as LAN. Blocking bogon networks on local interfaces can be harmful as they will block traffic which is necessary for proper local network operations, especially for IPv6. If local interfaces have proper rules which only allow from specific local sources, bogon blocking is unnecessary.

The firewall fetches an updated bogons list on the first day of each month from Netgate servers. The script runs at 3:00 a.m. local time, and sleeps a random amount of time up to 12 hours before performing the update. This list does not change frequently, and new IP address assignments are removed from the bogons list months before they are allocated, so a monthly update is adequate. To automatically update the list more frequently, change the **Update Frequency** for bogons under **System > Advanced** on the **Firewall & NAT** tab.

Note: The bogons list for IPv6 is quite large, and may not load if there is not enough memory in the system, or if the maximum number of table entries is not large enough to contain it. See *Firewall Maximum Table Entries* for information on changing that value.

See also:

For information on troubleshooting bogon updates and forcing manual updates, see *Troubleshooting Bogon Network List Updates*.

IPsec

When a site to site IPsec connection is enabled the firewall automatically adds rules which pass traffic necessary for the tunnel to connect and pass traffic. See *IPsec and firewall rules* for details.

Due to the nature of policy routing any traffic that matches a rule specifying a gateway will be forced out to the Internet and will bypass IPsec processing. Rules are added automatically to negate policy routing for traffic destined to remote VPN subnets, but they do not always have the intended effect. To disable the automatic negation rules, see *Disable Negate rules* and add a firewall rule at the *top* of the rules on the internal interface to pass traffic to the VPN *without a gateway set*.

See also:

Automatically added IPsec rules are discussed in further depth in *IPsec and firewall rules*.

Default Deny Rule

Rules that do not match any user-defined rules nor any of the other automatically added rules are silently blocked by the default deny rule (as discussed in *Default Deny*).

14.1.7 Configuring Firewall Rules

When configuring firewall rules in the pfSense® software GUI under **Firewall > Rules**, many options are available to control how the firewall matches and controls packets. This section covers each of these options.

See also:

- *Ordering of NAT and Firewall Processing*
- *Floating Rules*

Action

This option specifies whether the rule will *pass*, *block*, or *reject* packets.

Pass
: The firewall will allow packets matching this rule to pass.

  If the rule has state tracking enabled, the firewall creates a state table entry for the first packet of a connection. This state table entry allows related return packets to pass back through.

  See also:

  Stateful Filtering

Block
: The firewall will discard packets matching this rule.

Reject
: The firewall will discard packets matching this rule and, for supported protocols, the firewall will send a message back to the source indicating that it refused the connection.

See also:

See *Block vs. Reject* for a deeper description of these options and for help deciding between Block and Reject.

Disabled

Disables a rule without removing it from the rule list. This entry will appear faded in the rule list to indicate its inactive state.

Interface

The interface receiving packets to be matched by this rule. The GUI pre-sets this value to match the interface tab from which the user added or edited the rule. Changing this value will move the rule to the interface tab matching the new value.

Note: Rules on interface and group tabs only filter packets on the interface where packets *enter* the firewall (ingress). In other words, the interface where hosts *initiated* those packets.

For example, rules on the **LAN** tab match packets initiated from hosts on the LAN which pass through the firewall, such as connections to hosts on the Internet or other remote networks.

Address Family

The address family this rule will match: *IPv4*, *IPv6*, or both *IPv4+IPv6*. The rule will only match and act upon packets with the selected address family.

Tip: Firewall rules can utilize aliases which contain both IPv4 and IPv6 addresses. Rules will use whichever alias entries match its address family.

NAT64

When **Address Family** is set to *IPv6* the GUI displays a checkbox to **Enable NAT64** which changes this rule into a *NAT64* rule. NAT64 rules perform translation to allow IPv6-only hosts to reach IPv4 resources. Despite acting in a role similar to Outbound NAT, these rules are placed on **internal** interface *firewall* rules where packets *enter* the firewall, e.g. on the LAN tab.

When **Enable NAT64** is checked, the GUI displays an **Address Family Translation** section with the following option:

Source
: Configures the external **source** address to which this rule will translate IPv4-mapped connections. For example, the external WAN IPv4 address. This is typically left on *Automatic* which is the default, but can be set to a specific address or VIP as needed.

> **Warning:** While NAT64 is technically compatible with Outbound NAT, the NAT64 translation happens before Outbound NAT so it is not practical. See *NAT64 and other NAT* for details.

Tip: NAT64 is compatible with policy routing. See *NAT64 and Policy Routing* for details.

See also:

- *NAT64*

- *NAT64 Configuration Recipe*

Protocol

The IP protocol this rule will match, such as *TCP* or *UDP*. The drop-down list contains several common protocols.

Most options only match packets based on the IP protocol encoded in the packet, however some types support additional filtering behaviors:

TCP, UDP, SCTP
: These protocols support source and destination port numbers. When a rule is configured for one of these protocols, the GUI displays controls for ports.

TCP/UDP
: Matches both *TCP* and *UDP* packets with a single rule.

ICMP
: When a rule is configured for ICMP, the GUI displays an *ICMP Subtypes* option to filter specific types of ICMP messages.

Note: This field defaults to *TCP* for a new rule because it is a common choice and the GUI will display fields that users expect to see, such as source and destination ports.

To make the rule apply to any protocol, change this option to *Any*. A common mistake in creating a new ruleset is accidentally creating only TCP rules and then not being able to pass non-TCP packets such as ICMP, DNS, etc.

ICMP Subtypes

This multi-select list contains all possible ICMP subtypes which this rule can match. The GUI displays this option when a rule has the **Protocol** option set to *ICMP*.

When passing ICMP packets, the most secure practice is for rules to only pass required subtypes when feasible. The most common use case is for rules to pass only the *Echo Request* subtype which will pass ICMP "ping" packets.

Tip: Allowing an ICMP subtype of *any* is acceptable in modern networks. ICMP has a bad reputation in the past, but it is generally beneficial and has overcome that reputation on modern networks. Some older equipment may still have issues, however.

Source

The source IP address, subnet, or alias that this rule will match.

The **Source** option contains several different pre-defined types of sources:

Any
: Matches any address.

Address or Alias
: Matches a single IP address or *alias name*.

  When a rule is configured for this value, the **Source Address** field allows entering an alias name and supports auto-completion of compatible alias names.

See also:

Aliases

Network
Matches a range of addresses defined by an IP address and CIDR mask/prefix length.

PPPoE Clients
Macro which will match packets from the client address range for the PPPoE server if the PPPoE server is enabled.

L2TP Clients
Macro which will match packets from the client address range for the L2TP server if the L2TP server is enabled.

Interface Address
Macros which match all IP addresses configured on a firewall interface. This includes IP addresses of any address family on the selected interface, such as static IP addresses, *Virtual IP Addresses*, and dynamic IP addresses obtained from DHCP or PPPoE.

This list contains entries for each interface on the firewall.

Interface Subnets
Macros which match networks directly attached to a firewall interface. This includes networks for IP addresses of any address family including static IP addresses, *Virtual IP Addresses*, and dynamic IP addresses.

This list contains entries for each interface on the firewall.

> **Warning:** This **does not** match networks reachable *through* an interface, only networks for IP addresses configured on an interface.

> **Warning:** The *WAN subnets* value **does not** mean "The Internet" or "any remote host", it only matches the network(s) of the WAN interface IP address(es).

Invert Match

Invert Match will negate the matching behavior so the rule will match all packets *except* those with the specified **Source** value.

Note: **Invert Match** can lead to undesired rule behavior when configured in combination with *<interface> subnets* macros, such as *LAN subnets*, when the interface also uses Virtual IP addresses.

When configured in this manner the firewall will match packets against the interface network **OR** the VIP networks. For example, given a Subnet of `192.168.1.0/24`, a VIP of `10.0.0.1/32`, and a rule with a negated interface macro such as `pass on $LAN from any to ! $LAN_net`, packets destined to `192.168.1.100` will pass because the destination IP address does not match the VIP.

Source Port Range

Rules configured to match the TCP, UDP, or SCTP protocols can also match based on the source port of a packet.

The GUI hides this option behind a  **Display Advanced** button as it is rarely correct to match based on source port. In nearly all cases the source port must remain set to *any* as nearly all clients source TCP, UDP, and SCTP connections from a random port in the ephemeral port range (typically between 1024 through 65535).

The source port is almost never the same as the destination port, and it should never be configured as such unless the application in use is known to employ this atypical behavior.

It is typically safe to define a source port as a range from `1024` to `65535`.

Destination

The destination IP address, subnet, or alias that this rule will match. This operates the same as the **Source** option, but it checks the packet destination.

See also:

Source

The **Destination** field contains one additional macro:

This firewall (self)
: Matches all IP addresses on all firewall interfaces.

Destination Port Range

Rules configured to match TCP, UDP, or SCTP protocols can also match based on the destination port, port range, or an alias containing ports.

Configuring a destination port is necessary in many cases as it is more secure than allowing *any* port and the destination port is usually known in advance based on specific network services.

The drop-down lists contain common port values. Select *(other)* to enter a numerical port manually or use a port alias.

Tip: A rule will match a continuous range of ports starting at the lower port in the **From** field and ending at the higher port value in the **To** field, inclusive.

Log

When checked, if this rule matches a packet it will create a log entry in the firewall log.

See also:

Logging Practices

Description

Text describing the rule, such as its intended behavior or name of a service. The best practice is to clearly describe the purpose of the rule in this field.

The description is optional and does not affect functionality of the rule. The maximum length is 52 characters.

Advanced Options

Options in this section are less common or have functionality confusing to new users. As such, the GUI hides them by default. Click  **Display Advanced** to show all of the advanced options. If an option in this section of the page has been set, the GUI will automatically display this section when the rule is loaded in the future.

Source OS

Attempts to match a packet by guessing which operating system (OS) is running on the host initiating a connection. This is only possible on rules which match TCP packets.

This task is handled by passive OS fingerprinting ("p0f"). The p0f feature of pf determines the OS in use by comparing characteristics of the TCP SYN packet which initiates TCP connections with a fingerprints file.

Note: It is possible for users to change the fingerprint of one OS to mimic a different OS, especially with an open source OS such as a BSD or Linux variant. This isn't easy, but if a network contains technically proficient users with administrator or root level access to devices, it is possible.

Diffserv Code Point

Differentiated Services Code Point is a packet header a device or application can use to indicate how it prefers routers treat the packet. The most common use of this value is for quality of service or traffic shaping purposes.

Differentiated Services Code Point is often shortened to *Diffserv Code Point* or abbreviated as *DSCP* and sometimes referred to as the *TOS field*.

The **Diffserv Code Point** drop-down field sets the DSCP value that this rule will match. There are numerous options, each with special meaning. Consult the documentation for the device or application originating the packets for more detail on which values rules must match.

Note: This option only reads and matches the DSCP value. It **does not** set a value in packets.

The device or application generating the packets will set the DSCP field value in the packets it creates. For example, Asterisk sets DSCP values via its `tos_sip` and `tos_audio` configuration parameters. After that point it is up to the firewall and other interim routers to match and queue or act on the packets.

The downside of DSCP is that it assumes routers support or act on the field, which may or may not be the case. Different routers may treat the same DSCP value in unintended or mismatched ways. Worse yet, some routers will clear the DSCP field in packets entirely before passing them to the next hop. Also, the way pf matches packets, the DSCP value must be set on the first packet of a connection creating a state, as pf does not inspect each packet individually once it has created a state.

IP Options

When set, packets matching this rule can have values set for IP options. By default, pf does not match packets which contain IP options in order to deter OS fingerprinting, among other reasons.

Tip: Check this box to pass IGMP or other multicast packets containing IP options.

Disable Reply-To

When set, prevents the firewall from adding the `reply-to` keyword on this rule.

By default, the firewall adds the `reply-to` keyword to rules on WAN type interfaces to ensure that packets which enter a WAN will also leave via that same WAN. In certain cases this behavior is undesirable, such as when the firewall must route packets via a separate firewall/router within the network on the WAN interface. In these cases, check this option rather than disabling `reply-to` globally.

Tag and Tagged

The **Tag** and **Tagged** fields are useful in concert with floating rules. Using tags, the firewall can mark a packet with a specific string as it enters an interface and then act differently on a matched packet on the way out with a floating rule.

See also:

Marking and Matching

Maximum state entries this rule can create

Limits the maximum number of connection states, total, that this rule will allow. If this rule matches a packet for a new connection while it is at its connection limit, the firewall will skip this rule during evaluation. If a later rule matches, the firewall applies the action of that rule to the packet, otherwise it hits the default deny rule. Once the number of active connections permitted by this rule drops below this connection limit, the rule can match packets for new connections again.

Maximum number of unique source nodes

Limits the total number of unique source IP addresses which may simultaneously have connection states created by this rule. Each source IP address is allowed an unlimited number of connections, but the total number of distinct source IP addresses is restricted to this value.

Maximum number of established connections per host

Limits access based on established connection states per host. This value can limit a rule to a specific number of connections per source host (e.g. `10`), instead of a global connection total. This option controls how many fully established (completed handshake) TCP connections the rule will allow per host. This option is only available for use with TCP connections.

Maximum state entries per host

Limits connection states in total per host without considering if the connections are established. This setting works similar to the established count above, but it can work with any protocol.

Maximum new connections / per second

Limits the amount of new connection states this rule can create in a given time period. This option is only available for use with TCP connections. The **Max. src. conn. Rate** field sets the number of states and the **Max. src. conn. Rates** field sets the time period.

Rules can use this feature to attempt preventing a high TCP connection rate from overloading a server or the state table on the firewall. For example, a rule can limit incoming connections to a mail server, reducing the burden of being overloaded by spambots. It can also be used on outbound rules to set limits that can prevent any single host from filling up the state table on the firewall or making too many rapid connections, behaviors which are common with viruses.

The firewall will block any IP address exceeding the specified number of connections within the given time frame for one hour. Behind the scenes, this is handled by the `virusprot` table, named for its typical purpose of virus protection.

State timeout in seconds

Overrides the default timeout for states created by this rule. Any inactive connections will be closed when the connection has been idle for this amount of time.

The default state timeout depends on the firewall optimization algorithm in use. The optimization choices are covered in *Firewall Optimization Options*

Note: This option only controls states created in the inbound direction on the given interface, so it has limited usefulness on its own. Outbound packets for a connection will still have the default state timeout as they egress. To fully apply this new timeout, create a matching floating rule in the outbound direction with a similar state timeout value.

TCP Flags

By default, pass rules for TCP packets only check for the TCP SYN flag to be set, out of a possible list of SYN and ACK flags. This means that for a packet to match the rule, the SYN flag **must** be set and the ACK flag **must not** be set. Other flags are ignored.

This set of controls enables rules to match different flag combinations to account for more complex scenarios, such as working around asymmetric routing or other non-traditional combinations of packet flow.

The **Set** row controls which flags must be **set** to match the rule. The **Out of** row defines the list of flags that will be consulted on the packet to look for a match.

Tip: Flags which are **not checked** in the **Set** row but are **checked** in the **Out of** row **must not** be set in packets to match this rule.

The meanings of the most commonly used flags are:

SYN
: Synchronize sequence numbers. Indicates a new connection attempt.

ACK
Indicates ACKnowledgment of data. These are replies to let the sender know data was received OK.

FIN
Indicates there is no more data from the sender, closing a connection.

RST
Connection reset. This flag is set when replying to a request to open a connection on a port which has no listening daemon. Can also be set by firewall software to turn away undesirable connections.

PSH
Indicates that data should be pushed or flushed, including data in this packet, by passing the data up to the application.

URG
Indicates that the urgent field is significant, and this packet should be sent before data that is not urgent.

To allow TCP packets with any combination of flags set, check **Any Flags**.

No pfsync

Prevents states created by this rule from synchronizing data to high availability (HA) peers via *pfsync*. This isolates states for this rule to only this HA node.

State Policy

Optionally overrides the default *Firewall State Policy* for connection states created by this rule. This is only effective when the *State Type* for this rule is a type that creates states.

The available options are:

Use Global Default
Uses the global default state policy configured at **System > Advanced**, **Firewall & NAT** tab, in the **Advanced Options** section (*Firewall State Policy*).

Interface Bound States
Binds states to interfaces so that when a packet is inspected to determine if it matches an existing state, it must be on the interface where the state was created.

Floating States
Does not bind states to interfaces, allowing packets matching the source and destination of a state to pass no matter which interface they are traversing.

See also:

For more information on how these policies work, see *Firewall State Policy*.

State Type

Controls how this rule will perform state tracking for connections created by packets matching this rule.

Keep
The firewall will create and maintain a state table entry for packets passed by this rule.

This is the default, and the best choice in most situations.

Sloppy State
Similar to *Keep*, but the firewall will perform less strict state comparison checks. This is intended for scenarios with asymmetric routing.

When the firewall can only see half the packet flow of a connection, the default validity checks for state tracking will fail and the firewall will block packets which may be part of active connections. Mechanisms in pf that prevent certain kinds of attacks will not trigger during a sloppy state check.

Synproxy
Instructs pf to proxy incoming TCP connections.

TCP connections start with a three way handshake. The first packet of a TCP connection is a SYN from the source, which elicits a SYN ACK response from the destination, then an ACK in return from the source to complete the handshake. Normally the host behind the firewall will handle this on its own, but synproxy state has the firewall complete this handshake instead. This helps protect against one type of Denial of Service attack, SYN floods. This is typically only used with rules on WAN interfaces.

This type of attack is best handled at the target OS level today, as every modern operating system includes capabilities of handling this on its own. Because the firewall can't know what TCP extensions the back-end host supports, when using synproxy state, it announces no supported TCP extensions. This means connections created using synproxy state will not use window scaling, SACK, nor timestamps which will lead to significantly reduced performance in most all cases.

This option can be useful when opening TCP ports to hosts that do not handle network abuse well, where top performance isn't a concern.

None
This rule will not create states for packets matching the rule. This is only necessary in highly specialized advanced scenarios, which are not covered in this documentation as they are exceedingly rare.

Note: Setting *None* on interface tab or group rules only affects packets in the inbound direction. As such, it is not very useful on its own since the outbound rules will still create a state as the packets egress. Rules on interface or group tabs must be paired with a floating rule in the outbound direction which also has the same option set.

Packet Flow Data

Optionally overrides the default *Firewall Packet Flow Data* configuration for tracking data for states created by this rule. This is only effective when the *State Type* for this rule is a type that creates states.

Note: pfSense® Plus software version 24.03 or later is required to use the Packet Flow Data feature. This feature is not available on pfSense CE Software.

Global configuration for Packet Flow Data is at **Firewall > Packet Flow Data**.

See also:

Read the option descriptions in *Global Packet Flow Options* for information on how this behaves by default.

There are three options available for **Packet Flow Data** here in the rule configuration:

Use global default
Honor the global default value for tracking packet flow data.

See also:

Global Packet Flow Options

Always track Packet Flow Data
Always tracks packet flow data for states created by this rule, no matter what default behavior is configured. This is useful for tracking specific data when the default is *not* to track.

Never track Packet Flow Data
Never tracks packet flow data for states created by this rule, no matter what default behavior is configured. This is useful for excluding data from monitoring when the default is to track everything.

No XMLRPC Sync

Checking this box prevents this rule from synchronizing to other High Availability cluster members via XMLRPC.

See also:

High Availability

Warning: This does not prevent a rule on a secondary node from being overwritten by the primary.

VLAN Priority (Match and Set)

802.1p, also known as IEEE P802.1p or Priority Code Point, is a way to match and tag packets with a specific quality of service priority. Unlike DSCP, 802.1p operates at layer 2 with VLANs. However, like DSCP, the upstream router must also support 802.1p for it to be useful.

There are two options in this section. The first will match an 802.1p field so the firewall can act on it. The second will inject an 802.1p tag into a packet as it passes through this firewall. Some ISPs may require an 802.1p tag to be set in certain areas, such as France, in order to properly handle voice/video/data on segregated VLANs at the correct priority to ensure quality.

There are eight levels of priority for 802.1p, and each has a two letter code in the GUI. In order from lowest priority to highest, they are:

BK
Background

BE
Best Effort

EE
Excellent Effort

CA
Critical Applications

VI
Video

VO
Voice

IC
Internetwork Control

NC
Network Control

Schedule

Configures a schedule specifying the days and times this rule will be active. Outside of the scheduled time, the rule is effectively disabled and the firewall skips the rule.

The default value is *none* which means the rule will always be enabled.

See also:

Time Based Rules

Gateway

A gateway or gateway group through which the firewall will deliver packets matching this rule.

When set to *Default*, the firewall will consult the routing table to determine the next hop for a packet.

See also:

- *Policy routing*
- *Routing*

In/Out Pipe (Limiters)

Traffic shaper Limiters this rule will use to apply bandwidth limits to packets entering this interface (**In**) and exiting this interface (**Out**).

See also:

Limiters.

Ackqueue/Queue

ALTQ traffic shaper queues into which this rule will place matching packets entering and exiting this interface.

See also:

Traffic Shaper

Rule Information

When a firewall rule, port forward rule, or outbound NAT rule is created or updated the firewall records the login name of the user who modified the rule, the IP address from which they logged in, and timestamps on the rule to track when that user created and/or last changed the rule in question. If the firewall automatically created the rule, the note includes which action created the rule.

An example of a rule update tracking block is shown in Figure *Firewall Rule Time Stamps*, which is visible when editing a firewall rule at the bottom of the rule editing screen.

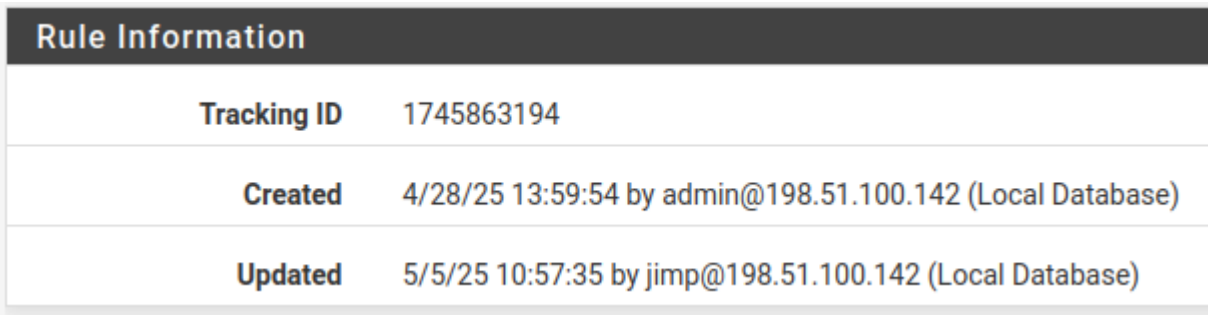

Fig. 13: Firewall Rule Time Stamps

Rule Tracking ID

Figure *Firewall Rule Time Stamps* also displays the rule **Tracking ID** which is a unique identifier the firewall assigns to a rule. This identifier allows the firewall to locate the rule and correlate actions between the ruleset, firewall logs, and other data tracking purposes.

Note: This value is created and maintained by the firewall itself, the tracking ID is not intended to be edited by administrators.

The firewall generates some rules automatically and/or dynamically, and tracking IDs for such rules may change when the ruleset reloads. Tracking IDs for manually created rules are static.

14.1.8 Ethernet (Layer 2) Rules

pfSense® Plus software versions 23.05 and later include support for rule-based pass/block filtering of packets based on Ethernet (Layer 2) header attributes. These are known as **Ethernet Rules**.

Processing of these rules is **not** enabled by default and can be togged under **System > Advanced**, **Firewall & NAT** tab.

When enabled, Ethernet rules are managed at **Firewall > Rules**, **Ethernet** tab.

See also:

- *WAN Connectivity with 802.1X Authentication Bridging and VLAN 0 PCP Tagging*
- *Ethernet Rules on Bridge Interfaces*

Ethernet Rules Overview

Layer 2 Interfaces

Ethernet rules are capable of operating on Layer 2 (L2) header information which is not visible to traditional firewall rules. To accomplish this, Ethernet rules operate at Layer 2 (L2) and are **only** processed on interfaces which carry L2 data.

Traditional Ethernet and VLAN interfaces will work, but certain types of VPN and tunneling interfaces will not. For example, OpenVPN in TAP mode can carry L2 information, while IPsec, WireGuard, and OpenVPN in TUN mode cannot.

As a general rule, if an interface has a MAC address, then it is capable of carrying L2 data.

Warning: The firewall will not generate an error if the user attempts to apply an Ethernet rule on an interface which is not capable of L2. These rules can never be matched as a non-L2 interface is not capable of triggering Ethernet rules.

Captive Portal

Captive Portal uses Ethernet rules behind the scenes to pass users through the portal. This works no matter what the current state of the Ethernet rules option is as these rules are managed automatically and not via the **Ethernet** tab.

Warning: Be careful adding manual Ethernet rules to interfaces involved in Captive Portal. Manual Ethernet rules are processed before Captive Portal rules, so there is a potential for interference.

Stateless

Ethernet rules do not keep state. As such, while block rules can work on their own, when making exceptions to blocks it is best to add rules in pairs to cover both the inbound and outbound direction, with the source and destination values on the rule reversed for the opposing direction.

Default Behavior

When Ethernet rules are inactive, all L2 traffic (other than Captive Portal) is passed by default so it can then be processed at L3 by regular rules. This **does not** affect the behavior of L3 rules. Traffic is still blocked there by default as usual.

When Ethernet rules are active there is no automatic hidden rule to block Ethernet traffic by default. This preserves the existing behavior and makes it less prone to be easily broken.

If an administrator wants to block all L2 traffic by default, they can first craft a ruleset with appropriate pass rules and then follow that with a rule to block any other Ethernet traffic. As the potential for mistakes and disruption is extremely high, this is not considered a best practice at this time.

Aliases

Ethernet rules can use Aliases for L3 source/destination matching but there is no support for MAC Address aliases at this time.

Enabling Ethernet Rules

To enable Ethernet rules:

- Navigate to **System > Advanced**, **Firewall & NAT** tab
- Locate the **Advanced Options** section
- Check **Enable Ethernet Filtering**
- Click **Save**

Managing Ethernet Rules

To manage Ethernet rules, navigate to **Firewall > Rules**, **Ethernet** tab. From there, rules are managed using the list view similar to other rules.

Note: The **Ethernet** tab only appears while the Ethernet Rules function is enabled. If the tab is not visible, *enable Ethernet Rules*.

Configuring Ethernet Rules

When editing an Ethernet rule the available options are similar to those found on *firewall rules* and *floating rules* with the following differences:

Protocol
A protocol specific to layer 2 for which this rule will apply.

ARP
Address Resolution Protocol

IPv4
IPv4 traffic

IPv6
IPv6 traffic

IEEE 802.1X
Network authentication traffic

VLAN (C-Tag)
Customer VLAN tag (e.g. first level)

VLAN (S-Tag)
Service VLAN tag (e.g. second level, double tagged)

Other
A protocol not listed in the drop-down, set manually in **Protocol Value**.

Protocol Value
To specify a protocol not in the list, enter its 16-bit hexadecimal **EtherType** (e.g. `0xffff`).

Source/Destination
Though Ethernet rules operate at L2, they can still act on the contents of the L3 source/destination (e.g. IPv4 or IPv6 addresses) in a packet using these fields.

Note: When setting a **Protocol** in addition to a **Source** or **Destination**, ensure the protocol matches the addess family of the source/destination. For example, when using an IPv4 address in **Source**, either set the **Protocol** to *IPv4* or *Any*.

MAC Filtering
Match a packet based on the L2 **Source MAC Address** or **Destination MAC Address**.

This option is in the **Advanced Options** section of the page.

Bridge To
When set, packets matching this rule will be sent out of the chosen interface without further processing. This can be used to send certain L2 packets out another interface, bypassing L3 rules (e.g. 802.1X authentication from an ISP).

This option is in the **Advanced Options** section of the page.

Package Support

There is a plugin hook available for packages to add their own Ethernet rules.

In the package metadata, define a filter rule callback:

```
<filter_rules_needed>package_rules</filter_rules_needed>
```

And then in the package PHP include file, add a function which returns the rules:

```
function package_rules($ruletype) {
    if ($ruletype === 'ether') {
            return '# add an ether rule' . PHP_EOL;
    }
}
```

14.1.9 Floating Rules

Floating Rules are a special type of advanced rule that can perform complicated actions not possible with rules on interface or group tabs. Floating rules can act on multiple interfaces in the inbound, outbound, or both directions. The use of inbound and outbound filtering makes designing rules highly complex and prone to user error, but they can be desirable in certain challenging scenarios.

Tip: Most firewall configurations will never have floating rules, or only have floating rules added by the traffic shaper.

See also:

- *Configuring Firewall Rules*
- *Ordering of NAT and Firewall Processing*
- *Traffic Shaper*

Precautions/Caveats

Floating rules can be a lot more powerful than other rules, but also more confusing. With floating rules it is easier for administrators to make an error with unintended consequences when passing or blocking traffic, which can be dangerous.

The firewall does not automatically add `reply-to` on floating rules in the inbound direction as it does for individual interface rules. Thus, floating rules have the same problem as interface groups: Return traffic passed by states created from floating rules will always exit the WAN with the default gateway, a reply packet cannot automatically return out a non-default WAN through which it entered the firewall.

Given the relative unfamiliarity of most administrators with floating rules, they may not think to look on the **Floating** tab for rules when maintaining the firewall, which increases the difficulty of firewall administration.

Take care when considering the source and destination of packets depending on the inbound and outbound direction. For example, rules in the outbound direction on a WAN typically have a local source of the firewall (after NAT) and remote destination.

Potential Uses

The most common use of Floating rules is for ALTQ traffic shaping. Floating rules are the only type of rules which can match and queue traffic without explicitly passing the traffic.

Another use of floating rules is to control traffic egressing from the firewall itself. Floating rules can prevent the firewall from reaching specific IP addresses, ports, and so on.

Other common uses are to ensure that no traffic can exit from other paths into a secure network, no matter what rules exist on other interfaces. Blocking outbound toward a secure network from all but approved sources reduces the likelihood of later accidentally allowing traffic in through another unintended path. Similarly, floating rules can be used to prevent traffic destined for private networks from exiting a WAN interface, to prevent VPN traffic from leaking.

Floating rules are useful for completely enacting state timeouts, tag/match operations, “no state” rules, and “sloppy state” rules for asymmetric routing.

Processing Order

In the inbound direction, floating rules work essentially the same as interface or group rules except that they are processed first. Processing in the outbound direction is more complicated.

The firewall processes floating rules after NAT rules, so rules in the outbound direction on a WAN can never match a private IP address source if the firewall also applies outbound NAT to connections on that interface. By the time a packet hits the floating rule, the source address of the packet is the post-NAT WAN IP address. In most cases this limitation can be overcome by applying a tag to a packet inbound on the LAN and then matching that tag in an outbound floating rule (*Marking and Matching*).

The firewall processes floating rules before interface group rules and interface rules, so that must also be taken into consideration.

See also:

See *Ordering of NAT and Firewall Processing* for a more detailed analysis of rule processing and flow through the firewall, including how NAT rules come into play.

Floating Rule Configuration

Most options available for floating rules are identical to those found on interface and group tab rules. However, floating rules have a few differences in available options and available choices.

See also:

- *Configuring Firewall Rules*

Match Action

The *match* action is unique to floating rules. A rule with the *match* action will not pass or block a packet, but only match it for purposes of assigning traffic to queues or limiters for traffic shaping. Match rules do not work with *Quick* enabled.

Quick

Quick controls whether the firewall stops processing rules when a packet matches this rule. Interface and group tab rules always behave in this manner, but on floating rules this behavior is optional. Without *Quick* checked, the rule will only take effect if no other rules match the packet. In other words, this option reverses the behavior of "first match wins" to be "last match wins".

Using this mechanism, administrators can craft a default action of sorts which will take effect only when no other rules match a packet, similar to the implicit default block rules on interfaces.

In most situations, the best practice is to check **Quick**. There are certain specific scenarios where leaving **Quick** unchecked is necessary, but they are rare. For most scenarios, the only rules without quick selected are *match* rules traffic shaper rules as the quick behavior is not compatible with the match action.

Interface

The **Interface** selection for floating rules a multi-select control. With this control a rule can apply to one, multiple, or all possible interfaces. Ctrl-click on interfaces to select them one by one, or use other combinations of click/drag or shift-click to select multiple interfaces.

Direction

Floating rules are not limited to the inbound direction like interface rules, they have the following direction choices:

any
: The firewall will process this rule for both inbound and outbound packets.

in
: The firewall will process this rule for inbound packets.

out
: The firewall will process this rule for outbound packets.

  The *out* direction is useful for filtering traffic from the firewall itself, for matching other undesirable traffic trying to exit an interface, or for fully configuring "sloppy state" rules, "no state" rules, or alternate state timeouts.

Marking and Matching

Using the **Tag** and **Tagged** fields, an administrator can mark a connection with an interface tab rule and then match that connection in the outbound direction with a floating rule. This is a useful way to act on outbound WAN connections from a specific internal host which the firewall could not otherwise match due to NAT masking the source. It can also be used similarly to apply traffic shaping outbound on WAN for connections specifically tagged on the way into the firewall.

For example, on a LAN rule, use a short string in the **Tag** field to mark a packet from a source of `10.3.0.56`. Then on a floating rule, quick, outbound on WAN, use **Tagged** with the same string to act on the traffic matched by the LAN rule.

14.1.10 Time Based Rules

Time based rules allow firewall rules to activate during specified days and/or time ranges. Time based rules function the same as any other rule, except they are effectively not present in the ruleset outside of their scheduled times.

Time Based Rules Logic

When dealing with time-based rules, the schedule determines when to apply the action specified in the firewall rule. When the current time or date is not covered by the schedule, the firewall acts as if the rule is not there. For example, a rule that passes traffic on Saturdays will only block it on other days if a separate block rule exists underneath it. The rules are processed from the top-down, the same as other firewall rules. The first match is used, and once a match is found, that action is taken if the rule is in schedule, and no other rules are evaluated.

Tip: Remember when using schedules that the rule will have **no effect** outside of their scheduled times. The rule **will not** have its action reversed because the current time is not within the scheduled time. Failing to account for this behavior could result in giving clients unintended access outside of the defined time ranges in a schedule.

Configuring Schedules for Time Based Rules

Schedules must be defined before they can be used on firewall rules. Schedules are defined under **Firewall > Schedules**, and each schedule can contain multiple time ranges. In the following example, a company wants to deny access to HTTP during business hours, and allow it all other times of the day.

Defining Times for a Schedule

To add a schedule:

- Navigate to **Firewall > Schedules**
- Click  **Add** to bring up the schedule editing screen, as seen in Figure *Adding a Time Range*.
- Enter a **Schedule Name**. This is the name that will appear in the selection list for use in firewall rules. Much like alias names, this name must only contain letters and digits, no spaces. For example: `BusinessHours`
- Enter a **Description** of this schedule, such as `Normal Business Hours`.
- Define one or more time ranges:

  - Set the **Month** by selecting a specific month and days, or by clicking the day of the week header for weekly recurring schedules.
  - Choose a **Start Time** and **Stop Time** which control when the rule is active on the selected days. The time cannot cross midnight on any day. A full day is *0:00* to *23:59*.
  - Enter an optional **Time Range Description** for this specific range, e.g. `Work Week`
  - Click  **Add Time** to add the choice as a range
  - Repeat **Month**, **Time**, and  steps for additional ranges
- Click **Save**

A schedule can apply to specific days, such as September 2, 2016, or to days of the week, such as Monday-Wednesday. To select any given day within the next year, choose the Month from the drop-down list, then click on the specific day or day numbers on the calendar. To select a day of the week, click its name in the column headers.

For this example, click on **Mon**, **Tue**, **Wed**, **Thu**, and **Fri**. This will make the schedule active for any Monday-Friday, regardless of the month. Now select the time for this schedule to be active, in 24-hour format. The hours for this example business are *9:00* to *17:00* (5pm). All times are given in the local time zone.

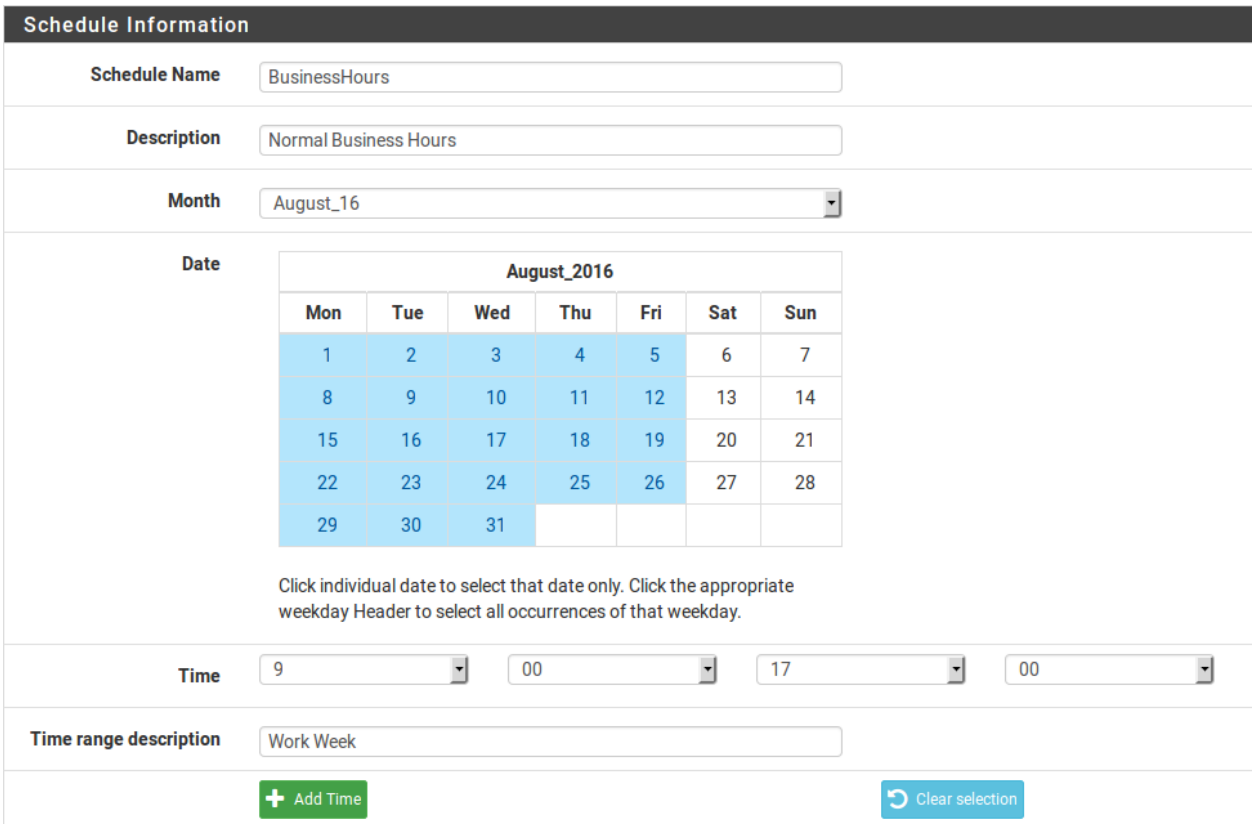

Fig. 14: Adding a Time Range

Once the time range has been defined, it will appear in the list at the bottom of the schedule editing screen, as in Figure *Added Time Range*.

To expand on this setup, there may be a half day on Saturday to define, or maybe the shop opens late on Mondays. In that case, define a time range for the identical days, and then another range for each day with different time ranges. This

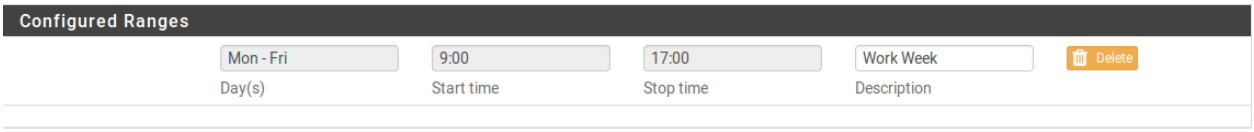

Fig. 15: Added Time Range

collection of time ranges will be the full schedule.

Once the schedule entry has been saved, the browser will return to the schedule list, as in Figure *Schedule List After Adding*. This schedule will now be available for use in firewall rules.

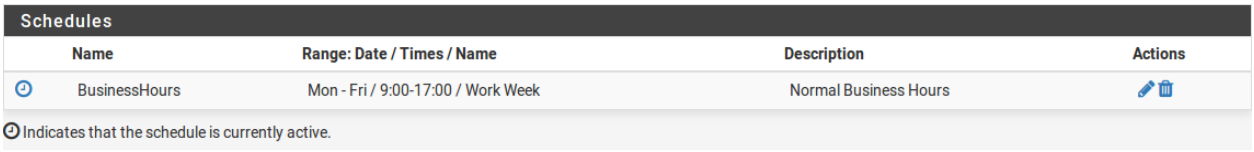

Fig. 16: Schedule List After Adding

Using the Schedule in a Firewall Rule

To create a firewall rule employing this schedule, create a new rule on the desired interface. See *Adding a firewall rule* and *Configuring Firewall Rules* for more information about adding and editing rules. For this example, add a rule to reject TCP traffic on the LAN interface from the LAN subnet to any destination on the HTTP port. In the advanced options for the rule, locate the **Schedule** setting and choose the *BusinessHours* schedule, as in Figure *Choosing a Schedule for a Firewall Rule*.

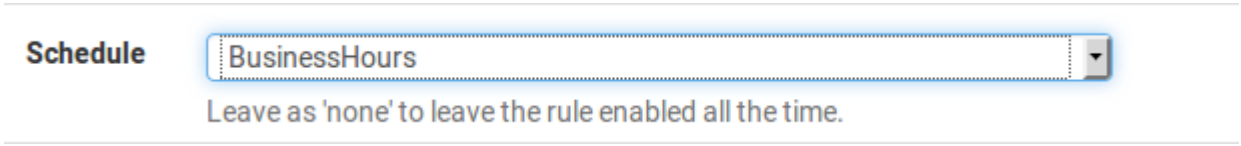

Fig. 17: Choosing a Schedule for a Firewall Rule

After saving the rule, the schedule will appear in the firewall rule list along with an indication of the schedule's active state. As shown in Figure *Firewall Rule List with Schedule*, this is a reject rule, and the schedule column indicates that the rule is currently in its active blocking state because it is being viewed at a time within the scheduled range. If the mouse cursor hovers over the schedule state indicator, a tooltip is displayed by the firewall showing how the rule will behave at the current time. Since this is being viewed inside of the times defined in the BusinessHours schedule, this will say "Traffic matching this rule is currently being denied". If there is a pass rule that would match the traffic out on port 80 from the LAN net after this rule, then it would be allowed outside of the scheduled hours.

Now that the rule is defined, test it both inside and outside of the scheduled times to ensure that the desired behavior is enacted.

Tip: By default, states are cleared for active connections permitted by a scheduled rule when the schedule expires. This shuts down access for anyone allowed by the rule while it was active. To allow these connections to remain open, check **Do not kill connections when schedule expires** under **System > Advanced** on the **Miscellaneous** tab.

	States	Protocol	Source	Port	Destination	Port	Gateway	Queue	Schedule	Description	Actions
☐	0/0 B	IPv4 TCP	LAN net	*	*	80 (HTTP)	*	none	BusinessHours	Block HTTP access during business hours	

Fig. 18: Firewall Rule List with Schedule

14.1.11 Viewing the pf ruleset

pfSense® software handles translating the firewall rules in the GUI into a set of rules which can be interpreted by the packet filter (PF).

Generated Rules

The PF rules generated by the firewall are in `/tmp/rules.debug`. However, that file **cannot** be edited to make persistent changes - the firewall will overwrite it during the next filter reload event.

Note: There is rarely a need to manually edit firewall rules generated by the GUI. In most cases if it appears to be necessary, something is incorrect with the configuration.

If the generated rules truly must be edited, then the edits must be made to the source code which generates the ruleset in `/etc/inc/filter.inc`. Such changes will be lost when updating to a new version.

Interpreted Rules

PF can interpret the rules slightly differently than the way they were generated by the filter code. To view the rule set as has been interpreted by PF, use one of the following methods.

Using the *SSH console* or *Command Prompt* field in the GUI, run the following:

Show Firewall Rules:

```
# pfctl -sr
```

Show NAT rules:

```
# pfctl -sn
```

Show all:

```
# pfctl -sa
```

For more verbose output including rule counters, ID numbers, and so on, use:

```
# pfctl -vvsr
```

There may be additional rules in anchors from packages or features such as UPnP. To view these rules, use:

```
# pfSsh.php playback pfanchordrill
```

14.1.12 Methods of Using Additional Public IP Addresses

Methods of deploying additional public IP addresses vary depending on how the addresses are delegated, the size of the allocation, and the goals for the specific network environment. To use additional public IP addresses with NAT, for example, the firewall will need *Virtual IP Addresses*.

There are two options for directly assigning public IP addresses to hosts: Routed public IP subnets and bridging.

Choosing between routing, bridging, and NAT

Additional public IP addresses can be put to use by directly assigning them on the systems that will use them, or by using NAT. The available options depend on how the addresses are allocated by the ISP.

Additional static IP addresses

Methods of using additional static public IP addresses vary depending on the type of assignment. Each of the common scenarios is described here.

Single IP Subnet on WAN

With a single public IP subnet on WAN, one of the public IP addresses will be on the upstream router, commonly belonging to the ISP, and another one of the IP addresses will be assigned as the WAN IP address on pfSense® software. The remaining IP addresses can be used with either NAT, bridging or a combination of the two.

To use the addresses with NAT, add Proxy ARP, IP alias or CARP type Virtual IP addresses.

To assign public IP addresses directly to hosts behind the firewall, a dedicated interface for those hosts must be bridged to WAN. When used with bridging, the hosts with the public IP addresses directly assigned must use the same default gateway as the WAN of the firewall: the upstream ISP router. This will create difficulties if the hosts with public IP addresses need to initiate connections to hosts behind other interfaces of the firewall, since the ISP gateway will not route traffic for internal subnets back to the firewall.

Figure *Multiple Public IP addresses In Use Single IP Subnet* shows an example of using multiple public IP addresses in a single block with a combination of NAT and bridging.

See also:

For information on configuration, NAT is discussed further in *Network Address Translation*, and bridging in *Bridging*.

Small WAN IP Subnet with Larger LAN IP Subnet

Some ISPs will allocate a small IP subnet as the "WAN side" assignment, sometimes called a transport or interconnect network, and route a larger "inside" subnet to the firewall. Commonly this is a /30 on the WAN side and a /29 or larger for use inside the firewall. The service provider router is assigned one end of the /30, typically the lowest IP address, and the firewall is assigned the higher IP address. The provider then routes the second subnet to the WAN IP address of the firewall. The additional IP subnet may be used by the firewall on a routed LAN or OPT interface with public IP addresses directly assigned to hosts, with NAT using Other type VIPs, or a combination of the two. Since the IP addresses are routed to the firewall, ARP is not needed so VIP entries are not necessary for use with NAT.

Because pfSense software is the gateway on the local segment, routing from the public local subnet hosts to LAN is much easier than in the bridged scenario required when using a single public IP subnet. Figure *Multiple Public IP Addresses Using Two IP Subnets* shows an example that combines a routed IP subnet and NAT. Routing public IP addresses is covered in *Routing Public IP Addresses*, and NAT in *Network Address Translation*.

WAN IP Address Assignments	
WAN Subnet	192.0.2.128/29
WAN Gateway	192.0.2.129
Usable IP Addresses	192.0.2.129-192.0.2.134
WAN IP Address	192.0.2.130
IP Alias VIP	192.0.2.131
Bridge Host	192.0.2.134

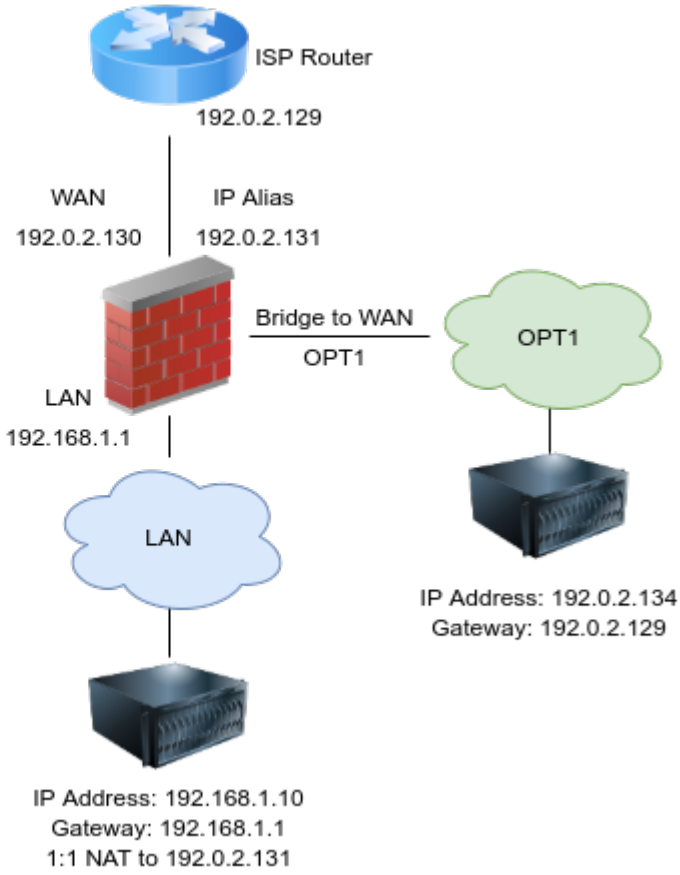

Fig. 19: Multiple Public IP addresses In Use Single IP Subnet

WAN IP Address Assignments	
WAN Subnet	192.0.2.128/30
WAN Gateway	192.0.2.129
WAN IP Address	192.0.2.130
Inside Subnet	192.0.3.0/26
OPT1 Address	192.0.3.1/26
OPT1 Usable Addresses	192.0.3.2-192.0.3.62

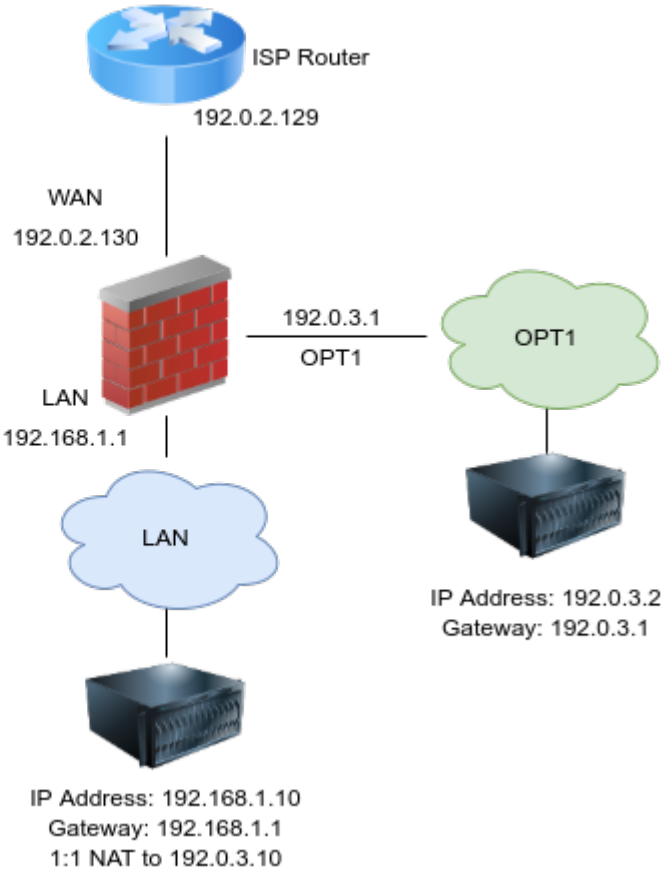

Fig. 20: Multiple Public IP Addresses Using Two IP Subnets

If the firewall is part of a High Availability cluster using CARP, the WAN side subnet will need to be a /29 so each firewall has its own WAN IP address plus a CARP VIP. The provider will route the larger inside subnet to the WAN CARP VIP in this type of configuration. The inside IP subnet must be routed to an IP address that is always available regardless of which firewall is up, and the smallest subnet usable with CARP is a /29. Such a setup with CARP is the same as illustrated above, with the OPT1 gateway being a CARP VIP, and the provider routing to a CARP VIP rather than the WAN IP address. CARP is covered in *High Availability*.

Multiple IP subnets

In other cases, a site may be allocated multiple IP subnets from the ISP. Usually when this happens, the site started with one of the two previously described arrangements, and later when requesting additional IP addresses the site was provided with an additional IP subnet. Ideally, this additional subnet will be routed to the firewall by the ISP, either to its WAN IP address in the case of a single firewall, or to a CARP VIP when using HA. If the provider refuses to route the IP subnet to the firewall, but rather routes it to their router and uses one of the IP addresses from the subnet as a gateway IP address, the firewall will need to use Proxy ARP VIPs, IP Alias VIPs, or a combination of IP Alias and CARP VIPs for the additional subnet. If at all possible, the provider should route the IP subnet to the firewall as it makes it easier to work with regardless of the firewall being used. It also eliminates the need to burn 3 IP addresses in the additional subnet, one for the network and broadcast addresses and one for the gateway IP address. With a routed subnet, the entire subnet is usable in combination with NAT.

Where the IP subnet is routed to the firewall, the scenario described in *Small WAN IP Subnet with Larger LAN IP Subnet* applies for an additional internal subnet. The subnet can be assigned to a new OPT interface, used it with NAT, or a combination of the two.

Additional IP Addresses via DHCP

Some ISPs require additional IP addresses to be obtained via DHCP. This is not a good means of obtaining multiple public IP addresses, and must be avoided in any serious network. A business-class connection should not require this. pfSense software is one of the few firewalls which can be used in any capacity with additional IP addresses from DHCP. This offers limited flexibility in what the firewall can do with these addresses, leaving only two feasible options.

Bridging

If the additional IP addresses from DHCP must be directly assigned to the systems that will use them, bridging is the only option. Use an OPT interface bridged with WAN for these systems, and the systems must be configured to obtain their addresses using DHCP.

Pseudo multi-WAN

The only option for having the firewall pull these DHCP addresses as leases is a pseudo multi-WAN deployment. Install one network interface per public IP address, and configure each for DHCP. Plug all the interfaces into a switch between the firewall and the modem or router. Since the firewall will have multiple interfaces sharing a single broadcast domain, enable **Suppress ARP messages** on **System > Advanced**, **Networking** tab to eliminate ARP warnings in the system log, which are normal in this type of deployment.

The only use of multiple public IP addresses assigned in this fashion is for port forwarding. Port forwards can be used on each WAN interface that uses an IP address assigned to that interface by the ISP DHCP server. Outbound NAT to the OPT WANs will not work because of the limitation that each WAN must have a unique gateway IP address to properly direct traffic out of that WAN. This is discussed further in *Multiple WAN Connections*.

14.1.13 Virtual IP Addresses

Some types of interfaces on pfSense® software can utilize more than one IP address at a time. The primary IP address for an interface comes from the interface settings, while Virtual IP (VIP) addresses facilitate the use of additional IP addresses in conjunction with NAT or local services.

VIP Types

There are four types of Virtual IP addresses available in pfSense: *IP Alias*, *CARP*, *Proxy ARP*, and *Other*. Each is useful in different situations. In most circumstances, pfSense software will need to answer ARP request for a VIP which means that IP Alias, Proxy ARP or CARP must be used. In situations where ARP is not required, such as when additional public IP addresses are routed by a service provider to the WAN IP address on the firewall, Other type VIPs can make it easier to use those addresses in NAT rules.

pfSense software will not respond to ICMP echo requests (pings) destined to Proxy ARP and Other type VIPs regardless of firewall rule configuration. With Proxy ARP and Other VIPs, NAT must be present on the firewall, forwarding traffic to an internal host for ping to function. See *Network Address Translation* for more information.

IP Alias

IP Aliases work like any other IP address on an interface, such as the actual interface IP address. They will respond to layer 2 (ARP) and can used as binding addresses by services on the firewall. They can also be used to handle multiple subnets on the same interface. pfSense software will respond to ping on an IP Alias, and services on the firewall that bind to all interfaces will also respond on IP Alias VIPs unless the VIP is used to forward those ports in to another device (e.g. 1:1 NAT).

IP Alias VIPs can use *Localhost* as their interface to bind services using IP addresses from a block of routed addresses without specifically assigning the IP addresses to an interface. This is primarily useful in HA with CARP scenarios so that IP addresses do not need to be consumed by a CARP setup (one IP each per node, then the rest as CARP VIPs) when the subnet exists only inside the firewall (e.g. NAT or firewall services such as VPNs).

IP Aliases on their own do not synchronize to XMLRPC Configuration Synchronization peers because that would result in an IP address conflict. One exception to this is IP Alias VIPs using a CARP VIP "interface" for their interface. Those do not result in a conflict so they will synchronize. Another exception is IP Alias VIPs bound to Localhost as their interface. Because these are not active outside of the firewall itself, there is no chance of a conflict so they will also synchronize.

CARP

CARP VIPs are primarily used with High Availability redundant deployments utilizing CARP (*CARP Overview*). CARP VIPs each have their own unique MAC address derived from their VHID, which can be useful even outside of a High Availability deployment.

See also:

For information on using CARP VIPs, see *High Availability*.

CARP VIPs may also be used with a single firewall. This is typically done in cases where the pfSense deployment will eventually be converted into an HA cluster node, or when having a unique MAC address is a requirement. In rare cases a provider requires each unique IP address on a WAN segment to have a distinct MAC address, which CARP VIPs provide.

CARP VIPs and IP Alias VIPs can be combined in two ways:

- To reduce the amount of CARP heartbeats by stacking IP Alias VIPs on CARP VIPs. See *Using IP Aliases to Reduce Heartbeat Traffic*.
- To use CARP VIPs in multiple subnets on a single interface. See *High Availability*.

Proxy ARP

Proxy ARP VIPs function strictly at layer 2, providing ARP replies for the specified IP address or CIDR range of IP addresses. This allows pfSense software to accept traffic targeted at those addresses inside a shared subnet. For example, pfSense software can forward traffic sent to an additional address inside its WAN subnet according to its NAT configuration. The address or range of addresses are not assigned to any interface on pfSense, because they don't need to be. This means no services on pfSense software itself can respond on these IP addresses.

Proxy ARP VIPs do not sync to XML-RPC Configuration Sync peers because doing so would cause an IP address conflict.

Other

Other type VIPs define additional IP addresses for use when ARP replies for the IP address are not required. The only function of adding an *Other* type VIP is making that address available in the NAT configuration drop-down selectors. This is convenient when the firewall has a public IP block routed to its WAN IP address, IP Alias, or a CARP VIP.

VIP Configuration Options

The options available for each VIP vary based on the selected type. This list contains all available options for all types, with the restrictions noted as needed.

Type
: Sets the type of VIP this will be, and changes the available options on the page. See *VIP Types* for a description of each type.

Interface
: The parent interface upon which this VIP will reside.

  For IP Alias type VIPs, this can also be a CARP VIP (*Using IP Aliases to Reduce Heartbeat Traffic*).

Address Type
: For Proxy ARP and Other type VIPs this option declares whether the VIP defines a single IP address or an entire subnet.

Addresses
: The IP address and subnet mask for this VIP.

Expansion
: For IPv4 Proxy ARP and Other type VIPs, this specifies whether or not a subnet address type VIP will be expanded into its individual IP address components in drop-down menus where VIPs can be selected, such as on NAT rules.

  Warning: For large subnets this can cause rendering issues in browsers as they may not properly handle large drop-down lists.

CARP Options
: These options are only available for CARP type VIPs:

Virtual IP Password
The secret key with which to protect the CARP heartbeat traffic. If peers do not agree on the key, they cannot coordinate their actions and will all appear as MASTER status.

VHID Group
The group identifier used to indicate between multiple hosts that they are coordinating control of the same address. VHIDs must be unique per layer 2.

For IPv4, this is commonly set to match the last octet of the IPv4 VIP address.

The VHID also influences the resulting MAC address of the VIP, where the last two characters of the MAC are the VHID in hexadecimal.

Advertising Frequency
Controls how often the master node sends out CARP heartbeat advertisements. Hosts transmitting faster than their peers assume control of the VIP.

Base
The base value of whole seconds between advertisements. The default of `1` is typically ideal, but can be raised in special cases.

Skew
1/256th fractions of a second added to the base. Typically the preferred primary node will have a skew of `1` or `0`, and secondary nodes will be around `100` or higher.

When XMLRPC is configured to synchronize VIPs, this value is automatically adjusted for the secondary node by adding `100` to this value.

CARP Mode (Plus Only)
pfSense Plus software has an option to choose how CARP operates, either in multicast or unicast mode.

Multicast
CARP heartbeats are advertised to the entire Layer 2 using multicast, and multiple peers can monitor for heartbeats and participate. This requires that all peers be connected to networks that support multicast (e.g. Ethernet switches or equivalent). It also requires that the underlying network does not manipulate or limit multicast.

Unicast
CARP heartbeats are sent directly to the specified **Peer Address** and do not use multicast. This allows CARP to operate on networks which do not support multicast, such as cloud provider networks and VPNs. However, this limits a cluster to two nodes since both nodes must send heartbeats to each other directly.

> **Warning:** The best practice is to avoid using unicast mode on traditional switched L2 infrastructure when possible. In unicast mode, CARP heartbeats are sourced from the interface MAC address and not the CARP MAC. Since switches do not see packets sourced from the CARP MAC, they may flood packets for unicast CARP VIPs to all ports. This behavior has significant security and performance concerns which are eliminated by using multicast mode instead.

Peer Address
The IP address of the peer node to which the firewall will send its unicast CARP heartbeats for this VIP.

> **Warning:** At this time the **Peer Address** cannot be an IPv6 link local address. This will be corrected in a future release. See Redmine #14385 for details.

Note: When VIPs are synchronized via XMLRPC, the primary node will adjust the VIP such that its own address on the parent interface is configured on the peer VIP. In scenarios where this is not correct, VIP synchronization may need to be managed manually.

Switch/Layer 2 Concerns

Description
Optional text to describe the VIP and/or its purpose, e.g. "VIP for PBX" or "NAT Subnet VIP".

Feature Comparison

Virtual IP Address Feature Comparison

This document summarizes and compares capabilities of the different Virtual IP Address types.

See *Virtual IP Addresses* for detailed information about each type of VIP.

VIP Features Table

Table 2: Virtual IP Address Feature Comparison

VIP Type	NAT	Binding	ARP/L2	Clustering	Subnet Mask	ICMP	Single/Range
IP Alias	Yes	Yes	Yes	See Notes	See Notes	Yes	Single
CARP	Yes	Yes	Yes	Yes	Yes	Yes	Single
Proxy ARP	Yes	No	Yes	No	n/a	No (1)	Either
Other	Yes	No	No	Yes (2)	n/a	No (1)	Either

Notes:

1. The ICMP column represents responses from the firewall itself without NAT. With 1:1 NAT or port forwards, any VIP will pass ICMP through to the target device.
2. "Other" type VIPs are for routed subnets, and CARP is irrelevant, so they are compatible with HA (See below)

Virtual IP Feature Summary

It is difficult to express all details of VIP capabilities in a table format, so this section contains a more thorough overview of the various types and what they can/cannot do a bullet point format.

IP Alias

- **Can** be used for NAT.
- **Can** be used by the firewall itself to bind/run services.
- Adds extra IP addresses to an interface.
- Generates ARP (Layer 2) responses for the VIP address.
- Can be in a **different subnet** than the **real** interface IP address when used directly on an interface.
- **Will** respond to ICMP ping if allowed by firewall rules.
- Must be added individually
- Subnet mask should match the interface IP, or `/32`. Matching the interface subnet is best. For IP addresses in different subnets at least one IP alias VIP **must** have the correct mask for the new subnet.
- Can be stacked on top of a CARP VIP to bypass VHID limits and lower the amount of CARP heartbeat traffic.
  - Stacked IP Alias VIPs will synchronize via XMLRPC.
  - Stacked IP Alias VIPs must be inside the same subnet as the CARP VIP upon which they are placed.
- Can be added to localhost for binding services in routed subnets. IP Alias VIPs bound to localhost will synchronize via XMLRPC

CARP

- **Can** be used for NAT.
- **Can** be used by the firewall itself to bind/run services.
- Generates ARP (Layer 2) traffic for the VIP.
- Can be used for clustering (master firewall and standby failover firewall.)
- CARP VIPs may be in other subnets.
- **Will** respond to ICMP ping if allowed by firewall rules.
- Must be added individually.
- Subnet mask **must** match the interface IP address.
- Generates its own MAC address for the VIP. This MAC is different than its physical parent interface.

Proxy ARP

- **Can** be used for NAT.
- **Cannot** be used by the firewall itself to bind/run services.
- Generates ARP (Layer 2) traffic for the VIP.
- Can be in a **different subnet** than the real interface IP.
- **Will not** respond to ICMP ping.
- Can be added individually or as a subnet to make a group of VIPs.

Other

- **Can** be used for NAT.
- **Cannot** be used by the firewall itself to bind/run services.
- Can be used if the address is routed to the firewall without needing ARP/Layer 2 messages. (e.g. Upstream provider routes a subnet to the WAN IP address)
- Can be in a **different subnet** than the real interface IP address.
- **Will not** respond to ICMP echo requests.
- Can be added individually or as a subnet to make a group of VIPs.
- Can be used with CARP, e.g. subnet routed to external CARP VIP.

14.1.14 Using EasyRule to Manage Firewall Rules

The EasyRule function found in the GUI and on the command line can add firewall rules quickly.

EasyRule in the GUI

In the pfSense® software GUI, this function is available in the Firewall Log view (**Status > System Logs**, **Firewall** tab).

The  icon next to the source IP address adds a **block** rule for that IP address on the interface. To be more precise, it creates or adds to an alias containing IP addresses added from Easy Rule and blocks them on the selected interface.

The  icon next to the destination IP address works similar to the block action, but it adds a more precise **pass** rule. This **pass** rule allows traffic on the interface but it must match the same protocol, source IP address, destination IP address, and destination port.

EasyRule in the Shell

The shell version of Easy Rule, `easyrule`, can manage EasyRule firewall rules and entries from a shell prompt. When the `easyrule` command is run without parameters, it prints a usage message to explain its syntax.

The way `easyrule` adds a block rule using an alias, or a precise pass rule specifying the protocol, source, and destination, work the same as the GUI version.

The general form of the command is:

```
# easyrule <action> <interface> <parameters>
```

action
: The action can be one of `pass`, `block`, `showblock`, or `unblock`. Each one takes different parameters and is explained later in this section.

interface
: The descriptive name of the interface, as seen in the GUI on the interface configuration page. For example: `WAN`, `LAN`, `DMZ`, `OFFICEVPN`. When using the descriptive names, it is not case sensitive.

  The interface value can also be the internal designation for the interface, such as `wan` or `opt2`.

Special names for certain groups are also available here: `openvpn` for OpenVPN tab rules, `ipsec` for IPsec tab rules, `pppoe` for PPPoE server tab rules, and `l2tp` for L2TP server tab rules.

Pass

Passing requires several details so it does not create an overly permissive rule. The destination port is optional if the protocol does not require a port (e.g. ICMP, OSPF, etc).

```
# easyrule pass <interface> <protocol> <source address> <destination address>␣
↪[destination port]
```

protocol
The name of the protocol to pass, or `any` to pass any protocol.

source address
The source of traffic for the pass rule.

Can be an IPv4/IPv6 address, subnet, alias name, or special network name such as `any`, `pppoe` or `l2tp`.

destination address
The destination of traffic for the pass rule.

Can be an IPv4/IPv6 address, subnet, alias name, or special network name such as `any`, `pppoe` or `l2tp`.

destination port
The destination port number if the protocol requires ports (`TCP`, `UDP`).

To pass traffic to any port, use `any`.

Note: The address family of the source and destination must match.

Example pass rule for a protocol that uses ports:

```
# easyrule pass wan tcp 1.2.3.4 192.168.0.4 80
```

Example pass rule for a protocol without ports:

```
# easyrule pass wan icmp 1.2.3.4 192.168.0.4
```

Block

Blocking only requires a source IP address to block:

```
# easyrule block <interface> <source address>
```

source address
The source of traffic to block.

Can be an IPv4/IPv6 address, subnet, alias name, or special network name such as `any`, `pppoe` or `l2tp`.

Block example:

```
# easyrule block wan 1.2.3.4
```

Show a Block

This program can also display the contents of addresses currently blocked by easyrule on an interface.

```
# easyrule showblock <interface>
```

```
# easyrule showblock wan
1.2.3.4/32
5.6.7.8/32
9.10.11.0/24
```

Remove a Block

```
# easyrule unblock <interface> <source address>
```

source address
The source of traffic to unblock. The address must already be blocked *by EasyRule*.

Note: This action **will not** remove block rules or entries that were not created by EasyRule.

Can be an IPv4/IPv6 address, subnet, alias name, or special network name such as `any`, `pppoe` or `l2tp`.

```
# easyrule showblock wan
1.2.3.4/32
5.6.7.8/32
9.10.11.0/24
# easyrule unblock wan 5.6.7.8
Host unblocked successfully
# easyrule showblock wan
1.2.3.4/32
9.10.11.0/24
```

14.1.15 Firewall Packet Flow Data

Starting with pfSense Plus software version 24.03 the firewall can directly export NetFlow v5 and IPFIX traffic flow data to one or more collectors using the `pflow(4)` feature in PF. The data is collected directly from firewall states and does not require a separate daemon, service, or add-on package.

Note: pfSense® Plus software version 24.03 or later is required to use the Packet Flow Data feature. This feature is not available on pfSense CE Software.

As this is a function of the firewall, this feature is located at **Firewall > Packet Flow Data**.

Flows can be tracked by default or only for specific rules, so the user has the flexibility to control the scope of exported data.

The feature supports up to 16 different export configurations to send data to multiple collectors and/or using different data formats.

Note: As this feature relies upon data from firewall states to function, it requires the firewall rules to keep state to generate that data. This is the default behavior, so it is unlikely to be a blocking issue for most users.

Warning: Packet Flow Data changes only happen for **new** states created after the feature has been activated or deactivated. When activating the feature, states that already exist will not start sending data, only new connections will. Similarly, when deactivating the feature, old states may continue to trigger export data.

Rebooting the device or resetting the states after changing the configuration will ensure that all states are handled appropriately.

Global Packet Flow Options

There are two options available on the main Packet Flow Data configuration page at **Firewall > Packet Flow Data**:

Enables Packet Flow Data Tracking and Exporting
: This option loads the required kernel module for `pflow(4)` and configures the packet flow data exporters in the OS.

  This option must be checked for the firewall to export flow data.

Enable Packet Flow tracking on all rules by default
: When checked, all firewall rules will track packet flow data for new states by default. This can be overridden on a per-rule basis if necessary.

  When unchecked, nothing is tracked by default and flow tracking must be enabled on each firewall rule manually.

  See also:

  For information on managing Packet Flow Data in firewall rules, see *Packet Flow Data*.

Packet Flow Exporters

Under the global options section the page contains a list of current exporter configurations.

The list displays the configuration properties of each current entry. Also on each line are several indicators and action icons:

- At the start of a line is a checkmark. If it's dark, the entry is enabled. If It's light, the entry is disabled. Clicking the checkmark icon will toggle the entry between enabled and disabled states.

  The text color for the entire line changes to a lighter shade for disabled entries as well.

-  - Edits the current entry
-  - Duplicates the current entry
-  - Deletes the current entry after a confirmation prompt.

Under the list is an  **Add** button to create new entries. This button is hidden when the list is full.

Exporter Options

Exporter entries define remote hosts capable of receiving and processing packet flow data (e.g. NetFlow or IPFIX). Up to 16 distinct exporters can be defined.

When creating or editing an exporter entry, the following options are available:

Description
Some text describing this entry (e.g. Collector host name, purpose, etc).

Enable
A checkbox which controls whether or not the exporter is active.

When checked, the firewall will export packet flow data to this host. When unchecked, this host is ignored.

Source IP Address
A drop-down menu containing local interfaces, VIPs, and other valid traffic sources. If the collector expects flow data packets to come from a specific source address, select it in this list.

If the destination is over a VPN, this likely should either be set to the corresponding VPN interface or another local interface.

Source Port
Source port for packet flow export. Leave blank to use a random port (default).

> **Warning:** This port must not already be in use anywhere on the firewall, including other exporters.
>
> If this option is set, the **Source IP Address** must also be set to a specific value.

Destination IP Address
IP address (IPv4 or IPv6) of the remote flow collector host, e.g.: `192.168.100.100` or `fd00:abcd::1`.

This outer transport can be either IPv4 or IPv6 no matter which **Flow Protocol** is active, but the address family must match the **Source IP Address**. For example, if the **Destination IP address** is set to an IPv6 address, the selected **Source IP Address** entry must also have an IPv6 address.

Destination Port
Destination port on the collector where it is listening for packet flow data.

Leave blank to use the default port, `2055`.

Flow Protocol
Format for packet flow data. Currently supports two formats, NetFlow v5 and IPFIX.

NetFlow v5
NetFlow v5 is more widely compatible with collectors but is more limited in the type of traffic it supports in flow data.

Note: The NetFlow v5 specification does not support IPv6. To track IPv6 flows, use IPFIX instead.

IPFIX
IPFIX supports IPv6 flow data, but is not supported by all collectors.

This protocol also includes RFC 8158 NAT44 flow information which can be utilized for centralized logging of NAT translation data.

Consult the documentation for the collector to determine which formats it supports.

Observation Domain
Observation Domain for flows to this exporter. This is an unsigned non-zero 32-bit integer (`1-4294967295`). Not all collectors support or honor this value, but it can be used to allow a collector to identify flows from devices in similar roles or locations.

Leave blank to use the default of `1`.

Packet Flow Data Example Configuration

This is a brief example of configuring the Packet Flow Data feature to export all flow data to a collector at on LAN at an address of `10.1.2.3` with otherwise default settings.

- Navigate to **Firewall > Packet Flow Data**
- Check **Enable Packet Flow Data Tracking and Exporting**
- Check **Enable Packet Flow tracking on all rules by default**
- Click **Save**
- Click  **Add** to create a new exporter
- Configure the settings as described in *Exporter Options*:

  Description
  Local NetFlow Collector

  Enable
  Checked

  Source IP Address
  LAN

  Source Port
  Empty

  Destination IP Address
  `10.1.2.3`

  Destination Port
  Empty

  Flow Protocol
  IPFIX

  Observation Domain
  Empty

- Click **Save**
- Click **Apply Changes**

At this point, new states will begin exporting flow data.

14.2 Aliases

Aliases are collections of addresses that allow many hosts to be acted upon by a small number of firewall rules. They can greatly simplify a ruleset and make it easier to understand and manage.

14.2.1 Aliases

Aliases define groups of ports, hosts, or networks. Aliases can be referenced by firewall rules, port forwards, outbound NAT rules, and several other areas. Using aliases results in configurations and rulesets which are significantly shorter, self-documenting, and easier to manage.

Note: These Aliases are collections of items for use by the firewall. Despite similar names, this is a completely different concept than "IP alias" type *Virtual IP Addresses*, which are a means of adding additional IP addresses to a network interface.

Aliases are located at **Firewall > Aliases** in the GUI. The page is divided into separate tabs for each general *type of alias*:

IP
: Lists *Host Aliases* and *Network Aliases*.

Ports
: Lists *Port Aliases*.

URLs
: Lists *URL Aliases* and *URL Table Aliases*.

All
: Shows all types of aliases, including *Built-In System Aliases*, in one large list.

When creating an alias, the GUI will sort the entry to the correct location based on the type of alias content, no matter which tab was used to create the alias.

Alias Features and Limitations

Administrators have a lot of flexibility when defining aliases. These abilities are a large part of how aliases can make firewall rulesets easier to manage.

Alias Sizing Concerns

When the firewall loads alias data it copies the contents into internal tables which it uses to quickly perform address matches.

The total size of all aliases/tables must fit in roughly **half** the amount of **Firewall Maximum Table Entries**, which defaults to `400000`.

See *Firewall Maximum Table Entries* for more information on this behavior.

Nested Aliases

Most aliases can be nested inside other aliases of similar types to collect entries into larger groups. For example, one `Servers` alias can nest an alias containing web servers, an alias containing mail servers, and an alias containing database servers all together.

To nest, aliases must be either the same or compatible types. For example, *Network Aliases* cannot nest *Port Aliases* since they are not the same type of alias. However, *Host Aliases* and *Network Aliases* can nest each other since they are compatible. *URL Table Aliases* can nest other URL table aliases, and *URL Aliases* can nest other URL aliases.

Hostnames in Aliases

Host and network type aliases support entries consisting of fully qualified domain name (FQDN) style hostnames (e.g. `host.example.com`) in regular or IDN format.

Tip: This feature is also useful for tracking dynamic DNS entries to allow users to access services from dynamic IP addresses.

For these entries to function, the firewall **must** be able to resolve hostnames using A or AAAA type DNS queries. This means that the firewall must have working DNS, the FQDN must exist, and the firewall must be able to resolve these hostnames using the DNS servers present in its configuration.

Warning: This feature only supports **forward** name resolution of FQDNs using A and AAAA records such as `host.example.com`.

Aliases **do not** support pattern matches, wildcard matches (e.g. `*.example.com`), SRV record lookups, or any other style of record comparison.

If a DNS query for a hostname returns multiple IP addresses, the firewall adds **all** of the IP addresses in the result **at the time of the query** to the alias.

Warning: This feature is *not* useful for controlling access to hostnames for large public web sites such as those served by content delivery network (CDN) providers. Such sites tend to have round-robin, localized, or randomized responses to DNS queries so the contents of the alias on the firewall do not necessarily match the response a client receives when it resolves the same hostname. This feature can work for smaller sites which have single addresses or sites which always return complete sets of addresses in their DNS responses.

The firewall periodically resolves and updates hostname entries in host or network type aliases. The default interval is `300` seconds (5 minutes). This behavior can be changed by adjusting the *Aliases Hostnames Resolve Interval*.

Mixing IPv4 and IPv6 Addresses in Aliases

IPv4 and IPv6 addresses can coexist inside the same alias. The firewall uses the appropriate type of addresses from the alias content as needed when a rule references the alias. This allows a single alias to function in IPv4 rules, IPv6 rules, and even IPv4+IPv6 rules.

Uses Beyond Firewall and NAT Rules

pfSense® software allows the use of aliases in several places outside of firewall and NAT rules. For example, they can be used with certain fields in OpenVPN and in static routes. GUI pages *will indicate* if and when a feature supports aliases.

Alias Types

The next sections describe the behavior of each alias type in detail. Any type-specific *configuration settings* are also covered in these sections.

Built-In System Aliases

pfSense® software includes several built-in **System Aliases** which are accessible to users. These include stock collections of networks and IP addresses as well as automatically generated and/or maintained collections.

These are visible on the **All** tab under **Firewall > Aliases** in the **System Aliases** section.

Note: Some of these System Aliases have multiple variations for IPv4, IPv6, and combined IPv4+IPv6. These are denoted by the number `4`, `6` or `46` near the end of the name, respectively. In most cases it is safe to use the IPv4+IPv6 version as the *firewall will use whichever address family is appropriate for a rule*, but some users may prefer to configure different rules for IPv4 and IPv6.

The current list includes the following entries:

bogons
: *Bogon networks*.

sshguard
: Hosts blocked by anti-brute-force login protection for SSH and the GUI.

snort2c
: Hosts blocked by IDS/IPS software.

virusprot
: Hosts which tripped firewall rate limit protections in advanced options (e.g. maximum source hosts for a rule).

_nexus_vpn_port_
: Netgate Nexus VPN port (*General Options*).

vpn_networks
: Networks for IPsec, OpenVPN, and PPPoE servers.

  Note: This may not be complete as it cannot detect networks made available via dynamic routing, pushed routes from OpenVPN, advanced/custom options, etc.

  ---

negate_networks
Networks to exclude from policy routing rules with any destination.

tonatsubnets
Networks for which the firewall will apply outbound NAT in Automatic and Hybrid modes.

loopback(4|6|46)
Local loopback addresses.

linklocal(4|6|46)
Link-local addresses which must not leave their own network.

private(4|6|46)
"Private" network allocations common for local private networks.

multicast(4|6|46)
Multicast networks.

reserved(4|6|46)
All current known reserved networks.

Host Aliases

Host type aliases contain entries consisting of individual IP addresses or fully qualified domain names (FQDNs).

When creating an alias, users may enter an IP address range such as `192.168.1.1-192.168.1.10` or a small subnet such as `192.168.1.16/28`. When saving the alias, the firewall translates that specification into a list of individual IP addresses.

Figure *Example Hosts Alias* shows an example of a host type alias which contains a list of public web servers.

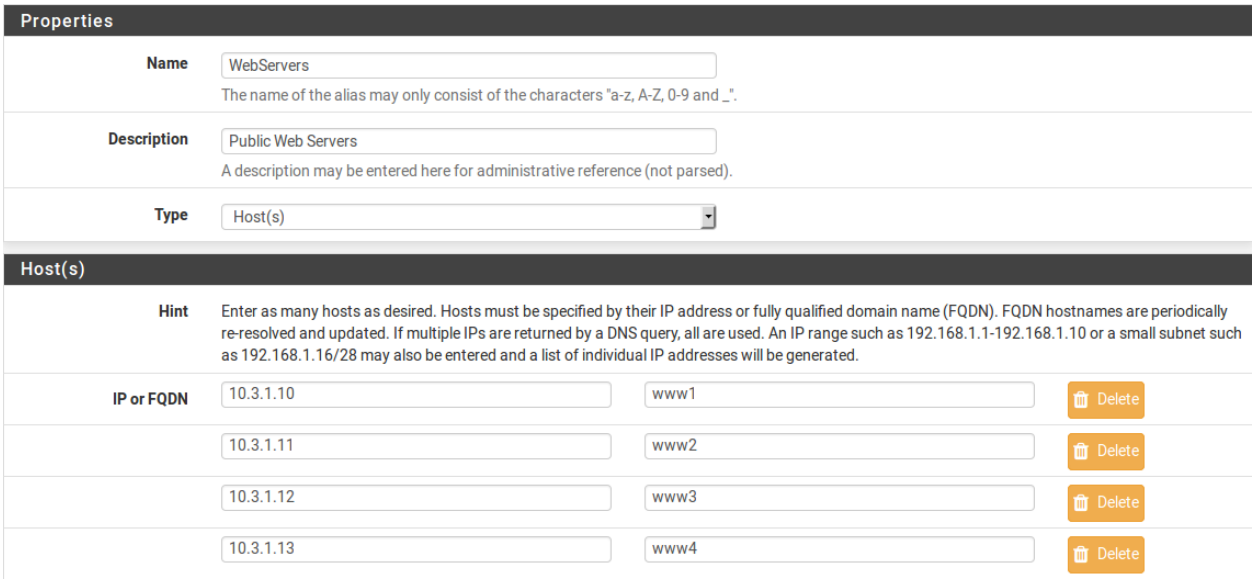

Fig. 21: Example Hosts Alias

Network Aliases

Network type aliases contain entries consisting of CIDR format networks/prefixes or fully qualified domain names (FQDN) for single addresses.

For subnets, select the CIDR mask that pertains to each entry. `/32` specifies a single IPv4 host, `/128` specifies a single IPv6 host, `/24` specifies `255.255.255.0`, `/64` specifies a normal IPv6 network, etc.

Hostnames (FQDNs) may also be specified, using a `/32` mask for IPv4 or `/128` for IPv6. This mask **is not** applied to addresses returned by DNS.

Figure *Example Network Alias* shows an example of a network alias.

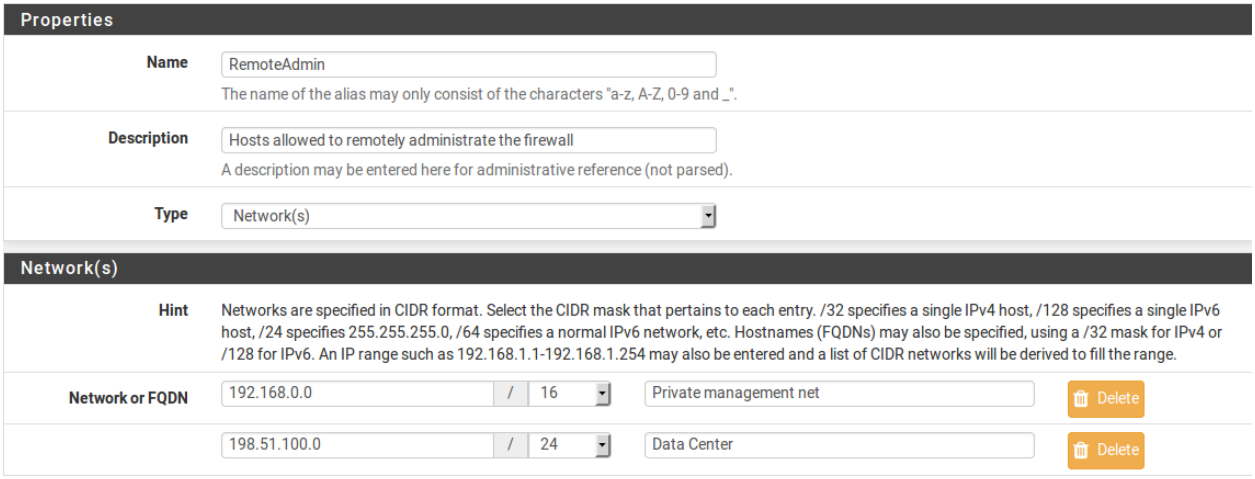

Fig. 22: Example Network Alias

When an alias entry contains an IPv4 range the firewall automatically translates the range to an equivalent set of IPv4 CIDR networks which exactly contain the range. This is shown in Figure *Example IP Range After*.

Fig. 23: Example IP Range Before

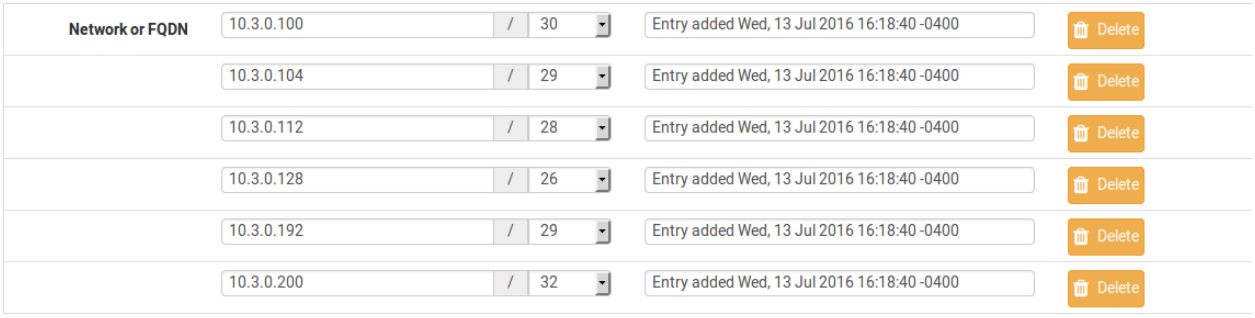

Fig. 24: Example IP Range After

Port Aliases

Port type aliases contain entries consisting of ports numbers and port ranges. A single port is an integer from `1-65535`. A port range is two ports separated by a colon (`:`), for example, `1194:1199`. Port ranges match the specified start and ending port numbers and all ports in between.

Port aliases **do not** have a direct relationship with any protocol. Firewall rules using a protocol of TCP, UDP, or SCTP may use port aliases to match port numbers for the protocol on the rule.

Figure *Example Ports Alias* shows an example of a port type alias.

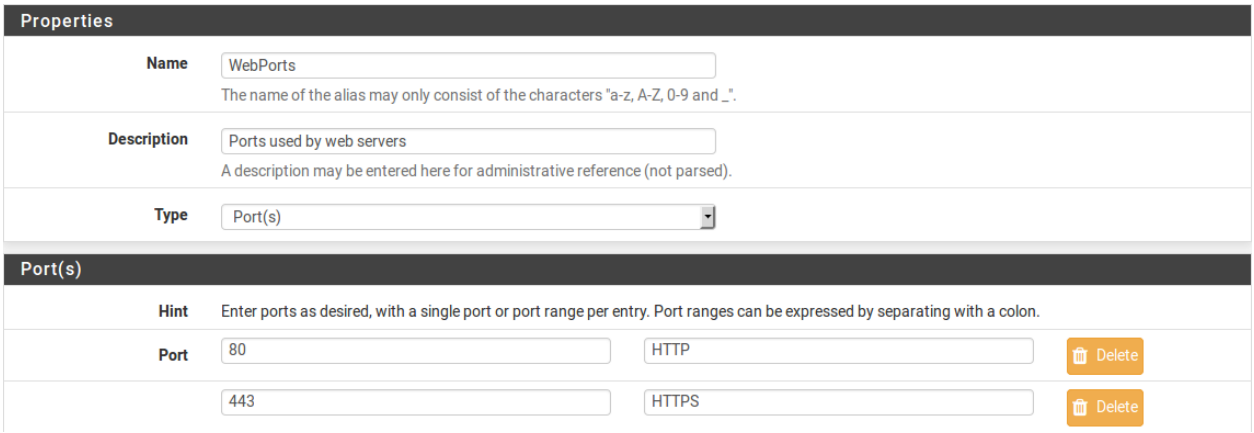

Fig. 25: Example Ports Alias

URL Aliases

URL type aliases contain one or more URLs which return a plain text a list of entries.

When creating the alias, the firewall reads up to **3,000** entries from each URL and imports them into an alias.

The exact behavior depends on the type of URL alias:

URL (IPs)
: The URLs must contain IP addresses, CIDR masked network entries, or FQDNs. The firewall creates a Network type alias from the content.

URL (Ports)
: The URL must contain only port numbers or port ranges. The firewall creates a Port type alias from the content.

URL Table Aliases

URL Table type aliases contain one or more URLs which return a plain text a list of entries, plus an update interval which indicates how frequently the firewall should re-fetch the URL contents.

URL Table type aliases download the content of the URLs into a special location on the firewall, then use that content for a `persist` table, also known as a file-based alias. The full contents of these alias are not directly editable in the GUI, but the GUI can display the *Firewall Table Contents*.

The drop-down list after the `/` in an entry of a URL Table alias controls the number of days after which the firewall re-fetches content from the stored URLs. The firewall checks once per day to determine if URL table aliases need updates.

URL Table aliases can be quite large, containing many thousands of entries. Some customers use them to hold lists of all IP address blocks in a given country or region, which can easily surpass 40,000 entries. The pfBlockerNG package uses this type of alias when handling country lists and other similar actions.

The exact behavior depends on the type of URL alias:

URL Table (IPs)
The URLs must contain IP addresses, CIDR masked network entries, or FQDNs. The firewall creates a Network type alias from the content.

URL Table (Ports)
The URL must contain only port numbers or port ranges. The firewall creates a Port type alias from the content.

Alias Configuration

Alias Settings

When editing an Alias entry, the following settings are available:

Name
A **Name** for the alias. The name may only consist of the characters `a-z`, `A-Z`, `0-9` and `_`.

Note: The name of an alias cannot conflict with reserved names for items such as interface names, gateway names, or internal PF keywords. Input validation will reject conflicting names.

Description
A **Description** for the alias.

Type
The **Type** for the alias, which alters the behavior of the alias and tells the firewall which types of entries can be added to the alias.

The following types are available:

Host
Host Aliases contain single IP addresses or FQDN hostnames.

Network
Network Aliases contain CIDR-masked lists of networks, FQDN hostnames, IP address ranges, or single IP addresses.

Port
Port Aliases contain lists of port numbers or ranges of ports for TCP or UDP.

URL (IP or Port)
URL Aliases contain items the firewall fetches from the specified URL(s) at the time the alias is created. Once created, the alias becomes a typical network or port type alias.

URL Table (IP or Port)
URL Table Aliases contain items the firewall fetches from the specified URL(s), but it periodically updates the content.

Entries
The lower section of the alias page contains the entries for the alias. The behavior of this section varies based on the selected *alias type*.

Creating an Alias

To create a new alias:

- Navigate to **Firewall > Aliases**
- Click  **Add**
- Enter settings as described in *Alias Settings*
- Enter the type-specific information for each member entry

  All *alias types* have a data field and a description field for each entry.

To add new entry to an alias, click  **Add** at the bottom of the list of entries.

To remove entries from an alias, click  **Delete** at the end of the row to remove.

When the alias is complete, click **Save** to store the alias contents.

Each manually-created alias is limited to **5,000 members**. Aliases which require larger amounts of entries should use *URL Table Aliases* instead.

> **Warning:** Some browsers have trouble displaying or using the alias editing view with more than around 3,000 entries.

Bulk Import Network Aliases

The GUI supports adding multiple entries for Host, Network, and Port type aliases in bulk using the import feature. This can be useful when importing long existing lists of addresses, such as for block lists or corporate networks.

To use the import feature:

- Navigate to **Firewall > Aliases**
- Navigate to the appropriate tab to match the desired alias type

  Use the **IP** tab for Host or Network aliases, use the **Port** tab for Port aliases.

- Click  **Import**
- Fill in the **Alias Name** and **Description**
- Enter the alias contents into the **Aliases to import** text area

  Each entry must be on a separate line.

  Importing from the **IP** tab allows entries containing IP addresses, CIDR masked networks, IP address ranges, or FQDNs.

  Importing from the **Port** tab allows entries containing port numbers and port ranges.

  The import process takes any text following a valid entry as the description for that entry.

- Click **Save**

The firewall imports the content into a normal alias which can be edited later.

Alias Usage

When a user types a letter into a form input which supports aliases, the GUI displays a list of matching aliases. The user can then select the desired alias from the list or type its name out completely.

Note: Alias autocompletion is not case sensitive but it is restricted by type. For example, the GUI will autocomplete a Network or Host type alias for a network field, but not a Port alias. Likewise, the GUI will autocomplate a Port alias in a port field, but not a Network alias.

Figure *Autocompletion of Hosts Alias* shows how the `WebServers` alias, configured as shown in Figure *Example Hosts Alias*, can be used in the **Destination** field when adding or editing a firewall rule.

- Edit the firewall rule
- Set the **Destination** drop-down to *Address or Alias*
- Then type the first letter of the desired alias: Enter `W` and the alias appears as shown.

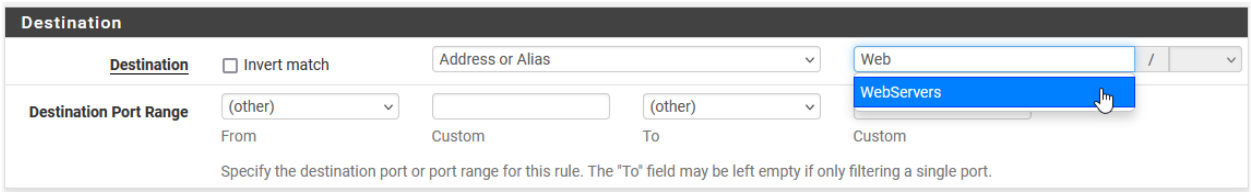

Fig. 26: Autocompletion of Hosts Alias

Figure *Autocompletion of Ports Alias* shows the autocompletion of the ports alias configured as shown in Figure *Example Ports Alias*. If multiple aliases match the letter entered, all matching aliases of the appropriate type are listed. Click on the desired alias to select it.

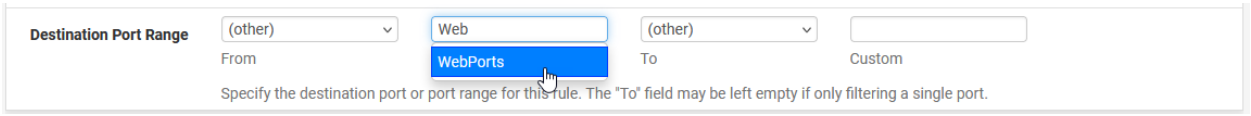

Fig. 27: Autocompletion of Ports Alias

Figure *Example Rule Using Aliases* shows the rule created using the `WebServers` and `WebPorts` aliases. This rule is on WAN, and allows any source to the IP addresses defined in the `WebServers` alias when using the ports defined in the `WebPorts` alias.

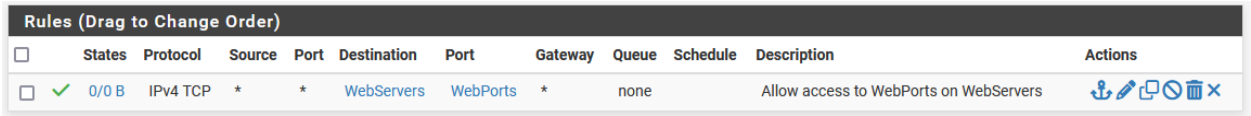

Fig. 28: Example Rule Using Aliases

Hovering the mouse cursor over an alias on the **Firewall > Rules** page shows a tooltip displaying the contents of the alias with the descriptions included in the alias. Figure *Hovering Shows Hosts Contents* shows this for the `WebServers` alias and Figure *Hovering Shows Ports Contents* for the `WebPorts` alias.

Fig. 29: Hovering Shows Hosts Contents

Fig. 30: Hovering Shows Ports Contents

Firewall Table Contents

The GUI page at **Diagnostics > Tables** displays the contents of tables defined by the firewall and by users.

The firewall stores aliases and other similar lists of addresses in a `pf` structure called a **table**. These tables can be relatively static, such as the bogons list or aliases, or dynamic for things like login protection lockout, IDS/IPS, or IP addresses exceeding connection limits.

An alias becomes a table once the firewall loads it into the ruleset.

If an alias contains a hostname the firewall populates the contents of the alias from the results of resolving hostnames using DNS. It periodically resolves the hostnames again and updates the table accordingly if the addresses change. Given this dynamic nature, viewing the table contents may be necessary to confirm which IP addresses are in a table at a given time.

Viewing Tables

To view the contents of a table:

- Navigate to **Diagnostics > Tables**
- Select the desired table from the **Table** drop-down

After making a selection the page will update to display the contents of the selected table.

The  icon at the end of each row in the table content removes individual entries from a table. Removing entries is best used for dynamic tables to remove an entry before it automatically expires. Tables defined manually or by a file will be refreshed when the system performs a filter reload, so it is best to edit an alias and remove an entry rather than removing it from this page.

Default Tables

The firewall includes several tables by default, depending on which features are enabled:

bogons/bogonsv6
: If any interface is configured with *Block Bogon Networks*, these tables will be present.

  The page offers an  **Update** button for the bogon tables which will immediately re-fetch the bogons data rather than waiting for the usual monthly update.

cpzoneid*
: Tables starting with this string are used internally by Captive Portal and are not meant to be managed manually.

negate_networks
: Networks for which the firewall has made policy route negation rules.

snort2c
: A dynamic table containing blocked offenders from IDS/IPS packages, Snort and Suricata.

sshguard
: A dynamic table containing clients that repeatedly failed login attempts for the GUI and SSH.

tonatsubnets
: When using automatic outbound NAT, this table contains the list of networks for which the firewall performs automatic outbound NAT.

  Inspecting the table can aid in diagnosing tricky NAT issues to confirm if a subnet will have automatic outbound NAT applied to its traffic.

virusprot
: A dynamic table containing addresses that have exceeded defined limits on firewall rules.

vpn_networks
: A list of remote networks reachable across VPNs.

CHAPTER

FIFTEEN

NETWORK ADDRESS TRANSLATION

15.1 Port Forwarding

Port forwarding is a type of inbound NAT which enables access to a specific port, port range, or protocol on an internal network device. Port forward rules rewrite the destination of a packet and then forward those packets to the new destination. This functionality is known by different names in various products, including "Destination NAT" or "Inbound NAT".

To *configure port forwarding rules*, navigate to **Firewall > NAT**, on the **Port Forward** tab.

"Port Forward" is a term familiar to users, but it is an oversimplification. Port forward rules can redirect entire protocols such as GRE or ESP in addition to redirecting specific TCP, UDP, and SCTP ports.

The most common uses of port forward rules are for hosting servers or using applications which require inbound connections from the Internet.

See also:

Hangouts Archive to view the May 2016 hangout for NAT on pfSense software version 2.3, The June 2016 hangout on Connectivity Troubleshooting, and the December 2013 Hangout on Port Forward Troubleshooting, among others.

15.1.1 Port Forwarding Risks

In a default configuration, pfSense® software does not allow any connections initiated from hosts on the Internet. This provides protection from attackers scanning the Internet searching for targets. Using port forward rules and corresponding firewall rules allows connections matching the rules through to local targets, potentially exposing them to attackers. The firewall does not know the difference between a packet with a malicious payload and one that is benign. However, the exposure is limited to the parameters set inside the port forward and corresponding firewall rule. Even if the firewall rules were to allow any inbound packets, the internal host would still only be exposed on ports/protocols set in the port forward rules.

Target systems must use local host-based controls to secure services forwarded through the firewall.

15.1.2 Port Forwarding and Local Services

Port forwards take precedence over services running locally on the firewall, such as the web interface, VPNs, and SSH. For example, say an administrator intended to allow remote web interface access on the WAN from a remote office using HTTPS on TCP port 443. A port forward rule on WAN for TCP 443 will take precedence and the web interface will no longer be accessible from the remote office through the WAN. This does not affect access on other interfaces, only the interface on the overlapping port forward rule.

15.1.3 Port Forward Rule Precedence

For inbound packets, port forward rules take precedence over 1:1 NAT rules. This allows port forwards to override 1:1 NAT rule behavior and forward specific ports to different internal targets or even the firewall itself.

See also:

- *Ordering of NAT and Firewall Processing*
- *1:1 NAT Rule Precedence*

15.1.4 Port Forward Rule Options

When creating or editing a port forward rule, the following settings are available:

Disable
Toggles whether or not this rule is active.

No RDR (NOT)
Prevents the firewall from redirecting packets matching the rule as they arrive. This is necessary if the packets would otherwise match a port forward rule, but those packets should not be redirected by the firewall.

This can override a forwarding action, which may be useful to allow access to a service on the firewall itself on an IP address used in 1:1 NAT rules, or another similar advanced scenario.

Most configurations will not use this field.

Interface
The ingress interface where this rule will apply.

Typically this is WAN or a WAN-type interface, but in some special cases it could be LAN or another internal interface.

Address Family
The address family for which this port forward rule will apply, either *IPv4* or *IPv6*.

This must match the address family of the destination IP address and redirect target IP address.

When an interface contains addresses of both families, the firewall will use the appropriate matching address. Additionally, when selecting an interface it must have an IP address which matches this family.

Protocol
The IP protocol this port forward rule will match.

This must be set to match the type of service the rule is forwarding, whether it is *TCP*, *UDP*, or another available choice.

Most common services are *TCP* or *UDP*, but consult the documentation for the service to confirm the correct value. The *TCP/UDP* option forwards both TCP and UDP together in a single rule.

> **Warning:** Though it can be tempting to use the *TCP/UDP* choice when the exact value is unclear, the best practice is to only allow in the specific protocol the service requires. Otherwise, a different unapproved daemon could be run on the target host to receive connections for the other protocol.

The page will display controls for ports when the **Protocol** is set to *TCP*, *UDP*, *TCP/UDP*, or *SCTP*.

Source

The source network and port which this rule will match to limit redirection.

These options are hidden behind an **Advanced** button by default, and set to *any* source.

The **Source** options restrict which source IP addresses and ports can access this port forward rule. These restrictions are not typically necessary, but can offer increased security if remote sources are limited and static.

If the port forward must be reachable from any location on the Internet, the source must be *any*. For restricted access services, use an alias here so only a limited set of IP addresses may access the port forward.

Unless the service absolutely requires a specific source port, the **Source Port Range** must be left as *any* since nearly all clients will use randomized source ports.

Tip: If a role requires source restrictions, a better practice is to use a VPN to allow access to these services instead of port forwarding or firewall rules. However, that may not always be viable.

Destination

The destination address this rule will match.

This is the external IP address which is the original destination of an incoming packet which the rule will redirect.

For port forward rules on WAN, in most cases this is *WAN Address*. If multiple public IP addresses are available, the destination may be a *Virtual IP* on WAN.

Invert Match changes the behavior so the port forward rule will match any packet that does not match the specified destination.

Destination port range

The destination port or range of ports this rule will match.

This is the external destination port which is the original destination port on an incoming packet which the rule will redirect.

Note: For a port forward rule to match a single port, enter the port in the **From port** box and leave the **To port** box blank.

The drop-down controls contain a list of common services. When set to *Other*, the fields can accept a port number or port alias name. When this field contains a port alias name, the same port alias name must be set as the **Redirect target port**.

Redirect target IP

The IP address where the rule will forward (redirect) incoming packets. The firewall will replcae the original destination address on the packet with this address and then forward it to the new destination.

When using an IPv6 redirect target, it must be of the same scope as the destination. For example, it is not possible to forward between link-local scope addresses (`fe80::/10`) and local (`::1`).

Note: This field is only compatible with aliases that contain a **single IP address**.

An alias containing multiple addresses will cause the rule to redirect connections to target hosts in a round-robin fashion, but it is not ideally suited to that task. If one of the target hosts is down, the rule will still forward connections to the unreachable target.

For situations requiring forwarding to multiple hosts, such as load balancing or failover scenarios, use the *HAProxy package*.

Redirect target port
The port number where this rule will forward (redirect) incoming packets. The firewall will replcae the original destination port on the packet with this port and then forward it to the new destination.

If the destination port is a range, this field defines where the forwarded port range begins. When a rule forwards a range of ports, e.g. `19000-19100`, a rule can only define the local starting point since the number of ports in the range must be identical.

This field allows a rule to redirect connections to a different port on the outside than the on the inside. For example, a port forward rule can redirect connections on external port `8888` to local port `80` for HTTP on an internal server. A list of common services is available to pick from in the drop down box.

The drop-down controls contain a list of common services. When set to *Other*, the fields can accept a port number or port alias name. When this field contains a port alias name, the same port alias name must be set as the **Destination port range**.

Description
Text describing the rule, such as its intended behavior or name of a service. The best practice is to clearly describe the purpose of the rule in this field.

The description is optional and does not affect functionality of the rule.

No XMLRPC Sync
Prevents this rule from synchronizing to other High Availability cluster members via XMLRPC.

See also:

High Availability

Warning: This does not prevent a rule on a secondary node from being overwritten by the primary.

NAT Reflection
Overrides global NAT reflection behavior for this rule.

Use system default
Respects the global NAT reflection settings.

Enable (NAT+Proxy)
Always performs NAT reflection for this rule using the NAT+Proxy method.

Enable (Pure NAT)
Always performs NAT reflection for this rule using the pure NAT method.

Disable
Never performs NAT reflection for this rule.

See also:

- *NAT Reflection*
- *Accessing Port Forwards from Local Networks*

Filter Rule Association

Optionally create a firewall rule which passes connections which matches the same packet parameters as this port forward rule.

> **Warning:** This is *very* important. A port forward rule only defines which packets the firewall will redirect, a firewall rule allows those packets to *pass* through to the redirect target. Without a firewall rule to pass the packets, the firewall will drop them and there is nothing for it to forward.

The available choices are:

None
Does not create a firewall rule.

Add associated filter rule
Creates a firewall rule linked with this port forward rule.

If an administrator changes the port forward rule, the firewall automatically updates the firewall rule to match.

The firewall replaces this choice with an entry pointing to the new associated firewall rule on save.

This is the default behavior and the best choice for most use cases.

Add unassociated filter rule
Creates a firewall rule separate from this port forward rule.

If an administrator changes the port forward rule, they must also manually update the firewall rule to match.

This can be useful if the firewall requires options or restrictions that cannot be set on a port forward rule.

Pass
Uses a special PF keyword on the port forward rule that passes matching packets without the need of a firewall rule.

Because there is no firewall rule, the firewall forwards **all** packets matching this rule to the target host.

Note: Rules using *Pass* can only work on the interface containing the default gateway for the firewall, they do not work with Multi-WAN.

15.1.5 Configuring Port Forward Rules

Port forward rules are located at **Firewall > NAT**, on the **Port Forward** tab.

See also:

The list of port forward rules works the same as the list of firewall rules for management. See *Introduction to the Firewall Rules screen* for details.

To create a new port forward rule:

- Navigate to **Firewall > NAT**, **Port Forward** tab
- Click  **Add** to create a new port forward rule at the top of the list
- Configure the rule as described in *Port Forward Rule Options*
- Click **Save**
- Click **Apply Changes**

Tracking Changes to Port Forward Rules

The firewall tracks changes to port forward rules in the same manner as firewall rules.

See also:

Rule Information

Firewall rules automatically created by associated NAT rules are also marked as such in the tracking information on the associated firewall.

15.1.6 Port Forwarding Configuration Examples

This section contains example scenarios and configurations for port forwarding.

See also:

- *Accessing Port Forwards from Local Networks*
- *Configuring NAT for a VoIP PBX*
- *Redirecting Client DNS Requests*

Example Port Forward Rule for HTTP (TCP/80)

This example demonstrates how to configure a port forward rule rule to redirect HTTP (TCP port `80`) inbound on WAN destined to the WAN IP address to the internal host at `10.3.0.15`.

To configure this rule:

- Navigate to **Firewall > NAT**, **Port Forward** tab
- Click  **Add** to create a new port forward rule at the top of the list
- Configure the rule as described in *Port Forward Rule Options* with the following options:

  Interface
  WAN

Address Family
IPv4

Protocol
TCP

Destination
WAN Address

Destination Port Range
HTTP

Redirect Target IP
Address or Alias, `10.3.0.15`

Redirect Target Port
HTTP

Description
`HTTP to web server`

- Click **Save**
- Click **Apply Changes**

Figure *Port Forward Example* shows the port forward configuration page with these values:

After clicking **Save**, the GUI displays the port forward rule list with the new rule, as shown in Figure *Port Forward List*.

Double check the firewall rule at **Firewall > Rules** on the tab matching the port forward rule interface. The rule should show that it will pass connections in to the target IP address on the expected target port, as shown in Figure *Port Forward Firewall Rule*.

If everything is configured correctly, the port forward rule will work when tested from outside the network.

See also:

Troubleshooting NAT Port Forwards

Accessing an Internal Target Using the External Destination Address

It takes additional work for clients behind the firewall to access services redirected by port forward rules using the external address. For example, when internal users must access public redirected services using hostnames from DNS.

This can be accomplished either by using NAT reflection or Split DNS, depending on the needs and capabilities of the clients.

See also:

- *NAT Reflection*
- *Accessing Port Forwards from Local Networks*

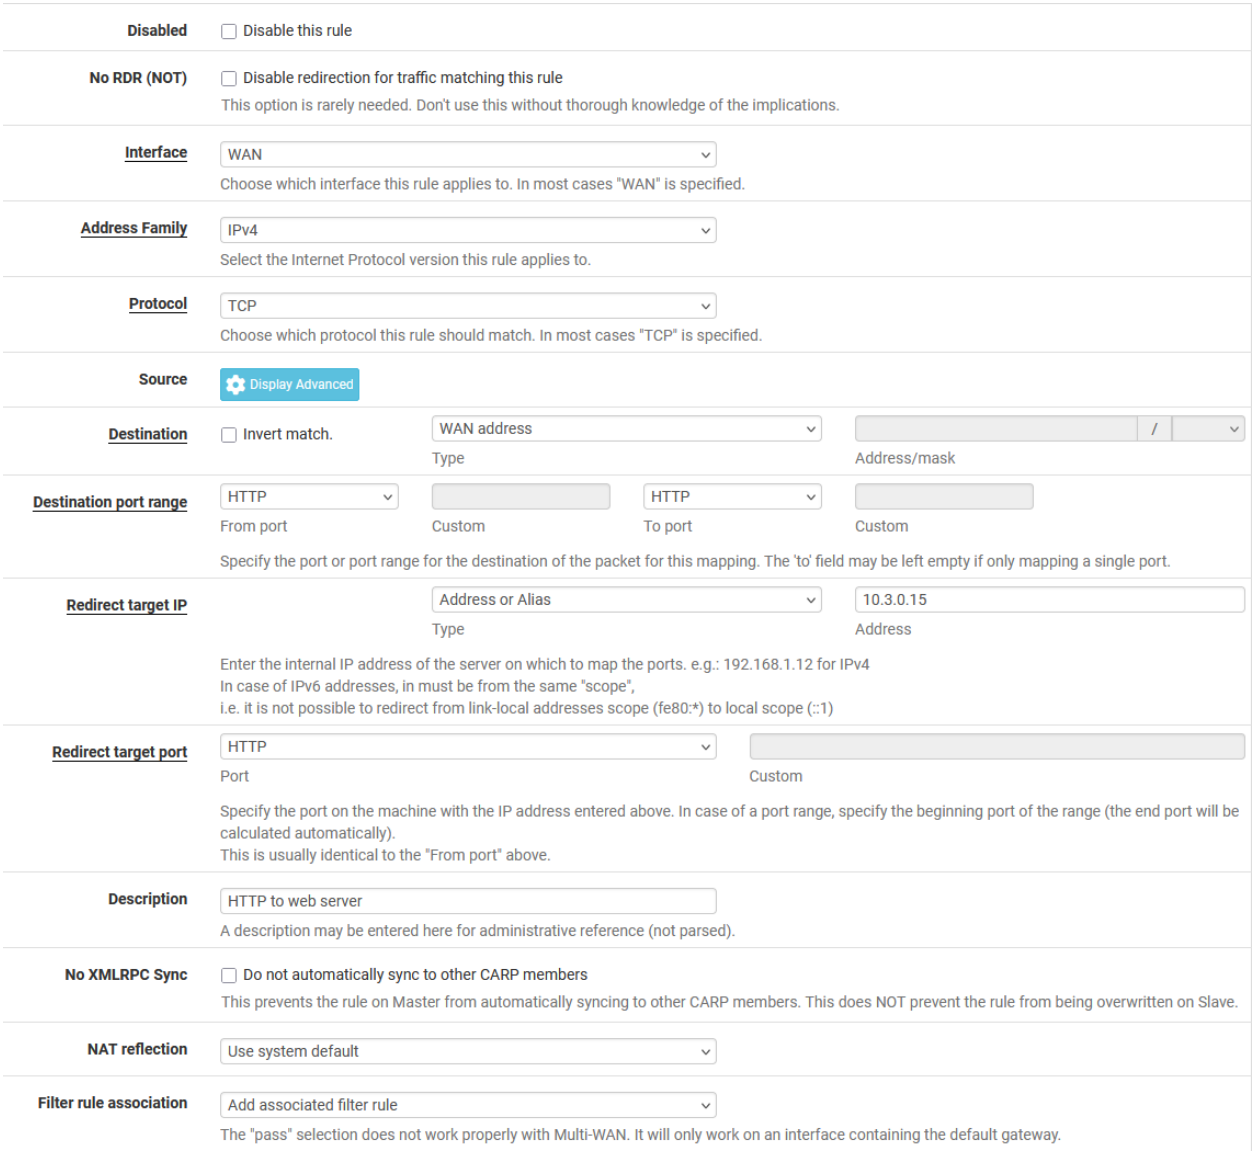

Fig. 1: Port Forward Example

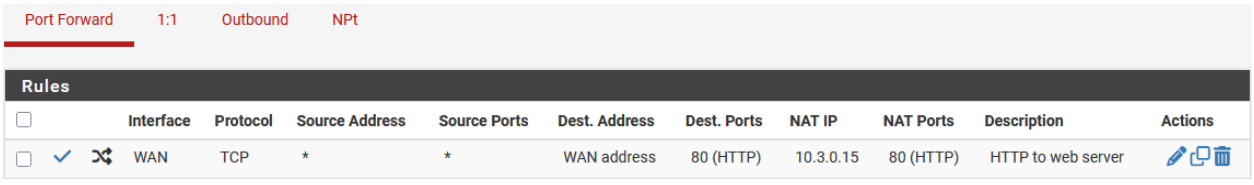

Fig. 2: Port Forward List

Fig. 3: Port Forward Firewall Rule

Outbound Redirection with Port Forwards

Port forward rules can transparently redirect packets attempting to egress from an internal network. Port forward rules which specify the *LAN* interface or another internal interface will redirect packets matching the rule to the specified target. This is most commonly used for redirecting all outbound DNS to one server.

See also:

Redirecting Client DNS Requests

Forwarding a Single Port to Multiple Targets

The firewall can only forward a single port to one internal host for each available public IP address when it forwards packets from any source.

For example, if a firewall has only one public IP address available, it can only forward TCP port `80` to one internal web server. Any additional servers must use alternate ports such as `8080`.

If a firewall has five public IP addresses available as Virtual IP addresses, then it can forward TCP port `80` to five internal web servers.

See also:

Virtual IP Addresses

Tip: For services such as HTTP and HTTPS, port sharing may be possible by using the *HAProxy package*. If the requests differ in some way, such as by different request hostnames, a proxy can make more advanced decisions about how to forward requests to multiple internal hosts.

The exception to this behavior is when port forward rules can match based on the source IP address of incoming connections.

If all sources are known in advance, rules can forward connections from those specific remote networks to different internal servers by matching those sources.

Figure *Port Forward Example with Different Sources*.

☐	✓	⇄	WAN	TCP	Bob	*	WAN address	22 (SSH)	10.3.0.5	80 (HTTP)	Redirect SSH from Bob to Bob's Server
☐	✓	⇄	WAN	TCP	Sue	*	WAN address	22 (SSH)	10.3.0.15	80 (HTTP)	Redirect SSH from Sue to Sue's Server

Fig. 4: Port Forward Example with Different Sources

If only some sources are known in advance, rules can forward connections from specific remote networks to one server while a later rule can forward connections from any source on the same port to a different target.

15.1.7 Service Self-Configuration With UPnP IGD & PCP

Some programs support Universal Plug-and-Play (UPnP IGD) or Port Control Protocol (PCP) to automatically configure port forward rules and firewall rules. That approach has even more security concerns, but in home use the benefits often outweigh the potential drawbacks.

See also:

UPnP IGD & PCP

15.2 1:1 NAT

1:1 NAT (pronounced "one-to-one NAT") maps one external IP address to one internal IP address. This usually maps a public IP address on a WAN type interface to a private IP address on a LAN type interface.

For outbound packets, 1:1 NAT rules translate the source address of all packets originating from an internal address to an external address as those packets exit the interface defined in the rule.

For inbound packets, 1:1 NAT rules translate the destination address of all packets initiated from external hosts (e.g. from the Internet) destined for the external IP address on the rule interface to the private IP address on the rule. The firewall then evaluates those packets against the firewall ruleset on the external interface (e.g. WAN). If firewall rules on the external interface permit packets matching a target of the internal IP address, those packets will pass to the internal IP address.

1:1 NAT rules can also translate entire subnets provided the subnets are the same size and align on proper subnet boundaries.

1:1 NAT rules do not change ports on packets, they remain static. For example, on outbound connections, 1:1 NAT rules preserve the source ports used by the local host, similar to using **Static Port** on outbound NAT rules.

15.2.1 1:1 NAT Risks

The risks of 1:1 NAT are essentially the same as the risks for port forwarding if firewall rules on the external interface pass packets, since they both may potentially admit harmful content into the local network.

There is some added risk with 1:1 NAT rules in that firewall rule mistakes can have more severe consequences. With port forward rules, packets are limited by constraints within the port forward rule and the firewall rule. If a port forward rule opens TCP port 80, then an allow all rule on WAN still only permits packets with a destination of TCP port 80 on that internal host. With 1:1 NAT rules in place and an allow all firewall rule on WAN, that rule exposes everything on that internal host to the Internet.

In either case, misconfigurations are always a potential hazard, and this alone is not a reason to avoid 1:1 NAT rules. Keep these behaviors in mind when configuring firewall rules and avoid permitting any connections not required by internal hosts.

15.2.2 1:1 NAT Rule Precedence

For outbound packets, 1:1 NAT rules take precedence over outbound NAT rules. This allows 1:1 NAT rules to override default behaviors defined in outbound NAT rules, including automatic outbound NAT.

For inbound packets, port forward rules take precedence over 1:1 NAT rules. This allows port forwards to override 1:1 NAT rule behavior and forward specific ports to different internal targets or even the firweall itself.

See also:

- *Ordering of NAT and Firewall Processing*
- *Outbound NAT Rule Precedence*
- *Port Forward Rule Precedence*

15.2.3 1:1 NAT Rule Options

When adding or editing a 1:1 NAT rule rule under **Firewall > NAT** on the **1:1** tab, each rule has the following options:

Disabled
Controls whether this 1:1 NAT rule is active.

No BINAT (NOT)
Excludes packets matching this 1:1 NAT rule from 1:1 NAT when packets would otherwise match another rule after this rule in the list.

Interface
The interface where the 1:1 NAT translation will take place, typically a WAN type interface.

The 1:1 NAT rule will only affect packets entering and exiting this specific interface. If there are multiple WAN type interfaces, nudging packets to use this interface may require static routing, policy routing, or equivalent configurations.

Address Family
The address family this rule will match: *IPv4* or *IPv6*. The rule will only match and act upon packets with the selected address family.

Tip: Though 1:1 NAT rules can be used with IPv6, in most cases *IPv6 Network Prefix Translation (NPt)* is a better fit for translating the prefix of IPv6 packets.

External subnet IP
The outside IP address to which this rule will translate the **Internal IP** address as packets enter or exit the **Interface**.

This is typically a Virtual IP address on **Interface**, or an IP address routed to the firewall on **Interface**.

Internal IP
The local IP address this rule will translate to the **External subnet IP** address as packets enter or exit the **Interface**.

This is typically an IP address behind this firewall. The device with this address must use this firewall as its gateway directly (attached) or indirectly (via static route).

Specifying a subnet mask here will translate the entire network matching the subnet mask. For example using `x.x.x.0/24` will translate anything in that subnet to its equivalent host address in the external subnet.

Destination
An optional restriction which limits packets the 1:1 NAT rule will match. The default value is *Any*. This field supports aliases when set to *Address or Alias*.

When a **Destination** value is present, the 1:1 NAT rule will only take effect for packets from or to addresses matching the value, depending on the direction:

- For outbound packets, the source must match the **Internal IP** address and the destination IP address must match this value.
- For inbound packets, the source IP address must match this value and the destination IP address must match the **External subnet IP** address.

Description
Text describing the rule, such as its intended behavior or name of a service. The best practice is to clearly describe the purpose of the rule in this field.

The description is optional and does not affect functionality of the rule.

NAT reflection
Overrides global NAT reflection behavior for this rule.

Use system default
Respects the global NAT reflection settings.

Enable
Always performs NAT reflection for this rule.

Disable
Never performs NAT reflection for this rule.

See also:

NAT Reflection

15.2.4 Configuring 1:1 NAT Rules

1:1 NAT rules are located at **Firewall > NAT**, on the **1:1** tab.

See also:

The list of 1:1 NAT rules works the same as the list of firewall rules for management. See *Introduction to the Firewall Rules screen* for details.

To create a new 1:1 NAT rule:

- Add a Virtual IP for the public IP address to be used for the 1:1 NAT rule as described in *Virtual IP Addresses*
- Navigate to **Firewall > NAT**, **1:1** tab
- Click  **Add** to create a new 1:1 NAT rule at the top of the list
- Configure the 1:1 NAT rule as described in *1:1 NAT Rule Options*
- Click **Save**
- Click **Apply Changes**

15.2.5 1:1 NAT Configuration Examples

This section contains example scenarios and configurations for 1:1 NAT.

See also:

- *Accessing Port Forwards from Local Networks*
- *Configuring NAT for a VoIP PBX*

Example Single IP Address 1:1 Configuration

This section demonstrates how to configure a 1:1 NAT rule with a single internal and external IP address.

In this example, a 1:1 NAT rule will map a local mail server to a public IP address. The external address is `198.51.100.210` which is a Virtual IP address on the WAN interface. The mail server resides on a DMZ segment using internal IP address `10.3.1.15`.

The 1:1 NAT rule to map `198.51.100.210` to `10.3.1.15` is shown in Figure *1:1 NAT Rule*.

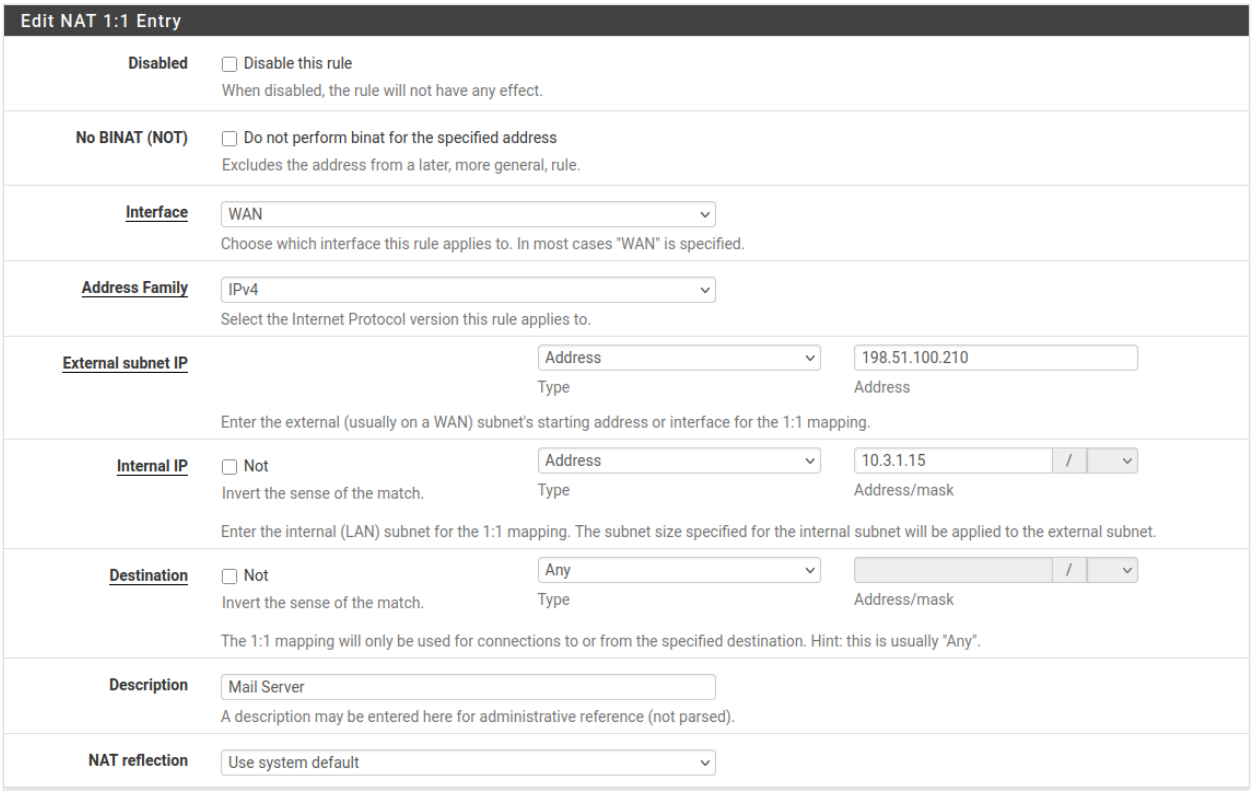

Fig. 5: 1:1 NAT Rule

Example IP Address Range 1:1 Configuration

A 1:1 NAT rule can map multiple external IP addresses using CIDR ranges. In this example, a 1:1 NAT rule maps a /30 CIDR range of IP addresses.

See also:

See *CIDR Summarization* for more information on summarizing networks or groups of IP addresses inside a larger subnet using CIDR notation.

Table 1: /30 CIDR Mapping Matching Final Octet

External IP	Internal IP
198.51.100.64/30	10.3.1.64/30
198.51.100.64	10.3.1.64
198.51.100.65	10.3.1.65
198.51.100.66	10.3.1.66
198.51.100.67	10.3.1.67

Figure *1:1 NAT rule for /30 CIDR range* shows how to configure 1:1 NAT to achieve the mapping listed in Table */30 CIDR Mapping Matching Final Octet*.

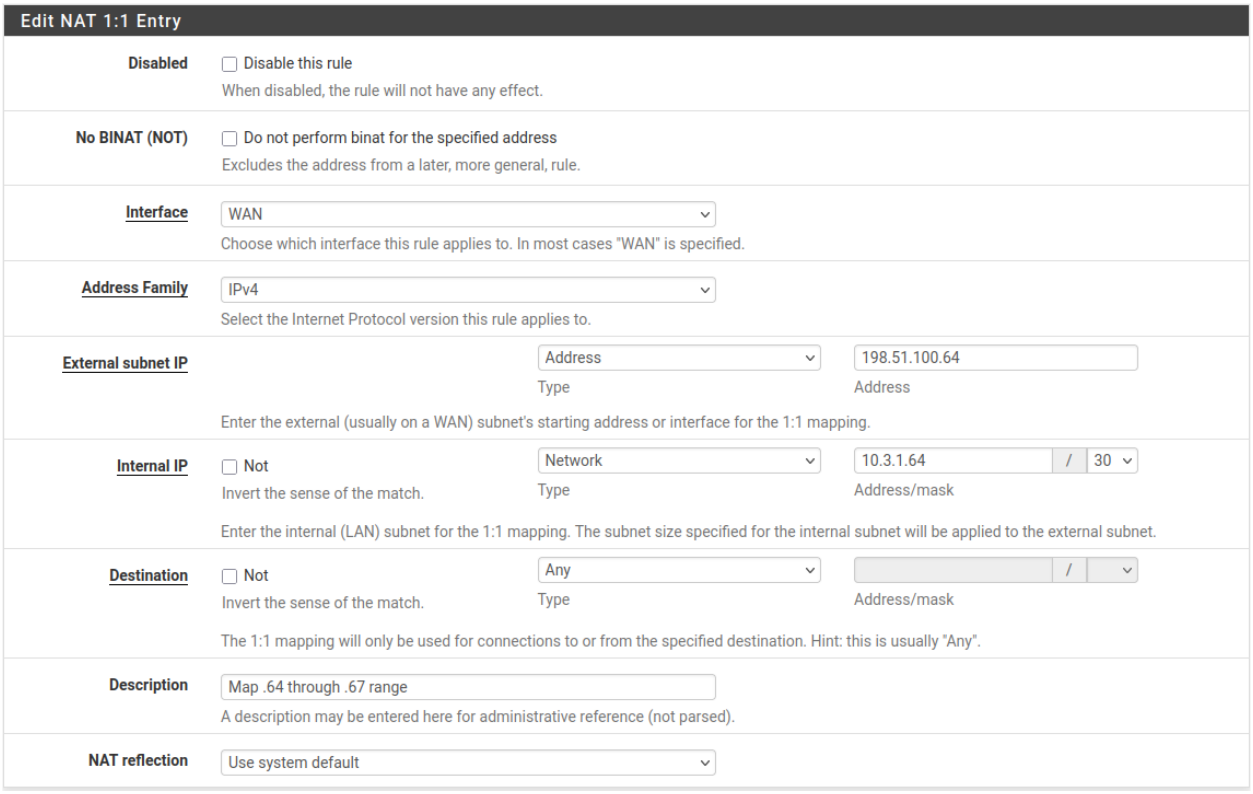

Fig. 6: 1:1 NAT rule for /30 CIDR range

The last octet of the IP addresses need not be the same on the inside and outside, but doing so makes it simpler to follow. For example, Table */30 CIDR Mapping Non-Matching Final Octet* is also valid.

Table 2: /30 CIDR Mapping Non-Matching Final Octet

External IP	Internal IP
198.51.100.64/30	10.3.1.200/30
198.51.100.64	10.3.1.200
198.51.100.65	10.3.1.201
198.51.100.66	10.3.1.202
198.51.100.67	10.3.1.203

Choosing an addressing scheme where the last octet matches makes the layout easier to understand and hence maintain.

1:1 NAT on the WAN IP, aka "DMZ" on Consumer Gateways

Some consumer gateways have what they call a "DMZ" feature which forwards all ports and protocols destined to the WAN IP address to a device on the LAN. This behavior is similar to a 1:1 NAT mapping between the WAN IP address and the IP address of the internal device.

However, the manner in which these devices use the term "DMZ" is unrelated to a DMZ in formal networking terminology. In fact, it is almost the opposite. A host in a traditional network DMZ is in an isolated network away from the other LAN hosts, secured away from the Internet and LAN hosts alike. In contrast, a "DMZ" host in the consumer gateway meaning is not only on the same network as the LAN hosts, but completely exposed to incoming Internet packets with little or no protection.

pfSense® software can perform 1:1 NAT using the WAN IP address to achieve a similar effect, with the caveat that doing so leaves all services running on the firewall itself inaccessible externally. As such, 1:1 NAT rules cannot use the WAN IP address in cases where pfSense software is hosting VPNs of any type, or cases where remote users must access other local services on the firewall. In some cases, this limitation can be mitigated by using a port forward for locally hosted services.

15.3 Ordering of NAT and Firewall Processing

Understanding the order in which firewalling and NAT occurs is important when configuring NAT and firewall rules. The basic logical order is illustrated by Figure *Ordering of NAT and Firewall Processing*. The figure also depicts where tcpdump ties in, since its use as a troubleshooting tool is described later in this documentation in *Packet Capturing*.

Each layer is not always hit in typical configurations, but the use of floating rules or manual outbound NAT or other more complicated configurations can hit each layer in both directions. The diagram only covers basic scenarios for inbound and outbound traffic.

In terms of how the ruleset is processed, the order is:

- Ethernet rules
- Outbound NAT rules
- Inbound NAT rules such as Port Forwards (including `rdr pass` and UPnP IGD & PCP)
- Rules dynamically received from RADIUS for IPsec and OpenVPN clients
- Internal automatic rules (pass and block for various items like lockout, snort, DHCP, etc.)
- User-defined rules:
  - Rules defined on the *floating tab*
  - Rules defined on interface group tabs (Including IPsec and OpenVPN)
  - Rules defined on interface tabs (WAN, LAN, OPTx, etc)
- Automatic VPN rules

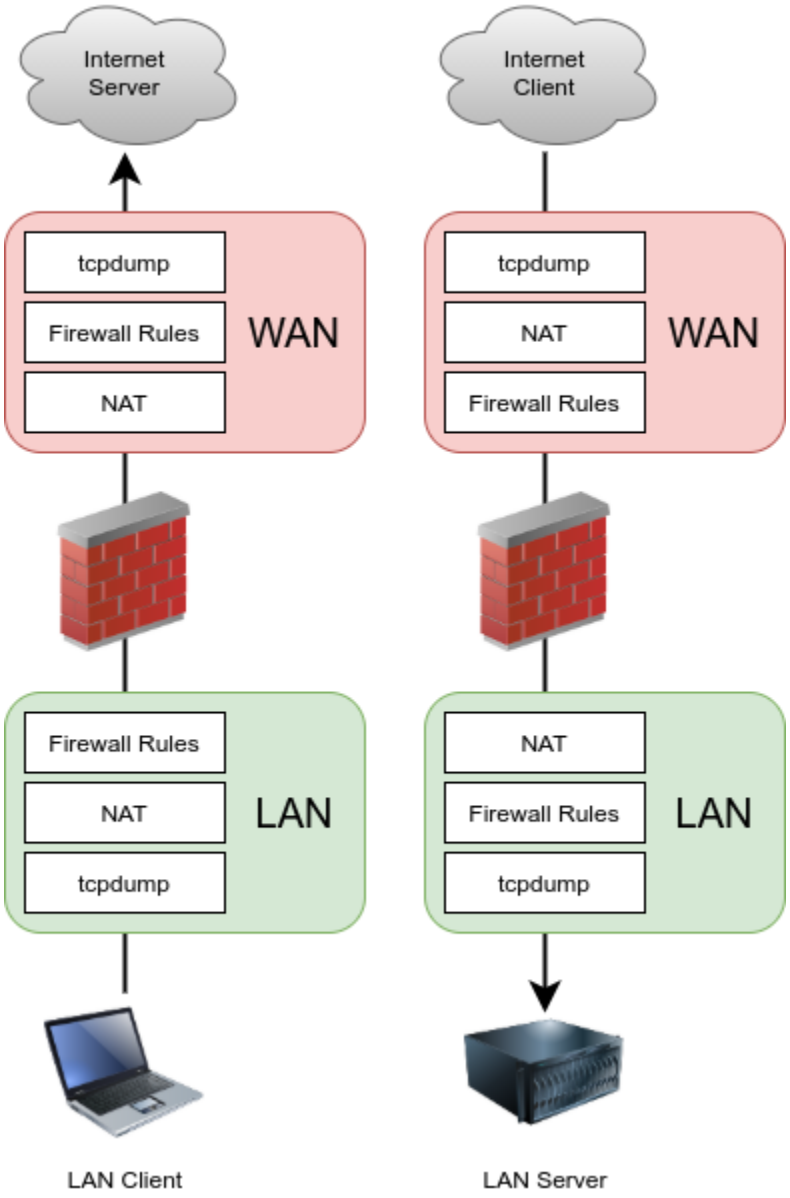

Fig. 7: Ordering of NAT and Firewall Processing

15.3.1 Firewall/NAT Processing Order Example

Traffic from LAN to WAN is processed as described in the following more detailed example. If a type of rules do not exist or do not match, they are skipped.

- Ethernet rules **inbound** on LAN
- Port forward rules then 1:1 NAT rules on the LAN interface (e.g. proxy or DNS redirects)
- Firewall rules for the LAN interface:
  - Floating rules **inbound** on LAN
  - Rules for interface groups including the LAN interface
  - LAN tab rules

  Note: This includes NAT64 rules, at which point the source and destination of matching IPv6 packets are translated to IPv4 as determined by the NAT64 rule parameters.

- 1:1 NAT rules then Outbound NAT rules on WAN
- Floating rules that match **outbound** on WAN
- Ethernet rules **outbund** on WAN

In this case, port forwards on WAN and WAN tab firewall rules do not apply.

For traffic initiated on the WAN, the order is the same but direction is reversed:

- Ethernet rules **inbound** on WAN
- Port forward rules then 1:1 NAT rules on the WAN interface (e.g. public services)
- Firewall rules for the WAN interface:
  - Floating rules **inbound** on WAN
  - Rules for interface groups including the WAN interface
  - WAN tab rules
- 1:1 NAT rules then Outbound NAT rules on LAN
- Floating rules that match **outbound** on LAN
- Ethernet rules **outbund** on LAN

`tcpdump` is always the first and last thing to see traffic, depending on the direction. First, on the incoming interface before any NAT and firewall processing, and last on the outbound interface. It shows what is on the wire. (See *Packet Capturing*)

See also:

See *Rule Processing Order* for more information about the firewall rule processing order.

Ethernet Rules notes

Ethernet (L2) rules are processed before NAT and traditional firewall rules (Floating, group, or per-interface) in the inbound direction. For outbound traffic, Ethernet rules are processed last after all other rules.

See also:

Ethernet (Layer 2) Rules

Floating Rules notes

Floating rules without `quick` set process as "last match wins" instead of "first match wins". Therefore, if a floating rule is set without `quick` and a packet matches that rule, then it also matches a later rule, the later rule will be used. This is the opposite of the other tab rules (groups, interfaces) and rules with `quick` set which stop processing as soon as a match is made. See *Floating Rules* for more details on how floating rules operate.

15.3.2 Extrapolating to additional interfaces

The previous diagram and lists only illustrate a basic two interface LAN and WAN deployment. When working with additional interfaces, the same rules apply. Traffic between two internal interfaces behaves the same as LAN to WAN traffic, though the default NAT rules will not translate traffic between internal interfaces so the NAT layer does not do anything in those cases. If Outbound NAT rules exist that match traffic between internal interfaces, it will apply as shown.

15.3.3 Rules for NAT

On the way into an interface, NAT applies before firewall rules, so if the destination is translated on the way in (e.g. port forwards rules then 1:1 NAT on WAN), then the firewall rules must match the translated destination. In the typical case of a port forward on WAN, this means the rule must match a destination of the target private IP address on LAN.

For example, with a port forward for TCP port 80 on WAN with an automatically added firewall rule, Figure *Firewall Rule for Port Forward to LAN Host* shows the resulting firewall rule on WAN. The internal IP address on the port forward is 10.3.0.15. Whether using port forward rules or 1:1 NAT rules, firewall rules on all WAN interfaces must use the internal IP address as the destination.

Fig. 8: Firewall Rule for Port Forward to LAN Host

On the way out of an interface, outbound NAT applies before firewall rules, so any floating rules matching outbound on an interface must match the source after it has been translated by 1:1 NAT rules or outbound NAT rules.

15.4 NAT Reflection

NAT reflection refers to the ability to access external services from the internal network using the external (usually public) IP address, the same as if the client were on the Internet. While many commercial and open source firewalls do not support this functionality at all, pfSense® software has solid support for NAT reflection, though some environments will require a split DNS infrastructure to accommodate this functionality.

When possible, split DNS is the preferred means of accessing resources so that the firewall is not involved in accessing internal services internally. Split DNS is covered at the end of this section in *Split DNS*.

15.4.1 Configuring NAT Reflection

To enable NAT Reflection globally:

- Navigate to **System > Advanced** on the **Firewall & NAT**
- Locate the **Network Address Translation** section of the page
- Configure the NAT Reflection options as follows:

  NAT Reflection mode for Port Forwards
  There are three available choices for NAT Reflection mode for port forwards, they are:

  Disable
  NAT Reflection will not be performed, but it may be enabled on a per-rule basis.

  NAT + Proxy
  Enables NAT Reflection using a helper program to send packets to the target of the port forward. This is useful in setups where the interface and/or gateway IP address used for communication with the target cannot be accurately determined at the time the rules are loaded. Reflection rules for use with the proxy are not created for ranges larger than 500 ports and will not be used for more than 1000 ports total between all port forwards. This mode does not work with UDP, only with TCP. Because this is a proxy, the source address of the traffic, as seen by the server, is the firewall IP address closest to the server.

  Pure NAT
  Enables NAT Reflection using only NAT rules in pf to direct packets to the target of the port forward. It has better scalability, but it must be possible to accurately determine the interface and gateway IP address used for communication with the target at the time the rules are loaded. There are no inherent limits to the number of ports other than the limits of the protocols. All protocols available for port forwards are supported. If servers are on the same subnet as clients, the **Enable automatic outbound NAT for Reflection** option will mask the source of the traffic so it flows properly back through the firewall.

  Reflection Timeout
  This option is only relevant to *NAT + Proxy* mode, and controls how long the NAT proxy daemon will wait before closing a connection. Specify the value in seconds.

  Enable NAT Reflection for 1:1 NAT
  This option allows clients on internal networks to reach locally hosted services by connecting to the external IP address of a 1:1 NAT entry. To fully activate the feature, check both **Enable NAT Reflection for 1:1 NAT** and **Enable automatic outbound NAT for Reflection**. The latter option is only necessary if clients and servers are in the same subnet.

  Enable automatic outbound NAT for Reflection
  When enabled, this option activates additional NAT rules for 1:1 NAT Reflection and Pure NAT mode NAT Reflection for port forwards. These additional rules mask the source address of the client to ensure reply traffic flows back through the firewall. Without this, connections between the client and server will fail as the server will reply directly back to the client using its internal IP address. The client will drop the connection since it expects a reply from the public IP address.

- Click **Save** to activate the new NAT reflection options

NAT Reflection Caveats

NAT reflection is a hack as it loops traffic through the firewall when it is not necessary. Because of the limited options pf allows for accommodating these scenarios, there are some limitations in the pfSense NAT + Proxy reflection implementation. Port ranges larger than 500 ports do not have NAT reflection enabled in NAT + Proxy mode, and that mode is also effectively limited to only working with TCP. The other modes require additional NAT to happen if the clients and servers are connected to the same interface of the firewall. This extra NAT hides the source address of the client, making the traffic appear to originate from the firewall instead, so that the connection can be properly established.

Split DNS is the best means of accommodating large port ranges and 1:1 NAT. Maintaining a split DNS infrastructure is required by many commercial firewalls even, and typically isn't a problem.

15.4.2 Split DNS

A preferable alternative to NAT reflection is deploying a split DNS infrastructure. Split DNS refers to a DNS configuration where, for a given hostname, public Internet DNS resolves to public IP address, and DNS on the internal network resolves to the internal, private IP address. The means of accommodating this will vary depending on the specifics of an organization's DNS infrastructure, but the end result is the same. NAT reflection is not necessary because hostnames resolve to the private IP addresses inside the network and clients can reach the servers directly.

Split DNS allows servers to see the true client IP address, and connections between servers and clients in the same subnet will go directly, rather than unnecessarily involving the firewall.

The only case that does not work properly with split DNS is when the external and internal port numbers are different. With split DNS, the port number has to be the same in both places.

DNS Resolver/Forwarder Overrides

If pfSense is acting as the DNS server for internal hosts, then host overrides in the DNS Resolver or DNS forwarder can provide split DNS functionality.

To add an override to the DNS Resolver:

- Navigate to **Services > DNS Resolver**
- Click  the under **Host Overrides** to reach the Host Override Options page
- Configure the host override as needed, using the internal IP address of the server. See *Host Overrides*. Figure *Add DNS Resolver Override for example.com* shows an example of a DNS override for `example.com` and `www.example.com`.
- Click **Save**
- Click **Apply Changes**

The DNS Forwarder works identically in this regard. If the DNS Forwarder is enabled instead of the DNS Resolver, add the overrides there.

An override is required for each hostname in use behind the firewall.

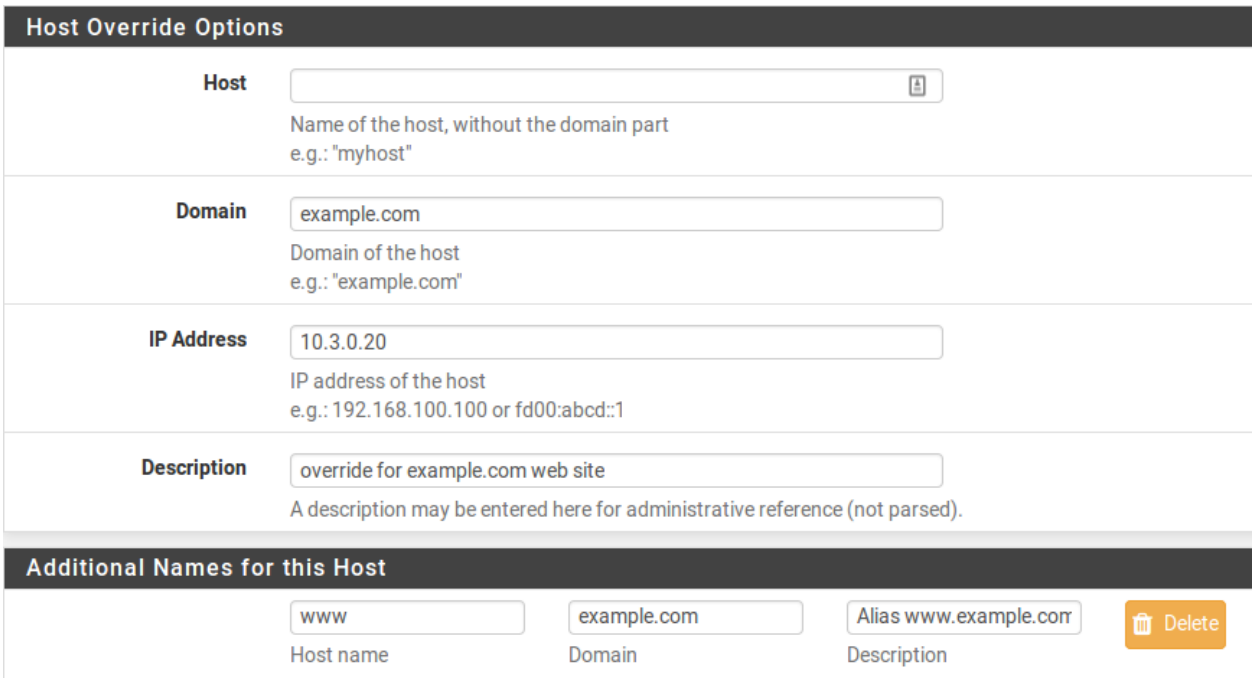

Fig. 9: Add DNS Resolver Override for example.com

Internal DNS servers

When using a separate DNS server on an internal network, such as Microsoft Active Directory, zones must be created by the DNS server administrator for all domains hosted inside the network, along with all other records for those domains (A, CNAME, MX, etc.).

In environments running the BIND DNS server where the public DNS is hosted on the same server as the private DNS, BIND's views feature is used to resolve DNS differently for internal hosts than external ones. Other DNS servers may support similar functionality. Check their documentation for information.

15.5 Outbound NAT

Outbound NAT, also known as *Source NAT*, controls how pfSense® software will translate the source address and ports of traffic leaving an interface. To configure Outbound NAT, navigate to **Firewall > NAT**, on the **Outbound** tab.

See also:

- *Ordering of NAT and Firewall Processing*

15.5.1 Outbound NAT Mode

There are four possible **Modes** for Outbound NAT:

Automatic Outbound NAT
: The default option, which automatically performs NAT from internal interfaces, such as LAN, to external interfaces, such as WAN.

Hybrid Outbound NAT
: Utilizes manual rules while also using automatic rules for traffic not matched by manually entered rules. This mode is the most flexible and easy to use for administrators who need a little extra control but do not want to manage the entire list manually.

Manual Outbound NAT
: Only honors the manually entered rules, and nothing more. Offers the most control, but can be tough to manage and any changes made to internal interfaces or WANs must be accounted for in the rules by hand. If the list is empty when switching from automatic to manual, the list is populated with rules equivalent to the automatically generated set.

Disable Outbound NAT
: Disables all outbound NAT. Useful if the firewall contains only routable addresses (e.g. public IP addresses) on all LANs and WANs.

  See also:

  Disabling Outbound NAT

Note: Even if rules are present in the Outbound NAT screen, the firewall will not honor those rules unless the **Mode** is set to **Hybrid Outbound NAT** or **Manual Outbound NAT**.

When changing the **Mode** value, click the **Save** button to store the new value.

In networks with a single public IP address per WAN, there is usually no reason to enable manual outbound NAT. If some manual control is necessary, hybrid mode is the best choice. In environments with multiple public IP addresses and complex NAT requirements, manual outbound NAT offers more fine-grained control over all aspects of translation.

Tip: For environments using High Availability with CARP, it is important to NAT outbound traffic to a CARP VIP address, as discussed in *High Availability*. This can be accomplished in either hybrid or manual mode.

As with other types of rules on pfSense software, the firewall considers outbound NAT rules from the top of the list down, and it uses the first rule which matches a packet.

Note: Outbound NAT **only** controls what happens to traffic *as it leaves an interface*. It **does not** control the interface a packet uses to exit the firewall. That is handled by the routing table (*Static Routes*) or policy routing (*Policy routing*).

15.5.2 Default Outbound NAT Rules

When set to the default **Automatic Outbound NAT** mode, the firewall maintains a set of NAT rules which translate connections sourced from internal networks to the IP address of a WAN interface through which those connections egress. The firewall also includes static route networks and remote access VPN networks in automatic NAT rules.

When outbound NAT is configured for **Automatic** or **Hybrid** modes, the GUI displays the automatic rules in the lower section of the screen labeled **Automatic Rules**.

If the Outbound NAT rule list is empty, switching to **Manual Outbound NAT** and saving will generate a full set of rules equivalent to the automatic rules.

15.5.3 Outbound NAT Rule Precedence

For outbound packets, 1:1 NAT rules take precedence over outbound NAT rules. This allows 1:1 NAT rules to override default behaviors defined in outbound NAT rules, including automatic outbound NAT.

See also:

- *Ordering of NAT and Firewall Processing*
- *1:1 NAT Rule Precedence*

15.5.4 Outbound NAT Rule Options

Outbound NAT rules are very flexible and are capable of translating traffic in many ways.

Unlike Firewall rules, the GUI displays the NAT rules in a single page with a column indicating which outbound interface is associated with each rule.

Click  from the Outbound NAT page to add a rule to the **top** of the list. Click  to add a rule to the bottom. Place specific rules at the top, and more general rules at the bottom. The rules are processed by the firewall starting at the top of the list and working down, and the firewall uses the first rule to match. Rules may be moved to match in the desired order.

When editing Outbound NAT rules, the options are split into multiple sections.

General Options

These options control general rule behavior and matching parameters.

Disabled
: Toggles whether or not this rule is active.

Do not NAT
: Prevents the firewall from applying NAT to packets matching the rule as they leave. This is necessary if the traffic would otherwise match a NAT rule, but must not have NAT applied.

  One common use for this is to add a rule exception so that the firewall does not apply NAT to its own IP addresses, especially in the case of CARP where such NAT would break Internet communication from a secondary node while it is in backup mode.

Interface
: The egress interface where this NAT rule will apply.

  Typically this is WAN or a WAN-type interface, but in some special cases it could be LAN or another internal interface.

Address Family
The address family for which this NAT rule will apply. In nearly all cases this will be *IPv4* or *IPv4+IPv6*.

Note: While it is possible to perform traditional outbound style overload NAT for IPv6 addresses, the best practice is to not apply NAT to IPv6 traffic. See *IPv6 and NAT* for details.

Protocol
The IP protocol this NAT rule will match.

In most cases, Outbound NAT will apply to *any* protocol, but occasionally it is necessary to restrict the protocol upon which the NAT will act. For example, to only perform static port NAT for UDP traffic from a PBX.

Source
The source network which this rule will match and then translate as it leaves the selected **Interface**.

This field supports the use of aliases if the **Type** is set to *Network or Alias*.

This is typically a LAN, DMZ, or VPN subnet. The **Source Port** is nearly always left blank to match all ports.

Note: Avoid using a source address of *any* as that will also match traffic from the firewall itself. This will cause problems with gateway monitoring and other firewall-initiated traffic.

Destination
The destination address this rule will match.

This field supports the use of aliases if the **Type** is set to *Network or Alias*.

In most cases, the **Destination** remains set to *any* so that the firewall will translate all traffic going to any destination through the selected **Interface**. However, the destination can be restricted when necessary. For example, to translate packets heading to a specific destination in a different way, such as only performing static port NAT to SIP trunk addresses.

Translation

These options control how NAT translates the source address for packets matching the rule.

Address
Controls what happens to the source address of traffic matching this rule.

The **Address** drop-down contains all defined Virtual IP addresses and subnets, and *Network or Alias* to manually enter a subnet for translation.

Most commonly, this is set to the Interface Address so the firewall translates the source IP address of connections the IP address of **Interface**, e.g. the WAN IP address.

Note: NAT rules cannot use an alias containing subnets for translation. They can only utilize host aliases or a single manually entered subnet.

Pool Options
Controls how outbound NAT translates source addresses when it has multiple addresses available for translation.

When an outbound NAT rule is configured to use a host alias or manually entered subnet, the rule can translate to a pool of addresses. This can help in large NAT deployments or in areas where several clients require static port to reach the same destination.

Only *Round Robin* types work with host aliases. Any type may be used with a subnet.

Default
Does not define any specific algorithm for selecting a translation address from the pool.

Round Robin
Loops through each potential translation address in the alias or subnet in turn.

Round Robin with Sticky Address
Works the same as *Round Robin* but maintains the same translation address for a given source address as long as states from the source host exist.

Random
Selects a translation address for use from the subnet at random.

Random with Sticky Address
Selects an address at random, but maintains the same translation address for a given source address as long as states from the source host exist.

Source Hash
Uses a hash of the source address to determine the translation address, ensuring that the translated address is always the same for a given source IP address.

Bitmask
Applies the subnet mask and keeps the last portion identical. For example if the source address is `10.10.10.50` and the translation subnet is `192.2.0.0/24`, the rule will change the address to `192.2.0.50`. This works similarly to 1:1 NAT but only in the outbound direction.

Port or Range
Specifies a specific *source* port for translation.

This is almost always left blank, but a client could require this behavior if the client selects a random source port when the server requires a specific source port.

Static Port
Maintains the original source port of the client packet when translating the the source IP address. Checking this option disables the **Port** entry box.

Some protocols require this behavior, such as IPsec without NAT-T. Some protocols behave better with this behavior, such as SIP and RTP.

Misc

No XMLRPC Sync
Prevents this rule from synchronizing to other High Availability cluster members via XMLRPC.

See also:

High Availability

> **Warning:** This does not prevent a rule on a secondary node from being overwritten by the primary.

Description
Text describing the rule, such as its intended behavior or name of a service. The best practice is to clearly describe the purpose of the rule in this field.

The description is optional and does not affect functionality of the rule.

Rule Information

This section works similar to the same section in firewall rules to track NAT rule creation and updates.

See also:

Firewall Rule Information

When switching from Automatic Outbound NAT mode to Manual Outbound NAT mode, the firewall marks that change as the source of the rules it creates.

15.5.5 Configuring Outbound NAT Rules

Outbound NAT rules are located at **Firewall > NAT**, on the **Outbound** tab.

See also:

The list of outbound NAT rules works the same as the list of firewall rules for management. See *Introduction to the Firewall Rules screen* for details.

To create a new outbound NAT rule:

- Navigate to **Firewall > NAT**, **Outbound** tab
- Select **Hybrid Outbound NAT** or **Manual Outbound NAT**

  See also:

  Outbound NAT Mode
- Click **Save**
- Click  to create a new outbound NAT rule to the top of the list
- Configure the rule as described in *Configuring Outbound NAT Rules*
- Click **Save**
- Click **Apply Changes**

15.5.6 Outbound NAT Configuration Examples

This section contains example scenarios and configurations for outbound NAT.

See also:

- *Configuring NAT for a VoIP PBX*
- *Configuring NAT for VoIP Phones*

Disabling Outbound NAT

If local interfaces only utilize public IP addresses, and thus NAT is not required to pass traffic through the firewall, disable NAT for routable local subnets. This can be achieved in several ways:

- If NAT is not required for any interface, set the outbound NAT mode to **Disable**.
- Using Hybrid Outbound NAT, create a rule set with **Do not NAT** set to match the routable subnets.
- Using Manual Outbound NAT, delete (or do not create) any NAT rules matching the routable subnets.

See also:

- *Outbound NAT Mode*

In any of the above cases, outbound NAT will no longer be active for those source IP addresses and pfSense software will then route public IP addresses without translation.

Static Port

By default, pfSense software rewrites the source port on all outgoing connections except for UDP port `500` (IKE for IPsec VPN traffic). Some operating systems do a poor job of source port randomization and some do not randomize source ports at all. This makes IP address spoofing easier and makes it possible to fingerprint hosts behind the firewall from their outbound traffic. Rewriting the source port eliminates these potential security vulnerabilities. Outbound NAT rules, including the automatic rules, will show  in the **Static Port** column on rules set to randomize the source port.

Source port randomization breaks some rare applications. The default Automatic Outbound NAT ruleset disables source port randomization for UDP `500` because it will almost always be broken by rewriting the source port. Outbound NAT rules which preserve the original source port are called **Static Port** rules and have  on the rule in the **Static Port** column. All other traffic has the source port rewritten by default.

Other protocols, such as those used by game consoles, may not work properly when NAT rewrites the source port. To disable this functionality, use the **Static Port** option.

To add a rule for a device which requires static source ports:

- Navigate to **Firewall > NAT**, **Outbound** tab
- Select **Hybrid Outbound NAT**

  See also:

  Outbound NAT Mode
- Click **Save**
- Click  to add a new NAT rule to the top of the list
- Configure the rule as described in *Configuring Outbound NAT Rules*

  The rule must match the traffic that requires static port, such as the source address of a PBX or a game console
- Check **Static Port** in the **Translation** section of the page
- Click **Save**
- Click **Apply Changes**

After making that change, the firewall will preserve the source port on outgoing traffic matching the rule. The best practice is to use strict rules when utilizing static port to avoid any potential conflict if two local hosts use the same source port to talk to the same remote server and port using the same external IP address.

15.6 Choosing a NAT Configuration

The best NAT configuration for a given deployment depends primarily on the number of public IP addresses available and the number of local services that require inbound access from the Internet.

15.6.1 Single Public IP Address per WAN

When only a single public IP per WAN is available, NAT options are limited.

For outbound connections, Outbound NAT is typically best left on automatic mode or hybrid with some small customizations.

For inbound connections, 1:1 NAT rules can be used with WAN IP addresses, but that can have drawbacks. In this case, the best practice is to only use port forwards.

15.6.2 Multiple Public IP Addresses per WAN

When multiple public IP addresses are available per WAN, numerous options are available for inbound and outbound NAT configuration. Port forwards, 1:1 NAT, and Hybrid or Manual Outbound NAT may all be desirable, depending on the needs of the site.

15.7 NAT and Protocol Compatibility

Some protocols do not work well with NAT and others will not work at all. Problematic protocols embed IP addresses and/or port numbers within packets (e.g. SIP and FTP), some do not work properly if the source port is rewritten (SIP from a PBX, IPsec), and some are difficult because of limitations of pf (PPTP). This section covers a sampling of protocols that have difficulties with NAT in pfSense® software, and how to work around these issues where possible.

15.7.1 Online Games

Games typically are NAT friendly aside from a couple caveats. This section refers to both PC games and console gaming systems with online capabilities. This section provides an overview of the experiences of numerous pfSense software users. Visit the Gaming category on the Netgate Forum to find more information.

Static Port

Some games do not work properly unless static port is enabled on outbound NAT rules. If a game has problems establishing a connection, the best thing to try first is enabling static port for traffic coming from the console. See *Static Port* for more information.

Multiple players or devices behind one NAT device

Some games have issues where multiple players or devices are behind a single NAT device. These issues appear to be specific to NAT, not pfSense, as users who have tried other firewalls experience the same problems with them as well. Search the Gaming category on the Netgate Forum for the game or system to find information from others with similar experiences.

Overcome NAT issues with UPnP IGD & PCP

Many modern game systems support Universal Plug-and-Play (UPnP IGD) and/or Port Control Protocol (PCP) to automatically configure any required NAT port forwards and firewall rules. Enabling UPnP IGD & PCP on pfSense software will typically allow games to work with little or no intervention. See *UPnP IGD & PCP* for more information on configuring and using UPnP IGD & PCP, and for information on potential security concerns.

15.7.2 FTP

FTP poses problems with both NAT and firewalls because of the design of the protocol. FTP was initially designed in the 1970s, and the current standard defining the specifications of the protocol was written in 1985. Since FTP was created more than a decade prior to NAT, and long before firewalls were common, it acts in ways that are very unfriendly toward NAT and firewalls.

pfSense software does not include an FTP proxy in the base installation but there is a client proxy available as an add-on package.

FTP Limitations

Because pf lacks the ability to properly handle FTP traffic without a proxy, and the FTP proxy package implementation is somewhat lacking, there are some restrictions on the usage of FTP.

FTP servers behind NAT

For FTP servers behind NAT, all relevant ports must be manually forwarded in to the server and allowed in firewall rules. Or in the case of 1:1 NAT, only the firewall rules are necessary. Depending on the FTP mode, server software, and client software, some server configuration may also be required.

FTP modes

FTP can act in multiple modes that change the behavior of the client and server, and which side listens for incoming connections. The complications of NAT and firewall rules depend on these modes and whether a remote client is attempting to reach a server behind pfSense, or if a client behind pfSense software is attempting to reach a remote server.

Active Mode

With Active Mode FTP, when a file transfer is requested, the client listens on a local port and then tells the server the client IP address and port. The server will then connect back to that IP address and port in order to transfer the data. This is a problem for firewalls because the port is typically random, though modern clients allow for limiting the range that is used. In the case of a client behind NAT, the IP address given would be a local address, unreachable from the server. Not only that, but a firewall rule would need to be added along with a port forward allowing traffic into this port.

When the FTP proxy package is in use and a client is behind pfSense software connecting to a remote server, the proxy attempts to do three major things: First, it will rewrite the FTP PORT command so that the IP address is the WAN IP address of the firewall, and a randomly chosen port on that IP address. Next, it adds a port forward that connects the translated IP address and port to the original IP address and port specified by the FTP client. Finally, it allows traffic from the FTP server to connect to that "public" port. With Multi-WAN, the proxy will only function on the WAN containing the default gateway.

When everything is working properly, this all happens transparently. The server never knows it is talking to a client behind NAT, and the client never knows that the server isn't connecting directly.

In the case of a server behind NAT, active mode is not usually a problem since the server will only be listening for connections on the standard FTP ports and then making outbound connections back to the clients. The outbound firewall rules must allow the server to make arbitrary outbound connections, and the rules must not policy route those connections out a WAN other than the one that accepted the inbound FTP connection.

Passive Mode

Passive Mode (PASV) acts somewhat in reverse. For clients, it is more NAT and firewall friendly because the server listens on a port when a file transfer is requested, not the client. Typically, PASV mode will work for FTP clients behind NAT without using any proxy or special handling at all.

Similar to the situation in the previous section, when a client requests PASV mode the server will provide the client with its IP address and a random port to which the client can attempt to connect. Since the server is on a private network, that IP address and port will need to be translated and allowed through the firewall. See *FTP Servers and Port Forwards* below for rule requirements. The FTP server must provide the public IP address to which clients connect, but some clients such as Filezilla are smart enough to ignore a given IP address if it is private, and will connect to the original server IP address instead.

Extended Passive Mode

Extended Passive Mode (EPSV) works similar to PASV mode but makes allowances for use on IPv6. When a client requests a transfer, the server will reply with the port to which the client should connect. The same caveats for servers in PASV mode apply here.

FTP Servers and Port Forwards

For FTP servers providing passive mode to clients, the configuration of the FTP server must define a passive port range and must also set the external NAT address, typically the WAN IP address of the firewall. The means of setting these values varies depending on the FTP server software implementation. Consult the FTP server documentation for more information. On the firewall, the passive port range must be forwarded in with port forwards along with TCP port 21.

For FTP servers providing active mode to clients, a port forward is only required for TCP port 21.

FTP Servers and 1:1 NAT

With 1:1 NAT, firewall rules must allow port 21 and the passive port range.

15.7.3 TFTP

Standard TCP and UDP traffic initiates connections to remote hosts using a random source port in the ephemeral port range, which varies by operating system but falls within 1024-65535, and the destination port of the protocol in use. Replies from server to client reverse that: The source port is the client destination port, and the destination port is the client source port. This is how pf associates the reply traffic with connections initiated from inside a network.

TFTP (Trivial File Transfer Protocol) does not follow this convention, however. The standard defining TFTP, RFC 1350, specifies the reply from the TFTP server to client will be sourced from a pseudo-random port number. The TFTP client may choose a source port of 10325 (as an example) and use the destination port for TFTP, port 69. The server for other protocols would then send the reply using source port 69 and destination port 10325. Since TFTP instead uses a pseudo-random source port, the reply traffic will not match the state pf has created for this traffic. Hence the replies will be blocked because they appear to be unsolicited traffic from the Internet.

TFTP is not a commonly used protocol across the Internet. The only situation that occasionally comes up where this is an issue is with some IP phones that connect to outside VoIP providers on the Internet using TFTP to pull configuration and other information. Most VoIP providers do not require this.

If TFTP traffic must pass through the firewall, a TFTP proxy is available which is configured under **System > Advanced** on the **Firewall & NAT** tab. See *TFTP Proxy* for more information.

15.7.4 PPTP / GRE

The limitations with PPTP in pfSense software are caused by limitations in the ability of pf to NAT the GRE protocol. As such, the limitations apply to any use of the GRE protocol, however PPTP has been the most common use of GRE in the wild.

The state tracking code in pf for the GRE protocol can only track a single session per public IP address per external server. This means if a PPTP VPN connection is in place, only one internal machine can connect simultaneously to the same a PPTP server on the Internet. A thousand machines can connect simultaneously to a thousand different PPTP servers, but only one simultaneously to a single server. A single client can also connect to an unlimited number of outside PPTP servers.

The only available work around is to use multiple public IP addresses on the firewall, one per client via Outbound or 1:1 NAT, or to use multiple public IP addresses on the external PPTP server. This is not a problem with other types of VPN connections.

Due to the extremely flawed security in PPTP (See *PPTP Warning*), including a complete compromise of the entire protocol, its usage should be discontinued as soon as possible, so this issue is not relevant given the current security standards.

15.8 IPv6 Network Prefix Translation (NPt)

Network Prefix Translation, or NPt for short, works similarly to 1:1 NAT but operates on IPv6 prefixes instead. NPt can be found under **Firewall > NAT** on the **NPt** tab.

NPt takes one prefix and translates it to another. So `2001:db8:1111:2222::/64` becomes `2001:db8:3333:4444::/64` and though the prefix changes, the remainder of the address will be identical for a given host on that subnet.

> **Warning:** NPt on pfSense software **does NOT** function like traditional outbound/overload NAT/PAT. NPt cannot be used to map an internal prefix to a different size prefix or single address in use on a WAN, it must be used with a routed prefix. That type of translation is possible with *outbound NAT rules*.
>
> NPt on pfSense software also **does not** function like NPT66 (RFC 6296), which also changes the host portion using specific mathematical rules so it does not change packet checksums. NPt on pfSense software is stateful and maintains the host portion of the address when translating.

There are a few purposes for NPt. With NPt, a LAN can utilize "private" IPv6 space (`fc00::/7`) and it can be translated by NPt to a public, routed, IPv6 prefix as it comes and goes through a WAN. This can help to avoid renumbering the LAN if external providers change, however since anything external that looked for the old prefix must also be adjusted, the usefulness of that can go either way, especially when the configuration must account for avoiding collisions in the `fc00::/7` space for VPN tunnels.

NPt is useful for SOHO IPv6 Multi-WAN deployments. The likelihood that a home or small business end user will have their own provider-independent IPv6 space and a BGP feed is very small. In these cases, the firewall can utilize a routed prefix from multiple WANs to function similarly to Multi-WAN on IPv4. As traffic leaves the second WAN sourced from the LAN subnet, NPt will translate it to the equivalent IP address in the routed subnet for that WAN. The LAN can either use one of the routed prefixes and do NPt on the other WANs, or use addresses in `fc00::/7` and do NPt on all WANs. The best practice is to avoid using the `fc00::/7` space for this task. For more information on Multi-WAN with IPv6, see *Configuring Multi-WAN for IPv6*.

When adding an NPt entry, there are few options to consider as NPt is fairly basic:

Disabled
: Toggles whether this rule is actively used.

Interface
: Selects the Interface where this NPt rule takes effect as the traffic exits.

Source IPv6 Prefix
: The local (e.g. LAN) IPv6 subnet and prefix length, typically the `/64` on LAN or other internal network.

Destination IPv6 Prefix
: The routed external IPv6 subnet and prefix length to which the Internal IPv6 Prefix will be translated. This is **NOT** the prefix of the WAN itself. It must be a network routed to this firewall via **Interface**

Description
: A brief description of the purpose for this entry.

Figure *NPt Example* shows an NPt rule where the LAN IPv6 subnet `2001:db8:1111:2222::/64` will be translated to `2001:db8:3333:4444::/64` as it leaves the `HE_CABLE` interface.

- *NAT64*

In its most common usage, Network Address Translation (NAT) allows multiple computers using IPv4 to be connected to the Internet using a single public IPv4 address. pfSense® software enables these simple deployments, but also accommodates much more advanced and complex NAT configurations required in networks with multiple public IP addresses.

NAT is configured in two directions: inbound and outbound. Outbound NAT defines how traffic leaving a local network destined for a remote network, such as the Internet is translated. Inbound NAT refers to traffic entering a network from a remote network. The most common type of inbound NAT is *port forwards*, which is also the type many administrators are most familiar with.

Hangouts Archive to view the May 2016 Hangout on NAT with pfSense software version 2.3 and the earlier August 2014 Hangout on Network Address Translation.

15.9 Default NAT Configuration

This section describes the default NAT configuration present on pfSense software. The most appropriate NAT configuration that can be determined is generated automatically. In some environments, this configuration may not be suitable, and pfSense software fully enables changing it from the web interface. This is a contrast from many other open source firewall distributions, which do not allow the capabilities commonly required in all but small, simple networks.

15.9.1 Default Outbound NAT Configuration

In a typical two-interface setup with LAN and WAN, the default NAT configuration automatically translates Internet-bound traffic to the WAN IP address. When multiple WAN interfaces are configured, traffic leaving any WAN interface is automatically translated to the address of the WAN interface being used.

Static port is automatically configured for IKE (part of IPsec). Static port is covered in more detail in *Outbound NAT* about Outbound NAT.

For detecting WAN-type interfaces for use with NAT, pfSense software looks for the presence of a gateway selected on the interface configuration if it has a static IP address, or pfSense software assumes the interface is a WAN if it is a dynamic type such as PPPoE or DHCP.

15.9.2 Default Inbound NAT Configuration

By default, nothing is allowed in from the Internet on the WAN interface. If traffic initiated on the Internet must be allowed to reach a host on the internal network, port forwards or 1:1 NAT are required. This is covered in the coming sections.

CHAPTER

SIXTEEN

ROUTING

One of the primary functions of a firewall is routing traffic. This chapter covers several topics related to routing including gateways, static routes, routing protocols, routing of public IP addresses, and displaying routing information.

16.1 Gateways

Gateways are the key to routing; They are routers on directly connected networks through which a host can reach other networks. The kind of gateway most people are familiar with is a *default* gateway, which is the router through which a host will communicate to the Internet or any other networks it doesn't have a more specific route to reach. Gateways are also used for static routing, where certain hosts or networks must be reached via specific routers. On most networks a gateway resides in the same subnet as one of the interfaces on a host. For example, if a firewall has an IP address of `192.168.22.5/24`, then a gateway to another network would have to be somewhere inside of `192.168.22.x` if the other network is reachable through that interface.

Note: One notable exception to this is point-to-point interfaces like those used in PPP-based protocols, which often have gateway IP addresses in another subnet because they are not used in the same way.

16.1.1 Gateway Address Families (IPv4 and IPv6)

When working with routing and gateways the functionality and procedures are the same for both IPv4 and IPv6 addresses. However, all of the addresses for a given route must involve addresses of the same family. For example, an IPv6 network must be routed through an IPv6 gateway. A route cannot be created for an IPv6 network using an IPv4 gateway address. When working with gateway groups the same restriction applies: All gateways in a gateway group must be of the same address family.

16.1.2 Managing Gateways

Before a gateway can be utilized for any purpose, it must be added to the firewall configuration.

If a gateway will be used for a WAN-type interface, it can be added on the configuration page for that interface (See *Interface Configuration Basics*), or it may be added first manually and then selected from the drop-down list on the interface configuration.

Dynamic interface types such as DHCP, PPPoE, and some assigned tunnel interfaces receive an automatic gateway that is noted as **Dynamic** in the gateway list. The parameters for such gateways can be adjusted the same as the parameters for a static gateway.

Note: Deleting a dynamic gateway will clear its custom settings but the dynamic gateway itself cannot be removed.

To add or manage gateways, navigate to **System > Routing**, **Gateways** tab.

On the screen there are a variety of options to manage gateway entries:

-  **Add** at the bottom of the list creates a new gateway
-  edits an existing gateway
-  creates a copy of an existing gateway
-  disables an active gateway
-  enables a disabled gateway
-  deletes a gateway

See also:

The individual options for gateways are discussed in detail in *Gateway Settings*.

Managing the Default Gateway

The **Default Gateway** section at the bottom of **System > Routing**, **Gateways** tab controls which gateway(s) are used by default when the firewall routes traffic. Traffic from the firewall itself will follow the default gateway, as will traffic passing through the firewall when it does not match policy routing rules or other more specific routes.

There are two controls in the section which set the default gateway for IPv4 and IPv6 respectively.

The default gateway can have one of the following values:

Automatic
: The firewall will automatically use gateways from this list (from the top down) for the default gateway, switching to the next item in the list if gateways fail or are marked down.

  For more control over this behavior, use a gateway group instead.

  Warning: This function can automatically select gateways from VPNs (e.g. IPsec, WireGuard, OpenVPN) and other sources, which may not be what the user intends. These gateways may not allow the firewall to reach the Internet, which may prevent regular traffic flow.

  The best practice for failover is to create a custom gateway group with viable Internet gateways in the intended order by tier rather than relying on the automatic behavior.

Gateway
: The selected single gateway is always used for the default gateway.

Gateway Group
The firewall uses the selected *gateway group* to select a default gateway. It will change from one gateway to another if the preferred default fails.

> **Warning:** This function does not support load balancing, only failover. When using a gateway group for the default gateway, the group must only have one gateway in each tier.

None
No default gateway for the address family will be added to the routing table.

Note: Though default gateway switching is handy for handling traffic from the firewall itself, it is not always the best fit for user traffic. When using gateway switching instead of policy routing the firewall states are not able to track gateway information which allows the firewall to selectively kill states for specific gateways. See *State Killing on Gateway Failure*.

16.2 Gateway Settings

When adding or editing a gateway, the GUI presents a page with the options for controlling gateway behavior.

The only required settings are the **Interface**, **Address Family**, **Name**, and the **Gateway** (IP address).

Interface
The interface through which the gateway is reached. For example, if this is a local gateway on the LAN subnet, choose the *LAN* interface here.

Address Family
Either *IPv4* or *IPv6*, depending on the type of address for this gateway.

Name
The **Name** for the gateway, as referenced in the gateway list, and various drop-down and other selectors for gateways. It can only contain alphanumeric characters, or an underscore, but no spaces. For example: `WANGW`, `GW_WAN`, and `WANGATE` are valid but `WAN GW` is not allowed.

Gateway
The IP address of the gateway. As mentioned previously, this must reside in a subnet directly configured on the selected **Interface**.

Note: Rare cases which require a gateway not in the interface subnet can still function, but require an additional setting. See the **Use Non-Local Gateway** option in *Advanced Gateway Settings* for details.

Disable Gateway Monitoring
By default, the gateway monitoring daemon will ping each gateway periodically to monitor latency and packet loss for traffic to the monitored IP address. This data is used for gateway status information and also to draw the Quality RRD graph. If this monitoring is undesirable for any reason, it may be disabled by checking **Disable Gateway Monitoring**. Note that if the gateway status is not monitored, then Multi-WAN will not work properly as it cannot detect failures.

Disable Gateway Monitoring Action
When set, the gateway monitoring daemon will take no action if the status of the gateway changes.

By default the gateway monitoring daemon will trigger actions on events when a gateway status changes, such as when a gateway becomes unresponsive, suffers from high latency, or when it recovers and returns to an online status. This allows the firewall to react to changes and perform tasks such as enacting gateway failover and recovery policies, changing gateways in load balancing gateway group tiers, and restarting services for various daemons utilizing the interface on which the gateway resides.

Disabling this behavior can be useful in certain situations if the administrator wants to monitor a gateway without that monitoring causing additional disruptions.

Tip: On firewalls with a single WAN or outbound path, gateway monitoring actions can typically be disabled since no actions are necessary if a gateway fails.

Monitor IP
The **Monitor IP** address option configures the IP address used by the gateway monitoring daemon to determine the gateway status using ICMP echo requests ("pings").

By default the gateway monitoring daemon will ping the gateway IP address. This is not always desirable, especially in the case where the gateway IP address is local, such as on a cable modem or fiber CPE. In those cases it makes more sense to ping something farther upstream, such as an ISP DNS server or a server on the Internet. Another case is when an ISP is prone to upstream failures, so pinging a host on the Internet is a more accurate test to determine if a WAN is usable rather than testing the link itself. Some popular choices include Google public DNS servers, or popular web sites such as Google or Yahoo. If the IP address specified in this box is not directly connected, a static route is added to ensure that traffic to the **Monitor IP** address leaves via the expected gateway. Each gateway must have a unique Monitor IP address.

The status of a gateway as perceived by the firewall can be checked by visiting **Status > Gateways** or by using the **Gateways** widget on the dashboard. If the gateway shows **Online**, then the monitor IP address is successfully responding to pings.

Static Route
By default the firewall adds static routes for gateway monitor IP addresses to ensure traffic to the monitor IP address leaves via the correct interface. Enabling this checkbox overrides that behavior so the user can manually manage routes or paths to monitor IP addresses.

Force State
When **Mark Gateway as Down** is checked, the gateway will always be considered down, even when pings are returned from the monitor IP address. This is useful for cases when a WAN is behaving inconsistently and the gateway transitions are causing disruption. The gateway can be forced into a *down* state so that other gateways may be preferred until it stabilizes.

State Killing on Gateway Failure
Optionally overrides the default behavior of the global State Killing on Gateway Failure option. See *State Killing on Gateway Failure*.

Use Global Behavior
Uses the default global behavior configured on **System > Advanced**, Miscellaneous tab.

Do not kill states on gateway failure
Excludes this gateway from the default state killing behavior.

Kill states using this gateway when it is down
Kills states for this gateway when it is down even if the global default setting would not do so.

Description
An optional **Description** of the gateway entry for reference. A short note about the gateway or interface it's used for may be helpful, or it may be left blank.

16.2.1 Advanced Gateway Settings

Several parameters can be changed to control how a gateway is monitored or treated in a Multi-WAN scenario. Most users will not need to alter these values. To access the advanced options, click the  **Display Advanced** button. If any of the advanced options are set, this section is automatically expanded. For more information on using multiple WAN connections, see *Multiple WAN Connections*.

Weight
When using Multi-WAN load balancing, if two gateways have different amounts of bandwidth, the **Weight** parameter adjusts the ratio at which connections are sent through each gateway.

For example if WAN1 has 50Mbit/s and WAN2 has 100Mbit/s, weight WAN1 as *1* and WAN2 as *2*. Then for every three connections that go out, one will use WAN1 and two will use WAN2. Using this method, connections are distributed in a way that is more likely to better utilize the available bandwidth. Weight from *1* to *30* may be chosen.

Data Payload
To conserve bandwidth, the `dpinger` daemon sends a ping with a payload size of `1` by default so that minimal data is contained within the ICMP echo request. ICMP data is padded in echo requests under `60` bytes, so any size below `60` will be equivalent in size on the wire.

Note: The default is not `0` because in some circumstances a CPE, ISP router, or intermediate hop may drop or reject ICMP packets without a payload. Since data sizes under `60` are padded, there is no advantage to using a size of `0`, especially when considering the potential for problems.

Latency Thresholds
The **Latency Thresholds** fields control the amount of latency that is considered normal for this gateway. This value is expressed in milliseconds (ms). The default values are **From** `200` and **To** `500`.

The value in the **From** field is the lower boundary at which the gateway would be considered in a warning state, but not down. If the latency exceeds the value in the **To** field, it is considered down and removed from service. The proper values in these fields can vary depending on what type of connection is in use, and what ISP or equipment is between the firewall and the monitor IP address.

Some common situations may require adjusting these values. For instance some DSL lines operate acceptably even at higher latency, so increasing the **To** parameter to `700` or more would lower the number of times the gateway would be considered down when, in fact, it was passing traffic sufficiently. Another example is a GIF tunnel to a provider such as he.net for IPv6. Due to the nature of GIF tunnels and load on the tunnel servers, the tunnel could be working acceptably even with latency as high as `900` ms as reported by ICMP ping responses.

Packet Loss Thresholds
Similar to **Latency Thresholds**, the **Packet Loss Thresholds** control the amount of packet loss to a monitor IP address before it would be considered unusable. This value is expressed as a percentage, `0` being no loss and `100` being total loss. The default values are **From** `10` and **To** `20`.

The value in the **From** field is the lower boundary at which the gateway would be considered in a warning state, but not down. If the amount of packet loss exceeds the value in the **To** field, it is considered down and removed from service. The proper values in these fields can vary depending on

what type of connection is in use, and what ISP or equipment is between the firewall and the monitor IP address.

As with latency, connections can be prone to different amounts of packet loss and still function in a usable way, especially if the path to a monitor IP address drops or delays ICMP in favor of other traffic. We have observed unusable connections with minor amounts of loss, and some that are usable even when showing 45% loss. If loss alarms occur on a normally functioning WAN gateway, enter higher values in the **From** and **To** fields until a good balance for the circuit is achieved.

Probe Interval
The value in the **Probe Interval** field controls how often a ping is sent to the monitor IP address, in *milliseconds*. The default is to ping twice per second (`500` ms).

In some situations, such as links that need monitored but have high data charges, even a small ping every second can add up. This value can be safely increased so long as it less than or equal to the **Alert Interval** and also does not violate the constraint on the **Time Period** listed below. Lower values will ping more often and be more accurate, but consume more resources. Higher values will be less sensitive to erratic behavior and consume less resources, at the cost of accuracy.

Note: The quality graph is averaged over seconds, not intervals, so as the **Probe Interval** is increased the accuracy of the quality graph is decreased.

Loss Interval
Time in milliseconds before packets are treated as lost. The default is `2000` ms (2 seconds). Must be greater than or equal to the **High Latency Threshold**.

If a circuit is known to have high latency while operating normally, this can be increased to compensate.

Time Period
The amount of time, in milliseconds, over which ping results are averaged. The default is `60000` (60 seconds, one minute). A longer **Time Period** will take more time for latency or loss to trigger an alarm, but it is less prone to be affected by erratic behavior in ping results.

The **Time Period** must be greater than **twice** the sum of the **Probe Interval** and **Loss Interval**, otherwise there may not be at least one completed probe.

Alert Interval
The time interval, in milliseconds, at which the daemon checks for an alert condition. The default value is `1000` (1 second). This value must be greater than or equal to the **Probe Interval**, because an alert could not possibly occur between probes.

Use Non-Local Gateway
The **Use non-local gateway through interface specific route** option allows a non-standard configuration where a gateway IP address exists outside of an interface subnet. Some providers attempting to scrape the bottom of the IPv4 barrel have resorted to this in order to not put a gateway into each customer subnet. Do not activate this option unless required to do so by the upstream provider.

16.3 Gateway Groups

Gateway groups are a set of gateways, but are treated as one entity in gateway fields of the GUI. Groups will appear in the gateway drop-downs available on, for example, firewall rule editing.

Gateway groups are managed from the **Gateway Groups** tab on **System > Routing**.

16.3.1 Gateway Group Options

When creating a gateway group, the following options are available:

Group Name
The name of this gateway group. The name must be less than 32 characters in length, and may only contain letters a-z, digits 0-9, and an underscore. This will be the name used to refer to this gateway group in the **Gateway** field in firewall rules. This field is required.

Gateway Priority
This list contains every gateway on the firewall to select which gateways will be a part of this group. The GUI will filter the list address family after the first selection.

Tier
The priority level for this gateway. The value may be from 1-5 or *Never* to exclude the gateway from this group.

Lower values are higher priority. For example, gateways on *Tier 1* are used before gateways on *Tier 2*, and so on.

Gateways on the same tier are used by the firewall for load balancing when possible. Load balancing naturally performs failover as failed gateways are removed from the pool available for load balancing.

Gateways on different tiers result in failover from gateways on lower tiers to those higher tiers. For example, if Tier 1 contains only one gateway and it fails, then the next tier (Tier 2) is checked for available gateways and the firewall uses those instead, and so on.

> **Warning:** Some firewall features which support gateway groups only support failover, not load balancing. For example, when using a gateway group for the default gateway or as a VPN endpoint, each gateway must be on a separate tier.

Virtual IP
When using a gateway group for failover in certain contexts which require binding a specific address, such as IPsec, this option controls which address on an interface is used for that purpose. For example, in an HA pair this could be a CARP VIP used as an endpoint for IPsec tunnels.

Leave it set to the default *Interface Address* when a specific address is not required by any use of the gateway group.

Keep Failover States
Controls the state-killing behavior for the gateway group when configured for failover. This behavior takes effect when a higher-priority gateway returns to an online state. Only affects states created by policy routing rules. This option overrides the global behavior (see *Gateway Monitoring*).

Keep states on gateway recovery
Policy routing states are unaffected when a higher-priority gateway returns to an online

state. Connections established on failover gateways will remain on those gateways until reconnected.

Kill states on gateway recovery
States created by policy routing rules using this gateway group are killed when a higher-priority gateway returns to an online state. This option does not affect traffic from the firewall itself.

Trigger Level

Configures how the firewall manages the gateway group entries when certain types of gateway events occur.

Member Down
Marks the gateway as down only when it is completely down, past one or both of the higher thresholds configured for the gateway. This catches the worst sort of failures, when the gateway is completely unresponsive, but may miss more subtle issues with the circuit that can make it unusable long before the gateway reaches that level.

Packet Loss
Marks the gateway as down when packet loss crosses the lower alert threshold (See *Advanced Gateway Settings*).

High Latency
Marks the gateway as down when latency crosses the lower alert threshold (See *Advanced Gateway Settings*).

Packet Loss or High Latency
Marks the gateway as down for either type of alert.

Description
Text describing the purpose of this gateway group.

16.3.2 Tier Priority Example

Example:

- WANGW: Tier1
- OPT1GW: Tier2
- OPT3GW: Tier3

In the example above OPT1GW would be used if WANGW fails, OPT3GW will be used if both WANGW and OPT1GW fail.

16.3.3 Connection-Based Round-Robin Load Balancing Example

Example:

- WANGW: Tier1
- OPT1GW: Tier1
- OPT3GW: Tier1

In the example above all gateways have the same **Tier** value. When this group is used by a firewall rule, connections matching that rule will perform connection-based round-robin load balancing between all of the gateways.

Note: If any of the gateways fail, they are automatically removed from active usage in the group, effectively resulting in failover in addition to load balancing.

16.3.4 See Also

Multi-WAN Guide

16.4 Static Routes

Static routes are used when hosts or networks are reachable through a router other than the default gateway. The firewall knows about the networks directly attached to it, and it reaches all other networks as directed by the routing table. In networks where an internal router connects additional internal subnets, a static route must be defined for those networks to be reachable.

Note: The routers through which these other networks are reached must first be added as gateways. See *Gateways* for information on adding gateways.

Static routes are managed at **System > Routing** on the **Routes** tab.

See also:

- *Accessing Firewall Services over IPsec*
- *Policy Routing Configuration*

16.4.1 Static Route Configuration

When adding or editing a static route, the following options are available:

Destination Network
The network and subnet mask reachable using this route. This may be an IPv4 address (subnet ID), IPv6 prefix, or an *alias*.

> **Warning:** When editing an alias which is used by a static route, the firewall makes changes to the routing table to reflect the new alias content as soon as the alias is saved. The firewall does not wait for the user to click **Apply Changes** in this circumstance.

Gateway
The router through which this network is reached.

Disabled
Check if the static route should not be used, only defined.

Description
Text to describe the route, its purpose, etc.

16.4.2 Managing Static Routes

To add a route:

- Navigate to **System > Routing** on the **Routes** tab
- Click  **Add** to create a new static route
- Fill in the configuration as described in *Static Route Configuration*
- Click **Save**
- Click **Apply Changes**

To manage existing routes, navigate to **System > Routing** on the **Routes** tab. On the screen there are a variety of options to manage routes:

-  edits an existing route
-  creates a copy of an existing gateway
-  deletes a route
-  disables an active route
-  enables a disabled route

16.4.3 Example Static Route

Figure *Static Routes* illustrates a scenario where a static route is required.

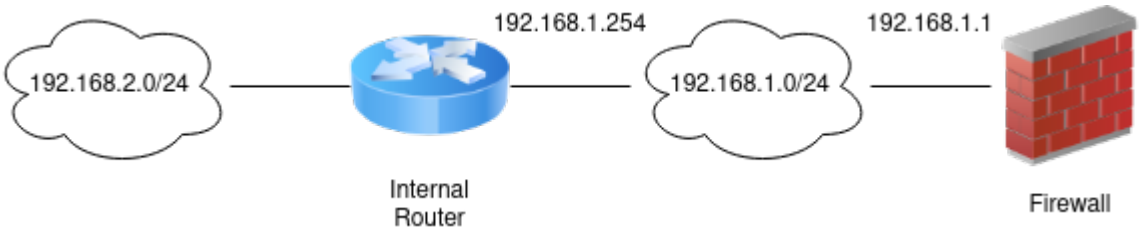

Fig. 1: Static Routes

Because the `192.168.2.0/24` network in Figure *Static Routes* is not on an interface directly connected to the firewall, a static route is required for the firewall to know how to reach that network. Figure *Static Route Configuration* shows the appropriate static route for the above diagram. As mentioned earlier, before a static route may be added a gateway must first be defined.

LAN firewall rules must allow traffic to pass from a source of the networks reachable via static routes on LAN, and outbound NAT must also accommodate these networks.

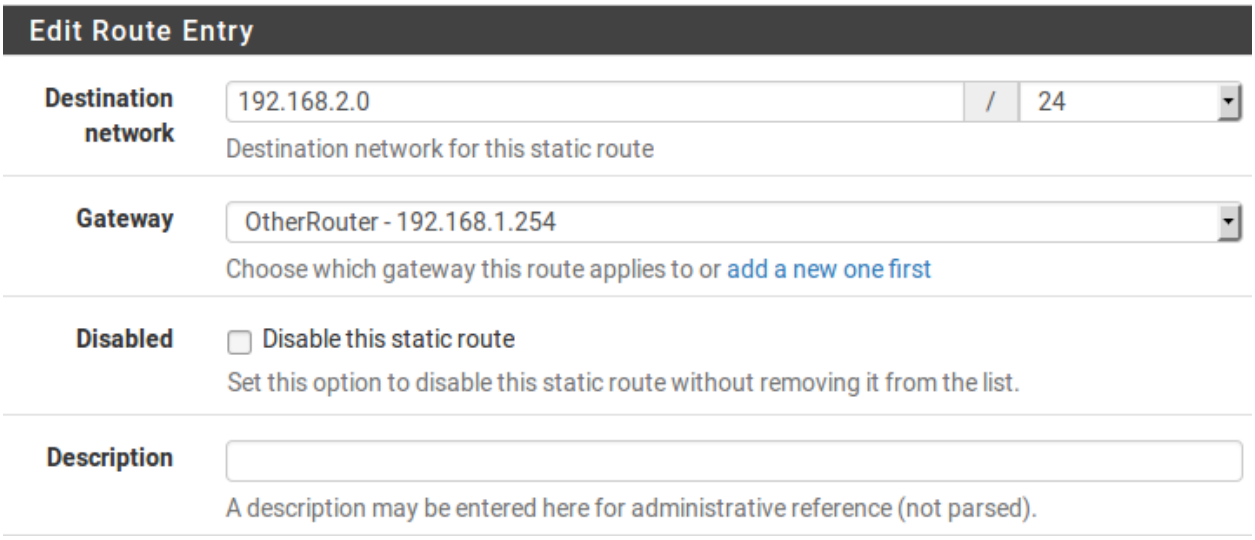

Fig. 2: Static Route Configuration

16.4.4 Bypass Firewall Rules for Traffic on Same Interface

In some environments using static routes, traffic ends up routing asymmetrically. This means the traffic will follow a different path in one direction than the traffic flowing in the opposite direction. Take Figure *Asymmetric Routing* for example.

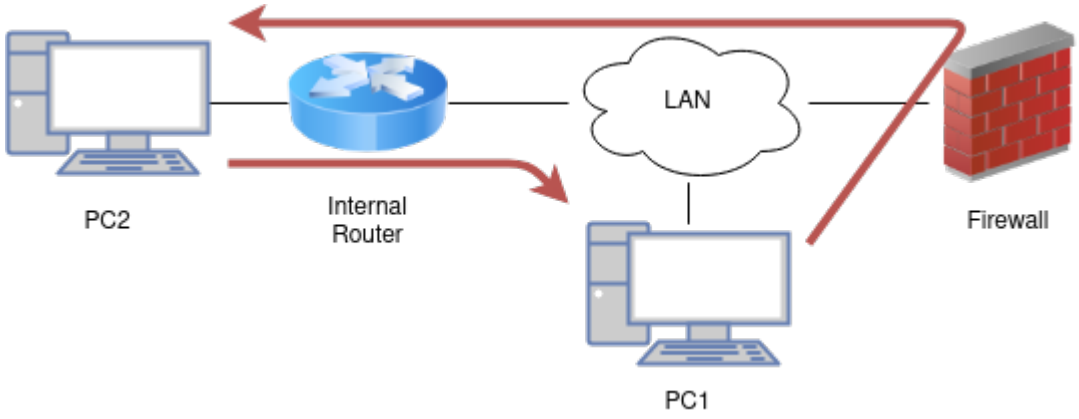

Fig. 3: Asymmetric Routing

Traffic from PC1 to PC2 will go through the firewall since it is the default gateway for PC1, but traffic in the opposite direction will go directly from the router to PC1.

Since this is a stateful firewall, it must see traffic for the entire connection to be able to filter traffic properly. With asymmetric routing such as in this example, any stateful firewall will drop legitimate traffic because it cannot properly keep state without seeing traffic in both directions. This generally only affects TCP, since other protocols do not have a formal connection handshake the firewall can recognize for use in state tracking.

Note: A connection may appear to work for a short time and then stop. This can be from the firewall removing a state which doesn't transition to a fully open state, or it may be from clients expiring an ICMP redirect.

In asymmetric routing scenarios, there is an option in the firewall GUI which can be used to prevent legitimate traffic from being dropped. The option adds firewall rules which allow all traffic between networks defined in static routes using a more permissive set of rule options and state handling. To activate this option:

- Click **System > Advanced**
- Click the **Firewall/NAT** tab
- Check **Bypass firewall rules for traffic on the same interface**
- Click **Save**

Alternatively, firewall rules may be added manually to allow similar traffic. Two rules are needed, one on the interface tab where the traffic enters (e.g. LAN) and another on the **Floating** tab:

- Navigate to **Firewall > Rules**
- Click the tab for the interface where the traffic will enter (e.g. **LAN**)
- Click  **Add** to add a new rule to the top of the list
- Use the following settings:

  Protocol
  TCP

  Source
  The local systems utilizing the static route (e.g. *LAN Net*)

  Destination
  The network on the other end of the route

  TCP Flags
  Check **Any flags** (Under **Advanced Features**)

  State Type
  Sloppy State (Under **Advanced Features**)

- Click **Save**
- Click the **Floating** tab
- Click  **Add** to add a new rule to the top of the list
- Use the following settings:

  Interface
  The interface where the traffic originated (e.g. **LAN**)

  Direction
  Out

  Protocol
  TCP

  Source
  The local systems utilizing the static route (e.g. *LAN Net*)

  Destination
  The network on the other end of the route

  TCP Flags
  Check **Any flags** (Under **Advanced Features**)

State Type
Sloppy State (Under **Advanced Features**)

- Click **Save**

If additional traffic from other sources or destinations is shown as blocked in the firewall logs with TCP flags such as "TCP:SA" or "TCP:PA", the rules may be adjusted or copied to match that traffic as well.

Note: If filtering of traffic between statically routed subnets is required, it must be done on the router and not the firewall since the firewall is not in a position on the network where it can effectively control that traffic.

See also:

- *Troubleshooting Asymmetric Routing*

16.4.5 ICMP Redirects

When a device sends a packet to its default gateway, and the gateway knows the sender can reach the destination network via a more direct route, it will send an ICMP redirect message in response and forward the packet as configured. The ICMP redirect causes a route for that destination to be temporarily added to the routing table of the sending device, and the device will subsequently use that more direct route to reach that destination.

This will only work if the client OS is configured to permit ICMP redirects, which is typically the case by default.

ICMP redirects are common when static routes are present which point to a router on the same interface as client PCs and other network devices. The asymmetric routing diagram from the previous section is an example of this.

ICMP redirects have a mostly undeserved bad reputation from some in the security community because they allow modification of a client routing table. However they are not the risk that some imply, as to be accepted, the ICMP redirect message must include the first 8 bytes of data from the original datagram. A host in a position to see that data and hence be able to successfully forge illicit ICMP redirects is in a position to accomplish the same end result in multiple other ways.

16.5 Multi-Path Routing

Current versions of pfSense® software include kernels built with the option `ROUTE_MPATH` which enables multi-path routing.

This allows the routing table to contain multiple entries to the same destination, which allows for weight-based balancing of traffic including Equal-cost multi-path routing (ECMP) if all gateways for a destination are weighted the same.

Warning: Currently multi-path routing can only be utilized by the dynamic routing daemon package *FRR*. The base system GUI does not currently support managing multiple routes to the same destination, but support is planned for future releases.

16.5.1 Multi-Path Routing Behavior

Packets may only take alternate paths when they are different in some way. When there are multiple paths to a destination the operating system computes outbound flow hashing for connections to decide which path to use for a packet. This concept is similar to the *LAGG Hash Algorithm*. The hashing takes the 5-tuple connection property set into account: "(protocol, source address, destination address, source port, destination port)".

For example, testing with ICMP only from one host to another with no variation may never see flows take a second path. In contrast, testing repeated TCP connections could take multiple paths if the source port is randomized. The best way to test is by using multiple sources and destinations passing through the firewall and not from the firewall itself.

16.5.2 View Nexthop Data

The first thing to check is the routing table to ensure that there are multiple routes to the same destination:

```
: netstat -rWn4
Routing tables

Internet:
Destination        Gateway            Flags    Nhop#    Mtu      Netif Expire
[...]
10.5.0.0/16        198.51.100.5       UGS          0   1500        ix3
10.5.0.0/16        203.0.113.5        UGS          0   1500        ix2
```

Note: The route table in the status output of the FRR package will also show multiple entries for the same destination with different `via` addresses.

Next, there are two items to check to verify that multi-path routing is taking effect: Nexthop data and Nexthop group data.

Check the nexthop data with `netstat -4onW` and/or `netstat -6onW`:

```
: netstat -4onW
Nexthop data

Internet:
Idx   Type         IFA                Gateway             Flags      Use Mtu       ␣
↪Netif     Addrif Refcnt Prepend
[...]
32           v4/gw 198.51.100.17      198.51.100.5       GS           0   1500      ␣
↪ix3                1
33           v4/gw 203.0.113.17       203.0.113.5        GS           0   1500      ␣
↪ix2                1
```

Check nexthop group data with `netstat -4OnW` and/or `netstat -6OnW`:

```
: netstat -4OnW
Nexthop groups data

Internet:
GrpIdx  NhIdx     Weight   Slots           Gateway     Netif  Refcnt
34        ------- ------- ------- ----------------- ---------       2
```

(continues on next page)

(continued from previous page)

```
              32       1       1      198.51.100.5       ix3
              33       1       1       203.0.113.5       ix2
```

The outputs of those commands should show both gateways and indicate that they belong to the same "group".

CHAPTER

SEVENTEEN

BRIDGING

17.1 Creating a Bridge

In pfSense® software, bridges are added and removed at **Interfaces > Assignments** on the **Bridges** tab. Using bridges, any number of ports may be bound together easily. Each bridge created in the GUI will also create a new bridge interface in the operating system, named `bridgeX` where `X` starts at 0 and increases by one for each new bridge. These interfaces may be assigned and used like most other interfaces, which is discussed later in this chapter.

To create a bridge:

- Navigate to **Interfaces > Assignments** on the **Bridges** tab.
- Click **Add** to create a new bridge.
- Select at least one entry from **Member Interfaces**. Select as many as needed using `Ctrl`-click.
- Add a **Description** if desired.
- Click **Show Advanced Options** to review the remaining configuration parameters as needed. For most cases they are unnecessary.
- Click **Save** to complete the bridge.

Note: A bridge may consist of a single member interface, which can help with migrating to a configuration with an assigned bridge, or for making a simple span/mirror port.

17.2 Advanced Bridge Options

There are numerous advanced options for a bridge and its members. Some of these settings are quite involved, so they are discussed individually in this section.

17.2.1 (Rapid) Spanning Tree Options

Spanning Tree is a protocol that helps switches and devices determine if there is a loop and cut it off as needed to prevent the loop from harming the network. There are quite a few options that control how spanning tree behaves which allow for certain assumptions to be made about specific ports or to ensure that certain bridges get priority in the case of a loop or redundant links. More information about STP may be found in the FreeBSD ifconfig(8) man page, and on Wikipedia.

Protocol

The **Protocol** setting controls whether the bridge will use IEEE 802.1D Spanning Tree Protocol (*STP*) or IEEE 802.1w Rapid Spanning Tree Protocol (*RSTP*). RSTP is a newer protocol, and as the name suggests it operates much faster than STP, but is backward compatible. The newer IEEE 802.1D-2004 standard is based on RSTP and makes STP obsolete.

Select STP only when older switch gear is in use that does not behave well with RSTP.

STP Interfaces

The **STP Interfaces** list reflects the bridge members upon which STP is enabled. `Ctrl`-click to select bridge members for use with STP.

Valid Time

Set the **Valid Time** for a Spanning Tree Protocol configuration. The default is `20` seconds. The minimum is `6` seconds and the maximum is `40` seconds.

Forward Time

The **Forward Time** option sets the time that must pass before an interface begins forwarding packets when Spanning Tree is enabled. The default is `15` seconds. The minimum is `4` seconds and the maximum is `30` seconds.

Note: A longer delay will be noticed by directly connected clients as they will not be able to pass traffic, even to obtain an IP address via DHCP, until their interface enters forwarding mode.

Hello Time

The **Hello Time** option sets the time between broadcasting of Spanning Tree Protocol configuration messages. The **Hello Time** may only be changed when operating in legacy STP mode. The default is `2` seconds. The minimum is `1` second and the maximum is `2` seconds.

Bridge Priority

The **Bridge Priority** for Spanning Tree controls whether or not this bridge would be selected first for blocking should a loop be detected. The default is `32768`. The minimum is `0` and the maximum is `61440`. Values must be a multiple of `4096`. Lower priorities are given precedence, and values lower than `32768` indicate eligibility for becoming a root bridge.

Hold Count

The transmit **Hold Count** for Spanning Tree is the number of packets transmitted before being rate limited. The default is `6`. The minimum is `1` and the maximum is `10`.

Port Priorities

The **Priority** fields set the Spanning Tree priority for each bridge member interface. Lower priorities are given preference when deciding which ports to block and which remain forwarding. Default priority is `128`, and must be between `0` and `240`.

Path Costs

The **Path Cost** fields sets the Spanning Tree path cost for each bridge member. The default is calculated from the link speed. To change a previously selected path cost back to automatic, set the cost to `0`. The minimum is `1` and the maximum is `200000000`. Lower cost paths are preferred when making a decision about which ports to block and which remain forwarding.

17.2.2 Cache Settings

Cache Size sets the maximum size of the bridge address cache, similar to the MAC or CAM table on a switch. The default is `100` entries. If there will be a large number of devices communicating across the bridge, set this higher.

Cache entry expire time controls the timeout of address cache entries in seconds. If set to `0`, then address cache entries will not be expired. The default is `240` seconds (Four minutes).

17.2.3 Span Port

Selecting an interface as the **Span port** on the bridge will transmit a copy of every frame received by the bridge to the selected interface. This is most useful for snooping a bridged network passively on another host connected to the span ports of the bridge with something such as Snort, tcpdump, etc. The selected span port may not be a member port on the bridge.

17.2.4 Edge Ports / Automatic Edge Ports

If an interface is set as an **Edge port**, it is always assumed to be connected to an end device, and *never* to a switch; It assumes that the port can never create a layer 2 loop. Only set this on a port when it will never be connected to another switch. By default ports automatically detect edge status, and they can be selected under **Auto Edge** ports to *disable* this automatic edge detection behavior.

17.2.5 PTP Ports / Automatic PTP Ports

If an interface is set as a **PTP port**, it is always assumed to be connected to a switch, and not to an end user device; It assumes that the port can potentially create a layer 2 loop. It should only be enabled on ports that are connected to other RSTP-enabled switches. By default ports automatically detect PTP status, and they can be selected under Auto **PTP ports** to *disable* this automatic PTP detection behavior.

17.2.6 Sticky Ports

An interface selected in **Sticky Ports** will have its dynamically learned addresses cached as though they were static once they enter the cache. Sticky entries are never removed from the address cache, even if they appear on a different interface. This could be used a security measure to ensure that devices cannot move between ports arbitrarily.

17.2.7 Private Ports

An interface marked as a **Private Port** will not communicate with any other port marked as a **Private Port**. This can be used to isolate end users or sections of a network from each other if they are connected to separate bridge ports marked in this way. It works similar to "Private VLANs" or client isolation on a wireless access point.

17.3 Bridging and Interfaces

A bridge interface (e.g. *bridge0*) itself may be assigned as interface. This allows the bridge to act as a normal interface and have an IP address placed upon it rather than a member interface.

Configuring the IP address on the bridge itself is best in nearly all cases. The main reason for this is due to the fact that bridges are dependent on the state of the interface upon which the IP address is assigned. If the IP address for the bridge is configured on a member interface and that interface is down, the whole bridge will be down and no longer passing traffic. The most common case for this is a wireless interface bridged to an Ethernet LAN NIC. If the LAN NIC is unplugged, the wireless would be dead unless the IP address was configured on the bridge interface and not LAN. Another reason is that if limiters must be used for controlling traffic, then there must be an IP address on the bridge interface for them to work properly. Likewise, in order for Captive Portal or a transparent proxy to function on an internal bridge the IP address must be configured on the assigned bridge and not a member interface.

17.3.1 Swapping Interface Assignments

Before getting too far into talking about moving around bridge interface assignments, it must be noted that these changes should be made from a port that is **not** involved in the bridge. For example, if bridging WLAN to LAN, make the change from WAN or another OPT port. Alternately, download a backup of `config.xml` and manually make the changes. Attempting to make changes to a port while managing the firewall from that port will most likely result loss of access to the GUI, leaving the firewall unreachable.

Note: It is tempting to create the bridge and then merely swap the interface assignments, but that won't work because it would end up with the bridge added to itself. For example, with LAN and WLAN, create a bridge LANBRIDGE, and then try to swap LAN and LANBRIDGE, it wouldn't work because LAN is specified in the bridge configuration.

Easy Method: Move settings to the new interface

The easiest, though not the quickest, path in the GUI is to remove the settings from the LAN interface individually (IP address, DHCP, etc) and then activate them on the newly assigned bridge interface.

Quick but Tricky: Reassign the Bridge as LAN

Though this method is a bit trickier than moving the settings, it can be much faster especially in cases where there are lots of firewall rules on LAN or a complex DHCP configuration. In this method, some hoop-jumping is required but ultimately the bridge ends up as the LAN interface, and it retains the LAN IP address, all of the former firewall rules, DHCP, and other interface configuration.

- Assign and configure the bridge members that have not yet been handled. Review the steps below to ensure the interface settings are correct even if the interfaces have already been assigned and configured.
  - Navigate to **Interfaces > Assignments**
  - Choose the interface from the **Available network ports** list
  - Click **Add**
  - Navigate to the new interface configuration page, e.g. **Interfaces > OPT2**

    Enable
    Checked

    Description
    `WiredLAN2` or similar

    IPv4 Configuration Type
    None

    IPv6 Configuration Type
    None

    Block private networks
    Unchecked

    Block bogon networks
    Unchecked
  - Click **Save**
  - Click **Apply Changes**
  - Repeat for additional unassigned future bridge members
- Create the new bridge
  - Navigate to **Interfaces > Assignments** on the **Bridges** tab
  - Click **Add** to create a new bridge
  - Enter a **Description**, such as `LAN Bridge`
  - Select all of the new bridge members **EXCEPT** the *LAN* interface in the **Member interfaces** list
  - Click Save
- Change the bridge filtering **System Tunable** to disable member interface filtering
  - Navigate to **System > Advanced**, **System Tunables** tab
  - Locate the entry for **net.link.bridge.pfil_member** or create a new entry if one does not exist, using that name for the **Tunable**

  - Click  to edit an existing entry
  - Enter `0` in the **Value** field
  - Click **Save**
- Navigate to **Interfaces > Assignments**
- Change the assignment of **LAN** to `bridge0`
- Click **Save**
- Assign and configure the old LAN interface as described previously, setting its IP configuration types to *None* and naming it `WiredLAN`
- Edit the bridge and select the newly assigned `WiredLAN` as a bridge member
- Change the bridge filtering **System Tunable** to enable bridge interface filtering
  - Use the procedure described previously, but set **net.link.bridge.pfil_bridge** to 1

Now the former LAN interface, along with the new bridge members, are all on a common layer 2 with the bridge assigned as LAN along with the other configuration.

Quickest but Most Difficult: Hand Edit config.xml

Hand editing `config.xml` can be very fast for those familiar with the configuration format in XML. This method is easy to get wrong, however, so be sure to have backups and install media nearby in case a mistake is made.

When hand editing `config.xml` to accomplish this task, do as follows:

- Assign the additional bridge members and set their IP configuration types to *None*
- Create the bridge, including *LAN* and *LAN2* and other bridge members
- Assign the bridge (e.g. as OPT2) and enable it, also with an IP configuration type of *None*
- Download a backup of `config.xml` from **Diagnostics > Backup/Restore**
- Open `config.xml` in a text editor that understands UNIX line endings
- Change the *LAN* assignment to `bridge0`
- Change the former *LAN* assignment to what used to be the bridge (e.g. *OPT2*)
- Edit the bridge definition to refer to *OPT2* and not *LAN*
- Save the changes
- Restore the edited `config.xml` from **Diagnostics > Backup/Restore**

The firewall will reboot with the desired setup. Monitor the console to ensure the settings were applied correctly and no errors are encountered during the boot sequence.

17.3.2 Assigned Bridge MAC Addresses and Windows

The MAC address for a bridge is determined randomly when the bridge is created, either at boot time or when a new bridge is created. That means that on each reboot, the MAC address can change. In many cases this does not matter, but Windows Vista, 7, 8, and 10 use the MAC address of the gateway to determine if they are on a specific network. If the MAC changes, the network identity will change and its status as public, private, etc. may need to be corrected. To work around this, enter a MAC address on the assigned bridge interface to spoof it. Then clients will always see the same MAC for the gateway IP address.

17.4 Bridging and Firewall Rules

Filtering with bridged interfaces functions similar to routed interfaces, but there are some configuration choices to alter exactly how the filtering behaves.

17.4.1 Apply Firewall Rules on Bridges or Interfaces

By default, firewall rules are applied on each member interface of the bridge on an inbound basis, like any other routed interface.

It is possible to decide whether the filtering happens on the bridge member interfaces, or on the bridge interface itself. This is controlled by two *System Tunables* values on **System > Advanced** on the **System Tunables** tab, as seen in Figure *Bridge Filtering Tunables*. The `net.link.bridge.pfil_member` tunable controls whether or not the firewall will honor rules on the bridge member interfaces. By default, this is on (`1`). The `net.link.bridge.pfil_bridge` tunable controls whether or not the firewall will honor rules on the bridge interface itself. By default, this is off (`0`). At least one of these must be set to `1`.

net.link.bridge.pfil_member	Packet filter on the member interface	1	
net.link.bridge.pfil_bridge	Packet filter on the bridge interface	0	

Fig. 1: Bridge Filtering Tunables

When filtering on the bridge interface itself, traffic will hit the rules as it enters from any member interface. The rules are still considered "inbound" like any other interface rules, but they work more like an interface group since the same rules apply to each member interface.

17.4.2 Firewall Rule Macros

Only one interface of a bridge will have an IP address set, the others will have none. For these interfaces, their firewall macros such as *OPT1 address* and *OPT1 net* are undefined because the interface has no address and thus no subnet.

If filtering is performed on bridge members, keep this fact in mind when crafting rules and explicitly list the subnet or use the macros for the interface where the IP address resides.

17.4.3 Ethernet Rules on Bridge Interfaces

Applying *Ethernet (Layer 2) Rules* on a bridge requires changing a *System Tunables* value at **System > Advanced** on the **System Tunables** tab.

The `net.link.bridge.ipfw` tunable controls whether or not the firewall will honor Ethernet rules on a bridge interface itself. Though the tunable name mentions IPFW, it controls all link-level packet filtering hooks on bridges.

By default, this tunable is off (`0`). To enable Ethernet rule filtering on bridge interfaces, this must be set to `1`.

17.5 Bridging Two Internal Networks

When bridging two internal networks as described in *Internal Bridges* there are some special considerations to take for certain services on the firewall.

Note: There are additional requirements and restrictions when bridging wireless interfaces because of the way 802.11 functions. See *Bridging and wireless* for more information.

17.5.1 DHCP and Internal Bridges

When bridging one internal network to another, two things need to be done. First, ensure that DHCP is only running on the interface containing the IP address and not the bridge members without an address. Second, an additional firewall rule may be necessary at the top of the rules on the member interfaces to allow DHCP traffic.

Note: This only applies to filtering being performed on member interfaces, not filtering performed on the bridge.

When creating a rule to allow traffic on an interface, normally the source is specified similar to *OPT1 Subnet* so that only traffic from that subnet is allowed out of that segment. With DHCP, that is not enough. Because a client does not yet have an IP address, a DHCP request is performed as a broadcast. To accommodate these requests, create a rule on the bridge member interfaces with the following settings:

- Navigate to **Firewall > Rules** on the tab for the bridge member
- Click  **Add** to add a new rule to the top of the list

  Protocol
  UDP

  Source
  `0.0.0.0`

  Source Port
  `68`

  Destination
  `255.255.255.255`

  Destination port
  `67`

  Description
  `Allow DHCP`

- Click **Save** and **Apply Changes**

The rule will look like Figure *Firewall rule to allow DHCP*.

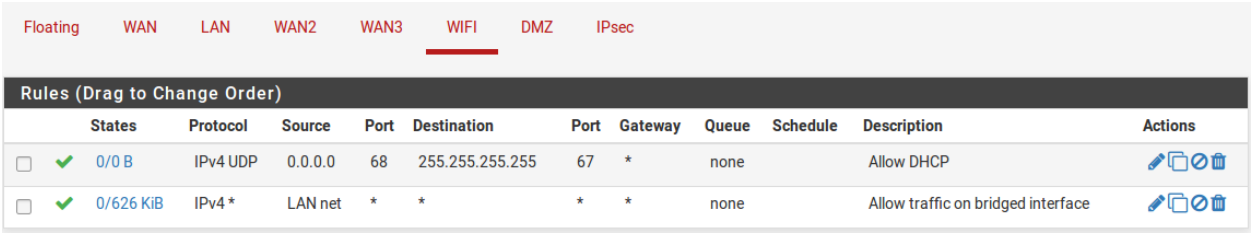

Fig. 2: Firewall rule to allow DHCP

After adding the rule, clients in the bridged segment will be able to successfully make requests to the DHCP daemon listening on the interface to which it is bridged.

DHCPv6 is a bit more complicated to allow since it communicates to and from both link-local and multicast IPv6 addresses. See Figure *Firewall Rule to Allow both DHCP and DHCPv6* for the list of required rules. These can be simplified with aliases into one or two rules containing the proper source network, destination network, and ports.

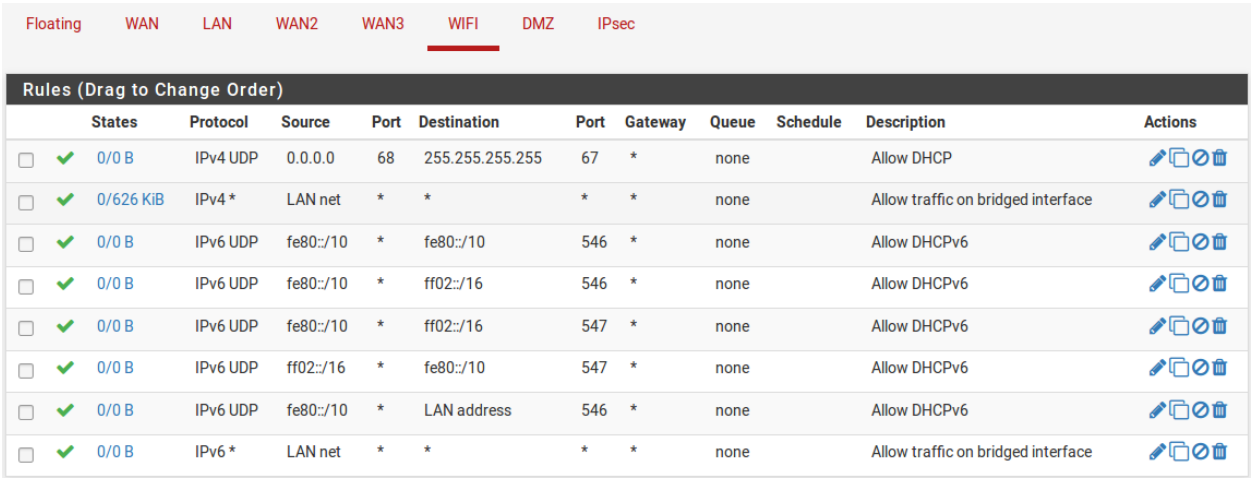

Fig. 3: Firewall Rule to Allow both DHCP and DHCPv6

17.6 Bridging interoperability

Bridged interfaces are different from normal interfaces, thus there are a few features that are incompatible with bridging and others where additional considerations are necessary to accommodate bridging. This section covers features that work differently with bridging than with non-bridged interfaces.

17.6.1 Captive portal

Captive portal (*Captive Portal*) is not compatible with transparent bridging because it requires an IP address on the interface being bridged, used to serve the portal contents, and that IP address must be the gateway for clients. This means that it is not possible, for example, to bridge LAN and WAN and hope to capture clients with the portal.

This can work when bridging multiple *local* interfaces to all route through pfSense® (e.g. LAN1, LAN2, LAN3, etc). It will work if the bridge interface is assigned, the bridge interface has an IP address, and that IP address is used as the gateway by clients on the bridge. See *Swapping Interface Assignments* for a procedure to place the IP address on an assigned bridge interface.

17.6.2 High Availability

High availability (*High Availability*) is not recommended with bridging. Some users have had mixed success with combining the two in the past but great care must be taken to handle layer 2 loops, which are unavoidable in a HA+bridge scenario. When two network segments are bridged, they are in effect merged into one larger network, as discussed earlier in this chapter. When HA is added into the mix, that means there will be two paths between the switches for each respective interface, creating a loop.

Managed switches can handle this with Spanning Tree Protocol (STP) but unmanaged switches have no defenses against looping. Left unchecked, a loop will bring a network to its knees and make it impossible to pass any traffic. STP may be configured on bridges to help, though there may still be unexpected results.

Consult switch documentation for information on STP configuration. Configure the switch to give preference to the port(s) on the primary node.

17.6.3 Multi-WAN

Transparent bridging by its nature is incompatible with multi-WAN in many of its uses. When using bridging between a WAN and LAN/OPT interface, commonly something other than pfSense will be the default gateway for the hosts on the bridged interface, and that router is the only device that can direct traffic from those hosts. This doesn't prevent multi-WAN from being used with other interfaces on the same firewall that are not bridged, it only impacts the hosts on bridged interfaces where they use something other than pfSense as their default gateway. If multiple internal interfaces are bridged together and pfSense is the default gateway for the hosts on the bridged interfaces, then multi-WAN can be used the same as with non-bridged interfaces.

17.6.4 Limiters

For limiters to function with bridging, the bridge itself must be assigned and the bridge interface must have the IP address and not a member interface.

17.6.5 LAN NAT

For port forwards on LAN to function in a bridge scenario, the situation is the same as Captive Portal: It will only function for LAN bridges and not WAN/LAN bridges, the IP address must be on the assigned bridge interface, and that IP address must be used as the gateway for local clients.

17.6.6 Mixing Bridged and NAT Segments

For hosts behind the NAT/routed segment, NAT must occur as traffic exits toward the bridged systems so that the return traffic will come back to the firewall.

For hosts on the bridged segment to reach hosts behind the NAT segment directly, a static route could be used on the bridged hosts or upstream gateway to send the "private" subnet traffic to the IP address of the firewall in the bridged network.

17.6.7 VLANs

A VLAN cannot use a bridge as a parent interface.

Normally each interface on the pfSense® firewall represents its own broadcast domain with a unique IP subnet. In some circumstances it is desirable or necessary to combine multiple interfaces onto a single broadcast domain, where two ports on the firewall will act as if they are on the same switch, except traffic between the interfaces can be controlled with firewall rules. Typically this is done so multiple interfaces will act as though they are on the same flat network using the same IP subnet and so that clients all share broadcast and multicast traffic.

Certain applications and devices rely on broadcasts to function, but these are found more commonly in home environments than corporate environments. For a practical discussion, see *Bridging and wireless*.

For services running on the firewall, bridging can be problematic. Features such as limiters, Captive Portal, and transparent proxies require special configuration and handling to work on bridged networks. Specifically, the bridge itself must be assigned and the only interface on the bridge with an IP address must be the assigned bridge. Also, in order for these functions to work, the IP address on the bridge must be the address used by clients as their gateway. These issues are discussed more in-depth in *Bridging interoperability*.

17.7 Types of Bridges

There are two distinct types of bridges: Internal bridges and Internal/external bridges. Internal bridges connect two local interfaces such as two LAN interfaces or a LAN interface and a wireless interface. Internal/external bridges connect a LAN to a WAN resulting in what is commonly called a "transparent firewall".

17.7.1 Internal Bridges

With an internal type bridge, ports on the firewall are linked such that they behave similar to switch ports, though with the ability to filter traffic on the ports or bridge and with much lower performance than a switch. The firewall itself is still visible to the local connected clients and acts as their gateway, and perhaps DNS and DHCP server. Clients on the bridged segments may not even know there is a firewall between them.

This type of configuration is commonly chosen by administrators to isolate and control a portion of the network, such as a wireless segment, or to make use of additional ports on the firewall in lieu of a proper switch where installing a switch would be impractical. Though it is not recommended, this type of bridge can also be used to join two remote networks over certain types of VPN connections.

See also:

The Hangouts Archive contains a video which includes practical examples of internal bridges: May 2015 Hangout on Wireless Access Points.

17.7.2 Internal/External Bridges

An Internal/External type bridge, also known as a "transparent firewall", is used to insert a firewall between two segments without altering the other devices. Most commonly this is used to bridge a WAN to an internal network so that the WAN subnet may be used "inside" the firewall, or internally between local segments as an in-line filter. Another common use is for devices behind the firewall to obtain IP addresses via DHCP from an upstream server on the WAN.

In a transparent firewall configuration the firewall does not receive the traffic directly or act as a gateway, it merely inspects the traffic as it passes through the firewall.

Note: Devices on the internal side of this bridge **must** continue to use the upstream gateway as their own gateway. Do not set any IP address on the firewall as a gateway for devices on a transparent bridge.

NAT is not possible with this style of bridge because NAT requires the traffic to be addressed to the firewall's MAC address directly in order to take effect. Since the firewall is not the gateway, this does not happen. As such, rules to capture traffic such as those used by a transparent proxy do not function.

17.8 Bridging and Layer 2 Loops

When bridging, care must be taken to avoid layer 2 loops, or a switch configuration must be in place that handles loops. A layer 2 loop is when, either directly or indirectly, the switch has a connection back to itself. If a firewall running pfSense has interfaces bridged together, and two interfaces are plugged into the same switch on the same VLAN, a layer 2 loop has been created. Connecting two patch cables between two switches also does this.

Managed switches employ Spanning Tree Protocol (STP) to handle situations like this, because it is often desirable to have multiple links between switches, and the network shouldn't be exposed to complete meltdown by someone plugging one network port into another network port. STP is not enabled by default on all managed switches, and is almost never available with unmanaged switches. Without STP, the result of a layer 2 loop is frames on the network will circle endlessly and the network will completely cease to function until the loop is removed. Check the switch configuration to ensure the feature is enabled and properly configured.

pfSense enables STP on bridge interfaces to help with loops, but it can still lead to unexpected situations. For instance, one of the bridge ports would shut itself down to stop the loop, which could cause traffic to stop flowing unexpectedly or bypass the firewall entirely.

In a nutshell, bridging has the potential to completely melt down the network unless anyone that plugs devices into the switch is careful.

CHAPTER

EIGHTEEN

VIRTUAL LANS (VLANS)

18.1 Terminology

This section defines the terminology required to successfully deploy VLANs.

Trunking
Trunking refers to a means of carrying multiple VLANs on the same physical switch port. The frames leaving a trunk port are marked with an 802.1Q tag in the header, enabling the connected device to differentiate between multiple VLANs. Trunk ports are used to connect multiple switches, and for connecting any devices that are capable of 802.1Q tagging and require access to multiple VLANs. This is commonly limited to the firewall or router providing connectivity between VLANs, in this case, the firewall running pfSense® software, as well as any connections to other switches containing multiple VLANs.

VLAN ID
Each VLAN has an identifier number (ID) for distinguishing tagged traffic. This is a number between `1` and `4094`.

> **Warning:**
>
> The default VLAN on switches is VLAN `1`, and this VLAN should not be used when deploying VLAN trunking. This is discussed further in *VLANs and Security*.
>
> Aside from avoiding the use of VLAN `1`, VLAN numbers may be chosen at will. Some designs start with VLAN `2` and increment by one until the required number of VLANs is reached. Another common design is to use the third octet in the subnet of the VLAN as the VLAN ID. For example, if the environment contains networks `10.0.10.0/24`, `10.0.20.0/24` and `10.0.30.0/24`, it is logical to use VLANs `10`, `20`, and `30` respectively. Choose a VLAN ID assignment scheme that makes sense for a given network design.

Parent interface
The physical interface where a VLAN resides is known as its **Parent Interface**. For example, `igb0` or `igc0`. When VLANs are configured on pfSense, each is assigned a virtual interface. The virtual interface name is crafted by combining the parent interface name plus the VLAN ID. For example, for VLAN `20` on `igb0`, the interface name is `igb0_vlan20`.

Note: The sole function of the parent interface is, ideally, to be the parent for the defined VLANs and not used directly. In some situations this will work, but can cause difficulties with switch configuration, and it requires use of the default VLAN on the trunk port, which is best to avoid as discussed further in *VLANs and Security*.

Access Port
An access port refers to a switch port providing access to a single VLAN, where the frames are not tagged with an 802.1Q header. Normal client-type devices are connected to access ports, which will comprise the majority of switch ports. Devices on access ports do not need knowledge of VLANs or tagging. They see the network on their port the same as they would a switch without VLANs.

Double tagging (QinQ)
QinQ refers to the double tagging of traffic, using both an outer and inner 802.1Q tag. This can be useful in large ISP environments, other very large networks, or networks that must carry multiple VLANs across a link that only supports a single VLAN tag. Triple tagging is also possible. pfSense software supports QinQ, though it is not a very commonly used feature. These types of environments generally need the kind of routing power that only a high end ASIC-based router can support, and QinQ adds a level of complexity that is unnecessary in most environments. For more information on configuring QinQ on pfSense software, see *QinQ Configuration*.

Private VLAN (PVLAN)
PVLAN, sometimes called **Port Isolation**, refers to capabilities of some switches to segment hosts within a single VLAN. Normally hosts within a single VLAN function the same as hosts on a single switch without VLANs configured. PVLAN provides a means of preventing hosts on a VLAN from talking to any other host on that VLAN, only permitting communication between that host and its default gateway. This isn't directly relevant to pfSense, but is a common question. Switch functionality such as this is the only way to prevent communication between hosts in the same subnet. Without a function like PVLAN, no network firewall can control traffic within a subnet because it never touches the default gateway.

18.2 VLANs and Security

VLANs are a great way to segment a network and isolate subnetworks, but there are security issues which need to be taken into account when designing and implementing a solution involving VLANs. VLANs are not inherently insecure, but misconfiguration can leave a network vulnerable. There have also been past security problems in switch vendor implementations of VLANs.

18.2.1 Segregating Trust Zones

Because of the possibility of misconfiguration, networks of considerably different trust levels should be on separate physical switches. For example, while the same switch could technically be used with VLANs for all internal networks as well as the network outside the firewalls, that should be avoided as a simple misconfiguration of the switch could lead to unfiltered Internet traffic entering the internal network. At a minimum, use two switches in such scenarios: One for outside the firewall and one inside the firewall. In many environments, DMZ segments are also treated separately, on a third switch in addition to the WAN and LAN switches. In others, the WAN side is on its own switch, while all the networks behind the firewall are on the same switches using VLANs. Which scenario is most appropriate for a given network depends on its specific circumstances, level of risk, and security concerns.

18.2.2 Using the default VLAN 1

Because VLAN 1 is the default ("native") VLAN, it may be used in unexpected ways by the switch. It is similar to using a default-allow policy on firewall rules instead of default deny and selecting what is needed. Using a different VLAN is always better, and ensure that only the ports are selected that must be on that VLAN, to better limit access. Switches will send internal protocols such as STP (Spanning Tree Protocol), VTP (VLAN Trunking Protocol), and CDP (Cisco Discover Protocol) untagged over the native VLAN, where the switches use these protocols. It is generally the best practice to keep that internal traffic isolated from data traffic.

If VLAN 1 must be used, take great care to assign every single port on every switch to a different VLAN except those that must be in VLAN 1, and do not create a management interface for the switch on VLAN 1. The native VLAN of the switch group should also be changed to a different, unused, VLAN. Some switches may not support any of these workarounds, and so it is typically easier to move data to a different VLAN instead of fussing with making VLAN 1 available. With VLAN ID 2 through 4094 to choose from, it is undoubtedly better to ignore VLAN 1 when designing a new VLAN scheme.

18.2.3 Using a trunk port default VLAN

When VLAN tagged traffic is sent over a trunk on the native VLAN, tags in the packets that match the native VLAN may be stripped by the switch to preserve compatibility with older networks. Worse yet, packets that are double tagged with the native VLAN and a different VLAN will only have the native VLAN tag removed when trunking in this way and when processed later, that traffic can end up on a different VLAN. This is also called "VLAN hopping".

As mentioned in the previous section, any untagged traffic on a trunk port will be assumed to be the native VLAN, which could also overlap with an assigned VLAN interface. Depending on how the switch handles such traffic and how it is seen by pfSense® software, using the interface directly could lead to two interfaces being on the same VLAN.

18.2.4 Limiting access to trunk ports

Because a trunk port can talk to any VLAN in a group of trunked switches, possibly even ones not present on the current switch depending on the switch configurations, it is important to physically secure trunk ports. Also make sure there are no ports configured for trunking that are left unplugged and enabled where someone could hook into one, accidentally or otherwise. Depending on the switch, it may support dynamic negotiation of trunking. Ensure this functionality is disabled or properly restricted.

18.2.5 Other Issues with Switches

Over the years there have been reports of rare cases where VLAN-based switches have leaked traffic across VLANs while under heavy loads, or if a MAC address of a PC on one VLAN is seen on another VLAN. These issues tend to be in older switches with outdated firmware, or extremely low-quality managed switches. These types of issues were largely resolved many years ago, when such security problems were common. No matter what switch from what brand is used for a network, research to see if it has undergone any kind of security testing, and ensure the latest firmware is loaded on the switch. While these issues are a problem with the switch, and not pfSense, they are part of a network's overall security.

Many of the items here are specific to particular makes and models of switches. Security considerations differ based on the switch being used on a network. Refer to its documentation for recommendations on VLAN security.

18.3 VLAN Configuration

This section covers how to configure VLANs in pfSense® software.

18.3.1 Console VLAN configuration

VLANs can be configured at the console using the **Assign Interfaces** function. The following example shows how to configure two VLANs, ID `10` and `20`, with `igb2` as the parent interface. The VLAN interfaces are assigned as **OPT1** and **OPT2**:

```
 0) Logout (SSH only)                  9) pfTop
 1) Assign Interfaces                 10) Filter Logs
 2) Set interface(s) IP address       11) Restart GUI
 3) Reset admin account and password  12) PHP shell + pfSense tools
 4) Reset to factory defaults         13) Update from console
 5) Reboot system                     14) Disable Secure Shell (sshd)
 6) Halt system                       15) Restore recent configuration
 7) Ping host                         16) Restart PHP-FPM
 8) Shell

Enter an option: 1

Valid interfaces are:

igb0   00:08:a2:09:95:b5   (up) Intel(R) PRO/1000 Network Connection, Version -
igb1   00:08:a2:09:95:b6   (up) Intel(R) PRO/1000 Network Connection, Version -
igb2   00:08:a2:09:95:b1 (down) Intel(R) PRO/1000 Network Connection, Version -
igb3   00:08:a2:09:95:b2 (down) Intel(R) PRO/1000 Network Connection, Version -
igb4   00:08:a2:09:95:b3 (down) Intel(R) PRO/1000 Network Connection, Version -
igb5   00:08:a2:09:95:b3 (down) Intel(R) PRO/1000 Network Connection, Version -

Do VLANs need to be set up first?
If VLANs will not be used, or only for optional interfaces, it is typical to
say no here and use the webConfigurator to configure VLANs later, if required.

Should VLANs be set up now [y|n]? y

WARNING: all existing VLANs will be cleared if you proceed!

Do you want to proceed [y|n]? y

VLAN Capable interfaces:

igb0    00:08:a2:09:95:b5   (up)
igb1    00:08:a2:09:95:b6   (up)
igb2    00:08:a2:09:95:b1
igb3    00:08:a2:09:95:b2
igb4    00:08:a2:09:95:b3   (up)
igb5    00:08:a2:09:95:b3   (up)

Enter the parent interface name for the new VLAN (or nothing if finished): igb2
Enter the VLAN tag (1-4094): 10
```

(continues on next page)

(continued from previous page)

```
VLAN Capable interfaces:

igb0    00:08:a2:09:95:b5   (up)
igb1    00:08:a2:09:95:b6   (up)
igb2    00:08:a2:09:95:b1
igb3    00:08:a2:09:95:b2
igb4    00:08:a2:09:95:b3   (up)
igb5    00:08:a2:09:95:b3   (up)

Enter the parent interface name for the new VLAN (or nothing if finished): igb2
Enter the VLAN tag (1-4094): 20

VLAN Capable interfaces:

igb0    00:08:a2:09:95:b5   (up)
igb1    00:08:a2:09:95:b6   (up)
igb2    00:08:a2:09:95:b1
igb3    00:08:a2:09:95:b2
igb4    00:08:a2:09:95:b3   (up)
igb5    00:08:a2:09:95:b3   (up)

Enter the parent interface name for the new VLAN (or nothing if finished): <enter>

VLAN interfaces:

igb2.10     VLAN tag 10, parent interface igb2
igb2.20     VLAN tag 20, parent interface igb2

If the names of the interfaces are not known, auto-detection can
be used instead. To use auto-detection, please disconnect all
interfaces before pressing 'a' to begin the process.

Enter the WAN interface name or 'a' for auto-detection
(igb0 igb1 igb2 igb3 igb4 igb5 igb2.10 igb2.20 or a): igb1

Enter the LAN interface name or 'a' for auto-detection
NOTE: this enables full Firewalling/NAT mode.
(igb0 igb2 igb3 igb4 igb5 igb2.10 igb2.20 a or nothing if finished): igb0

Enter the Optional 1 interface name or 'a' for auto-detection
(igb2 igb3 igb4 igb5 igb2.10 igb2.20 a or nothing if finished): igb2.10

Enter the Optional 2 interface name or 'a' for auto-detection
(igb2 igb3 igb4 igb5 igb2.20 a or nothing if finished): igb2.20

Enter the Optional 3 interface name or 'a' for auto-detection
(igb2 igb3 igb4 igb5 a or nothing if finished):<enter>

The interfaces will be assigned as follows:

WAN  -> igb1
```

(continues on next page)

(continued from previous page)

```
LAN  -> igb0
OPT1 -> igb2.10
OPT2 -> igb2.20

Do you want to proceed [y|n]? y

Writing configuration...done.
One moment while the settings are reloading... done!
```

After a few seconds, the firewall settings will reload and the console menu will reload.

18.3.2 Web interface VLAN configuration

In the system used for this example, WAN and LAN are assigned as `igb1` and `igb0` respectively. There is also an `igb2` interface that will be used as the VLAN parent interface.

To configure VLANs in the firewall GUI:

- Navigate to **Interfaces > Assignments** to view the interface list.
- Click the **VLANs** tab.
- Click  **Add** to add a new VLAN
- Configure the VLAN as shown in Figure *Edit VLAN*.

  Parent Interface
  The physical interface upon which this VLAN tag will be used. In this case, `igb2`

  VLAN tag
  The VLAN ID number, in this case, `10`

  VLAN Priority
  Leave at the default value, blank

  Description
  Some text to identify the purpose of the VLAN, such as `DMZ`
- Click **Save** to return to the VLAN list, which now includes the newly added VLAN `10`.
- Repeat the process to add additional VLANs, such as VLAN `20`. These can be seen in Figure *VLAN list*

To assign the VLANs to interfaces:

- Navigate to **Interfaces > Assignments**
- Click the **Interface Assignments** tab
- Select the VLAN to add from the **Available Network Ports** list, such as *VLAN 10 on igb2 (DMZ)*
- Click  **Add** to assign the network port
- Repeat the last two steps to assign *VLAN 20 on igb2 (Phones)*

When finished, the interfaces will look like Figure *Interfaces list with VLANs*

The VLAN-based OPT interfaces behave as any other OPT interfaces do, which means they must be enabled, configured, have firewall rules added, and services like the DHCP Server will need to be configured if needed. See *Interface Configuration Basics* for more information on configuring optional interfaces.

- *Configuring Switches with VLANs*
- *QinQ Configuration*

VLANs enable a switch to carry multiple discrete broadcast domains, allowing a single switch to function as if it were multiple switches. VLANs are commonly used for network segmentation in the same way that multiple switches can be used: To place hosts on a specific segment, isolated from other segments. Where trunking is employed between switches, devices on the same segment need not reside on the same switch. Devices that support trunking can also communicate on multiple VLANs through a single physical port.

This chapter covers VLAN concepts, terminology and configuration in pfSense® software.

18.4 Requirements

There are two requirements, both of which must be met to deploy VLANs.

1. **802.1Q VLAN capable switch**

   Every decent managed switch manufactured in the last 15 years supports 802.1Q VLAN trunking.

   Warning: VLANs **cannot** be used with an unmanaged switch.

2. **Network adapter capable of VLAN tagging**

   A NIC that supports hardware VLAN tagging or has long frame support is required. Each VLAN frame has a 4 byte 802.1Q tag added in the header, so the frame size can be up to 1522 bytes. A NIC supporting hardware VLAN tagging or long frames is required because other adapters will not function with frames larger than the normal 1518 byte maximum with 1500 MTU Ethernet. This will cause large frames to be dropped, which causes performance problems and connection stalling.

   Note: If an adapter is listed as having long frame support does not guarantee the specific implementation of that NIC chipset properly supports long frames. Realtek *rl(4)* NICs are the biggest offenders. Many will work fine, but some do not properly support long frames, and some will not accept 802.1Q tagged frames at all. If problems are encountered using one of the NICs listed under long frame support, the best practice is to try an interface with VLAN hardware tagging support instead. There are no known similar problems with NICs listed under VLAN hardware support.

Ethernet interfaces with VLAN hardware support:

`ae(4)`, `age(4)`, `alc(4)`, `ale(4)`, `bce(4)`, `bge(4)`, `bxe(4)`, `cxgb(4)`, `cxgbe(4)`, `em(4)`, `igb(4)`, `ixgb(4)`, `ixgbe(4)`, `jme(4)`, `msk(4)`, `mxge(4)`, `nxge(4)`, `nge(4)`, `re(4)`, `sge(4)`, `stge(4)`, `ti(4)`, `txp(4)`, `vge(4)`.

Ethernet interfaces with long frame support :

`axe(4)`, `bfe(4)`, `cas(4)`, `dc(4)`, `et(4)`, `fwe(4)`, `fxp(4)`, `gem(4)`, `hme(4)`, `le(4)`, `nfe(4)`, `nve(4)`, `rl(4)`, `sf(4)`, `sis(4)`, `sk(4)`, `ste(4)`, `tl(4)`, `tx(4)`, `vr(4)`, `vte(4)`, `xl(4)`.

CHAPTER

NINETEEN

MULTIPLE WAN CONNECTIONS

19.1 Multi-WAN Terminology and Concepts

This section covers terminology and concepts necessary to understand the deployment of multi-WAN functionality with pfSense® software.

See also:

WAN vs LAN Interfaces

19.1.1 Policy routing

Policy routing refers to a means of routing traffic by matching a policy, typically involving firewall rules or access control lists. This type of routing can consider more factors than the destination IP address of the traffic, as is done with the routing table in most operating systems and routers.

In pfSense software the **Gateway** field available when editing or adding firewall rules enables the use of policy routing. The **Gateway** field contains all gateways defined on the firewall under **System > Routing**, plus any gateway groups.

Policy routing provides a powerful means of directing traffic to use an appropriate path, since anything a firewall rule can match may be used as criteria for making policy routing decisions. Specific hosts, subnets, protocols, ports, and more can be used to direct traffic.

Note: Remember on per-interface rule tabs that all firewall rules, including policy routing rules, are processed in top down order, and the first match wins.

19.1.2 Gateway Groups

Gateway groups define how a chosen set of gateways provide failover and/or load balancing functionality. They are configured under **System > Routing**, on the **Gateway Groups** tab.

See also:

See *Gateway Groups* for more.

19.1.3 Failover

Failover refers to the ability to switch from one or more WANs to an alternate set of WANs if the preferred connections fail. This is useful for situations where traffic should utilize a specific WAN connection unless it is unavailable.

See also:

To fail from one *firewall* to another, rather than from one *WAN* to another, see *High Availability*.

19.1.4 Load Balancing

The **Load Balancing** functionality in pfSense software distributes **connections** over multiple WAN connections in a round-robin fashion. This feature operates on a **per-connection** basis, not a per-packet basis. If a gateway that is part of a load balancing group fails, the interface is marked as down and removed from all groups until it recovers, thus a load balanced configuration effectively also includes failover functionality.

19.1.5 Monitor IP Addresses

When configuring failover or load balancing, each gateway is associated with a monitor IP address (*Gateway Settings*). In a typical configuration, the firewall will ping this IP address and if it stops responding, the gateway is marked as down. Options on the gateway group can select different failure triggers besides packet loss. The other triggers are high latency, a combination of either packet loss or high latency, or when the circuit is down.

What constitutes failure?

The topic is a little more complex than "if pings to the monitor IP address fail, the gateway is marked as down." The actual criteria for a failure depend on the options chosen when creating the gateway group and the individual settings on a gateway.

The settings for each gateway that control when it is considered up and down are all discussed in *Advanced Gateway Settings*. The thresholds for packet loss, latency, down time, and even the probing interval of the gateway are all individually configurable.

19.1.6 State Killing/Forced Switch

When a gateway has failed, the firewall can optionally flush states to force clients to reconnect, and in doing so they will use a gateway that is online instead of a gateway that is down. This can be done for the entire state table or selectively for only gateways that are down. When clearing states for a specific gateway, it can only clear states created by policy routing rules.

This currently only works one-way, meaning that it can move connections off of a failing gateway, but it cannot force them back if the original gateway comes back online.

This is an optional behavior and it is **not** enabled by default as it can be disruptive. For information on changing this setting, see *State Killing on Gateway Failure*.

19.1.7 Default Gateway Switching

Traffic exiting the firewall itself will use the default gateway unless a static route sends the packet along a different path. If the default gateway is on a WAN that is down, daemons on the firewall will be unable to make outbound connections, depending on the capabilities of the daemon and its configuration.

The default gateway for the firewall can be set to a gateway group or set to an automatic mode, which will switch the default to the next available gateway if the normal default gateway fails, and then switched back when that WAN recovers. See *Managing the Default Gateway* for details.

Note: Daemons bound to non-default WANs which have no static routes influencing their outbound traffic may also fail in certain cases even when all WANs are online. See *Configuring the Firewall Default State Policy* for details.

19.2 Policy Routing, Load Balancing and Failover Strategies

This section provides guidance on common multi-WAN goals and how they can be achieved with pfSense® software.

19.2.1 Bandwidth Aggregation

One of the primary desires with multi-WAN is bandwidth aggregation. Load balancing can help accomplish this goal. There is, however, one caveat: If the firewall has two 50 Mbit/s WAN circuits, it cannot get 100 Mbit/s of throughput with a *single* client connection. Each individual connection must be tied to only one specific WAN. This is true of any multi-WAN solution other than MLPPP. The bandwidth of two different Internet connections cannot be aggregated into a single large "pipe" without involvement from the ISP. With load balancing, since individual connections are balanced in a round-robin fashion, 100 Mbit/s of throughput can only be achieved using two 50 Mbit/s circuits when multiple connections are involved. Applications that utilize multiple connections, such as download accelerators, will be able to achieve the combined throughput capacity of the two or more connections.

Note: Multi-Link PPPoE (MLPPP) is the only WAN type which can achieve full aggregate bandwidth of all circuits in a bundle, but MLPPP requires special support from the ISP. For more on MLPPP, see *Multi-Link PPPoE (MLPPP)*.

In networks with numerous internal machines accessing the Internet, load balancing will reach speeds near the aggregate throughput by balancing the many internal connections out all of the WAN interfaces.

19.2.2 Segregation of Priority Services

Consider a site which has a reliable, high quality Internet connection that offers low bandwidth, or high costs for excessive transfers, and another connection that is fast but of lesser quality (higher latency, more jitter, or less reliable). In these situations, services can be segregated between the two Internet connections by their priority. High priority services may include VoIP, traffic destined to a specific network such as an outsourced application provider, or specific protocols used by critical applications, amongst other options. Low priority traffic commonly includes any permitted traffic that doesn't match the list of high priority traffic. Policy routing rules can be setup to direct the high priority traffic out the high quality Internet connection, and the lower priority traffic out the lesser quality connection.

Another example of a similar scenario is getting a dedicated Internet connection for quality critical services such as VoIP, and only using that connection for those services.

19.2.3 Failover Only

There are scenarios where the best practice is to only use failover. For example, users who have a secondary backup Internet connection with a low bandwidth cap such as a 4G/LTE modem, and only want to use that connection if their primary connection fails. Gateway groups configured for failover can achieve this goal.

Another usage for failover is to ensure a certain protocol or destination always uses only one WAN unless it goes down.

19.2.4 Unequal Cost Load Balancing

pfSense software can achieve unequal cost load balancing by setting appropriate weights on gateways as discussed in *Advanced Gateway Settings*. By setting a weight on a gateway, it will be used more often in a gateway group. Weights can be set from *1* to *30*, allowing

Table 1: Unequal Cost Load Balancing

WAN_GW weight	WAN2_GW weight	WAN load	WAN2 load
3	2	60%	40%
2	1	67%	33%
3	1	75%	25%
4	1	80%	20%
5	1	83%	17%
30	1	97%	3%

Note that this distribution is strictly balancing the number of *connections*, it does not take interface throughput or existing load into account. This means bandwidth usage may not necessarily be distributed equally, though in most environments it works out to be roughly distributed as configured over time. This also means if an interface is loaded to its capacity with a single high throughput connection, the firewall will still direct additional connections to that interface.

19.3 Multi-WAN Caveats and Considerations

This section contains the caveats and considerations specific to multi-WAN in pfSense® software.

19.3.1 Multiple WANs sharing a single gateway IP

Due to the way pf handles multi-WAN connections, traffic can only be directed using the gateway IP address of a circuit, which is fine for most scenarios. If the firewall has multiple connections on the same ISP using the same subnet and gateway IP address, as is common when using multiple cable modems, an intermediate NAT device must be used on all but one of them so that the firewall sees each WAN gateway as a unique IP address.

When using the NAT device it can be configured to forward all traffic back to the firewall which can help with using that WAN for other services. However, some protocols, such as VoIP, will have problems if they use a WAN with NAT in such a configuration.

If at all possible, contact the ISP and have them configure the WAN circuits such that they are in different subnets with different gateways.

One exception to this is a PPP type WAN such as PPPoE. PPP type WANs are capable of having the same gateway on multiple interfaces, but each gateway entry must be configured to use a different monitor IP address (See *Gateway Settings*).

19.3.2 Multiple PPPoE WANs

When multiple PPPoE lines from the same ISP are present and the ISP supports Multi-Link PPPoE (MLPPP), it may be possible to bond the lines into a single aggregate link. This bonded link has total bandwidth of all lines together in a single WAN as seen by the firewall. Configuration of MLPPP is covered in *Multi-Link PPPoE (MLPPP)*.

19.3.3 Local Services and Multi-WAN

There are additional considerations with local services and multi-WAN, since any traffic initiated from the firewall itself will not be affected by policy routing configured on internal interface rules. Traffic from the firewall itself always follows the routing table. Hence static routes are required under some circumstances when using additional WAN interfaces, otherwise only the WAN interface with the default gateway would be used.

The firewall can be configured to change the default gateway if the preferred default fails. See *Managing the Default Gateway* for details.

In the case of traffic initiated on the Internet destined for any WAN interface, pfSense software automatically uses the `reply-to` directive in all WAN-type interface rules, which ensures the reply traffic is routed back out the correct WAN interface.

Note: Daemons bound to non-default WANs which have no static routes influencing their outbound traffic may also fail in certain cases even when all WANs are online. See *Configuring the Firewall Default State Policy* for details.

DNS Resolver

The default settings for the DNS Resolver require using failover for the default gateway to work properly with Multi-WAN. See *Managing the Default Gateway* for details. As an alternative to using default gateway switching, a few changes can be made to make the DNS Resolver more accommodating to Multi-WAN, including enabling forwarding mode. The details are described later in this chapter.

DNS Forwarder

The DNS servers used by the DNS forwarder must have gateways defined if they use an non-default WAN interface, as described later in this chapter. That is the only requirement for using the DNS forwarder in multi-WAN environments.

Dynamic DNS

Dynamic DNS entries can be set using a gateway group for their interface. This will move a Dynamic DNS entry between WANs in failover mode, allowing a public hostname to shift from one WAN to another in case of failure.

IPsec

IPsec is fully compatible with multi-WAN. A static route is automatically added for the remote tunnel peer address pointing to the specified WAN gateway to ensure the firewall sends traffic out the correct path when it initiates a connection. For mobile connections, the client always initiates the connection, and the reply traffic is correctly routed by the state table.

An IPsec tunnel may also be set using a gateway group as its interface for failover. This is discussed further in *Multi-WAN Environments*.

OpenVPN

OpenVPN multi-WAN capabilities are described in *OpenVPN and Multi-WAN*. Like IPsec, it can use any WAN or a gateway group.

CARP and multi-WAN

CARP is multi-WAN capable so long as all WAN interfaces use static IP addresses and there are at least three public IP addresses available per WAN. This is covered in *High Availability Configuration Example with Multi-WAN*.

19.3.4 IPv6 and Multi-WAN

IPv6 is also capable of performing in a multi-WAN capacity, but will usually require Network Prefix Translation (NPt) on one or more WANs. This is covered in more detail in *Configuring Multi-WAN for IPv6*.

19.4 Summary of Multi-WAN Requirements

This is a brief summary of configuration changes necessary for a fully implemented multi-WAN setup:

- Create a gateway group under **System > Routing** on the **Gateway Groups** tab
- Set a failover gateway group for the default gateway as described in *Managing the Default Gateway* (Technically optional but a best practice)
- Configure the DNS Resolver or Forwarder for Multi-WAN, starting by:
  - Use a failover gateway group for the default gateway (DNS Resolver in default resolver mode)
  - Set at least one unique DNS server for each WAN gateway under **System > General Setup** with a gateway set (DNS Resolver in forwarding mode or DNS Forwarder)
- Use the gateway group on LAN firewall rules

These topics are covered in detail by the following sections.

19.5 Load Balancing and Failover with Gateway Groups

Gateway Groups are necessary components of a Load Balancing or Failover configuration. The group itself does not cause any action to be taken, but when the group is used later, such as in policy routing firewall rules, the group settings define how the items utilizing the group will behave.

The same gateway may be included in multiple groups so that several different scenarios can be configured at the same time. For example, some traffic can be load balanced, and other traffic can use failover, and the same WAN can be used in both capacities by using different gateway groups.

A common example setup for a two WAN firewall contains three groups:

LoadBalance
: Gateways for WAN1 and WAN2 both on Tier 1

PreferWAN1
: Gateway for WAN1 on Tier 1, and WAN2 on Tier 2

PreferWAN2
: Gateway for WAN1 on Tier 2, and WAN2 on Tier 1

The best practice for any strategy is to have at least one failover group and to set that failover group to be used as the default gateway on the firewall. This ensures that the firewall always has a viable default gateway, and using a gateway group ensures that the correct gateways are used for this function and in the intended order. See *Managing the Default Gateway* for details.

19.5.1 Configuring a Gateway Group for Load Balancing or Failover

To create a gateway group for Load Balancing or Failover:

- Navigate to **System > Routing**, **Gateway Groups** tab
- Click  **Add** to create a new gateway group
- Fill in the options on the page as described in *Gateway Group Options*
- Click **Save**

Load Balancing

Any two gateways on the same tier are load balanced. For example, if *Gateway A*, *Gateway B*, and *Gateway C* are all Tier 1, connections would be balanced between them. Gateways that are load balanced will automatically failover between each other. When a gateway fails it is removed from the group, so in this case if any one of A, B, or C went down, the firewall would load balance between the remaining online gateways.

Weighted Balancing

If two WANs must be balanced in a weighted fashion due to differing amounts of bandwidth between them, that can be accommodated by adjusting the **Weight** parameter on the gateway as described in *Unequal Cost Load Balancing* and *Advanced Gateway Settings*.

Failover

The firewall prefers gateways on a **lower** number tier. If the gateways on the lowest number tier are down then it looks for gateways on a higher numbered tier.

For example, if *Gateway A* is on Tier 1, *Gateway B* is on Tier 2, and *Gateway C* is on Tier 3, then the firewall uses *Gateway A* first. If *Gateway A* goes down, then the firewall uses *Gateway B*. If both *Gateway A* and *Gateway B* are down, then the firewall uses *Gateway C*.

Complex/Combined Scenarios

By extending the concepts above for Load Balancing and Failover, complicated scenarios are possible that combine both load balancing and failover. For example, if *Gateway A* is on Tier 1, and *Gateway B* and *Gateway C* are on Tier 2, then *Gateway D* on Tier 3, the following behavior occurs: *Gateway A* is preferred on its own. If *Gateway A* is down, then traffic would be load balanced between *Gateway B* and *Gateway C*. Should either *Gateway B* or *Gateway C* go down, the remaining online gateway in that tier would still be used. If *Gateway A*, *Gateway B*, and *Gateway C* are all down, traffic would fail over to *Gateway D*.

Any other combination of the above can be used, so long as it can be arranged within the limit of **5** tiers.

19.5.2 Problems with Load Balancing

Some websites store session information including the client IP address, and if a subsequent connection to that site is routed out a different WAN interface using a different public IP address, the website will not function properly. This has been more common with banks and other security-minded sites. One method of working around this issue is to create a failover group and direct traffic destined to these sites to the failover group rather than a load balancing group. Alternately, perform failover for all HTTPS traffic.

The sticky connections feature of pf is intended to resolve this problem. It is safe to use, and should alleviate this scenario, but there is also a downside to using the sticky option. When using sticky connections, the firewall remembers an association between the *client IP address* and a given *gateway*, it is **not** based off of the destination. When the sticky connections option is enabled, a single client would not load balance its connections between multiple WANs, but it would be associated with whichever gateway it happened to use for its first connection. Once all of the client states have expired, the client may exit a different WAN for its next connection, resulting in a new gateway pairing. As such, it works best in environments with many clients where one client utilizing a single WAN does not have a large impact.

19.6 Interface and DNS Configuration

The first two items to configure for Multi-WAN are interfaces and DNS.

19.6.1 Interface Configuration

Setup the primary WAN as previously described in *Setup Wizard*. Then for the additional WAN interfaces, perform the following tasks:

- Assign the interfaces if they do not yet exist
- Visit the **Interfaces** menu entry for each additional WAN (e.g. **Interfaces > OPT1**)
- Enable the interface
- Enter a suitable name, such as `WAN2`
- Select the desired type of IP address configuration depending on the Internet connection type.
- Enter the remaining details for the type of WAN. For example, on static IP connections, fill in the IP address, subnet mask, and add or select a gateway.

19.6.2 DNS Configuration

DNS is critical for Internet connectivity. For multi-WAN to function correctly the firewall must always be able to resolve DNS for itself and on behalf of local clients utilizing the DNS Resolver or DNS Forwarder.

If the firewall configuration only includes DNS servers from a single WAN then an outage of that WAN results in a complete Internet outage since DNS will no longer function.

If the DNS Resolver is in resolver mode, see *DNS Resolver and Multi-WAN*.

If the DNS Resolver is set for **forwarding** mode or if the DNS Forwarder is in use, then the firewall must be configured with DNS servers for each WAN as described in *DNS Forwarding and Static Routes*.

DNS Resolver and Multi-WAN

The DNS Resolver can work with multi-WAN but the exact configuration depends on the desired behavior and current settings, especially the chosen *DNS Resolver mode*.

If the DNS Resolver is using its default resolver mode, such as for environments which require DNSSEC, then it can still function with multi-WAN but requires using failover for the default gateway. See *Managing the Default Gateway*.

Even in resolver mode if the firewall is set to use or fall back to remote DNS servers under **System > General**, **DNS Resolution Behavior**, then it is still useful to configure gateways for individual DNS servers as described in *DNS Forwarding and Static Routes*

DNS Forwarding and Static Routes

When using the DNS Resolver in forwarding mode or the DNS Forwarder, the firewall uses its routing table to reach the configured DNS servers. This means without any static routes configured, it will only use the WAN with the default gateway to reach DNS servers.

Gateways must be selected for each DNS server defined on the firewall. This forces the firewall to use a specific WAN interface to reach a given DNS server. At least one gateway from each WAN should be selected where possible.

Note: Most ISPs prohibit recursive queries from hosts outside their network, hence the firewall must use the correct WAN interface when accessing DNS servers for a specific ISP.

DNS servers obtained from a dynamic WAN are automatically routed back out the appropriate dynamic WAN.

To configure DNS server gateways:

- Navigate to **System > General Setup**
- Define at least one *unique* DNS server for each WAN
- Select an appropriate gateway for each DNS server so it uses a specific WAN

  Note: If the gateway entries for these WANs use DNS servers for their monitor IP addresses, ensure there is no conflict between those values and the selected gateways in this list.

Note: Each entry must be unique; the same DNS server cannot be entered more than once.

If using the DNS Resolver, ensure it is set for forwarding mode:

- Navigate to **Services > DNS Resolver**
- Check **Enable Forwarding Mode**
- Uncheck **Enable DNSSEC Support**
- Click **Save**, then **Apply Changes**

19.7 Multi-WAN and NAT

The default NAT rules generated by pfSense® software will translate any traffic leaving a WAN-type interface to the IP address of that interface. In a default two interface LAN and WAN configuration, pfSense software will NAT all traffic from the LAN subnet leaving the WAN interface to the WAN IP address. Adding more WAN-type interfaces extends this to NAT any traffic leaving a WAN-type interface to that interface IP address. This is all handled automatically unless Manual Outbound NAT is enabled.

Warning: NAT does not influence the path taken by connections, only how addresses on packets traversing an interface are translated by the firewall.

Policy routing firewall rules direct connections to specific WAN interfaces, and the Outbound and 1:1 NAT rules specify how the addresses on packets for those connections will be translated by the firewall as it leaves that WAN.

19.7.1 Multi-WAN and Manual Outbound NAT

If **Manual Outbound NAT** must be used with multi-WAN, ensure manual outbound NAT rules are present for all WAN-type interfaces.

19.7.2 Multi-WAN and Port Forwarding

Each port forward applies to a single WAN interface. A given port can be opened on multiple WAN interfaces by using multiple port forward entries, one per WAN interface. The easiest way to accomplish this is:

- Add a port forward on the first WAN connection as usual
- Click  to the right of that entry to add another port forward based on the selected one
- Change the **Interface** to the desired WAN
- Click **Save**

The `reply-to` keyword in pf, which the firewall automatically places on WAN-type interface rules by default, ensures that when traffic comes in over a specific WAN interface, the return traffic will go back out the way it came into the firewall. Thus, port forwards can be actively used on all WAN interfaces at any time, regardless of any failover configuration that may be present. This is especially useful for mail servers as an address on a secondary WAN can be used as a backup MX, allowing the site to receive mail even when the primary line is down.

See also:

This `reply-to` behavior is configurable, for information on this setting, see *Disable Reply-To*.

19.7.3 Multi-WAN and 1:1 NAT

1:1 NAT entries are specific to a single WAN interface and, like outbound NAT, they only control what happens to addresses on packets as they pass through an interface. Internal systems can be configured with a 1:1 NAT entry on each WAN interface, or a 1:1 entry on one or more WAN interfaces and use the default outbound NAT on others. Where 1:1 entries are configured, they always override any other Outbound NAT configuration for that specific interface.

If a local device must always use a 1:1 NAT entry on a specific WAN, then traffic from that device must be forced to use that specific WAN gateway with policy routing firewall rules.

19.8 Policy Routing Configuration

At this point the firewall is prepared for Multi-WAN but not fully configured. With default gateway switching the firewall will have basic failover, but it cannot yet use more advanced failover or load balancing behaviors without policy routing firewall rules in place.

See also:

For information on default gateway switching, see *Managing the Default Gateway*.

19.8.1 Configuring the Firewall Default State Policy

The default State Policy (*Firewall State Policy*) is not directly related to policy routing but can affect how it functions for traffic originating on the firewall itself.

Daemons bound to WANs that are not default, and which have no static route configured to control their outbound behavior, may fail to pass outbound traffic when the default policy is set to "Interface Bound States". This is common for certain types of VPN clients, such as OpenVPN. If these are necessary, consider changing the default policy to "Floating States".

See *Interface Bound States* for additional information on this failure case.

19.8.2 Configuring Firewall Rules for Policy Routing

Setting a **Gateway** on a firewall rule will cause traffic matching the rule to use the chosen gateway or group, following the configured behavior of the group.

The easiest way to configure a firewall for policy routing is to edit the existing default pass rule for the LAN and select the gateway group there. With that set, any traffic matching the default pass rule on the LAN will use the chosen gateway or group.

To make that edit:

- Navigate to **Firewall > Rules**, **LAN** tab
- Click  on the row with the default pass rule
- Click  **Display Advanced** under **Extra Options**
- Select the desired gateway group from the **Gateway** drop-down list
- Click **Save**
- Click **Apply Changes**

Only the most basic of deployments will be satisfied with that configuration, most configurations are more complex. Continue reading for more factors that can require additional configuration.

19.8.3 Bypassing Policy Routing

If there are other local interfaces, VPNs, MPLS interfaces, or traffic that must otherwise obey the routing table, then that traffic must be configured to bypass policy routing. This is simple to do by making a rule to match the traffic in question and then placing that rule **above** any rules that have a gateway configured, because the first rule to match is the one that is used.

This can be generalized by making an alias for any *RFC1918* traffic which would cover all private networks, and then using that in a rule. This alias would contain at least `192.168.0.0/16`, `172.16.0.0/12`, and `10.0.0.0/8`.

In Figure *Bypass Policy Routing Example Rules*, local and VPN traffic bypasses policy routing, HTTPS traffic prefers WAN2, and all other traffic is load balanced:

Rules (Drag to Change Order)

	States	Protocol	Source	Port	Destination	Port	Gateway	Queue	Schedule	Description	Actions
✓	0/0 B	*	*	*	LAN Address	443 80 22	*	*		Anti-Lockout Rule	⚙
☐ ✓	0/0 B	IPv4 *	LAN net	*	RFC1918	*	*	none		Bypass policy routing for local/VPN traffic	⚓ ✎ ⧉ ⊘ 🗑
☐ ✓ ⚙	0/0 B	IPv4 TCP	LAN net	*	*	443 (HTTPS)	PreferWAN2	none		Force HTTPS out WAN2, fail to WAN1	⚓ ✎ ⧉ ⊘ 🗑
☐ ✓ ⚙	0/10 KiB	IPv4 *	LAN net	*	*	*	LoadBalance	none		Load Balance LAN Traffic	⚓ ✎ ⧉ ⊘ 🗑

Fig. 1: Bypass Policy Routing Example Rules

19.8.4 Mixing Failover and Load Balancing

As shown in Figure *Bypass Policy Routing Example Rules*, failover and load balancing can be used at the same time by carefully ordering the rules on an interface. Rules are processed from the top down and the first match wins. By placing more specific rules near the top of the list, and the general "match all" style rules at the bottom, any number of different combinations are possible with rules using different gateways or groups.

19.8.5 Enforcing Gateway Use

There are situations where traffic should only ever use one gateway and never load balance or failover. In this example, a device must only exit via a specific WAN and lose all connectivity when that WAN fails.

First, set the **Gateway** on a firewall rule matching traffic from this device to a specific WAN Gateway. If that gateway is down, the rule will act as if the gateway was not set at all, so it needs to be taken a couple steps further.

Add a rule immediately below the rule matching the traffic, but set to reject or block instead. This rule must not have a gateway set.

Next, configure the firewall to omit rules for gateways that are down (*Gateway Monitoring*):

- Navigate to **System > Advanced** on the **Miscellaneous** tab
- Check **Do not create rules when gateway is down**
- Click **Save**

With that option enabled, the first rule will be omitted entirely, falling through to the next matching rule. This way, when the first rule is omitted automatically, traffic will be stopped by the block rule.

19.9 Verifying Functionality

After completing the multi-WAN configuration the best practice is to test the functionality to verify it functions as expected. The following sections describe how to test each portion of a multi-WAN configuration.

19.9.1 Testing Failover

Testing Multi-WAN in a controlled manner immediately after configuration is a key step in the process. Do not make the mistake of waiting until an Internet connection fails naturally for the first test, only to discover problems when they are much more difficult and stressful to fix.

First, navigate to **Status > Gateways** and ensure all WAN gateways show as **Online** under **Status**, as well as on the **Gateway Groups** tab. If they do not, verify that a proper monitor IP address is used as discussed in *Gateway Settings*.

Creating a WAN Failure

There are a number of ways to simulate a WAN failure. For any type, first try unplugging the target WAN interface Ethernet cable from the firewall.

For cable and DSL connections, try powering off the modem/CPE, and in a separate test, unplug the coax or phone line from the modem. For fiber, wireless, and other types of connections with a router outside of pfSense® software, try unplugging the Internet connection from the router, and also turning off the router itself.

All of the described testing scenarios will likely end with the same result. However, there are some circumstances where trying all these things individually will find a fault that would not have otherwise been noticed until an actual failure. One of the most common is unknowingly using a monitor IP address assigned to the DSL or cable modem. Hence when the coax or phone line is disconnected, simulating a provider failure rather than an Ethernet or modem failure, the monitor ping still succeeds since it is pinging the modem. From what the firewall was told to monitor, the connection is still up, so it will not fail over even if the upstream connection is actually down. There are other types of failure that can similarly only be detected by testing all the individual possibilities for failure. The monitor IP address can be edited on the gateway entry as covered in *Gateway Settings*.

Verifying Interface Status

After creating a WAN failure, refresh **Status > Gateways** to check the current status. As the gateway monitoring daemon notices the loss, the loss will eventually move past the configured alarm thresholds and it will mark the gateway as down.

19.9.2 Verifying Load Balancing Functionality

This section describes how to verify the functionality of a load balancing configuration.

Verifying HTTP Load Balancing

The easiest way to verify HTTP load balancing is to visit a website that displays the public IP address the client used to access the site. A page on the Netgate site is available for this purpose, and countless other sites offer the same functionality. Search for "what is my IP address" and numerous websites are returned that will show the public IP address making the HTTP request. Many of those sites tend to be full of advertisements, so Netgate provides a handful of sites which report only the client IP address:

- https://files00.netgate.com/ip
- https://files01.netgate.com/ip
- https://www.pfsense.org/ip

Browsers have a habit of keeping open server connections and caching results, so the best browser-based test is to either load multiple sites, or to close the browser window between attempts to load a site. During each connection attempt, a different IP address should be shown if load balancing is working correctly. If other traffic is present on the network, the IP address may not appear to change on every page load. Repeat the test several times and the IP address should change at least a few times. As an alternative to using a browser, command line utilities such as `curl` do not keep persistent sessions and are more accurate for testing this behavior.

If the IP address never changes, try several different sites, and make sure the browser is requesting the page again, and not returning something from its cache or using a persistent connection to the server. Other good steps include manually deleting the cache, closing and reopening the browser, and trying multiple web browsers. If all of those fail to return the expected result, then start troubleshooting the load balancer configuration further.

Testing load balancing with traceroute

The `traceroute` utility (or `tracert` in Windows) shows the network path taken to a given destination. See *Using traceroute* for details on using `traceroute`. With load balancing, running a `traceroute` from a client host behind the firewall should show a different path being taken for each attempt. Due to the way `traceroute` functions, wait at least one minute after stopping a traceroute before starting another test so that the states will expire, or try different destinations on each attempt.

Using Traffic Graphs

The real time traffic graphs under **Status > Traffic Graph** and on the Traffic Graphs dashboard widget are useful for showing the real time throughput on WAN interfaces. Only one graph at a time can be shown per browser window when using **Status > Traffic Graph**, but additional windows or tabs can be opened in the browser to see all WAN interfaces simultaneously. The traffic graphs widget for the Dashboard enables the simultaneous display of multiple traffic graphs on a single page to simplify this process. If load balancing is working correctly, activity will be observed on all WAN interfaces.

The RRD traffic graphs under **Status > Monitoring** are useful for longer-term and historical evaluation of WAN utilization.

Note: Bandwidth usage may not be exactly equally distributed, since connections are directed on a round robin basis without regard for bandwidth usage.

19.10 IPsec in Multi-WAN Environments

IPsec on pfSense® software can work well with multiple WAN connections.

19.10.1 Alternate / Non-Default WAN

When using Multi-WAN with IPsec, pick the appropriate **Interface** choice for the WAN-type interface to which the tunnel will connect. If the connection will enter via WAN, pick WAN. If the tunnel will use a different WAN, choose whichever OPT WAN interface is needed. The firewall will automatically add a static route to ensure that the traffic to the **Remote Gateway** uses the appropriate WAN.

19.10.2 Failover with Gateway Groups and Dynamic DNS

IPsec can fail between multiple WANs but it requires some coordination and relies upon *gateway groups* and *dynamic DNS*. If the first gateway goes down the tunnel will move to the next available WAN in the group. When the first WAN comes back up, the tunnel will be rebuilt there again.

Note: Due to its reliance on DNS, this type of failover can take several minutes to establish a tunnel after failover or recovery.

First, setup a failover type gateway group with only *one* gateway per tier.

Next, choose the failover gateway group from the **Interface** list on the IPsec phase 1 configuration.

Next, setup a new dynamic DNS entry for a hostname using the same gateway group as its interface. There are numerous dynamic DNS providers available for this purpose. The firewall will update the Dynamic DNS entry with the active WAN IP address when a WAN fails or recovers.

On the remote side of the tunnel, set the peer address to be the new dynamic DNS hostname. This peer will track updates to the hostname so that it will know to accept traffic from the newly activated WAN.

Note: If a peer happens to support multiple remote gateway addresses for a tunnel, and all WANs on the pfSense software side are static, that can be used instead of relying on DNS.

19.10.3 Failover with Routed IPsec and Dynamic Routing

In some environments it is possible to use routed IPsec (VTI) to achieve faster Multi-WAN failover.

This method uses one VTI IPsec tunnel per WAN connecting to the same number of WANs at the remote peer. These VTI tunnels are kept up at all times.

Dynamic routing is then setup on all of the tunnels using the *FRR Package* to select an active path to the remote endpoint. Depending on the protocols used (e.g. OSPF vs BGP) and settings, failover can happen in seconds instead of minutes.

19.11 Using OpenVPN with Multi-WAN

OpenVPN servers can be used with any WAN, or multiple WANs, as can OpenVPN clients. This document covers only a remote access OpenVPN server, but a similar process could be applied for site to site VPNs. For OpenVPN client instances on pfSense software, in most cases it's as simple as picking the gateway group for the interface.

There are many different ways to configure multiple WANs with OpenVPN on pfSense® software for remote access or site to site VPNs.

See also:

Many of these scenarios were covered during the September 2014 . "Advanced OpenVPN Concepts" presentation available through Hangouts Archive.

19.11.1 OpenVPN Configuration

First, get OpenVPN working as desired on the primary WAN interface. Once it is properly functioning, make a backup.

19.11.2 Bind to Localhost and Setup Port Forwards

The OpenVPN configuration needs to be adjusted so it can be reached from either WAN. The simplest way to do this is by changing the **Interface** on the VPN connection to be *Localhost*, and then adding a port forward on each WAN to redirect the OpenVPN port to *Localhost* (127.0.0.1).

For example: If there are two WANs and the OpenVPN server is running on port *1194*, set the **Interface** to *Localhost*, then add two port forwards:

WAN1
: *UDP*, Source any, Destination *WAN1 Address* port `1194`, redirect target `127.0.0.1` port `1194`

WAN2
: *UDP*, Source any, Destination *WAN2 Address* port `1194`, redirect target `127.0.0.1` port `1194`

19.11.3 Configure Clients

Clients may be configured to use the second WAN by adding a second *remote* statement to their configuration, such as:

```
remote x.x.x.x 1194 udp
```

Where `x.x.x.x` is the second WAN IP address or host name.

This process can be automated by using the OpenVPN Client Export package. When exporting a client, in **Host Name Resolution** choose one of:

Automagic Multi-WAN IPs (port forward targets)
: Adds a remote statement for each port forward found targeting the interface binding and port used by this VPN, uses the IP address of each WAN as-is.

Automagic Multi-WAN DDNS Hostnames (port forward targets)
: Like above, but uses the first located Dynamic DNS hostname for a given WAN. If the WAN is a private IP address, this may be the better choice.

19.11.4 More than two WAN connections

The same steps can be repeated to add more WAN connections. Add a port forward to any additional WAN. Clients will need an updated configuration file if another WAN is added later.

19.12 Multi-WAN on a Stick

In the router world, Cisco and others refer to a VLAN router as a "router on a stick" since it can be a functioning router with only one physical network connection. pfSense® software can be configured in this manner as well, using VLANs and a managed switch capable of 802.1q trunking. Most of the deployments running more than 5 WANs use this methodology to limit the number of physical interfaces required on the firewall. In such a deployment, the WAN interfaces all reside on one physical interface on the firewall, with the internal network(s) on additional physical interfaces. Figure *Multi-WAN on a stick* illustrates this type of deployment.

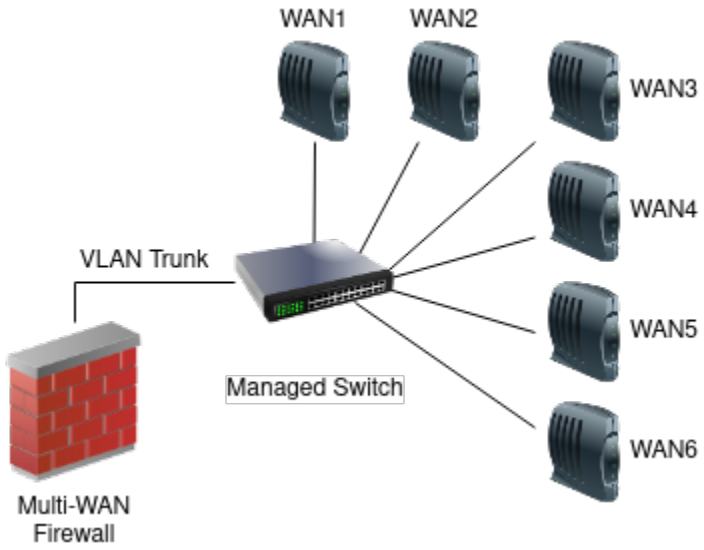

Fig. 2: Multi-WAN on a stick

19.13 Multi-Link PPPoE (MLPPP)

Multi-Link PPPoE (MLPPP) is a unique WAN option that bonds together multiple PPPoE lines from the same ISP to form one larger virtual circuit. This means a firewall can get the true aggregate bandwidth of all circuits in the bundle. For example, if a firewall has three 10 Mbit/s DSL lines in a bundle, it could potentially get 30Mbit/s from a single connection.

19.13.1 Requirements

The largest hurdle for MLPPP is that the ISP must support it on the circuits connected to the firewall. Few ISPs are willing to support MLPPP, so if an ISP is available that does, it would be worth taking advantage of that fact. Additionally, each line must be on a separate interface connected to the firewall running pfSense® software.

19.13.2 Setup

Setup for MLPPP is simple:

- Configure a WAN for a single line with the correct credentials
- Navigate to **Interfaces > Assign**, **PPPs** tab
- Click  to edit the entry for the PPPoE WAN
- Ctrl-click to select the other physical interfaces that belong to the same MLPPP bundle
- Click **Save**

The firewall will then attempt to bond the lines using MLPPP.

19.13.3 Caveats

One downside to using MLPPP is that troubleshooting is much more difficult. Statistics and status are not available for the individual lines. To determine the status, read through the PPP log, as there is not yet a way to query the lines separately. In some cases it's obvious if a line is down, as there may be a noticeable problem at the modem (out of sync) or that the maximum attainable bandwidth is reduced.

See also:

- *Troubleshooting Multi-WAN*
- *Configuring Multi-WAN for IPv6*

The multiple WAN (multi-WAN) capabilities in pfSense® software allow a firewall to utilize multiple Internet connections to achieve more reliable connectivity and greater throughput capacity.

> **Warning:** Before proceeding with a multi-WAN configuration, the firewall must have a functional two interface (LAN and WAN) configuration.

pfSense software is capable of handling numerous WAN interfaces, with multiple deployments using over 10 WANs in production.

All WAN-type interfaces are treated identically in the GUI. Anything that can be done with the primary WAN can also be done with an additional OPT WAN interface. There are no significant differences between the primary WAN and additional WANs.

This section starts by covering items to consider when implementing *any* multi-WAN solution, then covers multi-WAN configuration with pfSense software.

See also:

For a brief run-down of what to configure when setting up Multi-WAN on pfSense software, see *Summary of Multi-WAN Requirements*.

19.14 Choosing Internet Connectivity

The ideal choice of Internet connectivity depends largely upon the options available at a given location, but there are some additional factors to take into consideration.

19.14.1 Cable Paths

Speaking from the experience of those who have seen first hand the effects of multiple cable-seeking backhoes, as well as nefarious copper thieves, it is highly desirable to obtain connectivity choices for a multi-WAN deployment which utilize disparate cabling paths. In many locations, DSL connections as well as any others utilizing copper pairs are carried on a single cable subject to the same cable cut, and others from the same company such as fiber circuits may run along the same poles or conduits.

If one connection comes in over copper pair (DSL), choose a secondary connection utilizing a different type and path of cabling. Cable connections are typically the most widely available option not subject to the same outage as copper services. Other options include fiber service or fixed wireless coming in on a different path from copper services.

Two connections of the same type cannot be relied upon to provide redundancy in most cases. An ISP outage or cable cut will commonly take down all connections of the same type. Some people use multiple DSL lines or multiple cable modems, though the only redundancy that typically offers is isolating a site from modem or other CPE (Customer Premise Equipment) failure. Consider multiple connections from the same provider as a solution only for additional bandwidth, as the redundancy such a deployment offers is minimal.

19.14.2 Paths to the Internet

Another consideration when selecting Internet connectivity for a site is the path from the connection itself to the Internet. For redundancy purposes, multiple Internet connections from the same provider, especially of the same type, should not be relied upon as they could all fail concurrently.

With larger providers, two different types of connections such as a Fiber line and DSL will usually traverse significantly different networks until reaching core parts of the network. These core network components are generally designed with high redundancy and any problems are addressed quickly since they have widespread effects. Hence such connectivity is isolated from most ISP issues, but since they commonly utilize the same cable path, it still leaves a site vulnerable to extended outages from cable cuts.

19.14.3 Better Redundancy, More Bandwidth, Less Money

In the past, high-grade services such as DS1 or DS3 circuits were the choice for environments with high availability requirements. Generally the Service Level Agreements (SLA) offered on DS1 and DS3 connections were better than other types of connectivity, and those circuits were generally seen as more reliable. End users have largely left such circuits behind, however, because they are too slow or too costly by today's standards. With the multi-WAN capabilities on pfSense software a site can have more bandwidth and better redundancy for less money in many cases. Fiber services are rapidly becoming more widespread, shaking up this concept by providing extremely large amounts of bandwidth for relatively low cost, though such services may still have a less-than-desirable SLA for outage response.

Most organizations which require high availability Internet connections do not want to rely upon DSL, cable or other "lesser class" broadband Internet connections. While they are usually significantly faster and cheaper, the unfavorable SLA is enough to make many companies think twice. In areas where multiple lower cost broadband options are available, such as fiber and cable, the combination of pfSense software and two low cost Internet connections provides more bandwidth and better redundancy at a lower cost. The chance of two different broadband connections going down simultaneously is significantly less than the chance of any single service outage. Adding a backup Cable or DSL line to supplement a much faster fiber line ensures connectivity will continue when an outage occurs on the fiber line, even if it is a rare occurrence.

CHAPTER

TWENTY

VIRTUAL PRIVATE NETWORKS

20.1 Common deployments

There are four common uses of the VPN capabilities of pfSense, each covered in this section.

20.1.1 Site-to-site connectivity

Site-to-site connectivity is primarily used to connect networks in multiple physical locations where a dedicated, always-on, connection between the locations is required. This is frequently used to connect branch offices to a main office, connect the networks of business partners, or connect a network to another location such as a data center environment.

Before the proliferation of VPN technology, private WAN circuits were the only solution to connect multiple locations. These technologies include point-to-point dedicated circuits, packet switching technologies such as frame relay and ATM, and more recently, MPLS (Multiprotocol Label Switching) and fiber and copper based metropolitan Ethernet services. While these types of private WAN connectivity provide reliable, low latency connections, they are also very costly with recurring monthly fees. VPN technology has grown in popularity because it provides the same secure site to site connectivity using Internet connections that are generally much less costly.

20.1.2 Limitations of VPN connectivity

Performance is an important consideration when planning a VPN solution. In some networks, only a private WAN circuit can meet the requirements for bandwidth or latency. Latency is usually the biggest factor. A point to point DS1 circuit has end to end latency of about 3-5 ms, while the latency to the first hop on an ISP network will generally be at least that much if not higher. Metro Ethernet services or fiber circuits have end to end latency of about 0-3 ms, usually less than the latency to the first hop of an ISP network. That will vary some based on geographical distance between the sites. The stated numbers are typical for sites within a couple hundred miles of each other. VPNs usually see latency of around 30-60 ms depending on the Internet connections in use and the geographical distance between the locations. Latency can be minimized and VPN performance maximized by using the same ISP for all VPN locations, but this isn't always feasible.

Certain protocols perform very poorly with the latency inherent in connections over the Internet. Microsoft file sharing (SMB) is a common example. At sub-10 ms latency, it performs well. At 30 ms or higher, it's sluggish, and at more than 50 ms it's painfully slow, causing frequent hangs when browsing folders, saving files, etc. Getting a simple directory listing requires numerous round trip connections between the client and server, which significantly exacerbates the increased delay of the connection. In Windows Vista and Server 2008, Microsoft introduced SMB 2.0 which includes new capabilities to address the issue described here. SMB 2.0 enables the sending of multiple actions in a single request, as well as the ability to pipeline requests, meaning the client can send additional requests without waiting for the response from prior requests. If a network uses exclusively Vista and Server 2008 or newer operating systems this won't be a concern, but given the rarity of such environments, this will usually be a consideration. SMB 3.0 further improves in this area with support for multiple streams.

Two more examples of latency sensitive protocols are Microsoft Remote Desktop Protocol (RDP) and Citrix ICA. There is a clear performance and responsiveness difference with these protocols between sub-20 ms response times typically found in a private WAN, and the 50-60+ ms response times common to VPN connections. If remote users work on published desktops using thin client devices, there will be a notable performance difference between a private WAN and VPN. Whether that performance difference is significant enough to justify the expense of a private WAN will vary from one environment to another.

There may be other network applications in an environment that are latency sensitive, where the reduced performance of a VPN is unacceptable. Or all locations may be within a relatively small geographical area using the same ISP, where the performance of a VPN rivals that of private WAN connections.

20.1.3 Remote access

Remote access VPNs enable users to securely connect into a network from any location where an Internet connection is available. This is most frequently used for mobile workers (often referred to as "Road Warriors") whose job requires frequent travel and little time in the office, and to give employees the ability to work from home. It can also allow contractors or vendors temporary access to a network. With the proliferation of smart phones, users have a need to securely access internal services from their phones using a remote access VPN.

20.1.4 Protection for wireless networks

A VPN can provide an additional layer of protection for wireless networks. This protection is two-fold: It provides an additional layer of encryption for traffic traversing the wireless network, and it can be deployed in such a way that it requires additional authentication before access to network resources is permitted. This is deployed mostly the same as remote access VPNs. This is covered in *Additional protection for a wireless network*.

20.1.5 Secure relay

Remote access VPNs can be configured in a way that passes all traffic from the client system over the VPN. This is nice to have when using untrusted networks, such as wireless hotspots as it lets a client push all its Internet traffic over the VPN and out to the Internet from the VPN server. This protects the user from a number of attacks that are possible on untrusted networks, though it does have a performance impact since it adds additional hops and latency to all connections. That impact is usually minimal with high speed connectivity when the client and VPN server are relatively close geographically.

20.2 Choosing a VPN solution

Each VPN solution has pros and cons. This section will cover the primary considerations in choosing a VPN solution, providing the information necessary to choose the best solution for a given environment.

20.2.1 Interoperability

To interoperate with a firewall or router product from another vendor, the choices are limited by items supported by both sides.

Note: Interoperability in this sense isn't applicable with VPN types not listed here since they are not intended for site-to-site applications.

IPsec

IPsec is usually the best choice since it is included with nearly every VPN-capable device. It also prevents being locked into any particular firewall or VPN solution. For interoperable site-to-site connectivity, IPsec is usually the only choice.

OpenVPN

OpenVPN is interoperable with a few other packaged firewall/VPN solutions, but not many.

WireGuard

WireGuard, like OpenVPN, is compatible with only a few other packaged firewall and VPN solutions. However, as it is a more recently developed protocol, support is even more rare.

20.2.2 Authentication considerations

All VPN types on the firewall support user authentication except for WireGuard. IPsec can also work with shared keys, and both IPsec and OpenVPN can utilize certificates. Using OpenVPN with certificates, TLS authentication, and User Authentication is the most secure method. OpenVPN certificates can also be password protected, in which case a compromised certificate alone isn't adequate for connecting to a VPN if it is set to only use certificates. The lack of additional authentication can be a security risk in that a lost, stolen, or compromised system containing a key or certificate means whoever has access to the device can connect to a VPN until that loss is discovered and the certificate revoked.

While not ideal, a lack of username and password authentication on a VPN isn't as great a risk as it may seem. A compromised system can easily have a key logger installed to capture the username and password information and easily defeat that protection. In the case of lost or stolen systems containing keys, if the hard drive isn't encrypted, the keys can be used to connect. However adding password authentication isn't of great help there either, as usually the same username and password will be used to log into the computer, and most passwords are crackable within minutes using modern hardware when an attacker has access to an unencrypted drive. Password security is also frequently compromised by users with notes on their laptop or in their laptop case with their password written down. As with any security implementation, the more layers utilized, the better, but it's always a good idea to keep these layers in perspective.

20.2.3 Ease of configuration

None of the available VPN options are extremely difficult to configure, but there are differences between the options.

IPsec

Has numerous configuration options and can be difficult for the uninitiated.

OpenVPN

OpenVPN requires the use of certificates for remote access in most environments, which comes with its own learning curve and can be a bit arduous to manage. There is a wizard to handle the most common OpenVPN remote access configurations and the OpenVPN client export packages eases the process of getting the clients up and running.

WireGuard

Has few options, thus configuration is simple. Lacks facilities for automated configuration and deployment leading to increased manual management.

20.2.4 Multi-WAN capable

If users require the ability to connect to multiple WANs, IPsec, OpenVPN, and WireGuard are capable of handling such configurations.

20.2.5 Client availability

VPN Client software is a program that handles connecting to the VPN and handling any other related tasks like authentication, encrypting, routing, etc. For remote access VPNs, the availability of VPN client software is a primary consideration. All options are cross platform compatible with many different operating systems but some require installing third-party clients. IPsec in EAP-MSCHAPv2 mode, IPsec in EAP-TLS mode, and IPsec in Xauth mode are the only options with client support built into some popular desktop and mobile operating systems. Other operating systems vary and may include more or less IPsec modes or may even include OpenVPN or WireGuard, as is the case with many Linux distributions. If using built-in clients is a must, consult the operating system documentation for all required client platforms to see if a common option is available and then check to see if that mode is possible.

In some cases multiple remote access VPNs may be required to accommodate all clients. For example, IPsec could be used for some and OpenVPN for others. Some organizations prefer to keep things consistent, so there is a trade-off to be made but for the sake of compatibility it may be worth offering multiple options.

IPsec

IPsec clients are available for Windows, macOS, BSD, Linux, and others. Though the native clients may only support certain specific modes and configurations. General-use IPsec clients are not included in the OS except for some Linux and BSD distributions. macOS includes both IKEv2 and Cisco (xauth) IPsec support. There are free and commercial options available with a user-friendly GUI.

macOS 10.11, along with Windows 7 and later include support for IPsec in specific modes using IKEv2: EAP-TLS and EAP-MSCHAPv2. Both options are supported and are covered in *IPsec Mobile Clients Tab*.

The Cisco-style IPsec client included with macOS and iOS devices is fully compatible with IPsec using xauth. Configuration for the iOS client is covered in *Configuring IPsec IKEv2 Remote Access VPN Clients on iOS*.

Many Android phones also include a compatible IPsec client, which is discussed in *Configuring IPsec IKEv2 Remote Access VPN Clients on Android*.

OpenVPN

OpenVPN has clients available for Windows, macOS, all the BSDs, Linux, Solaris, and Windows Mobile, but the client does not come pre-installed in any of these operating systems.

Android devices can use a freely available OpenVPN client that works well and doesn't require rooting the device. That client is covered in *Installing the OpenVPN Client on Android*. There are other options available if the device is rooted, but that is beyond the scope of this documentation.

iOS also has a native OpenVPN client. For more information, see *Installing the OpenVPN Client on iOS*.

WireGuard

WireGuard clients are available for a variety of operating systems including Windows, macOS, FreeBSD, Linux, Android, iOS, and more. Some Linux installations include WireGuard but in most cases it requires installation of a third party client.

20.2.6 Firewall friendliness

VPN protocols can cause difficulties for many firewalls and NAT devices. This is primarily relevant to remote access connectivity, where users will be behind a myriad of firewalls mostly controlled by third parties with varying configurations and capabilities.

IPsec

IPsec uses both UDP port 500 and the ESP protocol to function. Some firewalls don't handle ESP traffic well where NAT is involved, because the protocol does not have port numbers like TCP and UDP that make it easily trackable by NAT devices. IPsec clients behind NAT may require NAT Traversal to function, which encapsulates the ESP traffic over UDP port 4500.

OpenVPN

OpenVPN is very firewall-friendly. Since it uses a single UDP or TCP port and is not affected by common NAT functions such as rewriting of source ports, it is rare to find a firewall which will not work with OpenVPN. The only possible difficulty is if the protocol and port in use is blocked. Some administrators use a common port like UDP 53 (usually DNS), or TCP 80 (usually HTTP) or TCP 443 (usually HTTPS) or to evade most egress filtering.

WireGuard

Similar to OpenVPN in this regard, WireGuard uses a single UDP port and thus is not affected by firewall and NAT issues which may affect other protocols.

20.2.7 Cryptographically secure

One of the critical functions of a VPN is to ensure the confidentiality of the data transmitted.

IPsec

Tunnels using pre-shared keys can be broken if a weak key is used. Use a strong key, at least 10 characters in length containing a mix of upper and lowercase letters, numbers and symbols. Use of certificates is preferred, though somewhat more complicated to implement.

OpenVPN

Encryption is compromised if the private keys of the PKI structure are compromised, though the use of multiple factors such as TLS authentication on top of PKI can mitigate some of the danger.

WireGuard

WireGuard encryption relies on pre-generated public/private key pairs and an optional pre-shared key. The peers only need the public keys of other peers, and the optional pre-shared key. The private keys and pre-shared key (if present) must be protected.

20.2.8 Support for NAT inside tunnels

While any use of NAT is undesirable, there are some occasions which can benefit from its use inside tunnels. Primarily, it can be useful for working around subnet conflicts or for setting up "outbound" style NAT when the remote endpoint only expects a single address (e.g. a VPN provider with no LAN-to-LAN routing)

IPsec

Support for NAT with IPsec depends on the mode, either tunnel or VTI.

Tunnel

Phase 2 entries in *tunnel* mode support BINAT (1:1) and Overload/PAT style NAT. See *NAT with IPsec Phase 2 Networks* for details.

VTI

Phase 2 entries in *VTI* mode can support NAT when using a special **IPsec Filter Mode** setting which is not compatible with tunnel mode. See *Filtered on Assigned IPsec Interfaces* for details.

OpenVPN

OpenVPN supports inbound (e.g. port forwards) and outbound NAT using the group OpenVPN tab and also on assigned interfaces. Depending on the environment and configuration there may be some special considerations, such as ensuring proper return routing for post-NAT subnets.

WireGuard

WireGuard supports inbound (e.g. port forwards) and outbound NAT using the group WireGuard tab and also on assigned interfaces. Some cases may require using single peer tunnels or carefully crafted **Allowed IPs** lists to ensure correct return routing. See *Design Considerations* and *WireGuard and Rules / NAT*.

20.2.9 Per-tunnel Firewall Rules

Each VPN type has a common group tab for rules, and some also support rules for individual tunnels.

Warning: Rules on group tabs are considered before per-interface rules. For per-interface rules to match, rules on the group tab must not match the same packets.

IPsec

IPsec in tunnel mode does not currently support per-tunnel rules, its traffic can only be filtered by rules on the IPsec tab.

Phase 2 entries in *VTI* mode can support per-interface rules when using a special **IPsec Filter Mode** setting which is not compatible with tunnel mode. See *Filtered on Assigned IPsec Interfaces* for details.

OpenVPN

When assigned as an interface, OpenVPN instances fully support per-tunnel rules. See *Assigning OpenVPN Interfaces*.

WireGuard

When assigned as an interface, WireGuard instances fully support per-tunnel rules. See *Assign a WireGuard Interface* and *WireGuard and Rules / NAT*.

20.2.10 Automatic Mobile Client Configuration

Depending on the deployment, mobile (Remote Access) clients can receive automatic configuration in certain cases.

IPsec

In IKEv2 mode, clients can automatically receive an IP address allocated from a pool, along with DNS configuration.

In IKEv1 mode with Xauth, in addition to the above, clients can also receive a list of networks to route across the VPN.

OpenVPN

OpenVPN clients can automatically receive an IP address allocated from a pool, and numerous additional options can be pushed to clients to control their behavior from the server side (routing, DNS, and many others).

WireGuard

WireGuard mobile clients must be configured statically. On the server side, a client tunnel address must be setup in the **Allowed IPs** for a peer. The same address must be configured on the client. This varies by OS/Platform, some read it from the configuration and other require it to be configured on interfaces via CLI commands. Networks to route must likewise be manually added on the client configuration **Allowed IPs** list and, depending on the client, may also need to be added to its operating system routing table.

20.2.11 Routing Support

IPsec

IPsec in *Tunnel* mode uses policies, not routes, and thus does not respect the operating system routing table.

IPsec in *VTI* mode supports static and dynamic routing (e.g. BGP, OSPF) and works with the operating system routing table.

OpenVPN

In SSL/TLS tun mode with multiple clients, OpenVPN uses its internal routing on client-specific configurations to determine which clients receive traffic for specific subnets. In this type of configuration, dynamic routing is not possible.

In SSL/TLS tun mode with a /30 subnet (one client per server), dynamic routing is possible using OSPF or BGP. In that configuration OpenVPN does not need to track internal routing and can rely on the operating system routing table alone.

In tap mode, dynamic routing is possible as packets can be handed off using L2/ARP information rather than relying on internal routing in OpenVPN.

WireGuard

WireGuard routes specific subnets to peers based on the **Allowed IPs** list, but also requires operating system routing table entries for traffic to enter a WireGuard tunnel.

When a WireGuard tunnel has more than one peer, the **Allowed IPs** list lets WireGuard determine internally which clients receive traffic for specific subnets. Due to this internal routing, dynamic routing is not possible in a configuration where WireGuard has multiple peers per tunnel.

For a WireGuard tunnel with a single peer, WireGuard can forward arbitrary networks to the peer without having them all listed in **Allowed IPs**. Thus, in this situation, it can take advantage of dynamic routing using BGP. OSPF is also possible but requires additional configuration.

See *WireGuard Routing* for more information.

20.2.12 Recap

Table *Features and Characteristics by VPN Type* shows an overview of the considerations provided in this section.

Table 1: Features and Characteristics by VPN Type

VPN Feature	IPsec	OpenVPN	WireGuard
User Authentication	Yes	Yes	No
Client included in most OSes	Varies by mode	No	No
Widely interoperable	Yes	No	No
Multi-WAN	Yes	Yes	Yes
Cryptographically secure	Yes	Yes	Yes
Firewall friendly	Yes (NAT-T or IKEv2)	Yes	Yes
In-tunnel NAT	Limited	Yes	Yes
Per-tunnel Firewall Rules	Limited	Yes	Yes
Automatic Mobile Config	Yes	Yes	No
Static Routing	Yes (VTI Only)	Internal	Internal
Dynamic Routing	Yes (VTI Only)	Varies	Varies

20.3 Remote Access Mobile VPN Client Compatibility

A variety of remote access ("mobile") VPN configuration styles are available to accommodate nearly any potential client. The table below shows which operating systems have compatible clients with some of the most common remote access VPN configurations.

Table 2: Mobile/Remote Access VPN Client Availability

Protocol/Operating System	Windows 10	Android	iOS	macOS
OpenVPN	3PA 1 2	3PA 4	3PA 6	3PA 2
WireGuard	3PA 3	3PA 3	3PA 3	3PA 3
IPsec PSK	?	Varies	?	?
IPsec RSA	?	Varies	?	?
IPsec IKEv2 EAP-MSCHAPv2/RADIUS	Yes	Yes (11+), 3PA (4.x+) 5	Yes	Yes
IPsec IKEv2 EAP-TLS	Yes	Yes (11+), 3PA (4.x+) 5	Yes	Yes

Legend:

- Yes = OS Native Client Available
- 3PA = Third Party Client Required
- Varies = Varies by device model and vendor options

Unless otherwise stated, UNIX clients (*BSD, Linux, etc) can support any style with manual configurations but the availability of GUI configuration tools varies by distribution.

20.4 VPNs and Firewall Rules

VPNs and firewall rules are handled somewhat inconsistently in pfSense® software. This section describes how firewall rules are handled for each of the individual VPN options. For the automatically added rules discussed here, the addition of those rules may be disabled by checking **Disable all auto-added VPN rules** under **System > Advanced** on the **Firewall/NAT** tab.

20.4.1 IPsec

Traffic necessary to establish configured and enabled IPsec tunnels is automatically allowed into the firewall as described in *Outer IPsec Traffic*.

Traffic encapsulated within an active tunnel mode IPsec connection is controlled via user-defined rules on the **IPsec** tab under **Firewall > Rules**. Traffic for VTI mode works the same way by default but can operate on a per-interface basis in certain conditions. See *Tunneled IPsec Traffic from Remote to Local* for details.

20.4.2 OpenVPN

OpenVPN does not automatically add rules to WAN interfaces. The OpenVPN remote access VPN Wizard offers to optionally create rules to pass WAN traffic and traffic on the OpenVPN interface.

Traffic encapsulated within an active OpenVPN connection is controlled via user-defined rules on the **OpenVPN** tab under **Firewall > Rules**.

OpenVPN interfaces may also be assigned similar to other interfaces. In such cases the **OpenVPN** tab firewall rules still apply, but there is a separate tab specific to the assigned VPN instance that controls traffic only for that one VPN.

20.4.3 WireGuard

WireGuard does not automatically add rules to WAN interfaces. Rules must be added to the appropriate WAN interface(s) to allow traffic to reach the ports for WireGuard instances.

Traffic encapsulated within WireGuard is controlled via user-defined rules on the **WireGuard** tab under **Firewall > Rules**.

WireGuard interfaces may also be assigned similar to other interfaces. In such cases the **WireGuard** tab firewall rules still apply, but there is a separate tab specific to the assigned VPN instance that controls traffic only for that one VPN.

20.5 IPv6 VPN and Firewall Rules

As mentioned briefly in *Firewall and VPN Concerns*, special care must be taken when routing IPv6 traffic across a VPN and using publicly routable subnets. The same advice also applies to IPv4 but it's much less common to have clients on both sides of an IPv4 VPN using publicly routable addresses.

The main issue is that because it's possible to route all the way from one LAN to the other LAN across the Internet, then traffic could be flowing unencrypted between the two networks if the VPN is down (or not present at all!). This is far from ideal because although connectivity is available, if any traffic were intercepted in between the two networks and that traffic was using an unencrypted protocol like HTTP, then it could compromise the network.

One way to prevent this is to not allow traffic from the remote IPv6 LAN in on the opposing side's WAN rules. Only allow traffic from the remote side's subnet on the firewall rules for whichever VPN type is being used to protect the traffic. An explicit block rule could also be added to the top of the WAN rules to ensure that this traffic cannot enter from the WAN directly. A better method is to use a floating rule to reject outbound traffic on WAN destined for VPN hosts/remote local networks. This way the insecure traffic never leaves the premises. With the rule set to log, the "leakage" would be obvious to someone monitoring the logs as it would be shown blocked outbound on WAN.

Another less obvious consequence of having dual stack connectivity between networks is that differences in DNS can cause unintended routing to take place. Suppose IPv4 VPN connectivity exists between two sites, but there is no IPv6 VPN, only standard IPv6 connectivity at both locations. If a local host is set to prefer IPv6 and it receives a AAAA DNS response with the IPv6 IP address for a remote resource, it would attempt to connect over IPv6 first rather than using the VPN. In cases such as this, care would be needed to make sure that DNS does not contain conflicting records or that floating rules are added to prevent this IPv6 traffic from leaking out WAN. A more in-depth article on these kinds of traffic leakage can be found in the IETF draft named draft-gont-opsec-vpn-leakages-00.

20.6 VPN Scaling

The advice on this page is intended to help firewall administrators handle increased VPN volume when using pfSense® software, both in terms of throughput and number of connected users.

Warning: The advice on this page is relayed from experience and from community members. The advice on this page may not apply to all environments or use cases, and has not been definitively proven to help, but is offered in case others find it useful.

See also:

This document won't cover all factors of choosing between VPN types or how to setup VPNs, that information can be found *elsewhere in this documentation* and in Hangouts Archive.

20.6.1 General Advice

No Artificial Limits

The firewall does not place any artificial limits on VPN connections. Any limitations encountered are due to settings, the hardware/environment, or the underlying technology.

Use External Authentication

For user-based authentication, the most efficient method of user management for large numbers of accounts is an external authentication source, such as a RADIUS server, LDAP server, Active Directory (Via LDAP or RADIUS/NPS), etc.

Check Logs

If additional users are unable to connect, look in the logs on both the client and server side for specific error messages before seeking support.

Use Hardware Acceleration

Using a *cryptographic accelerator* such as a QAT, IPsec-MB, AES-NI, or SafeXcel will help greatly with throughput and crypto-related tasks.

pfSense Plus software includes support for QAT, CESA, and SafeXcel hardware found on several Netgate Appliances. QAT is also available as an add-on card for certain models. IPsec-MB is also available on pfSense Plus for supported CPUs. pfSense Plus software and pfSense CE software both include support for AES-NI.

For more information on these devices and their capabilities, including how to configure and test them, see *Cryptographic Accelerator Support*.

Use AES-GCM or ChaCha20-Poly1305

Using efficient encryption will increase security and performance. Authenticated Encryption with Additional Data (AEAD) ciphers combine encryption and authentication in one step, eliminating the need for additional hashing. AES-GCM and ChaCha20-Poly1305 are both AEAD ciphers. IPsec and OpenVPN can use both AES-GCM and ChaCha20-Poly1305, while the only cipher supported by WireGuard is ChaCha20-Poly1305.

Client support varies by platform.

Use Accelerated Ciphers

Certain hardware may accelerate ciphers so that choices are faster or more efficient. For hardware sold by Netgate, see the Netgate Appliances page for performance data and recommendations.

Disable Performance-Limiting Mitigation Settings

While Netgate does not have data on if or by how much they may impact VPNs, CPU vulnerability mitigation methods such as Kernel PTI and MDS mode can potentially degrade total performance. The potential for exploitation is minimal since arbitrary code cannot be run on the firewall except by users which already have the equivalent of administrator-level access. To ensure this risk stays low, only allow trusted administrators to access the firewall GUI and shell (SSH or console). The settings to enable/disable these features are under **System > Advanced** on the **Miscellaneous** tab.

Check Tunnel Network/Virtual Address Pool Sizes

Both IPsec and OpenVPN can assign addresses to clients out of a pool for remote access/mobile VPNs. The sizing of this pool limits how many clients can connect. For example, the maximum number of users in a /24 pool is 252, but other settings may reduce that value. See the sections below for more specific advice.

Use "Secure Enough" Settings

While we do not recommend deliberately using weak configurations, in some cases trade-offs are made for security between two secure ciphers or settings where one may offer *even better* security, but the lower of the two is still secure. In these cases, using the "Secure Enough" option can provide efficiency vs increased security. So long as the decision is informed, there may be some performance gained without compromising security in an unacceptable way. For example, with AES-GCM a key length of 128 bits is still considered secure. A 256 bit key is more secure, but the 256 bit key could put more of a burden on the hardware.

Consider Split Tunneling

Configurations which send all client data over the VPN, including Internet-bound traffic, will consume more resources than those which only send traffic for specific subnets. There are plenty of valid reasons to use either kind of configuration, however, when resources are stretched thin, easing the traffic burden on the VPN may justify switching to split tunneling rather than tunneling everything. Depending on the type of VPN and client, this may require adjustments on the server, the client, or both. See the sections below for specific recommendations.

Use Multiple Firewalls

In some instances, the burden may be too great for any single firewall to handle. In cases like this, multiple firewalls can be used to handle the required number of clients or throughput, at a cost of greatly increased complexity. There is no way to automatically balance between nodes in this manner, but such a configuration could be manually managed. This would also likely require the capability to have multiple external addresses on the WAN so each firewall can work in parallel, and also increases the complexity of routing on the internal side.

Use TNSR

TNSR® software is capable of vastly increased total IPsec and WireGuard throughput compared to pfSense software. If pfSense software is unable to reach the throughput needs for a given use case, see the TNSR product page for more information.

20.6.2 Scaling IPsec

IPsec is well-suited to high throughput by default, especially given the advice above, but there are additional IPsec-specific tweaks which may help.

Note: See the TNSR product page for information about using TNSR for even larger total site-to-site throughput needs.

Optimal Encryption Settings

- Use QAT, IPsec-MB, or AES-NI capable hardware.
- In Phase 1 (IKE) settings, use:
  - *AES128-GCM* with *128 bit* key length for the Algorithm
  - *AES-XCBC* for the hash, which in this case is effectively a Pseudo-Random Function (PRF). This will yield the highest performance in combination with *AES128-GCM* on hardware which can accelerate both (e.g. AES-NI)

> **Warning:** While this may lead to higher performance when hardware is capable of accelerating this algorithm, it is less secure than other choices such as SHA256.
>
> Using a more secure algorithm is better in most use cases. IKE negotiation does not happen frequently unless there are large quantities of tunnels or mobile clients, so it may not be critical to accelerate this function in the majority of deployments.

- In Phase 2 (Child SA) settings, use:
  - *AES128-GCM* with *128 bit* key length for the Algorithm
  - **Do not select any Hash Algorithms**. A hash algorithm is unnecessary for AES-GCM as it already includes authentication.

Enable Multiple Phase 1 and Phase 2 Proposals

Multiple Phase 1 and Phase 2 encryption proposals may be configured in the GUI. Enabling multiple combinations of settings will allow peers to choose the most optimal settings which both sides support.

Enable Asynchronous Cryptography

IPsec cryptography jobs can be dispatched multi-threaded to run in parallel and increase performance. However, not all platforms and configurations fully support this function. To enable this capability, check **Asynchronous Cryptography** under **VPN > IPsec** on the **Advanced** tab.

> **Warning:** Be on the lookout for IPsec traffic drops/failures to pass with this setting enabled. See https://redmine.pfsense.org/issues/8964 for more information.

Split Tunneling

As mentioned above, split tunneling would only send traffic for specific subnets across the VPN rather than sending all traffic. On IPsec, this can be done in some cases by listing the specific networks in Phase 2 entries for the Mobile IPsec P1 rather than `0.0.0.0/0`. On the mobile clients tab, set **Provide a list of accessible networks to clients**. Even with that set, certain cases such as Windows 10 may require additional changes to direct clients to send only specific traffic over the tunnel.

20.6.3 Scaling OpenVPN

Use Data Channel Offload (Plus Only)

OpenVPN Data Channel Offload (DCO), a pfSense Plus exclusive feature, can potentially increase performance of OpenVPN well beyond the capabilities of traditional OpenVPN connections. Under ideal conditions OpenVPN with DCO can match or exceed the performance of WireGuard and IPsec.

DCO operates optimally when it is enabled on all peers, but it can still offer performance benefits when enabled on only one side.

Use IPsec or WireGuard Instead

If DCO cannot be enabled on all OpenVPN peers, then check if the peers are capable of using IPsec or WireGuard instead. IPsec and WireGuard are much more efficiently integrated into the operating system than traditional OpenVPN (without DCO), and both are capable of much greater throughput in that situation.

Use UDP

UDP has less overhead for tunneled data, and if a client has to retransmit, it won't compound the problem by retransmitting both inside and outside the tunnel. Unless there are extenuating circumstances which require TCP, use UDP.

Use TLS for Authentication Only

OpenVPN can use TLS for both authentication and for encryption of the control channel. Performing control channel encryption adds more overhead, which can add up with many clients. If control channel encryption is not required, consider using TLS for only authentication instead. No matter which option is chosen, traffic carried by OpenVPN is encrypted.

Encryption Algorithm

Use a CPU with QAT, IPsec-MB, or AES-NI when possible, and use AES-GCM for the Encryption Algorithm when possible. ChaCha20-Poly1305 may also give a performance boost if hardware acceleration is unavailable. Note that for AEAD ciphers such as AES-GCM and ChaCha20-Poly1305, OpenVPN ignores the setting for **Auth Digest Algorithm**.

Note: For OpenVPN, AES-GCM and ChaCha20-Poly1305 can only be used in SSL/TLS mode with a tunnel network that enables client/server mode (larger than /30).

Use Data Cipher Negotiation

Data cipher negotiation can be used to set preferences so that more efficient ciphers can be preferred by clients where possible, but others can be used when necessary. Set high-priority selections such as *AES-128-GCM* first, followed by others like *AES-128-CBC*.

Split Tunneling

As mentioned in the general section above, split tunneling only sends traffic for specific subnets across the VPN rather than sending all traffic. With OpenVPN, this can be done by **Unchecking** the **Redirect IPv4/IPv6 Gateway** option(s) and configuring **IPv4/IPv6 Local Network(s)** entries instead. Clients may still override this behavior remotely, however, so check the client configurations as well.

Concurrent Connections

The firewall does not impose any connection limits by default, but an administrator may have chosen to configure a limit on the number of connections via the **Concurrent Connections** setting on servers. Ensure this is either unset or set high enough to accommodate the required number of users.

Disable Compression

Though using compression is tempting to squeeze extra throughput out of slower links, it is both inefficient and insecure. Most data sent across VPNs in modern environments is already encrypted or otherwise uncompressible, which wastes CPU when attempting to compress. Additionally, vulnerabilities such as VORACLE can allow attackers to glean information about encrypted data when it has been compressed. Disabling compression will mitigate that attack and also reduce CPU overhead. On the server, set **Compression** to *Disable Compression*.

Duplicate Connections

Normally, if an OpenVPN client connects using the same username or certificate CN, the older connection is broken in favor of the new connection. This is more secure, but does not allow any given user to connect multiple times. Circumstances may necessitate supporting this, and in some environments it's not possible to give every device a unique username and/or certificate. Check **Duplicate Connection** in the OpenVPN server settings to allow multiple connections from the same user.

Topology

OpenVPN defaults to *subnet* topology which uses addresses more efficiently, but if the VPN was configured initially on older versions, or if an older guide was followed, it may still be using *net30* topology. Using a common example tunnel network of `10.0.8.0/24`, with *subnet* topology, the VPN can have a maximum of 252 users but with *net30*, it can only have 63. This is because in *net30* mode, each user receives a /30 subnet which utilizes four IP addresses for each user. In *subnet* mode, the server uses a single address and the client uses a single address, which is much more efficient.

Use UDP Fast I/O

This option is considered experimental by OpenVPN, but for those who have used it, it can result in much higher throughput. Not all platforms support this feature, however.

Increase Send/Receive Buffer

The default buffer size is safe, but not optimal. Increasing the buffer size to 512KiB on both sides can result in greater throughput. Results will vary by platform, internet link speed, and other factors. May require experimenting with multiple values to find the most efficient setting for a given environment.

Use Multiple Servers

OpenVPN is not multi-threaded so any single instance of OpenVPN is limited to using a single CPU. If a router has fast cores and not too many users, that may be OK, but it does not scale well. A workaround for this is to split users onto multiple servers. There are various means to reach this goal, including (but not limited to):

- Multiple servers on different WANs or ports, each with unique tunnel networks but otherwise identical settings (Same CA structure, encryption, etc).
  - Administrators could choose to manually configure pools of clients to connect to specific servers, but that does not scale well.
  - Clients may connect to any server configured in this manner so long as their settings line up properly.
  - Multiple servers can be listed in a single client configuration with additional `remote` statements.
  - Add `remote-random` to the client configuration so that clients will pick a random server when starting, which avoids overloading whichever server is listed first.
  - Servers could be run on multiple WANs to overcome single-circuit throughput limits.
- Multiple servers with completely unique settings (Different CA structure, different clients, etc)
  - More secure but more difficult to manage.
  - Clients must use different configurations to reach each server, no automated/built-in way to pick between them unless a specific client supports that function.
  - Good for isolating separate security levels (e.g. remote workers, remote administrators, vendors).

Process Efficiency

As a counterpoint to the above, each server will incur additional memory and other overhead to manage the process. When dealing with site-to-site VPNs, it is more efficient from a *memory* standpoint to use a single server with multiple clients (Peer to Peer SSL/TLS in client/server mode) vs servers for every node (Peer to Peer SSL/TLS with a /30 tunnel network). If memory is a limiting factor, use fewer servers. If CPU overhead is the limiting factor, use separate servers.

20.7 OpenVPN

20.7.1 OpenVPN Data Channel Offload (DCO)

OpenVPN Data Channel Offload (DCO) allows for huge performance gains when processing encrypted OpenVPN data by reducing the amount of context switching that happens for each packet. DCO accomplishes this by keeping most of the data handling tasks in the kernel rather than repeatedly switching between kernel and user space for encryption and packet handling. This makes the overall processing of each packet more efficient while also potentially taking advantage of hardware encryption offloading support in the kernel. DCO also adds support for multi-threaded encryption, allowing for even more performance gains.

Netgate worked with OpenVPN to develop and integrate support for OpenVPN Data Channel Offload (DCO) into FreeBSD and pfSense Plus software version 22.05 and later.

Warning: pfSense Plus software version 22.05 or later is required to use OpenVPN DCO. OpenVPN DCO is not available on pfSense CE Software.

DCO is not a change to the protocol, it is a change in how an endpoint processes encrypted data. Thus, DCO is beneficial even when only one endpoint is capable of DCO. That said, tunnels employing DCO on all peers will see the most benefit. With DCO on only one peer the performance improvement can still be notable but not as significant as the gains with DCO support on both endpoints.

Note: Some OpenVPN features and use cases are not compatible with DCO. See *Limitations* for a list of known DCO limitations.

See also:

OpenVPN Site-to-Site Configuration Example with SSL/TLS and DCO

Using OpenVPN DCO

DCO support is a per-tunnel option and it is **not** automatically enabled by default for new or upgraded tunnels. Existing tunnels will continue to function as they have in the past.

DCO can be enabled for both new and existing tunnels by using a simple checkbox option on OpenVPN server and client instances. The current best practice is to create a new tunnel with DCO to minimize the chance of problems with existing clients.

Limitations

There are a few limitations in OpenVPN DCO generally and in the current DCO implementation on FreeBSD/pfSense software, including:

- Encryption is limited to AES-256-GCM, AES-128-GCM, and ChaCha20-Poly1305.
- DCO support requires a TLS-based tunnel, such as SSL/TLS, SSL/TLS+User Auth, or User Auth.
- DCO support is only present in OpenVPN 2.6.0 and later.
- DCO is only compatible with UDP, it cannot be used with TCP.
- DCO is not yet able to utilize internal routing in OpenVPN (`iroute`). This means that although remote access use cases work, and site-to-site setups with one client per server work, it does not yet function with multiple site-to-site clients on a single server which require LAN-to-LAN routing.
- Using a `/30` or smaller tunnel network for peer-to-peer tunnels (one server with one client) is not compatible with DCO. There are problems with the code for this mode in OpenVPN which can lead to failed connections and instability.
- Compression is not supported with DCO. The GUI disables compression options when DCO is enabled for an instance, but for a client instance the server could still push a compression option which would make the client fail to pass traffic.
- Some features are not compatible with DCO or are not relevant with DCO. These options include:
  - Explicit exit notify
  - Inactivity timeouts
  - UDP fast I/O
  - Send/receive buffer sizes
- Per-peer data usage is not tracked properly.

  Until this is resolved peer data usage on the OpenVPN status page will not reflect the actual amount of data transferred between peers.

DCO and Routing

DCO does not currently honor internal routes from client-specific overrides (i.e. `iroute`) for multiple site-to-site clients on a single server, but it does honor kernel route destinations that would normally be ignored by non-DCO OpenVPN.

Assign clients static addresses in overrides (after patching #13274) and then setup custom routes in OpenVPN custom options with complete destinations defined or even setup FRR and exchange routes via BGP.

DCO and Hardware Cryptographic Acceleration

For optimal performance with DCO, ensure a hardware cryptographic accelerator is present and enabled.

See also:

- *Cryptographic Accelerator Support*
- *Cryptographic Hardware*

QAT currently offers the highest performance for AES-256-GCM. If the hardware supports QAT, enable QAT.

If there is no QAT device available but the CPU supports SIMD instruction sets, then enable IPsec-MB and use AES-GCM, ChaCha20-Poly1305, or even AES-CBC. This can also benefit uses of these ciphers which are not yet accelerated by QAT.

If the hardware does not support QAT or IPsec-MB but it does support AES-NI, ensure the AES-NI kernel module is **loaded** for optimal performance with AES-256-GCM. Though OpenSSL can utilize AES-NI without the module loaded, performance is poor in that state and can even be slower than with DCO disabled.

Note: pfSense Plus software supports ChaCha20-Poly1305 with OpenVPN DCO, but currently only IPsec-MB can accelerate that algorithm. At this time, neither AES-NI nor QAT can accelerate ChaCha20-Poly1305. Some newer QAT hardware may be capable of accelerating ChaCha20-Poly1305, but the current QAT drivers do not yet include support for that encryption algorithm.

20.7.2 OpenVPN Configuration Options

This section describes available options for use with OpenVPN for servers, clients, and custom options.

Server Configuration Options

These options are available in one or more modes for OpenVPN server instances, managed from **VPN > OpenVPN**, on the **Servers** tab.

Note: The options available to clients overlap significantly, and differences are called out where appropriate. See *Client Configuration Options* later in this document for details.

General Information

Description

Enter a description for this VPN instance, for reference.

Disabled

Check this box and click **Save** to retain the configuration, but not enable this instance. The firewall will stop the process for this instance, which will disconnect all peers from the VPN. Any other active instances are unaffected.

Unique VPN ID

A read-only field which shows the internal VPN ID and interface name for this OpenVPN instance.

Mode Configuration

Server Mode

The role for the server, which specifies how peers connect to a server instance. Changing this also affects which options the GUI displays on the rest of the page.

Peer to Peer (SSL/TLS)
A connection between local and remote networks that is secured by SSL/TLS.

This choice offers increased security as well as the ability for the server to push configuration commands to the remote peer router when using a 1:many style setup. Remote peer routers can also have certificates revoked to remove access if they become compromised.

Peer to Peer (Shared Key)
A connection between local and remote networks that is secured by a single shared key known to both peers.

This choice is easier to setup, but is less secure. If a shared key is compromised, a new key must be generated and then copied to any router or client using the old shared key. This mode requires a separate server instance for each client.

Danger: Shared key mode has been deprecated by OpenVPN as it is no longer considered sufficiently secure for modern requirements.

Shared key mode will be removed from future versions of OpenVPN. Users **should not** create any new shared key tunnels and should **immediately** convert any existing shared key tunnels to SSL/TLS mode.

When an SSL/TLS instance is configured with a `/30` tunnel network it behaves in a similar manner to shared key mode. The primary difference is the need to create and distribute the certificate structure to peers. See *OpenVPN Site-to-Site Configuration Example with SSL/TLS* for information on configuring OpenVPN in SSL/TLS mode.

Remote Access (SSL/TLS)
A mobile client setup with per-user X.509 certificates.

As with the peer-to-peer SSL/TLS connection type, using this method offers increased security as well as the ability for the server to push configuration commands to clients. Mobile clients can also

have keys revoked to remove access if a key is compromised, such as a stolen or misplaced phone or laptop.

Remote Access (User Auth)
A remote access server configuration that does not use certificates, but requires the end user to supply a username and password to authenticate.

This is less secure than using certificates, but simpler to deploy as every client will use the same configuration file and only their credentials are different.

Remote Access (SSL/TLS + User Auth)
Requires SSL/TLS and user authentication to connect.

This is the most secure choice available. Not only does it get the benefits of other SSL/TLS choices, but it also requires a username and password from the client when it connects. Client access can be removed not only by revoking the certificate, but also by changing the password. Also, if a compromised key is not immediately discovered, the danger is lessened because it is unlikely that the attacker has the keys and the password.

The OpenVPN wizard uses this mode when it configures a remote access VPN.

DCO (Plus Only)

Check **Enable Data Channel Offload (DCO) for this instance** to enable *OpenVPN Data Channel Offload (DCO)*.

DCO is a pfSense Plus exclusive feature that can potentially increase performance of OpenVPN well beyond the capabilities of traditional OpenVPN connections.

To be compatible with DCO the instance must use SSL/TLS in client/server mode. This can either be remote access or peer-to-peer so long as the tunnel network is large enough for multiple clients (e.g. `/24`).

DCO can be enabled on one or more peers but the greatest speed increase comes when all peers have DCO enabled.

Warning: Several OpenVPN options are not compatible with DCO, which are noted on *OpenVPN Data Channel Offload (DCO)* and elsewhere in the documentation where relevant.

Note: Some OpenVPN features and use cases are not compatible with DCO. See *Limitations* for a list of known DCO limitations.

Backend for authentication

One or more authentication servers to use when checking user credentials. This can be the *Local Database* (user manager) or it can be a RADIUS or LDAP server configured in the user manager.

Selecting multiple entries will use each one in turn. If authentication against an entry fails, the VPN will try the next server. It will continue this process until it has tried all selected entries.

This field is only present when using a **Server Mode** which requires user authentication.

Device Mode

OpenVPN can run in one of two device modes: *tun* or *tap*:

tun
Works on OSI layer 3 and performs routing on point-to-point interfaces.

tap
Can work at OSI layer 2 and can perform both routing and bridging if necessary.

Note: Not all clients support *tap* mode. Clients such as those found on Android and iOS only support *tun* mode in the apps most people can use. Some Android and iOS OpenVPN apps that require rooting or jailbreaking a device do support *tap*, but the consequences of doing so can be a bit too high for most users.

Endpoint Configuration

Protocol

The IP protocol clients will use to connect to this VPN.

UDP on IPv4/IPv6 only
UDP is the most reliable and fastest choice for running OpenVPN, and the best practice is to always use UDP when possible.

Connectionless protocols such as UDP are always the best practice to use when tunneling traffic.

This mode binds to a single interface and limits OpenVPN to only accepting IPv4 or IPv6 exclusively, not both at the same time.

TCP on IPv4/IPv6 only
Using TCP for a VPN is slower and can be more problematic. In some rare cases TCP can be work around limitations of a client environment, such as bypassing firewalls by running an OpenVPN server on TCP port `443`.

TCP is connection oriented with guaranteed delivery, which means any lost packets are retransmitted. This sounds like a good idea on the surface but TCP retransmissions will cause performance to degrade significantly on heavily loaded Internet connections or those with consistent packet loss.

TCP traffic frequently exists within tunnels and it is undesirable to retransmit lost packets of encapsulated VPN traffic. In cases where TCP is wrapped around TCP, such as a VPN tunnel using TCP as a transport protocol, when a packet is lost both the outer and inner lost TCP packets will be re-transmitted. Infrequent occurrences of this will be unnoticeable but recurring loss will cause significantly lower performance than UDP. If the traffic inside the tunnel requires reliable delivery, it will be using a protocol such as TCP which ensures that and will handle its own retransmissions.

This mode binds to a single interface and limits OpenVPN to only accepting IPv4 or IPv6 exclusively, not both at the same time.

> **Warning:** TCP mode is not compatible with DCO.

UDP on IPv4 and IPv6 on all interfaces (multihome)
This option binds to all interfaces using UDP for both IPv4 and IPv6. This mode allows OpenVPN to track incoming connections and respond back to clients using whichever IP address they used when connecting to the VPN. This works ideally with multiple WAN connections.

Since this mode can also work with both IPv4 and IPv6, clients of both types can be served by a single instance.

The primary downside of this mode is that since it binds to all interfaces, the port this instance uses cannot be used by any other service on the firewall. Also, since it does not bind specifically to a specific interface, return routing can be problematic in certain scenarios. Furthermore, outgoing connections will follow the routing table and cannot use specific interface addresses.

TCP on IPv4 and IPv6 on all interfaces (multihome)
Similar to the above, but using TCP instead of UDP.

Interface

Selects the interface, VIP, or failover group that the OpenVPN instance will use when communicating with peers. This also controls which interface the traffic from the instance will exit.

Note: The GUI hides this option if the **Protocol** is set to a multihome selection.

Several types of options are listed in the drop-down for **Interface**, and some have special behavior or use cases:

Interfaces
OpenVPN will bind to the interface address. If the interface is dynamic, such as DHCP, OpenVPN will automatically bind to the new address when it changes.

VIPs
OpenVPN will bind only to the specified VIP, which must be an IP alias or CARP type VIP.

Gateway Groups
For use with failover gateway groups. OpenVPN will bind to the address of the interface which contains the currently active gateway in the group. If that gateway becomes unreachable, it binds to the next one instead, and so on.

Localhost
Useful for multi-WAN deployments. Binding to localhost and utilizing port forwards to accept connections from several interfaces and/or ports is a versatile way to provide redundant OpenVPN connectivity for connecting clients.

Any
Binds to every address on every interface. Though tempting, this option is not recommended. When used with UDP, replies to Internet clients will always exit back out the default gateway WAN, which may be undesirable. If a use case calls for this type of behavior, consider selecting one of the **Protocol** options which uses multihome instead.

Local port

The port number upon which OpenVPN will listen for incoming connections from peers. Firewall rules must allow traffic to this port and this port must be specified in the client configuration.

The port for each server must be unique for each interface when using a standard UDP or TCP **Protocol** choice and must be globally unique if using a multihome **Protocol**.

Cryptographic Settings

This section controls how the VPN encrypts and validates traffic to and from peers.

Shared Key

> **Danger:** Shared key mode has been deprecated by OpenVPN as it is no longer considered sufficiently secure for modern requirements.
>
> **Shared key mode will be removed from future versions of OpenVPN**. Users **should not** create any new shared key tunnels and should **immediately** convert any existing shared key tunnels to SSL/TLS mode.
>
> When an SSL/TLS instance is configured with a `/30` tunnel network it behaves in a similar manner to shared key mode. The primary difference is the need to create and distribute the certificate structure to peers. See *OpenVPN Site-to-Site Configuration Example with SSL/TLS* for information on configuring OpenVPN in SSL/TLS mode.

When using a shared key instance, either check the **Automatically generate a shared key** box to make a new key, or uncheck the box to paste in a shared key from an existing OpenVPN tunnel. When generating the key automatically, return to the edit screen for this tunnel later to obtain the key which may be copied to the remote router.

TLS Authentication

TLS, or Transport Layer Security, can provide session authentication and encryption to ensure the validity of peers and to protect the control channel.

> **Warning:** When using an SSL/TLS mode the best practice is to use TLS Authentication. In addition to the added security benefit from the key requirement, a TLS key also protects against some SSL-based attacks such as Heartbleed which could otherwise compromise the VPN using the control channel.

Use a TLS Key
: Check the box to make the VPN utilize a TLS key. When unchecked the GUI hides the remaining related options.

Automatically generate a shared TLS authentication key
: The GUI offers this option when there is no existing TLS key. Leave this checked so the firewall will generate a new TLS key automatically when the instance is saved. Otherwise, uncheck the box to display the **TLS Key** field and paste in a TLS key.

  When generating the key automatically, return to the edit screen for this tunnel later to obtain the key, then copy the key to the remote peer.

TLS Key
: A text area containing the TLS key for this instance. This type of key is specific to OpenVPN and is not the same type of key used for an OpenSSL certificate.

  Tip: To generate a new key manually, use the command `openvpn --genkey secret /dev/stdout` from a shell command prompt (SSH, console, or GUI). On systems with older versions of OpenVPN, use `openvpn --genkey --secret /dev/stdout` instead.

TLS Key Usage Mode

TLS Authentication
In *TLS Authentication* mode OpenVPN uses the TLS key for HMAC authentication of control channel packets, protecting the peers from unauthorized connections.

TLS Encryption and Authentication
In *TLS Encryption and Authentication* mode OpenVPN uses the key for authentication, as above, but it also uses the key to encrypt control channel communication. This provides increased privacy and traffic control channel obfuscation.

Tip: In some cases this can also help OpenVPN avoid detection by network systems which identify OpenVPN traffic by its control packets.

TLS keydir Direction
The direction in which this VPN endpoint uses the TLS key. The TLS Key Direction must be set to complementary values on the server and clients. The default behavior uses `0` on server instances and `1` on client instances.

For example, if the server is set to `0`, clients must be set to `1`. Both peers may omit the direction in which case the TLS Key will be used bidirectionally.

Peer Certificate Authority

Select the certificate authority which signed the client or peer certificate(s) for this OpenVPN server instance.

Tip: If there are no entries in this list, first import or generate a certificate authority under **System > Certificates**, on the **CAs** tab.

Peer Certificate Revocation List

This optional field is for the Certificate Revocation List (CRL) this tunnel will use to check the validity of peer certificates.

A CRL is a list of certificates signed by a CA which are no longer valid. This could be due to a certificate being compromised or lost, such as from a stolen laptop, spyware infection, etc.

Tip: If there are no entries in this list, first import or generate a CRL at **System > Certificates**, on the **Certificate Revocation** tab.

OCSP Check

When set, OpenVPN will attempt to confirm client certificate validity using Online Certificate Status Protocol (OCSP) against the site listed in the **OCSP URL** field.

Server Certificate

The certificate used by the VPN instance to identify itself to peers. This certificate must contain appropriate properties marking it as a server certificate and not a user or client certificate.

Tip: If there are no entries in this list, first import or generate a certificate under **System > Certificates**, on the **Certificates** tab.

DH Parameters Length

The Diffie-Hellman (DH) key exchange parameters are used for establishing a secure communications channel. They may be regenerated at any time, and they are not specific to an OpenVPN instance. When importing an existing OpenVPN configuration these parameters do not need to be copied from the previous server nor does it require generating new parameters. The length of the desired DH parameters may be chosen from the drop-down box, either *1024*, *2048*, or *4096*. There is an additional choice for *ECDH Only* which disables traditional DH parameters and uses only ECDH.

Note: Due to the heavy computation involved in generating DH keys, the firewall contains a pre-generated set of keys for several common lengths as specified in RFC 7919. The DH group values specified in the RFC have been audited for security and are the safest values for use by end-users.

Should a use case require custom DH keys, generate new DH parameters manually by using the following shell commands:

```
# /usr/bin/openssl dhparam 2048 > /etc/dh-parameters.2048
# /usr/bin/openssl dhparam 3072 > /etc/dh-parameters.3072
# /usr/bin/openssl dhparam 4096 > /etc/dh-parameters.4096
```

ECDH Curve

Configures a specific elliptic curve to use for Elliptic Curve Diffie-Hellman key exchanges. This is only for use with ECDH TLS encryption.

OpenVPN uses the curve from the server certificate by default when configured with an ECDSA certificate. Otherwise, OpenVPN uses *secp384r1* as a fallback.

Encryption algorithm

These options define the cryptographic ciphers OpenVPN will use for this VPN.

Warning: At this time the only algorithm compatible with *OpenVPN Data Channel Offload (DCO)* is `AES-256-GCM`. When DCO is active these options are hidden to prevent invalid selections.

Data Encryption Negotiation
When set, OpenVPN will attempt to negotiate a compatible set of acceptable cryptographic data encryption algorithms from those selected in the **Data Encryption Algorithms** list.

This allows the client and server to agree on the most preferable cipher available without limiting the VPN to a single cipher. Legacy clients can still connect so long as the cipher they use is present in the list.

Note: Disabling this feature is deprecated. The option remains as a mechanism for legacy compatibility but it should not be disabled unless absolutely necessary.

Data Encryption Algorithms

The list of Data Encryption Algorithms OpenVPN may use for this VPN, in order of preference. The default selection uses AES-GCM in 256 and 128 bit varieties as well as ChaCha20-Poly135.

The best practice is to use AEAD ciphers such as AES-GCM and ChaCha20-Poly135. These ciphers combine encryption and authentication and thus do not require a separate hash algorithm. Aside from offering strong security, they are typically much faster than other ciphers as well.

Note: This feature is only supported in client/server mode, which means it only works with SSL/TLS modes where the tunnel network is large enough for multiple clients (e.g. larger than a `/30`).

In shared key mode or when using a `/30` tunnel network, OpenVPN only uses the value of **Fallback Data Encryption Algorithm**.

Fallback Data Encryption Algorithm

The Data Encryption Algorithm OpenVPN will use when it cannot negotiate an algorithm automatically. OpenVPN uses this value for shared key tunnels and for SSL/TLS configurations only capable of using a single client (`/30` tunnel network).

OpenVPN also uses this algorithm for older legacy clients which not only cannot negotiate a data encryption algorithm but have been compiled for a "small footprint", such as embedded devices.

The default is *AES-128-CBC*, which is AES 128 bit Cipher Block Chaining. This is a fine choice for most scenarios.

Auth Digest Algorithm

Selects the message digest algorithm OpenVPN uses for HMAC authentication of incoming packets. This is used for the data channel and if also for the control channel when the tunnel uses a TLS key. The GUI default of SHA256 is a good balance of security and speed.

When using AEAD ciphers such as AES-GCM, OpenVPN ignores this value for the data channel since AEAD ciphers already perform authentication. Even with an AEAD cipher, OpenVPN still uses this algorithm to authenticate the control channel when the tunnel uses a TLS key.

Note: OpenVPN defaults to SHA1 when this option omitted from its configuration. Unless both sides are set to a known value, use SHA1 here.

Certificate Depth

This option limits the valid length of a certificate chain. The default value limits a chain to *One (Client+Server)*. With that value, if an unauthorized intermediate CA signs a certificate, certificates signed by the rogue intermediate would fail validation. In cases when the certificate stricture requires chaining with intermediates, raise this limit to accommodate the longest allowed chain.

Strict User-CN Matching

Controls whether the firewall will enforce a strict match between the username supplied by the user and the Common Name of their user certificate when the firewall authenticates a user. When enabled, authentication fails if the two values do not match.

This prevents users from using their own credentials with the certificate from a different user and vice versa.

Client Certificate Key Usage Validation

When set, the authentication process verifies that a certificate supplied by a client contains the appropriate certificate properties to act as a client. This means that the certificate must include the extended key usage attribute for "TLS Web Client Authentication".

This prevents using certificates made for different purposes, such as e-mail signing or acting only as a server, from being used as a VPN client certificate.

Tunnel Settings

The tunnel settings section governs how traffic flows between the server and clients, including routing and compression.

IPv4/IPv6 Tunnel Network

These are the subnets used by the VPN. The exact usage depends on the mode and size of the subnet. The firewall uses these addresses for direct communication between tunnel endpoints even when connecting two existing remote networks. The value must be an unused, non-overlapping subnet. It must not be in use locally or at any remote site. One or both of **IPv4 Tunnel Network** and **IPv6 Tunnel Network** may be entered, or in the case of a tap bridge, neither.

For SSL/TLS modes with subnets large enough for multiple clients (e.g. **IPv4 Tunnel Network** is larger than `/30`), OpenVPN uses a client/server mode. In this situation, these values are the pools of addresses the OpenVPN server assigns to clients. The server end of the OpenVPN configuration will use the first address in this pool for itself, and assign additional addresses to connected clients as needed. The specific method of assignment varies based on the chosen value for **Topology**. In OpenVPN client/server mode the server can push settings to clients, and client-specific overrides can influence how clients behave. For site-to-site VPNs in this mode, an override must contain **IPv4/6 Remote Network/s** values which route subnets to specific clients (`iroute`).

For a site-to-site SSL/TLS server using IPv4 and an **IPv4 Tunnel Network** value of `x.x.x.x/30`, or a shared key server, OpenVPN uses peer-to-peer mode. In peer-to-peer mode, each server can only have one client. In this mode, clients do not require client-specific overrides or `iroutes` configuration, however, the server also cannot push routes or settings to the client.

Warning: These specific types of peer-to-peer modes are not compatible with *OpenVPN Data Channel Offload (DCO)*.

This field also accepts the name of a network type alias but it must only contain a single entry.

See also:

See *OpenVPN Site-to-Site Configuration Example with SSL/TLS* for more information on a site-to-multi-site example using a large tunnel network and `iroutes`.

Bridging Options

When using *tap* mode for a remote access SSL/TLS VPN, the GUI offers additional options to control bridging behavior in OpenVPN and client address assignment.

See also:

Bridging OpenVPN Connections to Local Networks

Bridge DHCP
When selected, OpenVPN passes through DHCP to the bridged. In the most common scenario, this is *LAN*.

Using this method connecting clients receive IP addresses from the same DHCP pool used by clients on the LAN.

Bridge Interface
This setting indicates to OpenVPN which interface will be used for the bridge. In most cases this is *LAN*.

> **Warning:** This does not create a bridge in the operating system, that must be done separately.

This option controls which existing IP address and subnet mask are used by OpenVPN for the bridge. Setting this to *none* will cause the **Server Bridge DHCP** settings below to be ignored.

Bridge Route Gateway
Makes OpenVPN push the **Bridge Interface** IPv4 address to connecting clients as a route gateway.

When the **IPv4 Tunnel Network** in OpenVPN is empty for a bridged VPN, connecting clients cannot automatically determine a server-side gateway for use with routes pushed to clients by the server.

Server Bridge DHCP Start/End
Defines a DHCP range from which OpenVPN can assign addresses to clients. If these settings are left blank, OpenVPN passes DHCP through to the bridge interface and it ignores the interface setting above.

When set, this range should be within the same subnet as the **Bridge Interface** but it should not overlap an existing in-use portion of the subnet, such as the current DHCP pool.

This allows a range of IP addresses to be set aside for use only by OpenVPN clients so they may be contained within a portion of the internal network rather than consuming IP addresses from the existing DHCP pool.

Redirect IPv4/IPv6 Gateway

When a **Redirect IPv4/IPv6 Gateway** option is selected the server pushes a message to clients instructing them to forward *all* traffic for that address family, including Internet traffic, over the VPN tunnel.

This option only works in SSL/TLS client/server modes (tunnel network larger than `/30`).

IPv4/IPv6 Local network(s)

These fields specify local networks reachable by VPN clients, if any. Entries must be in CIDR or prefix format (e.g. `192.168.56.0/24`) and they can be a host or network type alias name. The server pushes a route for these networks to clients when they connect.

To specify multiple subnets of a particular address family, enter the subnets separated by a comma, e.g. `192.168.2.0/24, 192.168.56.0/24` or use an alias.

This function relies upon the ability to push routes to the client. For IPv4 it is only valid in SSL/TLS client/server mode with a tunnel network larger than `/30`. It will always work for IPv6 provided the VPN does not use a similar too-small prefix.

Warning: If the server does not push any routes, clients will not receive a remote gateway value, which they may require. For example, pfSense® software will use the remote gateway value when creating a gateway for gateway monitoring and policy routing. If the server does not need to push any routes to the client, use a custom option to push the gateway value to clients, for example: `remote-gateway x.x.x.1`; where the IP address is the IP address of the tunnel on the server.

IPv4/IPv6 Remote Network

This option only appears for Peer-to-Peer type connection and it is not available for remote access servers.

OpenVPN adds operating system route table entries for the specified subnets which hand the traffic over to this OpenVPN instance for processing. Entries must be in CIDR or prefix format (e.g. `192.168.56.0/24`) and they can be a host or network type alias name.

To specify multiple subnets of a particular address family, enter the subnets separated by a comma, e.g. `192.168.2.0/24, 192.168.56.0/24` or use an alias.

For Peer-to-peer SSL/TLS servers in client/server mode (tunnel network larger than `/30`), each network listed in this field **must** also be present in a *client specific override* as a remote network entry for a client. Without that entry, OpenVPN has no way to determine which client should receive traffic for a network. The remote networks listed here in the server configuration inform the operating system routing table to deliver the traffic to OpenVPN, while the entries in an override associate networks with specific remote clients.

Shared key and SSL/TLS servers in peer-to-peer mode (`/30` tunnel network) do not need overrides as there can only be a single client per server.

Concurrent Connections

Specifies the number of clients that may be simultaneously connected to this OpenVPN server instance at any given time.

> **Warning:** This is a collective limit for **all** connected clients, not a per-user setting.

Compression

> **Warning:** Compression for encrypted traffic is dangerous and should be disabled when possible!
>
> The OpenVPN project has deprecated compression support and they will remove it from future versions.
>
> Read the text in this section carefully! Compression can potentially increase throughput but may allow an attacker to extract secrets if they can control compressed plain text traversing the VPN (e.g. HTTP). Before enabling compression, consult information about the VORACLE, CRIME, TIME, and BREACH attacks against TLS to decide if the use case for this specific VPN is vulnerable to attack.

When compression is enabled OpenVPN attempts to compress traffic crossing VPN before it performs encryption. This has a potential to save bandwidth usage for some traffic at the expense of decreased security and increased CPU utilization on both the server and client.

For high speed connections such as the usage of OpenVPN across a LAN, high speed low/latency WAN, or local wireless network, compression adds unnecessary overhead as the delay added by the compression may be more than the delay saved in transmitting the traffic.

If nearly all of the traffic crossing the OpenVPN connection is already encrypted (such as SSH, SCP, HTTPS, among many other protocols), do not enable LZO compression because encrypted data is not compressible and the LZO compression will cause slightly more data to be transferred than would be without compression. The same is true if the VPN traffic is almost entirely data that is already compressed.

Allow Compression
: Controls whether or not compression is allowed on the VPN, and how it is handled.

  Decompress incoming, do not compress outgoing
  : Asymmetric compression support. Accepts compressed packets from the remote peer but will not perform any compression on outgoing packets. This behavior allows for a smoother transition when peers use older versions of OpenVPN.

  Refuse any non-stub compression
  : When set, OpenVPN will refuse any attempt to compress packets. Compressed packets from peers are dropped.

  Compress packets
  : When set, OpenVPN allows compression and both accepts compressed packets from peers and also compresses packets before sending them to peers.

Compression
: This selector controls the handling of LZO compression for this OpenVPN instance when the settings allow compression. There are several possible settings each with slightly different behavior.

  Disable Compression
  : Omits compression directives from the OpenVPN configuration entirely. OpenVPN

will not perform compression, but other methods such as Client-Specific overrides or advanced options may override this behavior.

Disable Compression, retain compression packet framing
OpenVPN will not perform compression, but keeps the packet framing for compression. This allows compression to be changed later, for example by pushed settings. When set this way, OpenVPN will advertise support for LZ4 and LZO compression to peers using `IV_` variables. Always adds one extra framing byte to packets for compression.

Enable Compression (stub)
Similar to the previous setting, but it does not advertise compression support to peers.

Enable Compression (stub v2)
Similar to the previous setting but it utilizes a better framing that does not increase packet overhead when it cannot compress a packet.

LZ4 Compression
A newer compression algorithm offering best compression performance and lowest CPU consumption. May not be supported by older clients.

LZ4 Compression v2
The same as LZ4 compression but it utilizes a better framing that does not increase packet overhead when it cannot compress a packet.

LZO Compression
An older compression algorithm with wider support, especially from older clients.

Omit Preference + Disable Adaptive LZO Compression
Does not specify a compression directive in the OpenVPN configuration and also explicitly disables adaptive compression.

Adaptive LZO Compression
OpenVPN will periodically check the efficiency of data compression for VPN traffic and disable compression if it is performing poorly. This prevents OpenVPN from compressing already compressed or encrypted data.

LZO Compression (Legacy Style)
Enables LZO compression using the deprecated `comp-lzo yes` directive. This can help interoperation with older legacy clients which cannot be updated. When present in the configuration, the server can push a different value to clients as needed.

No LZO Compression (Legacy Style)
Disables LZO compression using the deprecated `comp-lzo no` directive. This can help interoperation with older legacy clients which cannot be updated. When present in the configuration, the server can push a different value to clients as needed.

Push Compression
When set, OpenVPN will push the selected compression settings to connecting clients.

Type-of-Service

When this option is enabled OpenVPN sets the Type-of-Service (TOS) IP header value of tunnel packets to match the encapsulated packet value. This may cause important traffic to be handled faster over the tunnel by intermediate hops at the cost of minor information disclosure.

The most common example is VoIP or video traffic. If the TOS bit is set to reflect the priority of the traffic it can help QoS along the path, but someone intercepting the traffic could see the TOS bit and gain some knowledge about the contents of the traffic inside the tunnel. For those who rely on TOS bits for QoS, the benefit may outweigh the information leak.

Inter-Client Communication

This option controls whether or not connected clients are able to communicate with one another. To allow this behavior, check the option. When unchecked, clients can only send traffic to the server or destinations beyond the server such as routed networks or the Internet.

Typically in remote access style deployments it is unnecessary for clients to reach each other, but there are use cases when it can be helpful. One example is remote web developers working together and running test servers on their local workstations. With this option activated, the developers can reach the other self-hosted test servers for collaborative development.

Duplicate Connections

Controls whether or not OpenVPN will allow multiple connections from the same user to work simultaneously.

This is primarily for security reasons so the same certificate cannot be used by multiple people or devices simultaneously. The best practice is to use a unique certificate for each connecting device, or at least for each user. Otherwise, if a client is compromised there is no way to revoke that one client alone; certificates must be reissued to all clients that share the same certificate.

By default OpenVPN will associate an IP address from its tunnel network with a specific certificate or username for a given session. If the same certificate connects again, the server assigns it the same IP address and will either disconnect the first client or cause an IP conflict where neither client will receive proper data.

If a setup that uses the same certificate in multiple locations is an absolute requirement and cannot be avoided, check **Duplicate Connections** to allow the non-standard behavior of multiple clients using the same certificate or username.

Duplicate Connection Limit

When active, the server will limit the number of simultaneous connections from the same client. New connections from the same client that exceed this limit will be denied by the server. To free up unused sessions and allow new connections from the same client more quickly, set lower values for **Ping settings**.

Note: Due to unstable connectivity in practice, clients may sometimes initially create multiple sessions on the server when establishing the tunnel. These extra temporary sessions will count towards the limit until they time out.

Client Settings

These settings control behavior of clients connecting to this sever.

Dynamic IP

Checking this box adds the `float` configuration option to the OpenVPN configuration. This allows clients to retain their connection if their IP address changes, similar to MOBIKE for IKEv2 in IPsec.

For clients on Internet connections where the IP address changes frequently, or mobile users who commonly move between different Internet connections, check this option for more stable connectivity. Where the client IP address is static or rarely changes, not using this option offers a small security improvement.

Topology

Sets the method OpenVPN uses to allocate addresses for clients in a client/server setup on *tun* device mode VPNs. The **Topology** option is relevant only when supplying a virtual adapter IP address to clients using *tun* mode on IPv4. Some clients may require this even for IPv6, such as OpenVPN Connect, though in reality IPv6 always runs with a subnet topology even when IPv4 uses *net30*. OpenVPN instances using *tap* mode always use *subnet* topology as well.

subnet
: Uses the first IP address in the subnet for the server and allocates one IP address per client in a single shared subnet.

  By default OpenVPN on pfSense® software prefers a topology style of *subnet* when using a **Device Mode** of *tun*. This is the only available style when using the *tap* **Device Mode**.

  Note: Some very old clients may not support this mode on certain platforms, such as before OpenVPN 2.1.x which as of this writing was over 10 years old, or before 2.3.x which was around 8 years ago. These clients are rare in practice on modern environments.

  Always make sure the client and associated drivers are fully up-to-date when using a *subnet* topology.

  ---

net30
: OpenVPN allocates a `/30` CIDR network (four IP addresses, two usable) to each connecting client, including one for the server itself. This style has a longer history, but can be confusing for administrators and users alike.

  Warning: The OpenVPN project has declared the *net30* style as deprecated, indicating it will be removed in future versions. Avoid using it when possible.

Ping Settings

Inactive

The amount of time, in seconds, which a client can be inactive before OpenVPN disconnects it for inactivity. OpenVPN bases activity on the last incoming or outgoing data channel packet, not control channel packets.

The default value is `300`. A value of `0` disables this feature.

Tip: For Peer-to-Peer SSL/TLS servers in client/server mode, the best practice is to set this to `0` so that site-to-site VPN tunnels stay up indefinitely.

Warning: This option is ignored in peer-to-peer modes, such as shared key mode and SSL/TLS with a blank or `/30` tunnel network. In those cases the option can cause the process to exit and not restart, resulting in a loss of service.

This option is not compatible with *OpenVPN Data Channel Offload (DCO)*.

Ping Method

The **Ping Method** controls OpenVPN monitoring of peers through the control channel and how it deals with unresponsive peers. There are two methods available: **Keepalive** and **Ping**:

Use Keepalive Helper
This method uses the **Interval** and **Timeout** values to automatically set common useful values for OpenVPN `ping` and `ping-restart` rather than defining behavior manually. The values are used locally and pushed to peers when possible.

Note: This is the best practice in nearly all use cases, as most environments do not necessitate the extra complexity of configuring the behavior manually.

Interval
Sets the interval, in seconds, between control channel pings as well as the idle period for the data channel before OpenVPN will send a control channel ping. The default value is `10` seconds.

Note: All peers must send pings at the expected intervals as OpenVPN does not echo responses.

Timeout
The amount of time, in seconds, OpenVPN will wait for a ping from a peer before it considers the peer to be down. The default value is `60` seconds.

In client/server mode, on the server this value is multiplied by `2` and it disconnects an individual session for a client; on the client the value is used as-is and it restarts the VPN process. In peer-to-peer mode this restarts the VPN process.

Define Ping Manually
This method offers more flexibility in how OpenVPN will send pings and expect responses from peers, but it is also more complicated.

Ping
Sets the interval, in seconds, between control channel pings as well as the idle period for the data channel before OpenVPN will send a control channel ping. The default value is `10` seconds.

Push ping to client
Controls whether or not the value of **Ping** is pushed to clients when OpenVPN is in client/server mode.

Ping restart or exit
Chooses between whether the OpenVPN process will restart on failure or exit.

ping-restart
In client/server mode, on a server this disconnects a client session when the client does not respond. In client/server mode on the client, as well as in peer-to-peer mode, it restarts the OpenVPN process when a peer fails to respond.

ping-exit
Causes the VPN process to exit entirely when a peer fails to respond.

> **Warning:** The VPN will not recover automatically when using this option. It requires manual intervention to start the VPN process again.

Ping restart or exit seconds
The amount of time, in seconds, OpenVPN will wait for a ping from a peer before it considers the peer to be down. The default value is `60` seconds.

Push to client
Controls whether or not **Ping restart or exit** and its associated value are pushed to clients when OpenVPN is in client/server mode.

Advanced Client Settings

DNS Default Domain

Configures a default domain name which clients will append to DNS requests. This can be helpful to ensure name resolution works properly for hosts on the local network where DNS name resolution is used.

For Microsoft Active Directory environments, this would usually be the Active Directory domain name.

DNS servers

When checked, the GUI allows configuring up to four DNS servers for use by clients while connected to the VPN.

For Microsoft Active Directory environments, this is typically the Active Directory Domain Controllers or DNS servers for proper name resolution and authentication when connected via OpenVPN.

Block Outside DNS

Makes Windows 10 clients block access to DNS server except across OpenVPN while connected, forcing clients to use only VPN DNS servers.

This is only relevant on Windows 10 clients using OpenVPN version 2.3.9 and later as they are the only clients prone to leak DNS requests in this way. The option has no effect on other platforms and they will ignore the directive.

Force DNS Cache Update

When checked, the OpenVPN server pushes a set of commands to Windows clients which flush and restart DNS caching to improve client handling of updated DNS servers from the VPN.

NTP servers

When checked, the GUI allows configuring one or two NTP servers which OpenVPN will push to clients for time synchronization. These values can be an IP address or FQDN.

NetBIOS Options

The **Enable NetBIOS over TCP/IP** option controls whether or not the GUI displays several other NetBIOS and WINS related options.

Node Type

The NetBIOS node type controls how Windows systems function when resolving NetBIOS names. The best practice is to leave this to *none* to accept the default value from Windows.

The available options include:

b-node
: Use broadcasts for NetBIOS name resolution. This would only be used in the case of a *tap* bridge as otherwise OpenVPN does not support broadcast messages.

p-node
: Point-to-point name queries to a WINS server. WINS has been deprecated on modern networks, so this option is not useful in most Windows networks.

m-node
: Broadcast then query name server. Similar to *b-node* but will fall back to DNS.

h-node
: Query name server first, then use broadcast. This option is the most likely to succeed in a current network with proper, functional, DNS.

Scope ID

A NetBIOS Scope ID provides an extended naming service for NetBIOS over TCP/IP. The NetBIOS scope ID isolates NetBIOS traffic on a single network to only those nodes with the same NetBIOS scope ID.

WINS Servers

Checking this box allows defining two WINS servers which provide name resolution for clients accessing and browsing NetBIOS resources across the VPN. WINS has been largely deprecated and removed from use, so it is unlikely that most modern environments would benefit from this behavior.

Advanced Options

Custom options

While the GUI supports many commonly used options, OpenVPN contains many more options that are unavailable in the GUI which certain use cases may require.

Custom options may be added in using the **Custom option** box with **each directive separated by a semicolon** (``;``). The firewall will pass the custom directives to OpenVPN.

See also:

These options are described further in *Custom Configuration Options*.

> **Warning:** Use with extreme caution. Due to the nature of how this field operates, the firewall cannot validate its contents. Invalid combinations of directives will cause the OpenVPN instance to fail.

Username as Common Name

Controls whether or not OpenVPN will use the username given by the client in place of the certificate common name for purposes such as determining Client Specific Overrides. This is only relevant when user authentication is enabled. This is typically the best practice, but not a requirement.

UDP Fast I/O

Controls whether or not OpenVPN will use fast I/O operations with UDP writes to its *tun* or *tap* device. This behavior optimizes the packet write event loop, improving CPU efficiency by 5% to 10%.

> **Warning:** OpenVPN considers this option experimental and it may not be supported on all platforms. This option is not compatible with OpenVPN bandwidth limiting.
>
> This option is also not compatible with *OpenVPN Data Channel Offload (DCO)*.

Exit Notify

Controls whether or not OpenVPN will send an explicit exit notification to connected UDP clients or peers when restarting or shutting down. This notification allows peers to immediately disconnect rather than wait for a timeout. This is only relevant to UDP modes as TCP natively supports closing connections.

In SSL/TLS Server modes, clients may be directed to reconnect or use the next server.

Disabled
Does not send an exit notification.

Reconnect to this server / Retry Once
In server mode this directs clients to reconnect to the same server. This is useful if there is only one server and it will be available again shortly.

For clients it directs them to retry sending the notification once before giving up.

Reconnect to next server / Retry Twice
In server mode this directs clients to reconnect to the **next** server if the client configuration contains multiple servers. This is useful to nudge clients to an alternate server if this server could be down for an extended period.

For clients it directs them to retry sending the notification twice before giving up.

Warning: The firewall ignores this option in Peer-to-Peer Shared Key mode and in SSL/TLS mode with a blank or `/30` tunnel network as it will cause the server to exit and not restart.

This option is not compatible with *OpenVPN Data Channel Offload (DCO)*.

Send/Receive Buffer

Configures a Send and Receive Buffer size for OpenVPN. The default buffer size can be too small in many cases, depending on hardware and network uplink speeds. Finding the best buffer size can take experimentation. To test the best value for a site, start at *512KiB* and test higher and lower values until testing results in peak performance.

Note: For remote access VPNs this may take experimentation with multiple types of clients on different devices, networks, and so on.

Warning: This option is not compatible with *OpenVPN Data Channel Offload (DCO)*.

Gateway Creation

Controls which types of gateways the firewall will automatically create for this VPN instance when assigned as an interface. The default behavior will create *both* IPv4 and IPv6 gateways but if the VPN will only ever carry one type of traffic, this option can limit that behavior so the GUI will not display an unnecessary gateway entry.

Verbosity level

Configures the amount of detail OpenVPN will log for this instance, which is useful for troubleshooting problems. Higher numbers will result in higher amounts of detail in the log. During normal operation the *default* selection is ideal.

Note: When set to higher levels, the OpenVPN status page and dashboard widget will cause additional logging as they interact with the Management process to poll information from the OpenVPN daemons.

Client Configuration Options

These options are available in one or more modes for OpenVPN client instances, managed from **VPN > OpenVPN**, on the **Clients** tab.

Many of these options are identical to the server options mentioned in *Server Configuration Options*. This section only notes the differences.

Server mode

For client instances, the server mode choices are limited to *Peer to Peer (SSL/TLS)* and *Peer to Peer (Shared Key)*. These choices pair with the server options of the same name and type.

Danger: Shared key mode has been deprecated by OpenVPN as it is no longer considered sufficiently secure for modern requirements.

Shared key mode will be removed from future versions of OpenVPN. Users **should not** create any new shared key tunnels and should **immediately** convert any existing shared key tunnels to SSL/TLS mode.

When an SSL/TLS instance is configured with a `/30` tunnel network it behaves in a similar manner to shared key mode. The primary difference is the need to create and distribute the certificate structure to peers. See *OpenVPN Site-to-Site Configuration Example with SSL/TLS* for information on configuring OpenVPN in SSL/TLS mode.

Interface

This option selects the interface, VIP, or failover group that the OpenVPN client instance will use for outgoing connections.

When a CARP type VIP is selected for the Interface on OpenVPN Client instances, the firewall will stop the OpenVPN instance when the CARP VIP is in a backup state. This prevents the secondary HA node from maintaining invalid routes or attempting to make outbound connections which can interfere with the active connection on the primary HA node.

Note: To ensure that a connection uses out the correct WAN when selecting a WAN which is not the default gateway, add a static route for the server IP address. Depending on the protocol in use and contents of the routing table, the firewall may not be able to send traffic out the correct WAN without a static route.

Local Port

For clients, the local port should be blank in nearly every case so that OpenVPN will use a randomized local port. This behavior is more secure, but some server configurations may require a specific source port.

Server host or address

The IP address or fully qualified domain name for the server.

Note: When using a hostname for the remote server address, OpenVPN will resolve the server host name on each connection attempt.

Server Port

The port on which the server is listening, typically `1194`.

Proxy Settings

Proxy Host or Address
: The IP address or fully qualified domain name for a proxy server through which this client must connect.

Proxy Port
: The port on which the proxy is listening for connections.

Proxy Auth Extra Options
: Extra authentication options. When set to *basic* or *ntlm* the GUI presents **Username** and **Password** fields to configure proxy authentication.

User Authentication Settings

Configures authentication option for SSL/TLS mode. This may be optional, depending on the server configuration.

Username and Password
: The user credentials to send, if required by the server.

Authentication Retry
: When set, OpenVPN will not retry a connection when authentication fails; the OpenVPN process will exit if it receives an authentication failure message instead. The default behavior is to retry authentication.

Cryptographic Settings

The settings in this section are identical to those on their corresponding options on the server side except for the new **Client Certificate** option. This option sets the certificate for use by this client.

Note: The client certificate, its key, and the associated CA certificate must all be imported to the firewall using the certificate manager before OpenVPN can use them.

Shared Key / TLS Authentication

These options work similar to the server side counterparts, but be aware that the key from the server **must be copied here exactly**. Do not generate a new key on the client if the server already has a key.

Limit Outgoing Bandwidth

This option limits the speed of outgoing VPN traffic to the given amount, specified in **bytes per second**. The value must be either empty or between `100` and `100000000`.

OpenVPN will not limit traffic when the field is empty.

Don't Pull Routes

When checked, the client ignores routes pushed from the server. This is useful in cases when the server pushes a default gateway redirect when this client does not need one, or if the server pushes routes for networks that this client prefers to handle in other ways.

Don't Add/Remove Routes

When checked, OpenVPN will not manage route table entries for this VPN. In this case, the routes must be managed manually. Routes that OpenVPN would normally add are instead passed to `--route-up script` using environmental variables.

Pull DNS

If this option is set, the firewall will use DNS servers assigned by the remote OpenVPN server for its own purposes, similar to if it had received a DNS server from a dynamic WAN.

Client Specific Overrides

Client specific overrides define custom settings which apply to only certain clients connecting to an SSL/TLS server in client/server mode. These settings are determined by the way a connecting client authenticates, either by their username or the common name of their certificate.

These options are additive, meaning the client will receive the options pushed by the server configuration and then the options defined on this client-specific override entry. Some settings will override the values received from the server, such as the Tunnel Networks, while others will combine and use both server and local values, such as Local Network definitions.

Tip: The "Prevent this client from receiving any server-defined client settings." option will make the client ignore any pushed settings from the server which are not defined on the override entry.

Client specific overrides are managed at **VPN > OpenVPN** on the **Client Specific Overrides** tab.

Purpose

Depending on the use cases, overrides may be a required part of a deployment, such as a site-to-site VPN with multiple clients connecting to a single server.

Overrides also enable special behavior such as configuring different routes for different clients, static IP addresses when connecting to the VPN, exceptions to default VPN behaviors, and many more scenarios.

Configuration

The following settings are available when configuring client specific overrides.

Description
Text describing the override entry, such as a user or site name, or its purpose.

Disable
Whether or not this override is enabled. When checked, the override is not active.

Common Name
The name of the user which OpenVPN will match when a client connects.

When using SSL/TLS authentication alone this matches the common name field of the certificate.

When using user authentication alone, the common name is undefined by default and will not match anything unless the **Username as Common Name** option is enabled on the OpenVPN server. With that set, this field will match the username.

When SSL/TLS and user authentication are both are active, the behavior is determined by the **Username as Common Name** option on the OpenVPN server. When checked, it matches the username. When unchecked, it matches the common name of the certificate. If multiple users share the same certificate, check that option.

The special name `DEFAULT` will trigger if the connecting user does not match any other existing overrides. This can be useful when adding options which are only possible on overrides, such as **Connection Blocking**.

Connection Blocking
When set, OpenVPN rejects clients matching this override. This can be used as an additional means of blocking a specific user, though this use case should only be temporary.

Note: Do not use this to permanently block a specific user if their credentials have been compromised or terminated. Instead, use a CRL to revoke the client certificate or make changes to the user account such as removing the account or changing its password.

Some administrators use this option to selectively allow clients on specific servers when they share a common CA structure. The best practice is to use a separate certificate structure for each VPN server, but that is not always possible.

Tip: To only allow users with an override to connect, create an override for the `DEFAULT` common name with this option set. With that in place, OpenVPN will reject all clients by default and will allow connections from clients matching other overrides which do not have this option set.

Server List

The OpenVPN servers for which this override will be active. Select one or more OpenVPN instances which will utilize this override. By default, with no entries selected, overrides are active for all servers.

Many use cases may call for using an override with only a specific VPN. For example if a client has a static IP address inside the VPN, that address may only be valid on one VPN server. Attempting to use that static address on a different VPN will fail.

Note: Multiple overrides can use the same common name, but such entries are only useful if they are active on different VPN instances.

IPv4/IPv6 Tunnel Network

A specific static virtual IPv4 network or network type alias with a single entry used for private communications between this client and the server expressed using CIDR notation (e.g. `10.0.8.5/24`).

On a server with *subnet* topology, or for IPv6, the client IP address and the subnet/prefix mask must match the **Tunnel Network** on the server.

On a server with *net30* topology, OpenVPN assumes the first IPv4 network address of the `/30` is the server address and it assigns the second network address to the client.

Note: These options express a preference, **not** a reservation. OpenVPN dynamically allocates addresses to connecting clients near the start of its tunnel network. An override will not prevent another client from using this address if it happens to be assigned the address dynamically.

IPv4/IPv6 Local Network/s

Networks located on the **server** side for which OpenVPN will push routes to this client. This can be a comma-separated list of networks in CIDR notation and it can also be a host or network type alias.

Note: This is functionally identical to the same fields on the OpenVPN server configuration. Values in these fields are added to the lists pushed by the server, so there is no need to duplicate those values here. Only exceptions or differences from the default entries should be in these fields.

IPv4/IPv6 Remote Network/s

Networks which can be reached **through this client**. OpenVPN will internally route traffic destined for these networks to this client (`iroute`).

The remote networks listed in the *server* configuration inform the operating system routing table to deliver the traffic to OpenVPN, while the entries in an override associate networks with specific remote clients.

Warning: Unlike local networks, entries in the remote network fields **must** be set in **both** the OpenVPN server **and** an override. For full routing functionality to a client network, both the operating system routing table and OpenVPN must know how to reach the network.

Redirect Gateway
When set, OpenVPN pushes a default gateway to the client so it will send all of its traffic, including Internet traffic, through this VPN.

Server Definitions
When set, OpenVPN will not push options from the server configuration to this client.

Remove Server Routes
When set, OpenVPN will not push routes to this client, but it will push other options.

DNS Default Domain
When set, the GUI presents a field in sets an alternate default DNS search domain which OpenVPN will push to this client.

DNS Servers
When set, the GUI presents four fields for alternative DNS servers OpenVPN will push to this client.

NTP Servers
When set, the GUI presents two fields for alternative NTP servers OpenVPN will push to this client.

NetBIOS Options
When set, the GUI presents fields for alternate NetBIOS options which OpenVPN will push to this client.

Advanced
Additional custom options for OpenVPN to apply to this client.

Each directive must be separated by a semicolon (`;`).

See also:

These options are described further in *Custom Configuration Options*.

Custom Configuration Options

OpenVPN offers a vast array of configuration options, many more than the most commonly used fields in the GUI. The **Custom Options** box enables using directives in OpenVPN which are not available directly in the GUI.

Warning: Each directive **must** be separated by a semicolon (`;`).

This section covers a few custom options users have found useful, but which are not common enough to add to the GUI. There are many more, and the OpenVPN man page details them all.

Warning: Exercise caution when adding custom options. The GUI cannot perform input validation on directives in this field. If an option is incorrect or invalid, the OpenVPN instance may not start.

View the OpenVPN logs under **Status > System logs** on the **OpenVPN** tab to ensure the options used are valid. Any invalid options will result in a log message, followed by the option that caused the error:

```
Options error: Unrecognized option or missing parameter(s)
```

Additional Servers

The `remote <address> <port> <protocol>` directive specifies servers to which a client can connect. This is primarily used on client instances to define multiple servers for redundancy. Clients will try the server defined in the GUI settings first and then any additional servers in the order given.

The address can be an IP address or FQDN. The port number defaults to `1194` and may be omitted if it is the default. The protocol can be either `udp` or `tcp`, and optionally can end in `4` or `6` to limit an FQDN server to either IPv4 or IPv6 respectively, if DNS contains records for both.

There are two primary strategies for which administrators use this type of configuration. One is for redundancy between multiple servers, and the other is for redundancy between multiple ports. The latter can be important for working around limitations on client networks, such as networks which only allow specific outbound ports. The two strategies can also be mixed as needed.

To specify multiple additional servers, consider a set of entries such as this:

```
remote vpn2.example.com 1194 udp4;
remote vpn3.example.com 1194 udp4;
remote vpn4.example.com 1194 udp4;
```

Contrast this with a set of servers which are crafted to work around network limitations:

```
remote vpn1.example.com 53 udp;
remote vpn1.example.com 123 udp;
remote vpn1.example.com 443 tcp;
remote vpn1.example.com 80 tcp;
remote vpn1.example.com 8080 tcp;
```

Another way the `remote` directive can be used is in the custom options of a peer-to-peer server instance (shared key or SSL/TLS with a tunnel network of `/30`). If both peers are defined as a server and each has a `remote` directive pointing to the other, then they will attempt connections in both directions and whichever connects first is used. This operates closer to IPsec where both peers can initiate. In practice this is not very useful as it's typically better to have one designated initiator, but there may be a rare use case which calls for this behavior.

The `remote-random` directive tells clients to connect to a random server from the list instead of the next available choice. This is particularly useful when trying to load balance clients between multiple servers, such as with public VPN providers.

Renegotiation Time

The `reneg-sec <seconds>` directive controls how often OpenVPN renegotiates authentication with clients. The default time is `3600` seconds (one hour). In most cases the clients renegotiate and continue on without interruption, however with multi-factor authentication (MFA) this can disrupt clients. With MFA, clients would need to utilize a fresh token each time OpenVPN renegotiates the VPN, which can range from inconvenient to impossible. With MFA mechanisms such as OTP or Google Authenticator there is no mechanism to supply a new code, so the VPN disconnects after an hour and the client must manually reconnect.

In these cases, it is common for administrators to disable the renegotiation:

```
reneg-sec 0;
```

This is less secure, but more convenient than forcing users to reauthenticate once per hour.

Alternately, the time limit can be raised to a higher value which is less inconvenient, such as `28800` (8 hours) for a typical workday, or `86400` (24 hours) to make it once per day.

Recursive Routing

The `allow-recursive-routing` directive allows OpenVPN to send non-OpenVPN traffic to the VPN server itself over the VPN. Certain rare use cases call for this behavior where the VPN server and a public service are both hosted on the same server, but portions of the public service are only available to clients connecting over the VPN. OpenVPN used to allow this by default, but now it must be explicitly enabled by this directive.

Control Pushed Options

The `push-remove <name>` directive selectively filters options pushed by OpenVPN servers. This allows clients to ignore certain directives that would normally be sent by servers, such as routes (`route` or `route-ipv6`), `keepalive`/`ping` values, compression options, default gateway (`redirect-gateway def1`), DNS options, and more.

In a client-specific override context this can be used to skip pushing certain items to a specific client and then supply a new value in its place.

Routing options

Note: Using the custom option box is not necessary to add most routes. To add additional routes for a particular OpenVPN client or server, use the **Local Network** and **Remote Network** boxes, which support multiple networks as comma-separated lists.

The `route` custom configuration option adds routes locally for networks that are reachable *through* the VPN, but is not necessary in most cases as the GUI **Remote Network** fields for IPv4 and IPv6 accomplish the same goal. Some users prefer to enter the routes in this box instead, however. It can also be useful for cases where the routing is ambiguous, such as in bridged VPNs, to manually define specific routes with gateways that cannot be automatically determined by OpenVPN.

The following example adds a route for `10.50.0.0/24`:

```
route 10.50.0.0 255.255.255.0;
```

To add a route with a specific gateway, add it after the netmask:

```
route 10.50.0.0 255.255.255.0 10.0.1.1;
```

To add multiple routes, separate them with a semicolon:

```
route 10.50.0.0 255.255.255.0;
route 10.254.0.0 255.255.255.0;
```

An OpenVPN server configuration using SSL/TLS in client/server mode can push additional routes to clients. The GUI can configure these using the **Local Network** field. To push the routes manually for `10.50.0.0/24` and `10.254.0.0/24` to all clients, use the following custom configuration option:

```
push "route 10.50.0.0 255.255.255.0";
push "route 10.254.0.0 255.255.255.0";
```

Note: Note the placement of the double quotes in these directives.

Redirecting the default gateway

OpenVPN can also redirect the default gateway to the VPN, so all non-local traffic from a client is sent through the VPN. This is great for untrusted local networks such as wireless hotspots, as it provides protection against numerous attacks that are a risk on untrusted networks. This is configurable in the GUI using the **Redirect Gateway** checkbox in the OpenVPN instance configuration.

To do this manually for IPv4, add the following custom option:

```
push "redirect-gateway def1";
```

The same value may be used as a custom option on the client side by entering `redirect-gateway def1` without specifying `push` . (Note the option is the letters `def` followed by the digit *one*, **not** the letter `L`.)

To do the same for IPv6, use:

```
push "redirect-gateway ipv6";
```

20.7.3 OpenVPN Firewall Rules

Permitting traffic to the OpenVPN server

A firewall rule must permit traffic to the OpenVPN server or clients will not be able to connect. Add a rule as follows:

- Navigate to **Firewall > Rules**, **WAN** tab
- Click  to create a new rule at the top of the list
- Set the options as follows:

  Protocol
  UDP

  Source
  any

  Destination
  WAN Address

  Destination port
  `1194`, or whichever port the server is using to listen

  Description
  `Allow traffic to OpenVPN Server`

- Click **Save**
- Click **Apply changes**

This rule is depicted in Figure *OpenVPN Server WAN Rule*.

Fig. 1: OpenVPN Server WAN Rule

If the client source addresses are known and do not change, then the source of the rule could be altered to limit traffic from only those clients. This is more secure than leaving the server exposed to the entire Internet, but that is often

necessary to accommodate clients with dynamic IP addresses, roaming clients, and so on. The risk of leaving the service exposed with most OpenVPN configurations is minimal, especially in cases where OpenVPN servers utilize TLS Authentication. With certificate-based authentication there is less risk of compromise than password-based solutions which can be susceptible to brute forcing. This presumes a lack of security holes in OpenVPN itself, which to date has a solid security track record.

Allowing traffic over OpenVPN Tunnels

By default, all traffic is blocked from entering OpenVPN tunnels. To allow traffic from remote OpenVPN hosts to make connections to resources on the local side through the VPN, add firewall rules under **Firewall > Rules**, on the **OpenVPN** tab.

As with other aspects of the firewall these rules only match traffic coming **into** the firewall from remote sources, they do not control traffic leaving from this firewall. Craft the rules accordingly.

Add an OpenVPN rule which passes all traffic as follows:

- Navigate to **Firewall > Rules**, **OpenVPN** tab
- Click  to create a new rule at the top of the list
- Set the options as follows:

  Protocol
  any

  Source
  any

  Destination
  any

  Description
  `Allow all on OpenVPN`

- Click **Save**
- Click **Apply changes**

To limit the traffic to only specific sources and destinations, adjust the rule(s) as needed. A strict ruleset is more secure, but more difficult to create.

Tip: Rules on the OpenVPN tab apply to **all** OpenVPN server and client instances. The OpenVPN interface may also be assigned (*Assigning OpenVPN Interfaces*) in which case there will be a separate firewall rule tab for that VPN, upon which rules can pass traffic for that specific VPN.

Rules on assigned OpenVPN interface tabs are processed *after* rules on the **OpenVPN** tab. Rules on the **OpenVPN** tab must not pass or block traffic too broadly or the firewall will stop processing before it gets to the assigned interface tab rules.

20.7.4 OpenVPN clients and Internet Access

For OpenVPN Remote Access clients to reach the Internet through the OpenVPN connection using IPv4, Outbound NAT must translate their traffic to a WAN IP address on the firewall.

The default automatic outbound NAT rules cover this scenario. If the firewall is using manual outbound NAT then manual rules must exist to perform outbound NAT on traffic from sources which include the OpenVPN tunnel network and remote network(s).

See also:

Outbound NAT

20.7.5 Assigning OpenVPN Interfaces

Assigning an OpenVPN interface as an OPT interface allows the firewall to perform complex NAT, policy routing, and tunnel-specific filtering.

Benefits of assigning an OpenVPN instance as an interface include:

- Adds a firewall tab under **Firewall > Rules**
- Adds `reply-to` to rules on the VPN interface tab to help with return routing
- Adds a gateway entry for the far side of the VPN for policy routing
- Allows the interface to be selected elsewhere in the GUI and packages for binding services and other tasks
- Allows fine-grained control of port forwards and outbound NAT for the VPN

Note: This does not change the functionality of OpenVPN, only how the firewall treats the interface.

Interface assignment and configuration

- Navigate to **System > Routing**
- Set the **Default gateway** options to a specific gateway or group, as long as they are not left at *Automatic* (*Managing the Default Gateway*)

  > **Warning:** If the default gateway remains set to *Automatic* the firewall may end up using the OpenVPN interface as the default gateway, which is unlikely to be the desired outcome.

- Navigate to **Interfaces > Assignments**
- Set the **Available network ports** field to the appropriate `ovpns` or `ovpnc` interface

  The GUI prints description of the VPN next to the interface name for reference.

- Click  **Add** to create the interface assignment

  The firewall assigns the interface an automatic `OPTx` interface name (e.g. `OPT1`)

  Figure *Assign OpenVPN Interface* shows `ovpns1` assigned as OPT1.

- Navigate to the interface configuration page, **Interfaces > OPTx**
- Check **Enable**

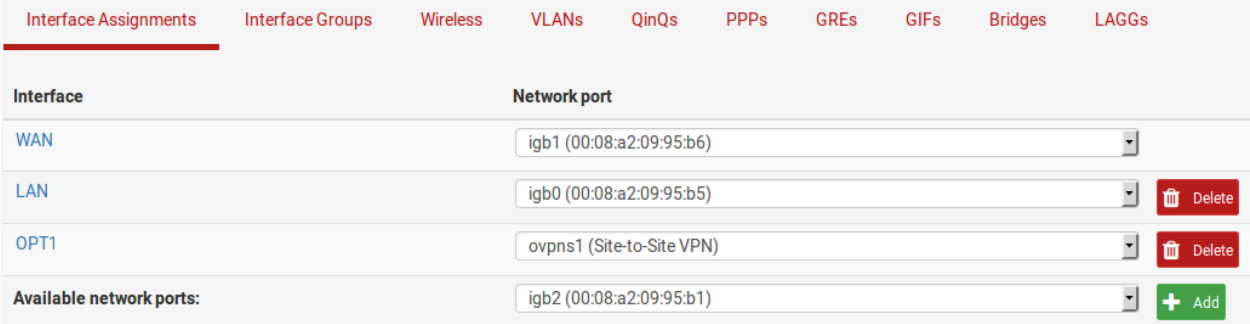

Fig. 2: Assign OpenVPN Interface

- Enter an appropriate **Description** which will become the interface name (e.g. `VPNServer`)
- Click **Save**
- Click **Apply Changes**
- Navigate to **VPN > OpenVPN** and edit the newly assigned instance using the appropriate tab (**Servers** or **Clients**)
- Do not make any changes
- Click **Save** to refresh the VPN configuration and restart its process

> **Warning:** This reinitialization is necessary for the VPN to recover from the assignment process.

Filtering with OpenVPN

When an OpenVPN interface is assigned the GUI contains a tab for the interface under **Firewall > Rules** dedicated to the specific VPN instance.

Rules on this tab govern traffic coming in from the remote side of the VPN and these rules also get the `reply-to` keyword which ensures traffic entering this VPN interface will exit back out the same interface. This can help with advanced NAT and routing configuration scenarios.

Note: Rules on assigned interface tabs are processed *after* rules on the OpenVPN tab. To match the rules on an assigned VPN tab, the traffic **must not match** any rules on the OpenVPN tab. Remove any "Allow All" or "Block all" style rules from the OpenVPN tab and craft more specific rules instead.

Firewall

Policy Routing with OpenVPN

The firewall automatically creates dynamic gateways for assigned and enabled OpenVPN interfaces. These gateways can be found under **System > Routing**, on the **Gateways** tab.

The firewall will create both IPv4 and IPv6 gateways by default but the **Gateway creation** option on OpenVPN instances can limit this behavior to either IPv4 or IPv6.

Firewall rules can use these gateways to direct traffic into the VPN using the **Gateway** field on LAN or other internal interface rules. These gateways can also be included in gateway groups for failover or load balancing.

Reaching Internet sites through the VPN may require more configuration. Either outbound NAT must be performed on the VPN interface before it leaves the firewall (e.g. For VPN services such as PIA, StrongVPN and similar) or the NAT must be performed on the remote side before it reaches the Internet. To perform outbound NAT on this firewall, switch to **Hybrid** or **Manual** outbound NAT mode and add outbound NAT rules on the assigned OpenVPN interface matching the appropriate traffic sources.

See also:

- *Policy routing*
- *Outbound NAT*

Warning: Do not use this automatic gateway for static routes, use the **Remote Network** field in the VPN configuration instead. Automatic gateways for assigned OpenVPN interfaces **do not** work properly for static routes.

NAT with OpenVPN

Assigned OpenVPN interfaces can utilize any type of NAT rules. This is useful when connecting two conflicting subnets or for making NAT rules specific to this a single VPN connection (outbound NAT, port forwards, or 1:1 NAT)

20.7.6 OpenVPN and Multi-WAN

OpenVPN is multi-WAN capable, with some caveats in certain circumstances. This section covers multi-WAN considerations with OpenVPN server and client configurations.

See also:

- *Multiple WAN Connections*
- *Routing*
- *OpenVPN Site-to-Site with Multi-WAN and OSPF*

OpenVPN assigned to a Gateway Group

A Gateway Group (*Gateway Groups*) may be selected as the **Interface** for an OpenVPN instance. Gateway groups for this purpose must be failover only (one gateway per tier), not load balancing.

Gateway groups can also be set to use a VIP for a specific gateway. When OpenVPN uses a gateway group set this way on a server instance, it will use the interface or VIP of the Tier 1 gateway in the group first. If that gateway goes down, it moves to tier 2, and so on. If the tier 1 gateway comes back up, the VPN will resume operating on that WAN immediately.

When used for a VPN server the server can only be active on one WAN at a time. Some of the other methods described below may be a better fit for most common circumstances, such as needing both WANs usable concurrently with the VPN. When used with OpenVPN clients, the outbound interface will be switched according to the gateway group tiers.

OpenVPN servers and multi-WAN

OpenVPN servers can use any WAN connection, though the methods vary depending on the specifics of a given configuration.

OpenVPN server using TCP

TCP is not the best practice protocol for OpenVPN. However, TCP can make multi-WAN OpenVPN easier to configure when the VPN is using an interface setting of *any*. OpenVPN servers using TCP will work properly on all WANs where the firewall rules allow the traffic to the OpenVPN server. A firewall rule is required for each WAN interface.

This works because of the connection-oriented nature of TCP. OpenVPN can reply back to the other end with the proper source preserved since it is part of an open connection.

Warning: This method should be considered a last resort. Using a *protocol* choice which includes *multihome* works properly for UDP on multiple WANs and is a better alternative. Only use TCP if the other methods are not viable.

OpenVPN server using UDP

OpenVPN servers with UDP are also multi-WAN capable, but with some caveats that aren't applicable with TCP.

The *protocol* choice for *UDP on IPv4 and IPv6 on all interfaces (multihome)* will work properly on all WANs and respond back using the address clients expect.

These other UDP modes in OpenVPN are limited by the connectionless nature of UDP. In these cases, the OpenVPN instance replies back to the client, but the Operating System selects the route and source address based on what the routing table believes is the best path to reach the peer. For non-default WANs, that will not be the correct path or the address the peer used when contacting this VPN.

Multiple Server Method

In certain cases each WAN may require its own OpenVPN server. The server instances may all use the same certificates. Only two parts of the OpenVPN configuration must change:

Tunnel Network
: Each server must have a unique **Tunnel Network** that does not overlap with any other tunnel network or internal subnet.

Interface
: Each OpenVPN server must specify a different WAN **Interface**.

Port forward method

An easier and more flexible option is to bind the OpenVPN server to *Localhost* or the *LAN* interface and use port forwards on each WAN to direct the OpenVPN port to the service. This method takes advantage of the `reply-to` functionality in `pf` which returns traffic flows back to the proper source via the interface from which the packet originated.

Note: This method requires minor manual intervention when used with the client export package. The **Host Name Resolution** option must be set to one of the automatic port forward methods otherwise the default export settings would have clients connecting to the wrong address. See *OpenVPN Client Export Package* for details.

Automatic Failover for Clients

OpenVPN clients can use multiple remote servers. If a client cannot reach the first server, it will attempt a connection to the second server, and so on until it runs out of servers. Then it starts over again.

See also:

Additional Servers describes this concept and its configuration in more detail.

This behavior can be used in combination with a multi-WAN OpenVPN server deployment to provide automatic failover for clients. If the OpenVPN servers use IP addresses of `198.51.100.3` and `203.0.113.5` with port `1194`, the `remote` lines in the client configuration file would be:

```
remote 198.51.100.3 1194 udp
remote 203.0.113.5 1194 udp
```

For clients configured on pfSense® software, the first `remote` is set by the **Server Host or Address** field in the GUI. Additional `remote` statements must be in the *Custom options* field.

This method has three notable behaviors that some may find undesirable:

- Clients will take at least 60 seconds to detect a failure and switch to the next server.

  This can be fine-tuned by adjusting the keep alive parameters that the server pushes to clients, but making it too sensitive will also be problematic.

- Any connection failure will cause clients to try the next server, even if it is not a WAN failure.
- Clients will **not** automatically reconnect to the first server when it recovers.

  Once a client connects to another server it will stay there until it gets disconnected again.

OpenVPN Clients and Multi-WAN

To use an OPT WAN interface, select it as the **Interface**. OpenVPN clients configured on the firewall will bind to the chosen **Interface**, but may require a manual static route for the server address to ensure traffic takes the correct path.

If the interface is set to *any*, the client will automatically follow the system routing table when selecting the interface and IP address it uses when connecting to the server.

Tip: For some cases, using the same gateway group for both the OpenVPN client and the system default route will result in the best failover behavior.

20.7.7 OpenVPN and High Availability

OpenVPN works well with high availability (HA) on pfSense® software. To provide an HA OpenVPN solution, configure the OpenVPN server or client to use a CARP VIP as its **Interface**. For HA server instances, configure clients to connect to the CARP VIP.

See also:

- *High Availability*
- *Troubleshooting VPN Connectivity to a High Availability Secondary Node*

When XMLRPC Configuration Synchronization settings are enabled, OpenVPN instances will automatically synchronize from the primary node to the secondary. The connection state is not retained between hosts so clients must reconnect when failover occurs, but OpenVPN will detect the connection failure and reconnect automatically.

When an OpenVPN client instance has a CARP VIP for its **Interface** the firewall will automatically shut down the client as needed while a CARP node is in a BACKUP state. This prevents OpenVPN from making unnecessary outbound connections and also prevents it from placing potentially conflicting information into the routing table. When the CARP VIP status transitions to MASTER, the firewall starts OpenVPN clients automatically.

20.7.8 Sharing a Port with OpenVPN and a Web Server

To be extra sneaky (or careful) with an OpenVPN server, take advantage of the `port-share` capability in OpenVPN which allows it to pass any non-OpenVPN traffic to another IP address behind the firewall.

The usual use case for this is to run the OpenVPN server on TCP port `443` while letting OpenVPN hand off HTTPS traffic from browsers to a web server in place of a port forward.

Warning: This requires using TCP for OpenVPN, and thus is likely to result in reduced VPN performance.

Locked-down networks frequently only allow traffic outbound to common ports such as `80` and `443` for security reasons. Running OpenVPN instances on these allowed ports can help users reach the VPN from restricted networks.

Note: Port sharing is only necessary if these two services must share the same port and IP address. If the firewall has multiple public IP addresses to use, or if there is no public HTTPS web server, then running OpenVPN on TCP port `443` directly without port sharing is a better practice to get the same net effect.

To configure port sharing:

- Move the firewall GUI from port `443` to an alternate port such as `4433`
- Configure an OpenVPN server to listen on TCP port `443`
- Add a firewall rule to pass traffic to the WAN IP address or VIP used for OpenVPN on port `443`
- Add the following to the *Custom options* of the OpenVPN instance:

```
port-share x.x.x.x 443;
```

  Replace `x.x.x.x` with the internal IP address of the web server to which OpenVPN will forward non-VPN traffic.

If an OpenVPN client is pointed to the public address it will connect to the VPN, while a web browser connecting to the same IP address will be connected to the web server.

20.7.9 Controlling Client Parameters via RADIUS

When using RADIUS as an authentication source for a VPN, pfSense® software supports receiving certain client configuration parameters from the RADIUS server as reply attributes.

Inbound firewall rules

Inbound firewall rules to govern traffic from the client to the server.

```
Cisco-AVPair = <IP_PROTO>:inacl#<NUM>=<rule>
```

- <IP_PROTO> is the address family / IP protocol (`ip` or `ipv6`)
- <NUM> is a rule number
- <rule> is a rule string in Cisco-style ACL format.

Note: Subnet masks must be **wildcard** style, not CIDR or traditional netmasks.

The firewall replaces the template strings `{clientip}` and `{clientipv6}` in rules with the Tunnel IP addresses of the connecting client.

FreeRADIUS example:

```
Cisco-AVPair = "ip:inacl#1=permit tcp host 192.168.5.10 host 192.168.6.3 eq 80",
Cisco-AVPair += "ip:inacl#2=permit udp host {clientip} host 192.168.33.4 eq 53",
Cisco-AVPair += "ip:inacl#3=permit ip 192.168.5.0 0.0.0.255 host 192.168.6.4",
Cisco-AVPair += "ipv6:inacl#1=permit icmp host {clientipv6} host 2001:DB8::10",
Cisco-AVPair += "ipv6:inacl#2=permit udp host 2001:DB8::4444 host 2001:DB8::7 range 1024␣
↪65535"
```

Outbound Firewall Rules

Outbound firewall rules to govern traffic from the server to the client.

```
Cisco-AVPair = <IP_PROTO>:outacl#<NUM>=<rule>
```

Aside from the `outacl` keyword, the format is the same as inbound rules.

DNS Servers

DNS servers that OpenVPN will push to this client.

```
Cisco-AVPair = dns-servers=x.x.x.x y.y.y.y
```

Separate multiple servers with spaces.

Routes

Additional route statements OpenVPN will push to the client.

```
Cisco-AVPair = route=x.x.x.x y.y.y.y
```

Specified as `x.x.x.x y.y.y.y` where the first parameter is a network address and the second is a subnet mask.

Static IP Address

A specific IP address OpenVPN will assign to the client.

```
Framed-IP-Address=x.x.x.x
Framed-IP-Netmask=255.255.255.0
```

If the OpenVPN server uses a *subnet* style **Topology** the RADIUS server must also send back an appropriate `Framed-IP-Netmask` value matching the VPN **Tunnel Network**.

When using a *net30* style **Topology**, the client receives this IP address and the server side is set as one IP address **lower** than the address given to the client.

Note: This currently only works for IPv4. The firewall does not support the `Framed-IPv6-Address` reply attribute at this time.

20.7.10 OpenVPN Adapter Address ICMP Behavior

When using the older *net30* topology, OpenVPN will not respond to ping on certain virtual addresses used solely for routing endpoints. Thus, in *net30* topology mode pinging the OpenVPN endpoint addresses is unreliable as a means of determining if the tunnel is passing traffic properly. Instead, ping something inside the remote subnet, such as the LAN IP address of the peer.

In contrast, subnet topology in OpenVPN does not use virtual addresses and per-client subnets so it does not have these limitations. OpenVPN servers and clients using *subnet* topology are capable of responding to ping requests on their interface addresses.

The OpenVPN FAQ addresses this behavior in the section titled *Why does OpenVPN's "ifconfig-pool" option use a /30 subnet (4 private IP addresses per client) when used in TUN mode?*:

> As 192.168.1.5 is only a virtual IP address inside the OpenVPN server, used as an endpoint for routes, OpenVPN doesn't bother to answer pings on this address, while the 192.168.1.1 is a real IP address in the servers O/S, so it will reply to pings.

This may seem a little counter-intuitive as an OpenVPN server interface may look like this in `ifconfig`:

```
tun0: flags=8051<UP,POINTOPOINT,RUNNING,MULTICAST> metric 0 mtu 1500
        inet6 fe80::202:b3ff:fe03:8028%tun0 prefixlen 64 scopeid 0xc
        inet 192.168.100.1 --> 192.168.100.2 netmask 0xffffffff
        Opened by PID 27841
```

While the client shows:

```
tun0: flags=8051<UP,POINTOPOINT,RUNNING,MULTICAST> metric 0 mtu 1500
        inet6 fe80::202:b3ff:fe24:978c%tun0 prefixlen 64 scopeid 0xa
```

(continues on next page)

(continued from previous page)

```
        inet 192.168.100.6 --> 192.168.100.5 netmask 0xffffffff
        Opened by PID 1949
```

In this case, `.5` or `.1` will **not** likely respond to ping. `.5` because it is a virtual address and `.1` because the client has no route to reach it directly. The `.5` and `.6` addresses are part of a `/30` subnet that encompasses `.4` to `.7` and trying to ping `.1` would go out the default route instead.

There are many cases where the far side of an OpenVPN tunnel **can** respond to ping, but not the local. This is also counter-intuitive, but works especially in cases where there is a site-to-site link. If the server shows its tun addresses as `x.x.x.1 -> x.x.x.2` and the client shows the reverse – `x.x.x.2 -> x.x.x.1`, then the far side will likely respond to ping from both ends.

OpenVPN is an open source VPN solution which can provide access to remote access clients and enable site-to-site connectivity. OpenVPN supports clients on a wide range of operating systems including all the BSDs, Linux, Android, macOS, iOS, Solaris, Windows, and even some VoIP handsets.

Every OpenVPN connection consists of a server and a client, for both remote access and site-to-site deployments. In the case of site-to-site VPNs, one firewall acts as the server and the other as the client. In most cases it does not matter which firewall acts in a particular role. Typically the location of the primary firewall will provide server connectivity for all remote locations, whose firewalls are configured as clients. This is functionally equivalent to the opposite configuration the primary location configured as a client connecting to servers running on the firewalls at the remote locations. In practice, the servers are nearly always run on a central location.

OpenVPN supports several types of authentication methods:

X.509 (also known as TLS, SSL, or PKI)
: Utilizes a certificate structure (CA, certificates, and keys). This offers strong security as it cannot be guessed or brute forced.

User authentication
Clients authenticate using credentials such as a username and password which are checked against a local user database, LDAP, or RADIUS server.

Some authentication sources also support multi-factor authentication via mechanisms such as mOTP.

X.509 and User authentication together
The most secure combination, combining multiple factors of authentication that the user has (e.g. certificates, keys) with something they know (credentials).

Shared key
Client and server share a single shared key known to both parties.

Danger: Shared key mode has been deprecated by OpenVPN as it is no longer considered sufficiently secure for modern requirements.

Shared key mode will be removed from future versions of OpenVPN. Users **should not** create any new shared key tunnels and should **immediately** convert any existing shared key tunnels to SSL/TLS mode.

When an SSL/TLS instance is configured with a `/30` tunnel network it behaves in a similar manner to shared key mode. The primary difference is the need to create and distribute the certificate structure to peers. See *OpenVPN Site-to-Site Configuration Example with SSL/TLS* for information on configuring OpenVPN in SSL/TLS mode.

Note: While OpenVPN utlizes TLS it is not a "clientless" SSL VPN in the sense that commercial firewall vendors commonly state. The OpenVPN client must be installed on all client devices and it is not browser-based. In reality no VPN solution is truly "clientless", and this terminology is nothing more than a marketing ploy. For more in depth discussion on SSL VPNs, this post from Matthew Grooms, an IPsec tools and former pfSense® software developer, in the mailing list archives provides some excellent information.

For general discussion of the various types of VPNs available in pfSense software and their pros and cons, see *Virtual Private Networks*.

20.7.11 OpenVPN and Certificates

The best practice is to use certificates for remote access and site-to-site VPNs because it allows access to be revoked for individual clients or sites. Ideally, certificates should be unique per device or at least per user.

If a client machine is compromised, stolen, or lost, or otherwise needs revoked, a shared certificate would have to be re-issued to all clients. If a client with an individual certificate is compromised, or access needs to be revoked for any other reason, simply revoke that certificate. No other clients are affected.

The pfSense software GUI includes a certificate management interface that is fully integrated with OpenVPN. Certificate authorities (CAs) and server certificates are managed in the Certificate Manager in the web interface, located at **System > Certificates**. User certificates are also managed in the web interface, as a part of the built-in user manager found at **System > User Manager**. Certificates may be generated for any user account created locally on the firewall except for the default admin account.

See also:

For further information on creating a certificate authority, certificates, and certificate revocation lists, see *Certificate Management*.

20.8 IPsec

IPsec provides a standards-based VPN implementation that is compatible with a wide range of clients for mobile connectivity and other devices for site-to-site connectivity. It supports numerous third party devices and is being used in production with devices ranging from consumer grade Linksys routers all the way up to IBM z/OS mainframes, and everything imaginable in between.

See also:

For general discussion of the various types of VPNs available in pfSense® software and their pros and cons see *Virtual Private Networks*.

pfSense software supports IPsec with IKEv1 and IKEv2, policy-based and route-based tunnels, multiple phase 2 definitions for each tunnel, NAT traversal, NAT on Phase 2 definitions, a large number of encryption and hash options, and many more options for mobile clients including EAP and xauth.

20.8.1 IPsec Terminology

Before delving too deeply into configuration there are a few terms used throughout the chapter which require explanation. Other terms are explained in more detail upon their use in configuration options.

IKE

IKE stands for *Internet Key Exchange* and comes in two different varieties: IKEv1 and IKEv2. Nearly all devices that support IPsec can use IKEv1. Most modern implementations also support IKEv2. The newer IKEv2 protocol is an updated version of IKE that solves some of the difficulties present in the earlier version. For example, IKEv2 has MOBIKE which is a standard for mobile clients that allows them to switch addresses dynamically. It also has built-in NAT traversal and standard mechanisms for reliability similar to DPD. In general IKEv2 provides a more stable and reliable experience provided both ends support it sufficiently.

ISAKMP Security Association

ISAKMP stands for Internet Security Association and Key Management Protocol. It gives both parties a mechanism by which they can set up a secure communications channel including exchanging keys and providing authentication.

An ISAKMP Security Association (ISAKMP SA or IKE SA) is a one-way policy which defines how traffic will be encrypted and handled. Each active IPsec tunnel will have two security associations, one for each direction. The ISAKMP Security Associations are setup between the public IP addresses for each endpoint. Knowledge of these active security associations is kept in the Security Association Database (SAD).

Security Policy

A security policy manages the complete specifications of the IPsec tunnel. As with security associations these are one-way, thus for each tunnel there will be one in each direction. These entries are kept in the Security Policy Database (SPD). The SPD is populated with two entries for each tunnel connection as soon as a tunnel is added. By contrast SAD entries only exist upon successful negotiation of the connection.

In pfSense software security policies for policy-based IPsec tunnels control which traffic will be intercepted by the kernel for delivery via IPsec.

Phase 1

There are two phases of negotiation for an IPsec tunnel. During phase 1 the two endpoints of a tunnel setup a secure channel between using ISAKMP to negotiate the IKE SA entries and exchange keys. This also includes authentication, checking identifiers, and checking the pre-shared keys (PSK) or certificates. When phase 1 is complete the two ends can exchange information securely, but they have not yet decided which traffic will traverse the tunnel or its encryption.

Phase 2

In phase 2 the two endpoints negotiate how to encrypt and send the data for the private hosts based on security policies. This part builds an entry referred to as a "Child SA". This forms the connection used to transfer data between the endpoints and clients whose traffic is handled by those endpoints. If the policies on both side agree and a phase 2 child SA is successfully established the tunnel will be up and ready for use.

Mobile IPsec

Mobile IPsec refers to IPsec connections from individual client devices rather than site-to-site connections. This is also commonly called a "Road Warrior" or "Remote Access" style VPN.

Th main purpose of a mobile IPsec VPN is for users who are not in the office who need to connect back to the main network. Common use cases are for employees working from home, sales personnel using Wi-Fi on a business trip, or even the boss from his cabin via LTE modem.

Most of these use cases are forced to deal with dynamic IP addresses, unknown IP addresses, NAT (regular and Carrier Grade NAT), and other complications. Without a router or firewall supporting IPsec a traditional IPsec tunnel will not work.

In telecommuting scenarios, it's usually undesirable and unnecessary to connect a entire home networks to the office network, and doing so can reduce security and introduce routing complications. This is where IPsec Mobile Clients are most useful.

Instead of relying on a fixed address for the remote end of the tunnel, Mobile IPsec uses authentication to allow distinguish between authorized users. For example, this could be a username and password with IKEv2 and EAP, a per-user Identifier and Pre-Shared Key pair, or a certificate.

20.8.2 IPsec Configuration

IPsec on pfSense® software offers numerous configuration options which influence the performance and security of IPsec connections. For most users performance is the most important factor. When crafting a configuration, carefully select options to ensure optimal efficiency while maintaining strong security and compatibility with equipment on both ends of a tunnel.

Tip: For low-to-moderate bandwidth usage deployments the options may not have significant impact on performance. Even so, take care not to use insecure options such as SHA1 or weak pre-shared keys.

Warning: pfSense software supports several options which are weak from a security standpoint. These are included for compatibility with third party vendors and equipment which do not support stronger options. The GUI includes warnings against using these options.

The next sections outline how to design an IPsec tunnel and the options available.

IPsec Tunnel Design

Before configuring an IPsec tunnel, a few general decisions must be made about how the tunnel will operate.

IPsec Modes

pfSense software supports several primary modes of IPsec operation:

Policy-based IPsec
: This mode uses policies to match specific combinations of traffic which are grabbed by the kernel and pushed through an IPsec tunnel. It also uses special "trap" policies to detect when traffic intends to use IPsec so that it can bring the tunnel up automatically. Only traffic specifically matching phase 2 child SA entries can use IPsec, and all traffic matching those entries will be taken over by IPsec.

  This mode is the most common and is supported by nearly all third party IPsec implementations.

Route-based IPsec (VTI)
: Routed IPsec uses a special Virtual Tunnel Interface (VTI) for each IPsec tunnel. The VTI interface is assigned and used like other interfaces. Phase 2 entries define addresses for the tunnel interface itself rather than policies which direct traffic to IPsec. Arbitrary traffic may cross VTI IPsec tunnels as traffic follows the system routing table. Static routes or dynamic routing daemons can control which traffic crosses a tunnel.

  Support for routed IPsec varies by vendor.

  By default traffic for VTI tunnels is filtered on the IPsec tab and cannot use per-interface rules, NAT, or `reply-to`. This can be changed in *Advanced IPsec Settings* using the **IPsec Filter Mode** option. Read the consequences of that option carefully before changing the behavior..

Mobile IPsec
: Similar to policy-based mode, but for remote access/mobile clients.

Transport Mode
: This mode encrypts all traffic from the external IP address on this firewall to the external IP address on the far side as defined in the phase 1 settings. Since all traffic sent between the two nodes will be encrypted, other tunneling methods that do not employ encryption, such as a GIF or GRE tunnel, can be safely used by the firewall between the endpoints.

  By default traffic for transport mode tunnels may experiece problems with keeping state appropriately among other filtering quirks. This can be improved by using the **IPsec Filter Mode** option in *Advanced IPsec Settings*. Read the consequences of that option carefully before changing the behavior.

Interface Selection

In many cases, the **Interface** option for an IPsec tunnel will be WAN, since the tunnels are connecting to remote sites. However, there are plenty of exceptions, the most common of which are outlined in the remainder of this section.

High Availability Environments

IPsec works well with high availability, with some caveats. See *IPsec in High Availability Environments* for details.

IP Alias VIP

If multiple IP addresses are available on an interface using IP Alias type VIPs, they will also be available in this list. To use one of those IP addresses for the VPN instead, select it here.

Multi-WAN Environments

IPsec supports multiple WANs in multiple configurations. See *IPsec in Multi-WAN Environments* for details.

Wireless Internal Protection

When configuring IPsec to add encryption to a wireless network as described in *Additional protection for a wireless network*, choose the OPT interface which corresponds to the wireless card. When using an external wireless access point, pick the interface which is connected to the wireless access point.

IPsec Tunnels Tab

IPsec VPN tunnels are managed by the **Tunnels** tab at **VPN > IPsec**. The page contains a list of tunnels with a brief summary of their settings along with various management controls.

See also:

See *Managing Lists in the GUI* for details on how to create and edit items in lists using the GUI.

Each IPsec tunnel contains a single phase 1 definition and one or more phase 2 definitions.

The  **Add P1** button creates a new IPsec phase 1 entry.

See also:

- *Phase 1* (Definition)
- *Phase 1 Settings*

After adding a phase 1 definition, click  **Show Phase 2 Entries** underneath a phase 1 entry to display and manage its phase 2 entries.

See also:

- *Phase 2* (Definition)
- *Phase 2 Settings*

Continue on for detailed information about IPsec settings.

Phase 1 Settings

The settings here control the phase 1 negotiation portion of the tunnel, as described previously.

General Information

Description
A name or brief description of the tunnel. The best practice is to enter a few words to describe the purpose of this VPN tunnel or about the remote end of the tunnel. For example `Remote Office`, `HQ Tunnel`, or `ATX to NYC`.

This functions as a reminder for anyone managing the firewall as to who or what will be using the tunnel. This description is also reflected in the IPsec status which makes it easier to match up status entries with a specific tunnel.

Disabled
Controls whether or not this tunnel (and its associated phase 2 entries) are active and used.

IKE ID
This is a read-only field containing the IKE identifier for this tunnel.

IKE Endpoint Configuration

Key Exchange Version
This can be *IKEv1*, *IKEv2*, or *Auto*.

See also:

The differences between IKEv1 and IKEv2 are discussed in *IKE*.

IKEv1
IKEv1 is more common and widely supported but has problems supporting common modern issues such as dealing with NAT or mobile clients.

IKEv2 (Default)
An updated version of the protocol which has increased capabilities and security, as well as built-in support for mobile clients and NAT.

Tip: IKEv2 is the best choice when supported by both endpoints.

Auto
This option uses IKEv2 when initiating, but will accept either IKEv2 or IKEv1 when responding.

Internet Protocol
The protocol for the *outside* of the tunnel. That is, the protocol that will be used between the outside peer addresses. In most cases this will be IPv4, but if both ends are capable of IPv6 that may be used instead. Whichever protocol is chosen here will be used to validate the **Remote Gateway** and the associated identifiers.

Note: On current versions of pfSense software IPv4 and/or IPv6 traffic may be carried inside a tunnel no matter which type of Key Exchange Version or Internet Protocol is used outside the tunnel.

Some third party vendors may only support this when using IKEv2, and on IKEv1 the inner and outer traffic may need to match when connecting to those third party implementations.

Interface
This determines which part of the network will be the termination point (end point) for the IPsec tunnel. If the tunnel will be connecting to a remote server, then WAN is likely the desired setting. This can also be a virtual IP address. A gateway group can also be used for automatic failover.

See also:

See *Interface Selection* earlier in this document for details on selecting the appropriate interface.

Remote Gateway
The address for the peer to which the tunnel will be established. This is most likely the WAN IP address of the remote device.

This may be set to an IP address or a fully qualified domain name (FQDN). When set to an FQDN the firewall periodically resolves the name using DNS and updates the tunnel when it detects a change.

To allow connections from any remote endpoint with tunnel mode phase 2 entries, use `0.0.0.0/0` for IPv4 or `::` for IPv6. When allowing connections from any remote endpoint the **Child SA Start Action** must be set to *None* and the **Peer Identifier** cannot be set to *Peer IP Address*.

Note: VTI tunnels require a specific remote endpoint address for their interface configuration. They cannot allow connections from "any" or unknown endpoints. Using an FQDN for the remote gateway is a viable workaround provided the remote peer is capable of using dynamic DNS.

Phase 1 Proposal (Authentication)

Authentication Method
An IPsec phase 1 can be authenticated using a pre-shared key (PSK) or certificates. The **Authentication Method** selector chooses which of these methods will be used for authenticating the remote peer. Fields appropriate to the chosen method will be displayed on the phase 1 configuration screen.

Mutual PSK
The peer is validated using a pre-defined string known to both endpoints. Since it is simple a string there is a possibility that it can be guessed. For this reason a long and complex key is more secure when using PSK mode.

Mutual Certificate
A TLS CA and certificate are used to verify the peer. During the phase 1 exchange each peer sends its certificate to the other peer and then validates it against a CA. The CA and certificate must be created for the tunnel before attempting to setup the phase 1.

See also:

IPsec Site-to-Site VPN Example with Certificate Authentication

Mutual Certificate (PKCS#11)
Similar to *Mutual Certificate* but the certificate is read from a locally attached PKCS#11 device.

Note: This option is only available when **Enable PKCS#11** is checked on the **Advanced** IPsec settings.

Mutual PSK+Xauth
Used with mobile IPsec and IKEv1. This selection enables xauth username and password verification along with a shared (or "group") pre-shared key.

See also:

IPsec Remote Access VPN Example Using IKEv1 with Xauth

Mutual Certificate+Xauth
Used with mobile IPsec and IKEv1. This selection enables xauth username and password verification along with certificate authentication using certificates on both the client and server.

Hybrid Certificate+Xauth
Used with mobile IPsec and IKEv1. This selection enables xauth username and password verification along with a certificate only on the server side. It is not quite as secure as *Mutual Certificate+Xauth* but it is easier on the clients.

EAP-TLS
Used with mobile IPsec and IKEv2. EAP-TLS verifies that certificates on the client and server are from the same shared CA, similar to *Mutual Certificate*. The client and server certificates require special handling:

- The server certificate must have the firewall hostname as it exists in DNS listed in its Common Name and again as a Subject Alternative Name (SAN). The firewall IP address must also be listed in a SAN.
- The identifier in phase 1 must also be set to match the firewall hostname as listed in the Common Name of the certificate.
- The client certificate must have the username listed as the common name and then again as a SAN.

The CA and server certificates must be generated before attempting to configure EAP-TLS. The CA and user certificate must be imported into the client.

See also:

IPsec Remote Access VPN Example Using IKEv2 with EAP-TLS

EAP-RADIUS
Used with mobile IPsec and IKEv2. This selection performs CA verification along with username and password authentication via RADIUS. A RADIUS server must be selected on the **Mobile Clients** tab. Though user certificates are not necessary EAP-RADIUS still requires that a CA and server certificate be present using the same attributes mentioned under *EAP-TLS*. The CA must be imported to, or globally trusted by, the client, but no user certificate.

See also:

IPsec Remote Access VPN Example Using IKEv2 with EAP-RADIUS

EAP-MSCHAPv2
Used with mobile IPsec and IKEv2. EAP-MSCHAPv2 works identically to EAP-RADIUS except the usernames and passwords are defined on the **Pre-Shared Key** tab under **VPN > IPsec** with the **Secret type** set to *EAP*. It also requires a CA and server certificate with the same properties listed previously. The CA must be imported to, or globally trusted by, the client, but no user certificate.

See also:

IPsec Remote Access VPN Example Using IKEv2 with EAP-MSCHAPv2

Negotiation Mode
(IKEv1 only) The type of authentication security used by this tunnel. This can be either *Main* or *Aggressive*.

Main
Main is the most secure mode as it is strict in its validation. It requires several packets between the peers to accomplish a successful negotiation due to the strict validation procedures, thus is slower.

Using *Main* mode is the best practice where possible due to its higher security.

Aggressive
Aggressive is generally the most compatible mode to use with other vendors and is the fastest mode. It is more forgiving with identifier types and tends to be more successful when negotiating with third-party devices.

Aggressive mode is faster because it sends all of the identifying information in a single packet, which also makes it less secure because the verification of that data is not as strict as that found in main mode.

Avoid aggressive mode due to its weaker security unless it is required for interoperability with a third party IPsec implementation.

Identifiers
Identifiers are used by IPsec to identify remote peers and associate specific peers with a tunnel and its related settings, such as authentication components (keys, certificates, etc).

My Identifier
Identifier type and value sent by this firewall to the far side. It is best left at *My IP Address* and the firewall will fill it in as needed. In some cases an FQDN or similar may be entered so that the value is constant.

Most settings are viable so long as both sides agree on the identifier type and value.

Peer Identifier
Identifies the remote peer on the other side of the tunnel. It is best left at *Peer IP Address* and the firewall will fill it in as needed. In some cases an FQDN or similar may be entered so that the value is constant.

Most settings are viable so long as both sides agree on the identifier type and value.

Identifier Types

My IP Address / Peer IP address
This choice is a macro that will automatically use the IP address on the interface, or the selected VIP, as the identifier.

For peers this is the IP address from which incoming IPsec packets are received by this firewall, which should match the value used in **Remote Gateway**.

IP Address
A specific static and manually-entered IP address to be used as the identifier. One potential use for this is when the firewall is behind NAT where the real external IP address could be used in this field.

Fully qualified domain name
A fully qualified domain name (FQDN) such as `host.example.com`. Enter a value in that format into the box. This value is sent as-is and is not resolved to an IP address.

When using *Mutual Certificate* authentication this can be used to match the CN or SAN of a certificate to ensure the correct certificate is associated with this tunnel endpoint.

User fully qualified domain name / E-mail
An e-mail address such as `vpn@example.com`.

ASN.1 Distinguished Name
When using *Mutual Certificate* authentication this can be set to the subject of the certificate which also ensures the correct certificate is associated with this tunnel endpoint.

For example: `/CN=host.example.com/C=US/ST=Texas/L=Austin/O=Example Co`

KeyID Tag
An arbitrary string to use as the identifier.

Dynamic DNS
A hostname to resolve and use as the identifier. This is mostly useful if the firewall is behind NAT and has no direct knowledge of its external IP address aside from a dynamic DNS hostname. This is only available for **My identifier**.

Any
In cases when the remote identifier is unknown or cannot be matched the **Peer Identifier** may be set to **Any**. This is more common on certain types of mobile configurations but it is a much less secure choice than matching the identifier properly.

Pre-Shared Key
(*Mutual PSK* authentication only) A string known by both peers used as a key to authenticate the tunnel, similar to a password. This key is case-sensitive and must be exactly the same on both endpoints.

The best practice is to make this as long and complex as possible. There is little incentive to keep the value simple as this only gets entered once on each peer and there is no need for a human to remember its contents.

Click  **Generate new Pre-Shared Key** to populate the field with a random string suitable for use as a key.

> **Warning:** This key must be as random as possible to protect the contents of the tunnel.

My Certificate
(*Mutual Certificate* authentication only) Defines the certificate which identifies this firewall. The CA which signed this certificate must be copied to the peer. If one is not shown, create or import it under **System > Cert Manager** on the **Certificates** tab.

Peer Certificate Authority
(*Mutual Certificate* authentication only) Defines the CA which has signed the certificate sent by the peer. This is used to validate the peer certificate. If it does not show in the list, import it under **System > Certificates** on the **Certificate Authorities** tab.

Phase 1 Proposal (Encryption Algorithm)

There are many options for encryption algorithms on both phase 1 and phase 2.

Encryption choices depend on the device to which the tunnel will connect and the hardware. AES-GCM is the most desirable cipher for both speed and security, but may not be widely supported by other vendors and equipment. AES with a 128-bit key length is a common choice on endpoints which lack support for AES-GCM.

Multiple combinations of these options can be defined using the  **Add Algorithm** button to add another line. The order of the entries is the order of preference so configure the strongest and/or most desirable settings first.

Encryption Algorithm
: Use the strongest available option supported by both endpoints. If both sides support AES-GCM, use *AES128-GCM* with a *128* bit **Key Length**. This will combine strong encryption and hashing together and can be accelerated by AES-NI. Failing that, use *AES* With a **Key Length** of *128* or whichever option is strongest in common between both sides.

Hash Algorithm
: Hash algorithms are used with IPsec to verify the authenticity of packet data and as a Pseudo-Random Function (PRF). These hash algorithms may also be referred to with HMAC (Hash Message Authentication Code) in the name in some contexts but that usage varies depending on the hardware or software in use.

  A tunnel configured for AES-GCM uses this solely as a PRF because AES-GCM performs hashing internally. The fastest choice to use in combination with AES-GCM on hardware capable of accelerating AES, such as AES-NI, is *AES-XCBC*. However, *AES-XCBC* is less secure than other algorithms such as *SHA256* and may not be supported by other platforms. For different types of **Encryption Algorithms**, use *SHA256* if possible. If the peer does not support any of these, use the strongest available option supported by the peer.

PRF
: Specifically set a manual Pseudo-Random Function different than the one the IPsec daemon would choose automatically based on the **Hash Algorithm**. This control is hidden by the GUI unless **PRF Selection** is enabled in the **Advanced Options** section at the bottom of the page.

DH Key Group
: The best practice is to use DH Group *14 (2048 bit)* or higher if both sides support it. Avoid using groups 1, 2, 22, 23, and 24 as they do not provide sufficient security. As with the other options, if the suggested value is not supported by the peer, use the strongest available option.

Note: IPsec uses this DH group for the first child SA when initially building a tunnel. The PFS option of a phase 2 entry is used for subsequent child SA entries and when rekeying.

Expiration and Replacement

The total lifetime for phase 1 defines how often the connection will be rekeyed or reauthenticated by the IPsec daemon.

Warning: Take care when crafting these values. Incorrect or sub-optimal values can lead to problems such as tunnels failing to renegotiate in a timely manner or multiple duplicate security associations.

See *Troubleshooting Duplicate IPsec SA Entries* for more details.

The specific values for these fields depend on the IKE mode and which mechanisms are supported by both endpoints. In most cases setting only the **Life Time** value will allow the firewall to choose the best options.

Life Time
The hard IKE SA life time, in seconds, after which the IKE SA will be expired. This value **must** be larger than **Rekey Time** and **Reauth Time** and cannot be set to the same value.

`28800` total seconds is a good balance of frequent rekeying without being too aggressive.

Tip: Set one endpoint to this recommended value, but use a higher **Life Time** on the other endpoint by at least 10% (e.g. `31680`) to help avoid overlap.

If left empty the value defaults to 110% of **Rekey Time** or **Reauth Time**, whichever is higher.

Rekey Time
Time, in seconds, before the IPsec daemon attempts to establish a new set of keys for the IKE SA. Only supported by IKEv2 and is the best choice for use with IKEv2.

Rekey works without interruption and allows both endpoints to seamlessly change to new keys on the fly. This is optimal, but implementation quality varies by vendor.

Leave blank to automatically calculate the value based on 90% of **Life Time**. Enter a value of `0` to disable rekeying.

Normally both sides will rekey as needed. If the tunnel often fails when a rekey event occurs, try disabling this feature on one side.

Note: Some clients, especially Windows clients behind NAT, misbehave when they receive a rekey request. In those cases it is safer to allow the client to initiate the rekey by disabling the option on the server.

Reauth Time
Time, in seconds, before an IKE SA is torn down and recreated from scratch by the IPsec daemon. This also includes a new round of authentication. Supported by IKEv1 and IKEv2, but should be avoided with IKEv2 where possible.

This process can be disruptive to traffic flow unless all peers support IKEv2 make-before-break (*Advanced IPsec Settings*) and overlapping IKE SA entries.

Leave blank to automatically calculate the value based on 90% of **Life Time**. Enter a value of `0` to disable reauthentication.

Rand Time
Introduces randomness into the rekey or reauthentication process to avoid both endpoints attempting to renegotiate simultaneously.

A random value up to this amount will be subtracted from **Rekey Time** or **Reauth Time** for each scheduled renegotiation to reduce the chance of collisions.

If left empty, the value defaults to 10% of **Life Time**. Enter `0` to disable randomness.

Warning: Disabling **Rand Time** increases the likelihood of simultaneous renegotiation which can lead to duplicate security associations.

See *Troubleshooting Duplicate IPsec SA Entries* for more details.

Advanced Options

Child SA Start Action

This option forces specific behavior performed by the IPsec daemon when loading a phase 2 configuration ("Child SA") during initial service startup. This happens at boot and when the service is restarted for any reason.

Default

Automatically chooses behavior based on other settings.

None (Responder Only)

The IPsec daemon will not attempt to initiate the tunnel. The tunnel will only be established by an initiation attempt from the far side. If DPD detects that the tunnel has failed, the tunnel will be left down rather than restarted. The far side must reconnect.

This is the default behavior for mobile IPsec and tunnels with unknown remote endpoints.

Initiate at Start (VTI or Tunnel Mode)

The firewall will attempt to establish the IPsec tunnel immediately when the IPsec daemon starts.

This is the default behavior for VTI mode.

Initiate on Demand (Tunnel mode only)

Traffic which matches the networks in phase 2 definitions for this tunnel ("interesting traffic") will trigger initiation of the tunnel.

This is the default behavior of tunnel mode.

Note: Finding "interesting" traffic relies on trap policies to function and trap policies are not compatible with VTI mode.

Child SA Close Action

Controls how the IPsec daemon behaves when a child SA (P2) is unexpectedly closed by the peer.

Default

Retains the default behavior based on other settings for the tunnel.

Close connection and clear SA

Removes the child SA and does not attempt to establish a new SA. This is the desired behavior when acting in a **Responder Only** or mobile IPsec role.

Restart/Reconnect

Immediately attempts to reconnect the child SA. This ensures that the tunnel reestablishes properly in cases that do not support trap policies such as routed IPsec (VTI). Set this on **one side only** if the tunnel does not reconnect after it disconnects, rekeys, or reauthenticates.

Warning: This option **must not** be set on both peers! Both peers would attempt to initiate and hold open multiple copies of each child SA.

Close connection and reconnect on demand

Clears the child SA and reinstalls trap policies to watch for interesting traffic. Will reestablish the tunnel on demand when traffic attempts to cross the tunnel.

This option is not compatible with modes which do not support trap policies such as routed IPsec (VTI).

NAT Traversal
(IKEv1 Only) Also known as NAT-T. NAT Traversal encapsulates ESP traffic for IPsec inside of UDP packets to more easily function in the presence of NAT. If this firewall or the firewall on the other end of the tunnel is behind a NAT device then NAT Traversal will likely be necessary for the tunnel to function properly.

Auto
(Default) Allows the IPsec daemon to detect and use NAT Traversal automatically when it determines one or both peers is behind NAT.

Force
Instructs the IPsec daemon to always use NAT Traversal for the tunnel. This can help if there is a known issue detecting NAT. It can also help with issues carrying ESP traffic between the two endpoints even when neither side is behind NAT.

IKEv2 integrates NAT Traversal natively so the option is unnecessary in that case.

MOBIKE
An extension to IKEv2 which handles multi-homed clients and clients which roam between different IP addresses. This is primarily used with mobile clients to allow them to switch remote addresses while keeping a connection active. Leave disabled unless the remote peer must change addresses dynamically.

Gateway Duplicates
Allows multiple phase 1 configurations to use the same remote endpoint address.

> **Warning:** This option also disables automatic static routes to the peer via specific WAN gateways. Traffic will follow the default route, not the selected tunnel interface, unless manual static routes redirect the traffic.

Split Connections
(IKEv2 Only) By default when an IKEv2 tunnel has multiple phase 2 definitions the settings are collapsed in the IPsec configuration such that all phase 2 combinations are held in a single child SA.

Split Connections changes this behavior to be more like IKEv1 where each phase 2 entry is configured by the daemon as its own separate child SA.

Certain scenarios require this behavior, such as:

- The remote peer does not properly handle multiple addresses in single traffic selectors. This is especially common in Cisco, Checkpoint, Fortinet, and Juniper equipment.
- Each child SA must have unique traffic selector or proposal settings. This could be due to the peer only allowing specific combinations of local/remote subnet pairs or different encryption options for each child SA.

PRF Selection
Enables a GUI control to specifically set a Pseudo-Random Function (PRF) rather than allow the IPsec daemon to choose one automatically based on the selected Hash Algorithm. Can be useful in combination with AEAD encryption algorithms such as AES-GCM.

Custom IKE/NAT-T Ports
In rare situations the remote endpoint may be running IPsec on alternate port numbers for IKE and NAT-T. These settings can accommodate such endpoints.

Remote IKE Port
The UDP port for IKE on the remote gateway. Leave empty for the default automatic behavior (Port `500` for IKE and `4500` for NAT-T)

Remote NAT-T Port
The UDP port for NAT-T on the remote gateway.

Note: If **Remote IKE Port** is empty and NAT-T contains a value the tunnel will use only NAT-T.

Dead Peer Detection
Dead Peer Detection (DPD) is a periodic check that the host on the other end of the IPsec tunnel is still alive. This detects when an IPsec peer has lost connectivity or is otherwise unreachable. If a DPD check fails the tunnel is torn down by removing its associated SAD entries and a fresh negotiation is attempted.

The default settings are sufficient for most connections. Increase the values for bad quality links to avoid tearing down a usable, but lossy, tunnel.

Delay
Time between DPD probe attempts. The default of `10` is best.

Max Failures
Number of failures before the peer is considered down. The default of `5` is best. This per-tunnel value is only honored for IKEv1.

Note: The default values of `10` seconds and `5` failures will result in the tunnel being considered down after approximately one minute.

Phase 2 Settings

The phase 2 settings for an IPsec tunnel govern how the tunnel handles traffic (e.g. policy-based or route-based, see *IPsec Modes*) as well as the encryption of that traffic.

Phase 2 entries are used in a few different ways, depending on the IPsec configuration:

- For policy-based IPsec tunnels this controls which subnets will enter IPsec. Multiple phase 2 definitions can be added for each phase 1 to allow using multiple subnets inside of a single tunnel.
- For route-based IPsec this controls the VTI interface addresses.
- For mobile IPsec this primarily controls the encryption for phase 2. It can also optionally be used by the IPsec daemon or export utilities to generate a list of networks to the clients for use in split tunneling.

Each phase 2 entry has the following options:

General Information

Description
A description for this phase 2 entry. Shows up in the IPsec status for reference.

A name or brief description for this entry. The best practice is to enter a few words to describe the purpose of this phase 2 entry or about the remote end of the tunnel. For example `TNSR VTI`, `DC Management`, or `ATX DMZ to NYC DMZ`.

This functions as a reminder for anyone managing the firewall. This description is also reflected in the IPsec status which makes it easier to match up status entries with a specific tunnel.

Disabled
An on/off switch for this phase 2 entry only.

Mode
The IPsec Mode for this phase 2 entry, which controls how the tunnel handles traffic. See *IPsec Modes* for more detailed explanations of each type of mode.

Tunnel IPv4
A policy-based tunnel that will carry traffic between IPv4 networks matching the specified **Local Network** and **Remote Network**.

Tunnel IPv6
A policy-based tunnel that will carry traffic between IPv6 networks matching the specified **Local Network** and **Remote Network**.

Transport
Encrypts all traffic between the endpoints. The **Local Network** and **Remote Network** are not set for transport mode, the addresses are based on the phase 1 settings.

Routed (VTI)
Routed IPsec using Virtual Tunnel Interfaces (e.g. `ipsecX`). The **Local Network** and **Remote Network** define the addresses used by the firewall for the VTI interface. Typically only one phase 2 entry is present for each address family (e.g. one for IPv4, one for IPv6)

See *Routed IPsec (VTI)* for more information.

Phase 1
A link to the IPsec phase 1 entry under which this phase 2 entry exists, along with its IKE ID.

P2 Reqid
The unique phase 2 request ID for this entry. It is used by IPsec in various contexts, such as for the IPsec VTI interface name.

Networks

Local Network

Tunnel Mode
Defines which subnet or host can be accessed from the other side of the VPN tunnel. This is typically the LAN or other internal subnet for the VPN. It can also be a single IP address if only one client needs to use the tunnel. The **Type** selector is pre-loaded with choices for each interface (e.g. *LAN subnet*), as well as *Address* and *Network* choices that allow entering an IP address or subnet manually.

Most often this is set to *LAN subnet* which means the entire LAN will be accessible from the remote network.

NAT/BINAT
Sets a *different* subnet or address which is used by IPsec to perform NAT on the local network addresses to make them appear to the remote peer as a different subnet.

Set to *None* to disable NAT for the tunnel.

See also:

For more details see *NAT with IPsec Phase 2 Networks*.

Routed (VTI) Mode
Sets the local IP address and subnet mask of the `ipsecX` interface.

Remote Network

Tunnel Mode
(Non-mobile only) Specifies the IP Address or Network which exists on the remote side of the VPN. This field operates similarly to the **Local Network** option.

Routed (VTI) Mode
Sets the remote IP address for the `ipsecX` interface tunnel network (the remote address of the VTI).

Phase 2 Proposal (SA/Key Exchange)

Protocol
Controls how IPsec protects its traffic.

ESP (Encapsulating Security Payload)
Encrypts traffic before sending it to the peer.

ESP is the correct choice in nearly all circumstances.

AH (Authenticated Header)
Provides assurance the traffic came from a trusted source but does not provide encryption. Rarely used in practice.

Note: With automatic VPN rules (*Disable Auto-added VPN rules*) the firewall automatically passes the appropriate ESP or AH protocol traffic from the remote endpoint. If automatic VPN rules are disabled, add manual rules to pass the traffic instead.

Encryption algorithms
Sets the encryption algorithms used when negotiating phase 2 child SA entries with peers. Must match values available to and configured on the peer.

In systems with AES-NI the fastest and most secure choice is AES-GCM if it is supported by the peer. When using AES-GCM do not select any options for **Hash Algorithms** in phase 2.

If both peers cannot use AES-NI then use AES with a 128-bit or higher key length.

This set of controls allows for multiple selections so that multiple choices will be accepted when acting as a responder or proposed when working as an initiator. The best practice is to only select a single desired cipher on both peers. In some cases, such as mobile clients, selecting multiple will allow a tunnel to work with a variety of clients. It can also be better when acting in both a responder and initiator role.

Hash algorithms
Controls which hash algorithms are used when negotiating phase 2 child SA entries with peers. Must match values available to and configured on the peer.

As with the Encryption Algorithms multiple hashes may be selected. The best practice is to select a single desired choice if possible.

See also:

For more discussions on the quality of the various hash types see *Phase 1 Settings*.

With AES-GCM as the **Encryption Algorithm** no **Hash Algorithm** should be selected as AES-GCM performs hashing on its own. When not using AES-GCM, the optimal choice for speed and security is **SHA256**.

PFS key group
Perfect Forward Secrecy (PFS) provides keying material with greater entropy which improves the cryptographic security of the connection. This comes at a cost of higher CPU usage during rekeying.

The options have the same properties as the DH key group option in phase 1 (See *DH key group*) and some products also refer to them as "DH" values even in phase 2.

The optimal choice for speed and security is *14 (2048 bit)*.

Note: When an IPsec tunnel is initially connected the first child SA will use the DH value from phase 1 in this context. The PFS value from phase 2 is used for subsequent child SA entries and when rekeying. This can lead to a misconfiguration not being noticed initially since it may work at first but fail after the first child SA expires.

Expiration and Replacement

Life Time
The hard child SA life time, in seconds, after which the child SA will be expired. This value **must** be larger than **Rekey Time** and cannot be set to the same value.

`3600` total seconds is a good balance of frequent rekeying without being too aggressive.

Tip: Set one endpoint to this recommended value but use a higher **Life Time** on the other endpoint by at least 10% (e.g. `5400`) to help avoid overlap.

If left empty the value defaults to 110% of **Rekey Time**. If both **Life Time** and **Rekey Time** are empty it defaults to `3960`.

Rekey Time
Time, in seconds, before the child SA establishes a new set of keys. This works without interruption and allows both endpoints to seamlessly change to new keys on the fly.

Leave blank to automatically calculate the value based on 90% of **Life Time**. If both **Life Time** and **Rekey Time** are empty it defaults to `3600`. Enter a value of `0` to disable rekeying.

Note: If rekeying is disabled connections can be interrupted while a new child SA is negotiated after an old entry expires.

Rand Time
Introduces randomness into the rekey process to avoid both endpoints attempting to renegotiate simultaneously.

A random value up to this amount will be subtracted from **Rekey Time** for each scheduled renegotiation to reduce the chance of collisions.

If left empty the value defaults to 10% of **Life Time**. Enter `0` to disable randomness.

Warning: Disabling **Rand Time** increases the likelihood of simultaneous renegotiation which can lead to duplicate security associations.

See *Troubleshooting Duplicate IPsec SA Entries* for more details.

Keep Alive

Methods which will attempt to keep this phase 2 entry up and active over time.

See also:

See *Configuring IPsec Keep Alive* for additional discussion on these options.

Automatically ping host
For use on non-mobile tunnel mode entries. This option tells the firewall to initiate a ping periodically to the specified IP address. This option only works if the firewall has an IP address inside of the **Local Network** for this phase 2 entry and the value of the ping host here is inside the **Remote Network**.

This option will not initiate a tunnel if its phase 1 **Child SA Start Action** is set to *Responder Only*. This option will also not initiate VTI mode tunnels as they do not support trap policies.

Keep Alive
Enables a periodic check to see if the child SA is connected and initiates when it is down. This function does not send traffic inside the tunnel.

This option works for VTI and tunnel mode phase 2 entries.

For IKEv2 without split connections this only needs enabled on the first phase 2 entry.

See also:

See *Configuring IPsec Keep Alive* for additional information.

IPsec Mobile Clients Tab

The **Mobile Clients** tab under **VPN > IPsec** contains settings which influence the authentication and configuration of mobile clients. These are specific to mobile tunnels and separate from the typical phase 1 and phase 2 negotiation.

See also:

- *Mobile IPsec*
- *Choosing a Mobile IPsec Style*
- *Remote Access Mobile VPN Client Compatibility*

Warning: The behavior of these fields varies by the type of mobile connection in use. Check type-specific documentation such as those linked on *Choosing a Mobile IPsec Style* for recommendations relevant to a given use case.

Enable

IKE Extensions
When checked, enables support for mobile IPsec in the GUI. The GUI will prompt to create an IPsec phase 1 entry for mobile connections if one does not already exist.

Extended Authentication

User Authentication
Specifies which authentication sources will be used when authenticating mobile users.

This list contains *Local Database* which is users from the *User Manager* or the *IPsec Pre-Shared Keys Tab*, as well as RADIUS and LDAP servers defined on the firewall.

See also:

See *Authentication Servers* for information on managing entries for this list.

Group Authentication
When set, the authentication process checks group membership of the user and their privileges. The groups are checked for either "User - VPN: IPsec with Dialin" or "WebCfg - All pages" privileges.

Authentication Groups
A list of available *groups from the user manager*. Only members of the selected groups will pass authentication.

When using EAP-RADIUS, group membership is determined by responses from a RADIUS server. See *RADIUS Groups* for details.

Note: The IPsec daemon only supports the specification of a single group for a user in the Class attribute, while pfSense® software supports specifying multiple semicolon delimited groups. See the strongSwan eap-radius Plugin documentation for more details.

RADIUS Accounting
When enabled, the IPsec daemon will attempt to send RADIUS accounting data for **all** tunnels, not only connections associated with mobile IPsec. The RADIUS server must be selected in the **User Authentication** list above.

> **Warning:** Do not enable this option unless the selected RADIUS servers are always online and capable of receiving RADIUS accounting data. Tunnels will be disconnected if RADIUS accounting data is enabled and fails to send, even if they are not mobile clients.

Client Configuration

Virtual Address Pool
Defines the pool of IP addresses from which dynamic client addresses are assigned. For example, `10.3.200.0/24`.

Note: This subnet must not already be in use on an interface or elsewhere on the firewall or local network.

Virtual IPv6 Address Pool
Same as above, but for IPv6 addresses.

RADIUS IP Address Priority
When set, the IPv4/IPv6 address pool is used if address is not supplied by RADIUS server. When unset, a client only receives an IP address if RADIUS provides one.

RADIUS Advanced Parameters
Advanced options for tuning RADIUS behavior. Typically only required when under high load or when using two-factor or similar out-of-band authentication methods with RADIUS.

Retransmit Base
Base to use for calculating exponential back off. Default value is `1.4`.

Retransmit Timeout
Timeout in seconds before sending first retransmit. Default value is `2`.

Retransmit Tries
Number of times to retransmit a packet before giving up. Default value is `4`.

Sockets
Maximum number of sockets (ports) to use when communicating with a RADIUS server. Increase for high load environments with many frequent authentication requests. Default value is `1`.

Network List
Controls whether the client will attempt to send all of its traffic across the tunnel or only traffic for specific networks.

If this option is checked the networks defined in the **Local Network** options for the mobile phase 2 definitions will be sent to the client. If this option is unchecked clients will attempt to send **all** of their traffic, including Internet traffic, across the tunnel.

Note: Not all clients and mobile IPsec modes respect this option. Some, such as Windows, require routes to be added on the client side in certain configurations like IKEv2.

Save Xauth Password
When checked, clients that support this control message will allow the user to save their credentials when manually entered during Xauth authentication.

This is mainly respected by Cisco-based Xauth clients like those found on iOS and macOS.

DNS Default Domain
When checked, the GUI offers a text box for a value the firewall will push to clients as their default domain suffix for DNS requests.

For example if this is set to `example.com` and a client requests `host`, then the DNS request will be for `host.example.com`.

Split DNS
Controls how the client will send DNS requests to the DNS Server supplied (if any).

The following behaviors are available:

- If this option is unchecked, the client will send all of its DNS requests to the provided DNS Server(s).
- If the option is checked and the text box is empty, and a **DNS Default Domain** is set, then only requests for that domain name will go to the provided DNS Server(s).

- If the options is checked and a value is entered in the text box, then only requests for the domain(s) entered in the box will be forwarded to the provided DNS Server(s).

DNS Servers
When **Provide a DNS server list to clients** is checked and DNS server IP addresses are entered, the firewall sends these values to clients for making DNS requests while the VPN is connected.

Note: If mobile clients will route to the Internet over the VPN, ensure the clients get a DNS Server from the firewall using this option and that they do not have **Split DNS** enabled.

Without this configuration clients will send DNS requests to servers they were assigned by their ISP, however, clients will route the request across the tunnel and the queries will most likely fail.

WINS Servers
Works similar to DNS servers, but for WINS.

WINS is rarely used on modern networks and is best left disabled.

Phase 2 PFS Group
Overrides the PFS setting for all mobile phase 2 entries.

The best practice is to set this value on the phase 2 entries individually.

Login Banner
A brief bit of text sent to the client for display after the login process succeeds. Optional and only works on some Xauth clients.

IPsec Pre-Shared Keys Tab

The **Pre-Shared Keys** tab under **VPN > IPsec** defines key and identifier pairs which are used for authenticating IPsec tunnels. Primarily this is intended for use with mobile IPsec but there are occasional use cases for site-to-site tunnels as well.

Identifier
A string used to identify a peer. This is typically a username, a hostname, an E-mail address, or an IP address.

Secret Type
The type of secret to associate with this identity. It can be one of two types:

PSK
A traditional pre-shared key for use with most IKEv1 mobile IPsec configurations, site-to-site tunnels, and similar use cases.

EAP
An EAP key for use with IKEv2 mobile IPsec EAP-MSCHAPv2 authentication.

Pre-Shared Key
The contents of the key. As with a pre-shared key on an IPsec tunnel, this should be as long and complex as feasible. However, since this may be manually entered by a human in a manner similar to a password it might need to be more user-friendly than the key for a site-to-site tunnel.

Warning: The contents of these passwords must be known to the IPsec daemon and thus they must be stored in plain text (*Password Storage Security Policies*). If this is not acceptable, consider using RADIUS-based authentication instead.

Additional options are available for EAP type keys:

Identifier Type
Manually sets the type of the **Identifier** field to override automatic behavior.

See also:

See *Phase 1 Proposal (Authentication)* for explanations of the different identifier types.

Virtual Address Pool
A static IP address to assign to this particular peer. Leave blank to assign a random address from the pool defined on the **Mobile Clients** tab.

> **Warning:** This configuration creates a new pool which **must not** overlap existing pools. As such, this address must be **outside** of the pool defined on the **Mobile Clients** tab and **different from** any other pool defined on other PSK tab entries or Mobile Group Pool entries (Plus only).

DNS Server
A DNS server that the firewall will push to only this peer. Leave blank to use the DNS server value(s) from the **Mobile Clients** tab.

IPsec Mobile Group Pools Keys Tab (Plus Only)

The **Mobile Group Pools** tab under **VPN > IPsec** defines additional group mappings to address pools. This is most useful when utilizing EAP-RADIUS and supplying a Class attribute to identify pool membership for an authenticated user. Additional Mobile Group Pools are only used when **Group Authentication** is enabled in the **Mobile Clients** tab under **VPN > IPsec**

Groups
A string of comma separated group names. Must not overlap with the Authentication Groups selected on the **Mobile Clients** tab or the Groups of any previously configured Mobile Group Pool.

Virtual Address Pool
A subnet of addresses to assign to peers which map to this Mobile Group Pool.

> **Warning:** This configuration creates a new pool which **must not** overlap existing pools. As such, this address must be **outside** of the pool defined on the **Mobile Clients** tab and **different from** any other pool defined on other PSK tab entries or Mobile Group Pool entries (Plus only).

DNS Server
A DNS server that the firewall will push to peers in this group. Leave blank to use the DNS server value(s) from the **Mobile Clients** tab.

Advanced IPsec Settings

The **Advanced Settings** tab under **VPN > IPsec** contains options which control IPsec daemon behavior and how traffic is handled with IPsec.

IPsec Logging Controls
These options control which areas of the IPsec daemon generate log messages and their level of detail. For information on viewing the log, see *IPsec Logs*.

In most cases the optimal settings are the default: **IKE SA**, **IKE Child SA**, and **Configuration Backend** set to *Diag*, and all others set to *Control*.

Configure Unique IDs as
Controls how the IPsec daemon treats new connections with an identifier which matches an existing connection. In most cases a new connection is intended to replace an older connection, but certain use cases such as mobile clients may require multiple connections from the same remote identifier.

Yes (Replace)
The new connection is accepted by the IPsec daemon and it replaces the old connection, which is disconnected.

No
The new connection is accepted and the old connection is replaced only if the peer sends an `INITIAL_CONTACT` notification.

Never
The new connection is always allowed, and `INITIAL_CONTACT` notifications are ignored.

Keep
The new connection is rejected and the old connection remains active.

IPsec Filter Mode
Experimental. Controls how the firewall filters IPsec traffic.

Filter IPsec Tunnel, Transport, and VTI on IPsec tab (enc0)
The default behavior. Rules on the IPsec tab filter all IPsec traffic, including tunnel mode, transport mode, and VTI mode.

This is limited in that it **does not** allow for filtering on assigned VTI or transport mode interfaces, and does not allow for NAT or `reply-to` to function for VTI rules. It can also cause problems with connection state tracking for transport mode traffic.

> **Warning:** This mode requires special changes to the rules to work around incompatibilities between the default firewall state policy and the way VTI traffic is handled by the OS. See *IPsec VTI Filtering* for details.

Filter IPsec VTI and Transport on assigned interfaces, block all tunnel mode traffic
Enables firewall rules for assigned VTI and transport mode interfaces, NAT on VTI interfaces, and `reply-to` for rules on assigned VTI interface tabs. This also allows transport mode to properly filter traffic in both directions, such as with GRE tunnels protected by transport mode IPsec.

However, when set to filter on assigned VTI interfaces, **all tunnel mode traffic is blocked**.

> **Warning:** Do not set this option unless all IPsec tunnels are using VTI or Transport Mode.
>
> This option is incompatible with mobile IPsec as mobile IPsec is only capable of using tunnel mode.

IP Compression
Propose support for IPComp compression.

> **Warning:** Though the option is present in the GUI, the underlying operating system does not yet fully support IP compression.

Enable PKCS#11 Support
When set, enables support for PKCS#11 tokens in IPsec. This includes activating the `pcscd` daemon and enabling GUI controls in IPsec phase 1 for activating PKCS#11 authentication.

Strict Interface Binding
When set, the IPsec daemon configuration binds only to the interfaces required by the configuration, rather than binding to all interfaces.

This option is more secure but is known to break with interfaces which have dynamic IP addresses. Only enable this option in environments where it has been lab tested and proven to work as intended.

Unencrypted Payloads in IKEv1 Main Mode
Some IPsec implementations send the third Main Mode message unencrypted, probably to find the PSKs for the specified ID for authentication. This is similar to Aggressive Mode, and has the same security implications: A passive attacker can sniff the negotiated Identity, and start brute forcing the PSK using the HASH payload. The best practice is to keep this option disabled unless the implications are fully understood and compatibility to such devices is required (for example, some SonicWall devices).

Maximum IKEv1 Phase 2 Exchanges
IKEv1 phase 2 rekeying for one VPN gateway can be initiated in parallel. By default only `3` parallel rekeys are allowed. Undersized values can break VPN connections with many phase 2 definitions. If unsure, set this value to match the largest number of phase 2 entries on any phase 1.

Enable Cisco Extensions
Enables the Unity plugin which provides support for Cisco Extensions such as `Split-Include`, `Split-Exclude`, and `Split-DNS` for IKEv1 XAuth mobile clients. This allows clients which support these extensions to obtain values automatically when connecting to a mobile IPsec VPN.

Strict CRL Checking
When set, the IPsec daemon requires availability of a fresh CRL for peer authentication based on certificate signatures to succeed. Primarily useful when the CRL is obtained dynamically (e.g. OCSP).

> **Warning:** If there is no CRL available for a CA, validation will fail.

Make Before Break
Controls whether IKEv2 Reauthentication uses Make-before-Break or Break-before-Make when an IKE Security Association (SA) expires. Must be supported by both peers.

Only relevant for IKEv2 tunnels using reauthentication, it does not affect IKEv1 tunnels or IKEv2 tunnels set to rekey.

Break-before-Make (Unchecked, Default)
Deletes IKE and Child SAs before reauthenticating and making a new set of SAs. This behavior is standard and well-supported, but disruptive as there is a small gap between the old and new SA set in which IPsec connectivity is unavailable.

Make-before-Break (Checked)
Reauthenticates and makes a new SA set before deleting the old SA set. This eliminates the connectivity disruption, but requires that both endpoints support overlapping IKE and Child SA entries.

Asynchronous Cryptography
Allows cryptographic framework jobs to be dispatched in a multi-threaded manner to increase performance. Jobs are handled in the order they are received so that packets will be reinjected in the correct order.

> **Warning:** This option can increase performance, but may be unstable on certain hardware. When enabling this option, test connectivity during a maintenance window to ensure proper behavior. See Bug #8964 for details.

Custom Ports
Rare situations may require the firewall to listen for inbound IPsec packets on alternate port numbers for IKE and NAT-T. These settings can accommodate such cases, but affect every tunnel on the firewall.

Leave empty for the default behavior, which is to use UDP port `500` for IKE and `4500` for NAT-T.

Auto-exclude LAN Address
Set up an automatic IPsec bypass for traffic to and from the LAN subnet, so it does not get captured by policy-based IPsec.

Additional IPsec Bypass
Configures additional manual IPsec bypass behavior. When set, the GUI exposes the **IPsec Bypass Rules** control.

IPsec Bypass Rules
Custom rules which allow traffic matching combinations of **Source Address** and **Destination Address** pairs to be excluded from IPsec policies.

Source Address
The source address or network to exclude, and its mask.

Destination Address
The corresponding destination address or network to exclude, and its mask.

Note: These values are considered *together*. A packet must match **both** the source and destination to bypass IPsec policies.

These rules are useful to exclude traffic between multiple local networks, especially when a policy-based IPsec tunnel is set to use `0.0.0.0/0` as the remote network.

20.8.3 Choosing a Mobile IPsec Style

Currently only one type of mobile IPsec may be configured at a time, though there are multiple different styles to choose from.

- *IKEv2 with EAP-MSCHAPv2* for local username and password authentication
- *IKEv2 with EAP-RADIUS* for remote username and password authentication
- *IKEv2 with EAP-TLS* for per-user certificate authentication
- *Xauth+PSK* for local or remote username and password authentication
- Xauth+RSA for certificates and local or remote username and password authentication
- *Pre-Shared Key* for basic IPsec connectivity from older clients
- *L2TP/IPsec* for local or remote username and password authentication with clients that do not support one of the above methods.

See also:

- *Configuring IPsec IKEv2 Remote Access VPN Clients on Windows*
- *Configuring IPsec IKEv2 Remote Access VPN Clients on Ubuntu*
- *Configuring IPsec IKEv2 Remote Access VPN Clients on Android*
- *Configuring IPsec IKEv2 Remote Access VPN Clients on macOS*
- *Configuring IPsec IKEv2 Remote Access VPN Clients on iOS*

As of this writing, most **current** operating systems natively support IKEv2 or can use an app/add-on. It is currently the best available choice. Windows 7 and later, Android 11 and later, macOS 10.11 (El Capitan) and later, iOS 9 and later, and most Linux distributions have support built in for IKEv2. There is also a simple-to-use strongSwan IKEv2 app for various operating systems including older versions of Windows as well as Android 4.x and later.

Note: All IKEv2 types require a certificate structure including at least a Certificate Authority and a Server Certificate, and in some cases user certificates. For more information on Certificates, see *Certificate Management*. Clients can be picky about certificate attributes, so pay close attention to this chapter when creating the certificate structure.

Warning: When generating a **Server Certificate** for use with IKEv2, the **Common Name** of the certificate must be the hostname of the firewall as it exists in DNS. The name must be repeated again as an FQDN type Subject Alternative Name (SAN). The SAN step is handled automatically by the Certificate Manager on current versions of pfSense® software. The IP address of the firewall must also be present as an IP Address type SAN when possible. This information will be repeated later when relevant, but requires extra emphasis due to its importance. See *Create a Server Certificate*

IKEv2 with EAP-MSCHAPv2

With support for IKEv2 now widespread, IKEv2 with EAP-MSCHAPv2 is an ideal choice for current operating systems. Though there are several variations, EAP-MSCHAPv2 is the easiest to configure since it does not require generating or installing per-user certificates and does not require a working RADIUS server. The CA Certificate must still be installed onto the client as a trusted root certificate.

Tip: Many current clients will also work with a server certificate generated by the *ACME Package*. ACME certificates are already trusted by most clients natively, thus using ACME will bypass the need to install a CA entry on those clients.

EAP-MSCHAPv2 allows for username and password authentication using passwords stored on the **Pre-Shared Keys** tab under **VPN > IPsec** (*IPsec Pre-Shared Keys Tab*). These passwords are stored in plain text, so it is not as secure as using a RADIUS server, though it is more convenient.

See also:

- *IPsec Remote Access VPN Example Using IKEv2 with EAP-MSCHAPv2*

IKEv2 with EAP-RADIUS

EAP-RADIUS works identically to EAP-MSCHAPv2 except that user authentication happens via RADIUS. When EAP-RADIUS is chosen, a RADIUS server must be selected on the **Mobile Clients** tab. The RADIUS server must accept and understand EAP requests and it must also allow MSCHAPv2. Password security is left up to the RADIUS server. VPN access can be optionally limited by *RADIUS group* membership using the **Group Authentication** options on the **Mobile Clients** tab.

EAP-RADIUS is typically the best choice when a RADIUS server is available.

See also:

- *IPsec Remote Access VPN Example Using IKEv2 with EAP-RADIUS*

IKEv2 with EAP-TLS

EAP-TLS uses per-user certificate authentication instead of username and password authentication. As such, EAP-TLS requires generating certificates for each user, which makes it a bit more cumbersome from an administration standpoint. Certificates are validated against the CA similar to OpenVPN. The CA certificate, user certificate and its associated key must all be imported to the client properly.

Warning: When creating user certificates, the username must be used as the certificate common name and as a DNS/FQDN type Subject Alternative Name. If the same name is not present in both places, clients may not be validated properly. This is handled automatically by the Certificate Manager on current versions of pfSense software.

See also:

- *IPsec Remote Access VPN Example Using IKEv2 with EAP-TLS*

IKEv1 with Xauth and Pre-Shared Keys

Xauth+PSK works on a majority of platforms, the notable exception being current versions of Android. Windows XP through Windows 8 can use the Shrew Soft client, but Windows 10 does not currently work with any available client. macOS and iOS can use their built-in client to connect.

Note: When using Xauth, local users must exist in the **User Manager** and those users must have the `User - VPN - IPsec Xauth Dialin` privilege.

See also:

- *IPsec Remote Access VPN Example Using IKEv1 with Xauth*

IKEv1 with Xauth and RSA Certificates

Xauth+RSA works in most of the same conditions as Xauth+PSK, though it does in fact work on current Android devices. Certificates must be made for each user, and the certificates must be imported into the clients.

IKEv1 with Pre-Shared Keys Only

Pre-Shared Key only IPsec VPNs for mobile IPsec have become rare in modern times. Support was not very common, only found in the Shrew Soft client, some very specific Android versions such as those from Motorola, and in other third-party clients. They are not very secure, and are no longer recommended for general use. The only time they may be needed is in cases when client devices cannot support any other method.

See also:

- *IPsec Remote Access VPN Example Using IKEv1 with Pre-Shared Keys*

L2TP/IPsec (IKEv1)

L2TP/IPsec is a unique combination that, unfortunately, does not work very well in practice. In this style of setup mobile IPsec is setup to accept Transport Mode connections which secure all traffic between the public IP address endpoints of clients and the firewall. An L2TP connection is made across this transport mode channel to tunnel user traffic in a more flexible way. Though support for this model is found in most versions of Windows, MAC, Android, and other Operating Systems, they are all picky in different incompatible ways about what will work.

For example the Windows client does not work properly when the client system is behind NAT, which is the most common place that a VPN client would find itself. The problem is in an interaction between the client and the IPsec daemon used on pfSense, strongSwan. The strongSwan project states that it is a bug in the Windows client, but it is unlikely to be fixed since both strongSwan and Windows have focused their mobile client efforts on more modern and secure implementations such as IKEv2 instead.

Warning: L2TP/IPsec should be avoided when possible.

See also:

- *L2TP/IPsec Remote Access VPN Configuration Example*

20.8.4 NAT with IPsec Phase 2 Networks

pfSense® software supports for NAT on policy-based IPsec phase 2 entries to make the local network appear to the remote peer as a different subnet or address. This can be used to work around subnet conflicts or connect to vendors without renumbering a local network.

Warning: NAT is not currently compatible with route-based VTI IPsec tunnels without configuring an **IPsec Filter Mode** which is incompatible with tunnel-based IPsec. See *Advanced IPsec Settings* for details.

Configuration

NAT is configured by the **NAT/BINAT Translation** options on an IPsec phase 2 entry in tunnel mode, in combination with the **Local Network** settings.

Local Network
Values of **Type** and **Address** specify the **actual** local network (e.g. LAN subnet).

NAT/BINAT Translation
Values of **Type** and **Address** specify the **translated** network visible to the far side.

NAT Types

There are two main modes for NAT with IPsec:

Binat - 1:1 NAT
When both the actual and translated local networks use the same subnet mask, the firewall will directly translate the networks to one another inbound and outbound. Can also be used for single addresses.

This allows remote host to directly contact local hosts using their equivalent NAT addresses, provided that IPsec rules allow the traffic to pass.

NAT - Overload/PAT Style
If the Local Network is a subnet, but the **NAT/BINAT Translation** address is set to a single IP address, then a 1:many NAT (PAT) translation is set up that works like an outbound NAT rule on WAN. All outbound traffic will be translated from the local network to the single IP address in the NAT field.

Note: Inbound traffic from the remote network to individual local hosts is not possible in this mode.

Warning: NAT+IPsec cannot be configured between two different sized subnets (e.g. It cannot NAT a /24 subnet to a /27 subnet).

Example

Consider an IPsec tunnel to a Vendor which requires `172.16.5.0/24` for the network on this firewall. However, the LAN is actually `192.168.1.0/24`, and renumbering is not feasible.

To accommodate this scenario, set the phase 2 values as follows:

Local Network

Type
Network

Address
`192.168.1.0/24`

NAT/BINAT Translation

Type
Network

Address
`172.16.5.0/24`

Firewall Rules

NAT is processed before firewall rules, so firewall rules on the IPsec tab refer to the network in **Local Network**.

Remote End Notes

The far side of the tunnel does not need any knowledge of the actual **Local Network**. Their tunnel is built between their local network and the **NAT/BINAT Translation** value.

Packet Capturing Quirk

In a packet capture, the **Local Network** addresses are shown on outbound traffic, not the translated address. This does not indicate any problem.

20.8.5 Routed IPsec (VTI)

Route-based IPsec is an alternative method of managing IPsec traffic. It uses `if_ipsec(4)` from FreeBSD for Virtual Tunnel Interfaces (VTI) and traffic is directed using the operating system routing table. It does not rely on strict kernel security association matching like policy-based (tunnel mode) IPsec.

A routed IPsec tunnel creates an `ipsecX` interface at the operating system level and this interface has its own IP address. The `ipsecX` interface must be assigned so it can be used for purposes such as static or dynamic routing, daemon binding, traffic monitoring, and so on.

Once assigned, the IPsec interface also gains an automatic gateway which provides policy routing and gateway group capabilities.

Note: Routed IPsec is not replacing traditional tunnel mode IPsec or transport mode. The mode choice is up to the user when creating an IPsec phase 2 entry. Any mode may be used at the same time, subject to the caveats listed later in this document.

See also:

The Hangouts Archive contains a video which covers Routed IPsec.

Prerequisites

First pick a transit network. This is similar to choosing a tunnel network for a WireGuard, GRE, or OpenVPN instance. Typically this is a `/30` network in an unused subnet. This example uses `10.6.106.0/30`.

IPsec Configuration

- Create an IPsec Phase 1 entry as usual
- Create a Phase 2 entry under this Phase 1 with the following settings:

  Description
  Some useful relevant text (e.g. `HQ VTI Tunnel`)

  Mode
  Routed (VTI)

  Local Network Address
  `10.6.106.1`

  Remote Network Address
  `10.6.106.2`

  Proposal
  Set as needed to match the other end.

- Click **Save**
- Click **Apply Changes**

In most cases only a single phase 2 entry is necessary as all traffic for a specific address family can be carried over a single interface. A common use case for a second phase 2 is to setup an IPv6 address if the first is setup for IPv4 (or vice versa).

When using IKEv2 without split connections these addresses will all use the same underlying `ipsecX` interface. With IKEv1 or with IKEv2 and split connections active then each phase 2 will be a separate `ipsecX` interface which must be assigned and used independently.

Tip: The default case of IKEv2 without split connections is the best practice. Avoid using the other cases unless required by a third party.

IPsec Interface Assignment

- Navigate to **System > Routing**
- Set the **Default gateway** options to a specific gateway or group, as long as they are not left at *Automatic* (*Managing the Default Gateway*)

> **Warning:** If the default gateway remains set to *Automatic* the firewall may end up using the IPsec VTI interface as the default gateway, which is unlikely to be the desired outcome.

- Navigate to **Interfaces > Assignments**
- Pick the new `ipsecX` interface from the **Available Network Ports** list
- Click **+ Add**
- Note the new interface name, e.g. *OPT1*
- Navigate to **Interfaces > [New Interface Name]**
- Check **Enable**
- Give the interface a more suitable name using the **Description** field (e.g. `VTI_HQ`)
- Click **Save**
- Click **Apply Changes**

The firewall creates a gateway automatically which can be used for static routing, policy routing, and so on.

At this point the interface is available for use like any other interface. It can be used for packet captures, traffic graphs, binding daemons, routing protocols, and so on.

Routing

No traffic will attempt to cross the IPsec tunnel until routing is configured except for gateway monitoring probes (if enabled).

Static Routes

To setup static routes navigate to **System > Routing**, **Static Routes** tab. Add new routes there using the assigned IPsec interface gateway.

Typically there will be one static route per remote destination network, similar to how there would be one phase 2 entry per remote destination network with tunnel mode IPsec.

Dynamic Routes

As an alternative to manually managing static routes, assigned IPsec VTI interfaces can be used with the *FRR Package* for dynamic routing such as BGP and OSPF.

Policy Routes

To policy route traffic across a routed IPsec tunnel, use the assigned IPsec interface gateway in firewall rules as usual for policy routing.

Note: This may not work as expected without NAT and/or `reply-to`, which require special settings. See *Routed IPsec Firewall Rules* for details.

See also:

Policy Routing Configuration

Routed IPsec Firewall Rules

By default routed IPsec traffic appears to the OS on both the per-tunnel `ipsecX` interface and the `enc0` interface. When set this way **traffic must be passed on the IPsec tab**.

This can be changed, however. The behavior of firewall rules for traffic inside an IPsec tunnel depends on the **IPsec Filter Mode** option in the *Advanced IPsec Settings*.

To utilize features such as per-interface rules, NAT, and `reply-to` with routed IPsec the **IPsec Filter Mode** option must be set to filter on assigned interfaces. This option is not compatible with tunnel mode so it is only feasible if all tunnels on the firewall are using VTI or transport mode.

Warning: Staying on the default filter mode requires special changes to the rules to work around incompatibilities between the default firewall state policy and the way VTI traffic is handled by the OS. See *IPsec VTI Filtering* for details.

See also:

- *IPsec and firewall rules*
- *Advanced IPsec Settings*

Caveats

Routed IPsec works best when both sides support routed IPsec. It can still work when only one side supports routed IPsec, but most of its benefits are lost.

Rather than managing IPsec Phase 2 entries, routes must be managed instead. Since this can be automated with dynamic routing protocols this is not a large concern.

Firewall rule processing can be confusing as mentioned in *Routed IPsec Firewall Rules*. Some features such as NAT require special settings to function.

20.8.6 IPsec and firewall rules

Outer IPsec Traffic

pfSense® software automatically adds hidden firewall rules which allow traffic required to establish enabled IPsec tunnels. The traffic required to establish a tunnel includes:

- UDP port `500` (or a custom configured **Remote IKE Port** on a tunnel)
- UDP port `4500` (or a custom configured **Remote NAT-T Port** on a tunnel)
- The *ESP* protocol

The automatic rules restrict the source to the **Remote Gateway** IP address (where possible) destined to the Interface IP address specified in the tunnel configuration. When mobile client support is enabled the same firewall rules are added except with the source set to *any*.

To override the automatic addition of these rules check **Disable all auto-added VPN** rules under **System > Advanced** on the **Firewall & NAT** tab. When that box is checked firewall rules must be manually added to allow appropriate traffic on the correct interface(s) from the expected source(s).

Tunneled IPsec Traffic from Remote to Local

The behavior of firewall rules for traffic **inside** an IPsec tunnel depends on the **IPsec Filter Mode** option in the *Advanced IPsec Settings*.

Filtered on IPsec Tab

By default traffic passed inside a tunnel from the remote end is filtered by rules configured under **Firewall > Rules** on the **IPsec** tab (`enc0`). Those rules allow and restrict resources made accessible to remote IPsec users.

Note: By default all traffic from remote VPN hosts is blocked as there are no rules on the IPsec tab until they are manually added by a firewall administrator.

In this default mode traffic for transport and VTI mode tunnels does not always behave in a desirable way. This mode prevents VTI from using per-interface rules, NAT, or `reply-to`; transport mode can have issues tracking state properly.

Filtered on Assigned IPsec Interfaces

If all tunnels on the firewall are VTI or transport mode, then set the **IPsec Filter Mode** to filter on assigned interfaces instead. When set this way, assigned VTI interfaces can use per-interface rules, NAT, and `reply-to` as one would typically expect. Additionally, transport mode filtering works as expected with rules on the interfaces involved in transport mode (e.g. WAN, tunneling protocols like GRE, etc).

The downside of this mode is that all tunnel mode traffic is dropped and only VTI or transport mode traffic can be filtered as it is handled on separate interfaces (e.g. `ipsec1`, not the shared `enc0` interface).

Tunneled IPsec Traffic from Local to Remote

To control traffic in the other direction, from local networks to remote IPsec VPN connected devices or networks, use rules on the **local** interface where the **local** device resides. For example, connectivity from hosts on LAN to VPN destinations is controlled by rules on the **LAN** tab.

20.8.7 Using IPsec with Multiple Subnets

pfSense® software handles multiple IPsec networks using separate IPsec phase 2 entries which define source and destination pairs to pass through a tunnel.

For example, to accommodate the table below, define two Phase 2 entries on both sides:

Site A	Site B
`172.16.0.0/24`	`10.0.0.0/24`
`172.16.1.0/24`	

On the Site A Firewall:

- `172.16.0.0/24` to `10.0.0.0/24`
- `172.16.1.0/24` to `10.0.0.0/24`

On the Site B Firewall:

- `10.0.0.0/24` to `172.16.0.0/24`
- `10.0.0.0/24` to `172.16.1.0/24`

This works for any additional networks on either side, such as multiple local interfaces, mobile VPN clients, networks on the other end of VPNs connected to the remote router, etc.

Supernetting Example

If the equipment to which the tunnel connects does not support multiple phase 2 entries, it may be necessary to employ supernetting/CIDR summarization to fit the networks into a single phase 2.

Tip: This technique can also be used to keep the phase 2 list shorter and more manageable.

It is also more reliable to use fewer phase 2 entries as there is less to negotiate when building or rekeying tunnels. Note that this only applies to IKEv1 or IKEv2 with Split Connections, as IKEv2 uses a single child SA by default.

For example, consider the networks in the following table:

Site A	Site B
`192.168.0.0/24`	`10.0.0.0/24`
`192.168.1.0/24`	
`192.168.2.0/24`	

Due to the fact that the subnets are close to each other they can be grouped into a larger network in the tunnel definition: `192.168.0.0/22`.

Note: This larger subnet also includes `192.168.3.0/24` due to the way subnet math and boundaries work. If that is unacceptable then an alternate solution may be required, such as firewalling that subnet off or using different equipment at the end which does not support multiple networks.

20.8.8 Configuring IPsec Keep Alive

There are two methods which can make the firewall attempt to keep a non-mobile IPsec tunnel up and active at all times: automatic ping and periodic check. These options are available in the settings for each IPsec phase 2 entry.

See also:

See *Keep Alive* for additional details on these settings.

Automatic Ping

This method utilizes ICMP echo requests sent to a specific remote host across the VPN to match policies which will start a tunnel and keep it active.

For tunnel mode (policy-based) IPsec tunnels traffic destined to the **Remote Network** will attempt to initiate the tunnel when it is down. This is because the generated ping will match trap policies in the kernel and be considered "interesting traffic" for IPsec.

Warning: Due to the reliance on policies this method is not capable of initiating a VTI mode tunnel. It can send periodic traffic across a VTI mode tunnel if a use case requires that behavior.

This option will also not initiate a tunnel if its phase 1 **Child SA Start Action** is set to *Responder Only*.

Unlike other mechanisms such as DPD, this periodic traffic sent across the tunnel is treated like other traffic crossing the tunnel. This traffic would count as tunnel activity and reset any idle counters on the far side.

Note: Any IP address within the **Remote Network** of the phase 2 definition may be used. It does not have to reply or even exist.

Warning: For this feature to work the firewall **must** have an IP address assigned inside the **Local Network**. Otherwise it cannot generate the necessary traffic to match the phase 2 policies and traffic cannot enter the tunnel.

Periodic Check

This method utilizes a periodic status check which looks at the list of connected IPsec tunnels and will initiate entries which are not currently connected.

As this does not rely on tunnel traffic or trap policies it is compatible with any IPsec tunnel mode, including VTI mode.

IKEv1 vs IKEv2

Whether or not this option should be enabled on every phase 2 entry for a tunnel depends on the tunnel configuration.

IKEv1 or IKEv2 with Split Connections
: In these modes each phase 2 entry results in a separate child SA entry which can be connected separately. In this case, the keep alive options may be set on each phase 2 entry individually as needed. If all phase 2 entries must stay connected, then it must be enabled on every entry.

IKEv2 without Split Connections
: In this mode the phase 2 entries are combined into a single child SA entry and all combinations of phase 2 entries are connected as a single group. In this case the keep alive options need only be enabled on the **first** phase 2 entry for a tunnel.

See also:

See *IPsec phase 1 Advanced Options* for more information on how the **Split Connections** option works.

20.8.9 Testing IPsec Connectivity

The easiest test for an IPsec tunnel is a ping from one client station behind the firewall to another on the opposite side. If that works, the tunnel is up and working properly.

As mentioned in *Accessing Firewall Services over IPsec* traffic initiated from pfSense® software will not normally traverse a tunnel without extra routing. That said, there is a quick way to test the connection from the firewall itself by manunally specifying a source address when issuing a ping.

There are two methods for performing this test: the GUI, and the shell.

Specifying a Ping Source in the GUI

In the GUI, a ping may be sent with a specific source as follows:

- Navigate to **Diagnostics > Ping**
- Fill in the settings as follows:

  Host
  Enter an IP address which is on the remote router within the remote subnet listed for the tunnel phase 2 (e.g. `10.5.0.1`)

  IP Protocol
  The address family of the host being used (e.g. *IPv4* for `10.5.0.1`)

  Source Address
  Select an interface or IP address on the local firewall which is inside the local Phase 2 network (e.g. Select *LAN* for the LAN IP address)

  Maximum number of pings
  Set an appropriate value which will be high enough to be meaningful yet low enough that it doesn't take too long to run. The default value of `3` ideal.

- Click **Ping**

If the tunnel is working properly ping replies will be received by the firewall from the LAN address at Site B. If replies are not received, move on to the *Troubleshooting IPsec VPNs* section.

Note: Typically the first ping or two may be lost during tunnel negotiation, so the best practice is to use at least `3`.

If the first attempt did not produce any results, try again. If it still fails, try once more with a slightly higher **Maximum number of pings** value.

Specifying a Ping Source in the Shell

Using the shell on the console or via ssh, the ping command can be run manually and a source address may be specified with the `-S` parameter. Packets generated by `ping` will not attempt to traverse the tunnel without using `-S` or a static route.

The syntax for a proper test is:

```
#  ping -S <Local LAN IP Address> <Remote LAN IP Address>
```

Where the *Local LAN IP Address* is an IP address on an internal interface within in the local subnet definition for the tunnel, and the *Remote LAN IP Address* is an IP address on the remote router within the remote subnet listed for the tunnel.

In most cases this is the LAN IP address of the respective firewalls. For example, if the LAN IP address at site A is `10.3.0.1` and the LAN IP address at site B is `10.5.0.1`, then the following command would send a test ping from site A to site B:

```
#  ping -S 10.3.0.1 10.5.0.1
```

If the tunnel is working properly, ping replies will be received by the firewall from the LAN address at Site B. If replies are not received, move on to the *Troubleshooting IPsec VPNs* section.

20.8.10 Client Routing and Gateway Considerations

When the VPN endpoint is the default gateway for a network there are normally no problems with routing. When a client PC sends traffic it will go to its default gateway, over the tunnel, and out the other end. However, if the firewall is not the default gateway for a given network, then other routing measures will need to be taken.

As an example, imagine that the firewall is the gateway at Site B but not Site A. This is illustrated in Figure *Site-to-Site IPsec Where the VPN Endpoint is not the Gateway*. The device PC1 at Site B sends a ping to PC2 at Site A. The packet leaves PC1, travels through the firewall at Site B, traverses the tunnel, exits the firewall at Site A, and on to PC2. What happens on the way back? The gateway on PC2 is a different router entirely. The reply to the ping will be sent to the gateway router and most likely be tossed out, or even worse, it may be sent out the Internet link and be lost that way.

There are several ways around this problem. The best practice depends on the circumstances of a given use case.

- A static route could be entered into the gateway router that will redirect traffic destined for the far side of the tunnel to the VPN endpoint.

  Even with this route, additional complexities are introduced because this scenario results in asymmetric routing as covered in *Bypass Firewall Rules for Traffic on Same Interface*.

- A static route could be added to the client systems individually so that they know to send that traffic directly to the VPN endpoint and not via their default gateway.

  Unless there are only a very small number of hosts that need to access the VPN, this is a management headache and should be avoided.

- Make the VPN endpoint the default gateway and let it handle the Internet connection instead of the existing gateway.

  In some situations this is easier than attempting to setup complicated routing, but it may not be acceptable to network administrators or management.

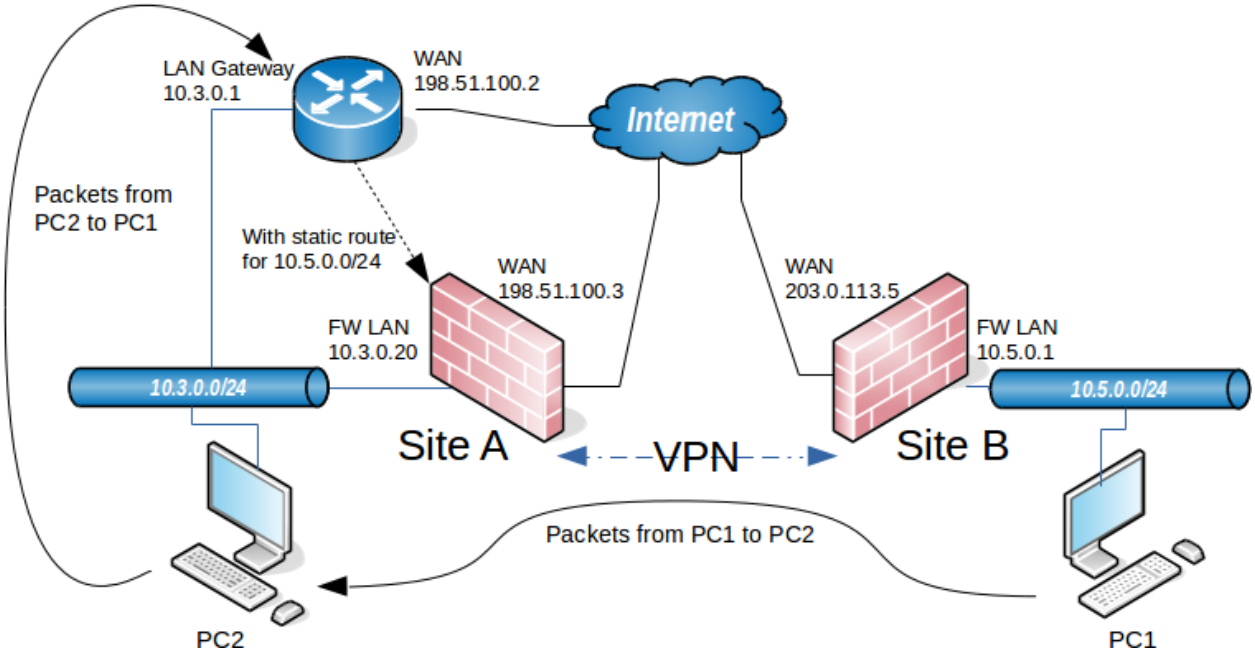

Fig. 3: Site-to-Site IPsec Where the VPN Endpoint is not the Gateway

20.8.11 Configuring Third Party IPsec Devices

Any VPN device which supports standard IPsec may be connected to a device running pfSense® software. pfSense software is used in production in combination with numerous vendors' equipment, and will most likely work fine with any IPsec capable devices encountered in other networks. Connecting devices from two different vendors can be troublesome regardless of the vendors involved because of configuration differences between vendors, in some cases bugs in the implementations, and the fact that some of them use proprietary extensions. Some examples are provided at the end of this chapter for several common Cisco devices.

To configure an IPsec tunnel between pfSense software and a device from another vendor, the primary concern is to ensure that the phase 1 and 2 parameters match on both sides. For the configuration options on pfSense, where it allows multiple options to be selected, only select one of those options and ensure the other side is set the same. The endpoints will attempt to negotiate a compatible option when multiple options are selected, however that is frequently a source of problems when connecting to third party devices. Configure both ends to what are believed to be matching settings, then save and apply the changes on both sides.

Once the settings match on both ends of the tunnel, attempt to pass traffic over the VPN to trigger its initiation then check the IPsec logs on both ends to review the negotiation. Depending on the situation, the logs from one end may be more useful than those from the opposite end, so it is good to check both and compare. The pfSense software side typically provides better information in some scenarios, while on other occasions the other device provides more useful logging. If the negotiation fails, determine whether it was phase 1 or 2 that failed and thoroughly review the settings accordingly, as described in *Troubleshooting IPsec VPNs*. The side that is initiating often cannot see why, so check the logs on the responding side first.

Terminology Differences

Another frequent source of failures is differences in terminology between vendors. Here are a few common things to look out for:

Policy-Based VPN/IPsec
: The type of IPsec used by pfSense software in tunnel mode. Policies are defined which control traffic entering the tunnel (e.g. Phase 2 entries).

Encryption Domain, Policy, Proxy ID
: A network definition used in Phase 2 to control which traffic will be handled by IPsec.

  On some platforms, including Palo Alto, these "Proxy ID" definitions are used in Phase 2 (IPsec) negotiation to inform the remote peer about traffic selectors for networks involved in the VPN. In these cases, they help with negotiation between a device supporting only route-based IPsec and a device that only supports policy-based IPsec.

Route-Based VPN/IPsec
: The type of IPsec used by pfSense software in VTI mode. There is an IPsec interface which routes similar to other interfaces and obeys the routing table, rather than relying on policies.

S2S or L2L
: Short for Site-to-Site or LAN-to-LAN, distinguished from a mobile client style VPN.

Perfect Forward Secrecy (PFS)
: Some vendors have different names for PFS. It may only be a toggle which uses the same value as the Phase 1 **DH Group**, others label it with full text or the acronym, others label it **DH Group**. It may also be labeled **MODP** in some implementations.

Transform Set
: On Cisco devices, a set of parameters which define Phase 2 handling such as encryption and hash algorithms.

ISAKMP Policy
: On Cisco devices, a set of parameters that define Phase 1 (IKE) handling such as authentication, encryption, and hash algorithms, and others.

Proposals
: On Juniper and Fortigate, sets of options that define parameters for Phase 1 (IKE) or Phase 2 (IPsec) handling.

NAT Exemption or no-nat
: On Juniper and Cisco, exceptions to NAT that must be made to ensure that traffic traversing a VPN does not have NAT applied. Not generally relevant to IPsec on pfSense software since NAT is not performed on IPsec by default.

Lifebytes or Traffic Lifetime
: Limits on the amount of traffic sent over a VPN before it renegotiates. Not currently supported in the pfSense software GUI. If present on a remote device it may need to be disabled.

Compatible Devices

Nearly any device supporting standard IPsec can be connected with pfSense software. This page lists devices reported to work by users, though it should not be considered complete.

> **Warning:** Ensure firmware is up-to-date on devices before attempting to configure IPsec. Older devices and firmware may not support modern secure algorithms and standards.

- Adtran
- Cisco routers
- Cisco PIX and ASA firewalls
- Checkpoint NG
- DLink VPN Routers
- Draytek VPN routers
- IBM z/OS mainframes
- IPCop
- Juniper routers and firewalls
- Kerio Control
- LANCOM VPN Routers with LCOS
- Linksys VPN Routers
- m0n0wall
- Mikrotik
- Nortel Contivity
- Palo Alto Networks
- Sonicwall
- StoneGate Firewall/VPN
- Ubiquiti Unifi Security Gateway

- Watchguard
- Zyxel firewalls

. . . and many more.

If a device is not listed and is known to work with pfSense software for IPsec, please *submit a documentation update*.

Consult the device documentation for IPsec configuration details.

20.8.12 Accessing Firewall Services over IPsec

With an out of the box configuration it is not possible to query SNMP or other similar services on the LAN interface address of a remote firewall running pfSense® software over a tunnel mode IPsec VPN connection.

Note: Most of the advice in this document only applies to tunnel mode, not routed IPsec (VTI). See *Routed IPsec (VTI)* for details.

Fred Wright explained in a post to the m0n0wall mailing list on September 12, 2004 why this is, and it's the same reason here.

> Due to the way IPsec tunnels are kludged into the FreeBSD kernel, any traffic *initiated* by m0n0wall to go through an IPsec tunnel gets the wrong source IP (and typically doesn't go through the tunnel at all as a result). Theoretically this *shouldn't* be an issue for the *server* side of SNMP, but perhaps the server has a bug (well, deficiency, at least) where it doesn't send the response out through a socket bound to the request packet. You can fake it out by adding a bogus static route to the remote end of the tunnel via the m0n0wall's LAN IP (assuming that's within the near-end tunnel range). A good test is to see whether you can ping something at the remote end of the tunnel (e.g. the SNMP remote) *from* the m0n0wall. There's an annoying but mostly harmless side-effect to this - every LAN packet to the tunnel elicits a no-change ICMP Redirect.

Most notably this is a problem for UDP services bound to all interfaces (*) and ICMP. In these cases, a reply uses the "closest" address to the client from the perspective of the system routing table. Without a route present matching the desired destination this results in using the IP address of the interface containing the default gateway.

Service Binding Workaround

Some services have options which make it possible to change the interface binding so that the daemon only binds to a specific interface or IP address (e.g. the IP address of the internal network on the local end of the VPN) on the firewall. The interface binding for SNMP, NTP, the DNS Forwarder, and several other services can be set in this way.

With the daemon bound to only that specific address, that is also the only address it can use to reply, and thus it can generate the expected replies which will properly take the IPsec path back to the other end.

Static Route Workaround

If changing the service binding is not possible, or for full connectivity between the endpoints, use static routes to work around the situation.

Note: When both endpoints must be accessed, a static route is required on each endpoint.

Setting up a static route is done by first adding a gateway pointing to the LAN IP address of the firewall (See *Gateways*) and then adding a static route using this gateway (See *Static Routes*).

Warning: Do not attempt to use this method with routed IPsec (VTI). See *Routed IPsec (VTI)* for details.

Add Gateway

First, add a gateway for the address of the firewall itself:

- Navigate to **System > Routing** on the **Gateways** tab
- Click  **Add** to add a gateway
- Configure the following settings:

  Interface
  LAN

  Name
  `IPsecGW` or another appropriate name, as desired.

  Gateway
  Enter the LAN IP address of **this** firewall.

  Disable Gateway Monitoring
  Checked

- Click **Save**
- Click **Apply Changes**

Add Route

Now add this route in the GUI:

- Navigate to the **Static Routes** tab
- Click  **Add**
- Configure the following settings:

  Destination Network
  The **remote** VPN network

  Gateway
  IPsecGW or whichever name was used when creating the gateway

  Description
  `Allow firewall itself to communicate over VPN`

- Click **Save**
- Click **Apply Changes**

Test

Perform a test as described in *Testing IPsec Connectivity* using the address of the far side system and the local address that system is attempting to query.

Routed IPsec (VTI)

The previous advice in this document does not generally apply to route-based IPsec (VTI mode) since it operates in a fundamentally different way than policy-based IPsec (tunnel mode).

With VTI mode IPsec the routing table contains proper routes back to the remote end using the VTI interfaces. Responses will utilize these routes to select the IPsec interface when looking up the path back across the tunnel.

This may mean the remote end should query the address of the IPsec interface directly so that the responses are received from a matching address, but whether or not this is necessary depends on the service and client.

The *Service Binding Workaround* can still help here if queries must be made to and from the LAN IP address directly, but the static route method must not be used as it will conflict with the routing necessary for VTI traffic to function.

20.9 WireGuard

20.9.1 WireGuard Settings

WireGuard Package Settings

The WireGuard package contains the following configurable options:

Enable
Controls whether or not the WireGuard service itself is enabled or disabled.

Note: The WireGuard service cannot be disabled when one or more tunnels is assigned to an interface via *Interface Configuration*.

Keep Configuration
Controls whether or not the tunnel/peer configurations and package settings will persist when the package is removed.

Endpoint Hostname Resolve Interval
Controls how often peer endpoint hostnames are resolved and updated by the WireGuard service. By default this is `300` seconds (5 minutes).

Track System Resolve Interval
This option overrides the **Endpoint Hostname Resolve Interval** setting and configures the WireGuard service to track and use the system *Aliases Hostnames Resolve Interval*.

Interface Group Membership
Controls which WireGuard tunnels are implicit members of the WireGuard interface group. By default this is `All Tunnels`.

Tip: See *Rule Methodology* for more on **Interface Groups** and **Rule Processing Order**.

Hide Secrets
Controls whether or not secrets (private and pre-shared keys) are hidden in the user interface.

Warning: **Hide Secrets** only hides secrets in the user interface. It does not obfuscate secrets for storage in the pfSense® software configuration file, `config.xml`. For more information on password storage and protecting configuration file backups see *Password Storage Security Policies*

WireGuard Tunnel Settings

When creating or editing a WireGuard tunnel, the following options are available:

Enable
Controls whether or not this WireGuard tunnel is enabled or disabled.

Note: A WireGuard tunnel cannot be disabled while assigned as an interface.

Description
A short text description of this WireGuard tunnel.

Listen Port
The local port upon which this WireGuard tunnel will listen for incoming traffic from peers, and the port from which it will source outgoing packets. The default port is `51820`, additional tunnels must use a different port.

Note: The GUI will automatically suggest the next highest available port.

Interface Keys
The private and public key pair for this WireGuard tunnel. The public key is derived from the private key and does not need to be entered separately. The GUI will display the public key automatically when possible. When entering a new private key manually, the public key will be available after saving the tunnel.

The private key will stay only on this firewall, the public key will be copied to peers.

A new set of keys can be generated by the  **Generate** button.

Tip: Click **Copy** under the public key to copy it to the clipboard.

Interface Addresses
A list of IPv4 and/or IPv6 addresses which will be assigned to this WireGuard tunnel.

Note: Interface addresses are configured here only for WireGuard tunnels that are not assigned to an interface via *Interface Configuration*.

WireGuard Peer Settings

When creating or editing a WireGuard peer, the following options are available:

Enable
Controls whether or not this WireGuard peer is enabled or disabled.

Tunnel
Controls which WireGuard tunnel to associate with this peer. The default is *Unassigned*.

Tip: Peers can easily be staged or moved between tunnels using this option.

Description
A short text description of this peer.

Dynamic Endpoint
This option controls whether a WireGuard peer should be considered dynamic. Uncheck this option for a peer that has a fixed, static endpoint address or hostname.

Endpoint
The IP address or hostname of the remote WireGuard peer, from which the peer will connect to this firewall, and to which this WireGuard instance will send traffic destined for this peer.

This can be left empty if the peer endpoint is unknown, such as for dynamic remote access clients. When empty, the tunnel will track the endpoint dynamically based on the key used by the peer. Additionally, when empty, this firewall cannot initiate traffic on the tunnel to the peer until the remote peer sends traffic.

Endpoint Port
The port used by the peer for WireGuard traffic. The default port is `51820` if left empty.

Note: If the **Endpoint** is empty, this value is ignored.

Keep Alive
An interval, in seconds, at which an empty packet is sent to the peer to keep the session active. This can improve handling through stateful firewalls. Disabled by default.

Public Key
The public key of this peer.

Pre-Shared Key
An optional pre-shared key which provides an additional layer of symmetric-key cryptography on top of the public key cryptography for post-quantum resistance.

A new pre-shared key can be generated by the  **Generate** button.

Tip: Click **Copy** under the public key to copy it to the clipboard.

Allowed IPs
List of networks **on the peer side** which the firewall can reach through this peer. For example, on a site-to-site VPN this would be the tunnel address of the peer and any LAN segments reachable via this peer.

When a tunnel has multiple peers this list allows WireGuard to determine which peer will receive traffic for destinations routed through the WireGuard interface.

The networks listed here are transformed into proper subnet start boundaries prior to validating and saving.

Warning: These networks cannot be duplicated between multiple peers on the same tunnel, they must be unique. Otherwise, only the last peer in the list will be configured properly.

Note: All traffic may be associated with a peer by using `0.0.0.0/0` for IPv4 or `::/0` for IPv6, but this won't work for a tunnel with multiple peers. Only the last peer in the list will be configured properly.

Note: Routes are not automatically created in the system routing table. Routes for networks other than the tunnel network itself must be configured separately using *static* or *dynamic* routes.

Tip: For those familiar with OpenVPN, the internal routing used by WireGuard is similar to `iroute` statements which associate remote networks with specific clients.

20.9.2 Design Considerations

One of the main considerations when choosing a WireGuard implementation layout is whether to use one tunnel with many peers, or one tunnel per peer.

Routing to WireGuard Peers

WireGuard uses what it calls "Cryptokey Routing" to map traffic inside WireGuard to a specific peer which is then encrypted using the public key for that peer. In practice, this means that when multiple peers are defined on a WireGuard instance, it must have all networks which will be routed to each peer defined on the peer. This can make managing networks and routes cumbersome.

When there is only one peer on a wireguard interface, it can instead assume that the one peer is the correct destination for all traffic which crosses the interface (e.g. **Allowed IPs** set to `0.0.0.0/0` or `::/0`). And in that case, a routing protocol such as BGP or OSPF can manage the operating system routing to the neighbor instead of static routes.

Design Style

WireGuard does not have a concept of "Client" and "Server" per se, but depending on the configuration the firewall can behave in a manner similar to a "Client" (initiates locally, remote never initiates) or "server" (never initates, remotes always initiate).

Technically every WireGuard tunnel is a peer to peer connection, but there are three main ways a WireGuard tunnel can be configured depending on whether or not a peer endpoint is known or defined:

- Site-to-Site (peer endpoint filled in on both sides)
- Remote Access "Server" (endpoint only filled in on remote peers)
- Remote Access "Client" (endpoint only filled in locally, not on the "server" peer)

Any of those roles can technically be configured no matter how the peer endpoint settings are defined, but not defining an endpoint on one side or the other limits the capacity in which a peer can operate.

In the case of remote access style setups, the peer endpoint address is typically unknown and can change at any time. In this case, the peer endpoint can be left blank and WireGuard will accept connections from any remote address, validating the key instead.

Note: WireGuard supports roaming automatically, and can detect when a peer has changed IP addresses. WireGuard will recognize that authenticated data is coming from a new address and update itself accordingly.

20.9.3 WireGuard Limitations

There are a few limitations of the WireGuard implementation in FreeBSD which must be taken into consideration when deciding if WireGuard fits the needs of a use case.

Response Sourcing

WireGuard does not bind itself to an interface or a specific address on the firewall, but instead can accept traffic on any local IP address. This makes it very flexible, but can cause problems with functionality which requires traffic to use a specific address. When a WireGuard peer contacts the firewall, the firewall will respond from the address the peer used to contact it, if possible.

There are certain cases where this may not function as expected, such as when a peer was communicating with a CARP VIP which changed status.

Remote Peer Endpoint Requirements

When this firewall initiates a packet to a remote WireGuard endpoint, the source will be based on the main IP address on the WAN interface with the default gateway. If a remote endpoint expects to communicate with a different address, it is unlikely to work.

In this case, the problem can be worked around by updating the remote peer to use the correct endpoint address.

If this firewall is the only peer to initiate traffic in the tunnel, an outbound NAT rule could be crafted which matches the incorrect source address and translates it to the expected address.

Another alternative is to remove the remote endpoint from the peer configuration on this firewall, and set the remote endpoint to use the expected peer address for this firewall. If the remote peer always initiates traffic and sends to the expected address, replies will use that address.

High Availability

The address selection behavior mentioned earlier can cause some unexpected behavior with CARP.

For example, if a CARP node goes into maintenance mode during ongoing communication with a peer, the CARP VIP will no longer be available for use by WireGuard and the CARP node may respond to the client using its interface address instead. This can cause the remote peer to continue attempting communication with that specific node, and not the node holding MASTER status for the CARP VIP. This isn't a problem when a CARP node is powered off or reboots, as in those cases the CARP node cannot issue the unexpected responses.

When initiating traffic to a remote endpoint it can't be properly sourced from a CARP VIP. Outbound NAT cannot work around this limitation as the state created by outbound NAT is tied to a specific HA node. If that node fails, the other node cannot utilize the same state as it doesn't match its own local address. Allowing the remote peer to always initiate can work around this limitation.

Multi-WAN

If a client contacts the firewall via its WAN2 address, the firewall will respond from its WAN2 address as expected. However, if this firewall initiates, the traffic will always leave via the interface with the default route unless the routing table sends the traffic by another path.

If the only concern is connectivity, this may be acceptable. However, it is not acceptable if the intent is to cause WireGuard to use WAN2 for its initiated traffic.

For remote peers with static addresses, this can be worked around by adding a static route for the remote endpoint address using the correct WAN gateway.

20.9.4 Configure a WireGuard Tunnel

To configure a WireGuard Tunnel:

- Navigate to **VPN > WireGuard > Tunnels**
- Click  **Add Tunnel**
- Fill in the WireGuard Tunnel settings as described in *WireGuard Package Settings*
- Click **Save Tunnel**
- Add firewall rules on **Firewall > Rules**, **WAN** tab to allow UDP traffic to the port for this WireGuard tunnel (*WireGuard and Rules / NAT*)
- Add firewall rules on the common **Firewall > Rules**, **WireGuard** tab to pass traffic inside the VPN (*WireGuard and Rules / NAT*)

Configure a WireGuard Peer

To configure a WireGuard peer:

- Navigate to **VPN > WireGuard > Peers**
- Click  **Add Peer**
- Fill in the WireGuard Peer settings as described in *WireGuard Peer Settings*
- Click **Save Peer**
- Repeat the add/configure steps if there are multiple peers

Additional Configuration Steps

After configuring the WireGuard tunnel, there are a few more optional steps depending on the requirements of the use case:

- Navigate to **System > Routing**
- Set the **Default gateway** options to a specific gateway or group, as long as they are not left at *Automatic* (*Managing the Default Gateway*)

> **Warning:** If the default gateway remains set to *Automatic* the firewall may end up using the WireGuard interface as the default gateway, which is unlikely to be the desired outcome.

- Assign the WireGuard interface as a new OPTx interface (*Assign a WireGuard Interface*)
- Add firewall rules specific to this tunnel on **Firewall > Rules**, **OPTx** tab to pass traffic inside the VPN (*WireGuard and Rules / NAT*)
- Setup one of the alternate routing methods as described in *WireGuard Routing*, if needed.

20.9.5 Assign a WireGuard Interface

Some functionality for WireGuard interfaces depends upon them being assigned as their own interfaces on the firewall. Benefits of assignment include:

- Adds a firewall tab under **Firewall > Rules**
- Allows the interface to be selected for use with NAT rules
- Allows the interface to be selected throughout the GUI and packages for various purposes
- Rules on assigned interface tabs get `reply-to` which ensures return routing will exit back the expected interface for inbound connections.

Assignment Procedure

To assign the interface:

- Navigate to **System > Routing**
- Set the **Default gateway** options to a specific gateway or group, as long as they are not left at *Automatic* (*Managing the Default Gateway*)

> **Warning:** If the default gateway remains set to *Automatic* the firewall may end up using the WireGuard interface as the default gateway, which is unlikely to be the desired outcome.

- Navigate to **Interfaces > Assignments**
- Select the appropriate `tun_wg<number>` interface in the **Available network ports** list

  The description of the tunnel is printed next to the interface name in the list.

- Click  **Add** to assign the interface as a new OPT interface (e.g. OPT1)
- Navigate to the Interface configuration page, **Interfaces > OPTx**
- Check **Enable**
- Enter an appropriate **Description** which will become the interface name (e.g. `WG_S2S`)
- Configure an appropriate **MTU** value for the WireGuard interface

  The appropriate *MTU* varies depending on the MTU of the underlying circuit. WireGuard overhead is approximately `80` Bytes for IPv6 packets and `60` Bytes for IPv4 packets.

  On WANs with `1500` byte MTUs, the MTU for WireGuard interfaces should be `1420` for VPNs carrying IPv6 packets, or `1440` for VPNs which only carry IPv4 traffic.

  Other WAN types with smaller MTUs, such as PPPoE, should subtract the overhead from their actual WAN MTU. When in doubt, use a slightly lower value to avoid excess fragmentation.
- Configure interface addresses and gateways as necessary
- Click **Save**
- Click **Apply Changes**

20.9.6 WireGuard and Rules / NAT

There are multiple concerns with firewall rules for WireGuard.

External Traffic

Firewall rules must pass traffic on WAN to the WireGuard **Listen Port** for a tunnel if remote WireGuard peers will initiate connections to this firewall. The protocol is always UDP, and the default port is `51820`.

Tunneled Traffic

Firewall rules must pass traffic on WireGuard interfaces to allow traffic inside the VPN, assuming remote connections should be allowed to local internal hosts. Use rules on the WireGuard group tab or rule tabs for assigned interfaces.

Rules on the WireGuard group tab are considered first and can match traffic on any WireGuard interfaces whether or not they are assigned.

Assigned WireGuard interfaces get their own individual rule tabs and will only match traffic on that specific tunnel interface. Rules on assigned WireGuard interface tabs also get `reply-to` which ensures that traffic entering a specific assigned WireGuard interface exits back out the same interface. Without that, return traffic will follow the default gateway.

Warning: Rules on the WireGuard group tab are matched first, so ensure rules on the group tab are removed, disabled, or do not match traffic which requires `reply-to`.

NAT functions on WireGuard interfaces once assigned. Outbound NAT, 1:1 NAT, and port forwards all work as expected.

Note: The firewall will automatically perform Outbound NAT on traffic exiting assigned WireGuard interfaces when using the default **Automatic Outbound NAT** mode (*See Outbound NAT*).

20.9.7 WireGuard Routing

WireGuard can work with both static and dynamic routing, depending on the environment.

Static Routing

WireGuard routing can be handled manually to reach remote LAN segments in addition to the tunnel network itself. To setup static routes:

Warning: Before assigning the interface, make sure default gateway for the firewall is not set to *Automatic* or the firewall may end up using the `tun_wg<num>` interface as the default gateway, which is unlikely to be the desired outcome.

- Assign the WireGuard interface for this peer (*Assign a WireGuard Interface*)
- Create a gateway using the peer address (*Gateways*)
- Add static routes using this gateway for the WireGuard tunnel

Dynamic Routing

WireGuard can work with dynamic routing, but there are some special considerations to take into account.

Note: This has only been tested with FRR.

The primary requirement to use dynamic routing with WireGuard is that there can only be one peer per WireGuard tunnel. When more than one peer is connected to a single WireGuard tunnel, WireGuard requires **Allowed IPs** to decide where to send specific networks. In that case, having to define these networks manually negates the purpose of dynamic routing. Using a single peer allows WireGuard to send any traffic it needs across the interface, including arbitrary networks.

BGP
: BGP works without any special configuration. Define the neighbor using the WireGuard interface address of the peer.

OSPF
: OSPF works, but needs special settings because it cannot utilize multicast traffic to find neighbors.

  In the OSPF settings of FRR:

  - Set the WireGuard interface **Network Type** to *Non-Broadcast* mode
  - Add a manual entry on the **Neighbors** tab using the WireGuard interface address of the peer

Other routing protocols have not been tested. If a routing protocol relies on broadcast or multicast traffic, it is unlikely to work.

Return Routing

When allowing inbound connections from arbitrary remote networks, use rules only on assigned WireGuard interface tabs only to ensure proper return routing.

Assigned WireGuard interfaces get their own individual rule tabs and will only match traffic on that specific tunnel interface. Rules on assigned WireGuard interface tabs also get `reply-to` which ensures that traffic entering a specific assigned WireGuard interface exits back out the same interface. Without that, return traffic will follow the default gateway.

- *WireGuard VPN Client Configuration Example*

20.9.8 WireGuard Overview

WireGuard is a new VPN Layer 3 protocol designed for speed and simplicity. It performs nearly as fast as hardware-accelerated IPsec and has only a small number of options in its configuration.

Due to this simplicity, WireGuard lacks many of the conveniences of more complicated VPN types which can help automate large deployments. Thus, while its performance scales well, the management can become cumbersome for large numbers of peers.

WireGuard behaves unlike other traditional VPN types in several ways:

- It operates completely in the kernel

- Configuration is placed directly on the interfaces
- It has no concept of connections or sessions
- It has no facilities for user authentication
- There is minimal logging from the kernel
- It does not bind to a specific interface or address on the firewall, it accepts traffic to any address on the firewall on its specified port

WireGuard instances consist of a tunnel and one or more peer definitions which contain the necessary keys and other configuration data.

WireGuard interfaces carry Layer 3 information and above.

To use WireGuard, upgrade to the latest version of pfSense Plus or pfSense CE software then install the WireGuard package from the *Package Manager*.

- *L2TP Server Configuration*
- *Troubleshooting Cisco VPN Pass Through*

VPNs provide a means of tunneling traffic through an encrypted connection, preventing it from being seen or modified in transit. pfSense® software offers several VPN options: IPsec, OpenVPN, WireGuard and L2TP. This section provides an overview of VPN usage, the pros and cons of each type of VPN, and how to decide which is the best fit for a particular environment. Subsequent sections discuss each VPN option in detail.

L2TP is purely a tunneling protocol and does not offer any encryption of its own. It is typically combined with another method of encryption such as IPsec in transport mode. Because of this, it doesn't fit in with most of the discussion in this chapter. See *L2TP VPN* for more information on L2TP.

20.10 PPTP Warning

pfSense software does not include a PPTP server. Despite the attraction of its convenience, PPTP **must not be used** under any circumstances because it is no longer secure. This is not specific to the implementation of PPTP that was in pfSense software; Any device that utilizes PPTP is no longer secure.

PPTP relies upon MS-CHAPv2 which has been completely compromised. Intercepted traffic can be decrypted by a third party 100% of the time, so consider any traffic carried in PPTP unencrypted. Migrate to another VPN type as soon as possible. More information on the PPTP security compromise can be found at https://isc.sans.edu/diary/End+of+Days+for+MS-CHAPv2/13807 and https://www.cloudcracker.com/blog/2012/07/29/cracking-ms-chap-v2/.

CHAPTER

TWENTYONE

L2TP VPN

21.1 L2TP and Firewall Rules

By default, when the L2TP server is enabled, firewall rules **will not** be automatically added to the chosen interface to permit UDP port `1701`. A firewall rule must be added to whichever interface the L2TP traffic will be entering, typically WAN, the WAN containing the default gateway, or IPsec.

21.2 L2TP and Multi-WAN

L2TP uses UDP port `1701`. Because L2TP relies on UDP, the server may have issues using any WAN that is not the default gateway. The daemon will respond from the firewall using the closest address to the client, following the routing table, which is the WAN with the default gateway for remote clients.

21.3 L2TP Server Configuration

To use L2TP, first browse to **VPN > L2TP**. Select **Enable L2TP server**.

> **Warning:** L2TP is **not** a secure protocol by itself; it only provides tunneling, **it does not perform encryption**.

See also:

L2TP/IPsec is a way to secure L2TP traffic by sending it through an encrypted IPsec tunnel. This may be used in combination with a mobile IPsec setup to configure L2TP+IPsec; see *L2TP/IPsec Remote Access VPN Configuration Example* for details.

21.3.1 Interface

The **Interface** setting controls where the L2TP daemon will bind and listen for connections. This is typically the *WAN* interface accepting inbound connections.

21.3.2 IP Addressing

Before starting, determine which IP addresses to use for the L2TP server and clients and now many concurrent clients to support.

Server Address
An *unused* IP address outside of the **Remote Address Range**, such as `10.3.177.1` as shown in Figure *L2TP IP Addressing*.

Remote Address Range
The addresses to be assigned to clients when they connect. Usually a new and unused subnet, such as `10.3.177.128/25` (`.128` through `.255`).

Number of L2TP users
Controls how many L2TP users will be allowed to connect at the same time, in this example `13` has been selected.

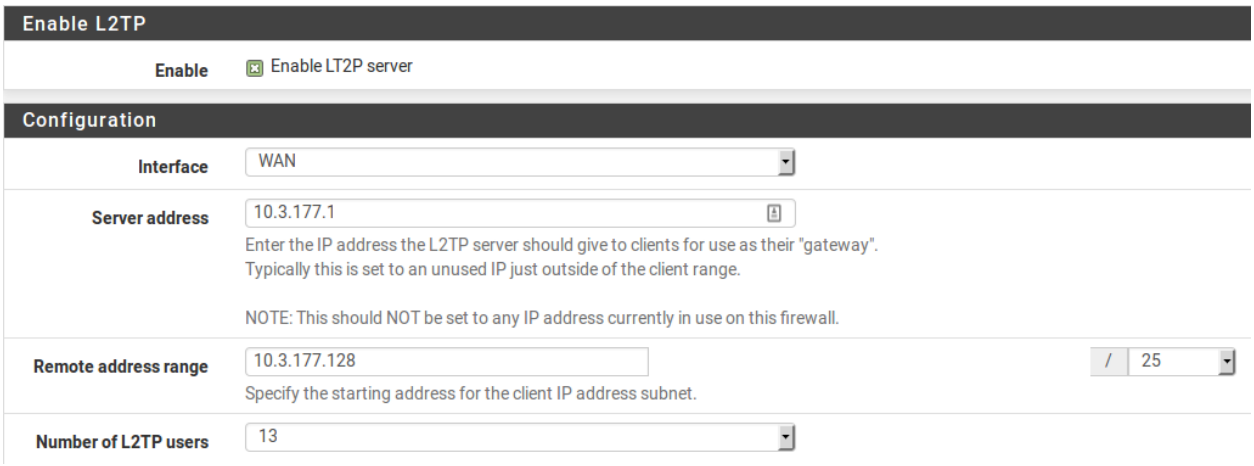

Fig. 1: L2TP IP Addressing

DNS servers can also be defined for end users when needed. Fill in the **Primary** and **Secondary L2TP DNS server** fields with the DNS server IP addresses for connecting clients.

21.3.3 Authentication

Secret
Required by some L2TP implementations, similar to a group password or pre-shared key. Support for this varies from client to client. Leave the field blank unless it is known to be required. If required, enter and confirm the secret.

Authentication Type
Decides between *PAP*, *CHAP*, or *MS-CHAPv2* authentication for users. Support for this can vary from client to client and it may also depend on the RADIUS server as well. The *CHAP* based types are more secure, but *PAP* is more widely compatible.

Users may be authenticated from the local user database, or via an external RADIUS server. This can be used to authenticate L2TP users from Microsoft Active Directory (see *Authenticating from Active Directory using RADIUS/NPS*) as well as numerous other RADIUS capable servers.

If using RADIUS, check the **Use a RADIUS server for authentication** box and fill in the RADIUS server and shared secret. For authentication using the local user database, leave that box unchecked. Users must be added manually on the

Users tab of the **VPN > L2TP** screen unless using RADIUS. See *Adding Users* below for more details on the built-in authentication system.

21.3.4 Save changes to start L2TP server

After filling in the aforementioned items, click **Save**. This will save the configuration and launch the L2TP server.

21.3.5 Configure firewall rules for L2TP clients

Browse to **Firewall > Rules** and click the **L2TP VPN** tab. These rules control traffic from L2TP clients. Until a firewall rule has been added to allow traffic, all traffic initiated from connected L2TP clients will be blocked. Traffic initiated from the LAN to L2TP clients is controlled using LAN firewall rules. Initially an allow all rule may be desired here for testing purposes as shown in Figure *L2TP VPN Firewall Rule*, and once functionality has been verified, restrict the ruleset as desired.

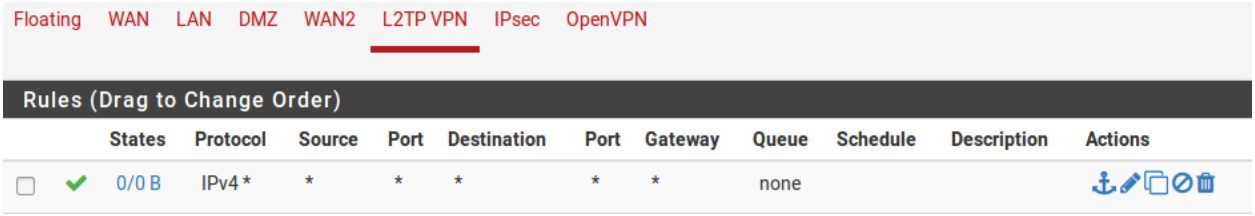

Fig. 2: L2TP VPN Firewall Rule

Note: Remember that a rule must also be added to the interface receiving the L2TP traffic, typically WAN or IPsec, to pass UDP to the firewall with a destination port of `1701`.

21.3.6 Adding Users

Adding users to the built-in L2TP users system is simple. To add local users:

- Navigate to **VPN > L2TP**, **Users** tab. The users screen as shown in Figure *L2TP Users Tab* will be presented.
- Click  **Add** to show the form used to add users.

Fig. 3: L2TP Users Tab

- Enter the **Username**, **Password** and **Confirm Password** for a user, as in Figure *Adding a L2TP User*.
- Enter a static **IP assignment** if desired.
- Click **Save**, and then the user list will return.

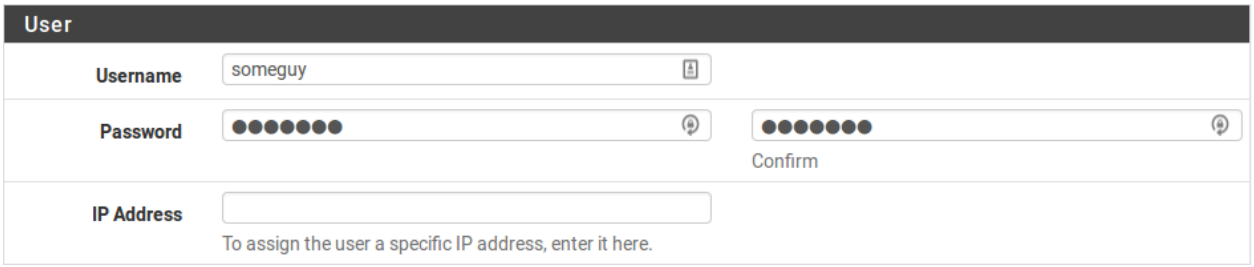

Fig. 4: Adding a L2TP User

- Repeat the process for each user to add.

To edit an existing user, click . Users may be deleted by clicking .

See also:

- *L2TP/IPsec Remote Access VPN Configuration Example*
- *Troubleshooting L2TP*
- *L2TP Logs*

pfSense® software can act as an L2TP VPN server. L2TP is purely a tunneling protocol that offers no encryption of its own, so it is typically combined with some other encryption technique, such as IPsec.

Warning: While pfSense software supports L2TP over IPsec, it has severe limitations and problems compared to other types of remote access VPNs and it should be avoided unless absolutely necessary. Current best practices incldluing using IKEv2 IPsec, OpenVPN, or WireGuard for remote access VPNs.

Most L2TP/IPsec clients **will not** work properly in common scenarios. The most common problem scenario is Windows clients behind NAT, which is nearly all Windows clients in practice. The Windows L2TP/IPsec client and the strongSwan IPsec daemon are not fully compatible when the client is behind a NAT device, which leads to failure. In the few situations where L2TP/IPsec can function properly it still suffers from security and performance concerns compared to other types of remote access VPNs.

See also:

IPsec Remote Access VPN Example Using IKEv2 with EAP-MSCHAPv2 contains a walkthrough for configuring IKEv2, which is a much more flexible solution.

There are also recipes for other types of remote access VPNs in *pfSense® software Configuration Recipes*.

See also:

For general discussion of the various types of VPN implementations available in pfSense software and their pros and cons, see *Virtual Private Networks*.

21.4 L2TP Security Warning

L2TP on its own is not encrypted, so it is not intended for private traffic. Some devices, such as Android, offer an L2TP-only client which is capable of connecting back to pfSense software but it should only be used for traffic that is already encrypted, or if the traffic is not considered private. For example, tunneling Internet traffic so it appears to originate from another location.

CHAPTER

TWENTYTWO

SERVICES

22.1 DHCPv4 Server

The DHCPv4 server in pfSense® software allocates addresses to IPv4 DHCP clients and automatically configures them for network access. By default, the DHCPv4 server is enabled on the LAN interface and configured to serve addresses in the LAN subnet (e.g. `192.168.1.0/24`).

To alter the behavior of the IPv4 DHCP server, navigate to **Services > DHCP Server** in the web interface. This page contains a tab for each interface capable of offering DHCPv4 service. The behavior of the IPv4 DHCP server for an interface is controlled on each tab, along with static IP address mappings and related options.

Warning: The DHCPv4 server cannot be active on any interface if the *DHCPv4 Relay* service is in use.

22.1.1 Settings Tab

When using the Kea DHCP backend there is a **Settings** tab with global options to control DHCP server behavior not specific to a given interface. The options on the **Settings** tab are covered in *Kea Settings Tab*.

22.1.2 Choosing an Interface

The DHCP configuration page contains a tab for each interface with a static IP address. Each interface has its own separate DHCP server configuration, and they may be enabled or disabled independently of one another. Before making any changes, visit the tab for the correct interface.

Note: The settings available on the page vary depending on the active DHCP backend (Kea or ISC DHCP). Differences are noted where applicable.

22.1.3 General Options

DHCP Backend
This read-only field displays the current DHCP backend, either Kea DHCP or ISC DHCP.

The backend can be changed under **System > Advanced**, **Networking** tab (*Server Backend*).

Enable
The first setting on the tab enables or disables DHCP service for the interface. To turn on DHCP for the interface, check **Enable DHCP server on [name] interface**. To disable the service, uncheck the box instead.

Deny unknown clients
Controls how the DHCP server handles requests from clients which it does not know.

Note: This option is per-pool, meaning that if unknown clients are denied in the default range, another pool of IP addresses may be defined that allows clients instead.

Can be set to one of the following values:

Allow All Clients
This is the default behavior. The DHCPv6 server will answer requests from any client requesting a lease. In most environments this is normal and acceptable behavior, but in restricted or secure environments this behavior is undesirable.

Allow known clients from any interface
With this option set, clients with static mappings defined on any interface will receive leases from this pool. This is a more secure practice but requires much more management overhead.

Allow known clients from only this interface
With this option set, clients with static mappings defined on this interface will receive leases from this pool. This is a more secure practice but requires much more management overhead.

Note: This will protect against low-knowledge users and people who casually plug in devices. Be aware, however, that a user with knowledge of the network could hardcode an IP address, subnet mask, gateway, and *DNS* which will still give them access. They could also alter/spoof their MAC address to match a valid client and still obtain a lease. Where possible, couple this setting with static ARP entries, access control in a switch that will limit MAC addresses to certain switch ports for increased security, and turn off or disable unused switch ports.

Ignore Denied Clients (ISC Only)
When checked, the ISC DHCP daemon will ignore denied clients rather than responding with a rejection message.

Note: This option is not compatible with high availability failover.

Ignore Client Identifiers
When set, the DHCP server will not record a unique identifier (UID) in client lease data if present in the client DHCP request.

This option may be useful when a client can dual boot using different client identifiers but the same hardware (MAC) address.

Note: This server behavior violates the official DHCP specification.

DNS Registration
Controls the *DNS Registration* behavior of this interface.

Track Server
Follows the default behavior for DNS Registration configured on the **Settings** tab.

Enable
Ignores the default setting and enables DNS Registration for DHCP clients on this interface.

Disable
Ignores the default setting and disables DNS Registration for DHCP clients on this interface.

Early DNS Registration
Controls the *Early DNS Registration* behavior of this interface.

Track Server
Follows the default behavior for Early DNS Registration configured on the **Settings** tab.

Enable
Ignores the default setting and enables Early DNS Registration for DHCP clients on this interface.

Disable
Ignores the default setting and disables Early DNS Registration for DHCP clients on this interface.

22.1.4 Primary Address Pool

Subnet
A read-only field with the current subnet on this interface.

Subnet Range
The range of available addresses inside the interface subnet, for reference and to help determine the desired range for DHCP clients. The network address and broadcast address are excluded, but interface addresses and Virtual IP addresses are not excluded.

Address Pool Range
This defines the DHCP address range, also referred to as the Scope or Pool. This range can be as large or as small as the network needs, but it must be wholly contained within the subnet.

Addresses between the entered values, inclusive, will be used for clients which request addresses via DHCP.

From
The starting address of the pool.

Must be lower than the **To** address.

To
The ending address of the pool.

Must be higher than the **From** address.

Note: The default LAN DHCP range is based off of the subnet for the default LAN IP address. It is `192.168.1.100` to `192.168.1.199`.

Additional Pools

The **Additional Pools** section defines extra pools of addresses inside of the same subnet. These pools can be used to craft sets of IP addresses specifically for certain clients, or for overflow from a smaller original pool, or to split up the main pool into smaller chunks with a GAP of non-DHCP IP addresses in the middle of what used to be the pool. A combination of the MAC Address Control options may be used to guide clients from the same manufacturer into a specific pool, such as VoIP phones.

To add a new pool, click  **Add Address Pool** and the screen will switch to the pool editing view, which is nearly the same as the normal DHCP options, except a few options that are not currently possible in pools are omitted. The options behave the same as the others discussed in this section. Items left blank will, by default, fall through and use the options from the main DHCP range.

Note: See the MAC Address Control section below for specifics on directing clients into or away from pools.

22.1.5 Server Options

WINS Servers
Defines up to two WINS Servers (Windows Internet Name Service) which the server provides to clients.

Note: WINS is deprecated, but still active on some legacy networks.

DNS Servers
Defines up to four DNS server IP addresses which the server provides to clients. To use custom DNS Servers instead of automatic choices, fill in the DNS server IP addresses.

Tip: When using the DNS Resolver or DNS forwarder in combination with high availability clustering, specify a CARP Virtual IP address on this interface as the only DNS server.

When left empty, the firewall will automatically determine which addresses to supply to clients depending on the DNS configuration on this firewall:

- If the firewall is using the built-in DNS Resolver or DNS Forwarder to handle DNS, leave these fields blank and it will automatically assign itself as the DNS server for client devices.
- If the DNS Resolver or Forwarder is disabled and these fields are left blank, the firewall will pass on whichever DNS servers are defined under **System > General Setup**.

Tip: In networks with Windows servers, especially those employing Active Directory, the best practice is to use those servers for client DNS.

22.1.6 OMAPI (ISC Only)

Options for OMAPI service provided by the DHCP server, which allows querying and controlling the DHCP server remotely.

OMAPI Port
Set the port that OMAPI will listen on. The default port is `7911`, leave blank to disable.

Only the first OMAPI configuration is used, configurations on other interface tabs are ignored.

OMAPI Key
Enter a key matching the selected **Key Algorithm** to secure connections to the OMAPI endpoint.

Generate New Key
When checked, generates a new key based on the selected algorithm when the settings are saved.

Key Algorithm
The algorithm used to generate the OMAPI key.

22.1.7 Other DHCP Options

Gateway
This may also be left blank if this firewall is acting as the gateway for the network on this interface. If that is not the case, fill in the IP address for the gateway to be used by clients on this interface. When using CARP, fill in the CARP Virtual IP address on this interface here.

Domain Name
Specifies the domain name passed to the client to form its fully qualified hostname. If the **Domain Name** is left blank, then the domain name of the firewall it sent to the client. Otherwise, the client is sent this value.

Domain Search List
Controls the DNS search domains that are provided to the client via DHCP. If multiple domains are present and short hostnames are desired, provide a list of domain names here, separated by a semicolon. Clients will attempt to resolve hostnames by adding the domains, in turn, from this list before trying to find them externally. If left blank, the Domain Name option is used.

Note: The **Domain Search List** is provided via DHCP option `119`. Support for this option varies by Operating System and version. See *Using DHCP Search Domains on Windows DHCP Clients*.

Default lease time
Controls how long a lease will last when a client does not request a specific lease length. Specified in seconds, default value is `7200` seconds (2 hours)

Maximum lease time
Limits a requested lease length to a stated maximum amount of time. Specified in seconds, default value is 86400 seconds (1 day).

Failover Peer IP (ISC Only)
If this firewall is part of a High Availability failover cluster, enter the real IP address of the other node in this subnet here.

Do not enter a CARP Virtual IP address.

Note: When **Failover Peer IP** is configured in a High Availability setup, the failover node should be available when the service is started to allow lease pool information to be synchronized; failing this, the DHCPD service will not respond to DHCPDISOVER requests.

Static ARP (ISC Only)
This checkbox works similar to denying unknown MAC addresses from obtaining leases, but takes it a step further in that it also restricts any unknown MAC address from communicating with this firewall. This stops would-be abusers from hardcoding an unused address on this subnet, circumventing DHCP restrictions.

Note: When using static ARP, all systems that need to communicate with the firewall must be listed in static mappings before activating this option, especially the system being used to connect to the firewall GUI. Also be aware that this option may prevent people from hardcoding an IP address and talking to the firewall, but it does not prevent them from reaching each other on the local network segment.

Time Format Change (ISC Only)
By default, the ISC DHCP daemon maintains lease times in UTC. When this option is checked, the times on the DHCP Leases status page are converted to the local time zone defined on the firewall.

Statistics Graphs (ISC Only)
This option, disabled by default, activates RRD graphing for monitoring the DHCP pool utilization.

Ping Check (ISC Only)
When checked, the DHCP server will attempt to ping a client address before allocation to ensure it is not in use by another device.

22.1.8 Dynamic DNS (ISC Only)

For Dynamic DNS settings, click **Display Advanced** to the right of that field, which displays the following options:

DHCP Registration
Check the box to enable registration of DHCP client names in DNS using an **external** DNS server (not on the firewall).

DDNS Domain
The domain name used for registering clients in DNS

DDNS Hostnames
When set, forces the dynamic DNS hostname to match the hostname on a static mapping instead of taking the name given by the client.

Primary DDNS Address
The DNS server used for registering clients in DNS

Secondary DDNS Address
The secondary DNS server used for registering clients in DNS

DNS Domain Key Name
The name of the encryption key used for DNS registration

Key Algorithm
The algorithm used to generate the **DDNS Domain Key Secret** value.

DDNS Domain Key Secret
The secret for the key used for DNS registration

DDNS Client Updates
How the DHCP server handles Forward entries when a client indicates it wishes to update DNS itself.

Allow
Prevents DHCP from updating Forward entries, allowing the client to make the update request itself.

Deny
Indicates that DHCP will do the updates and the client should not.

Ignore
Specifies that DHCP will do the update and the client can also attempt the update, usually using a different domain name.

DDNS Reverse
When set, attempts to add reverse DNS entries.

22.1.9 MAC Address Control

For MAC Address Control, click **Display Advanced** to show the lists of allowed and denied client MAC addresses. Each list is comma-separated and contains portions of MAC addresses. For example, a group of VoIP phones from the same manufacturer may all start with the MAC address `aa:bb:cc`. This can be leveraged to give groups of devices or users separate DHCP options.

Allow
A list of MAC Addresses to allow in this pool. If a MAC address is in the allow box, then all others will be denied except the MAC address specified in the allow box.

Deny
A list of MAC Addresses to deny from this pool. If a MAC address is in the deny list, then all others are allowed.

It is best to use a combination of allow and deny to get the desired result, such as: In the main pool, leave allow blank and deny `aa:bb:cc`. Then in the VoIP pool, allow `aa:bb:cc`. If that extra step is not taken to allow the MAC prefix in the additional pool, then other non-VoIP phone clients could receive IP addresses from that pool, which may lead to undesired behavior.

This behavior may also be used to prevent certain devices from receiving a DHCP response. For example to prevent Example brand printers from receiving a DHCP address, if MAC addresses all start with `ee:ee:ee`, then place that in the deny list of each pool.

22.1.10 NTP Servers

To specify NTP Servers (Network Time Protocol Servers), click the **Display Advanced** button to the right of that field, and enter IP addresses for up to four NTP servers.

22.1.11 TFTP Server

click the **Display Advanced** button next to **TFTP** to display the TFTP server option. The value in the TFTP Server box, if desired, must be an IP address or hostname of a TFTP server. This is most often used for VoIP phones, and may also be referred to as "option 66" in other documentation for VoIP and DHCP.

22.1.12 LDAP URI

Click the **Display Advanced** button next to **LDAP** to display the **LDAP Server URI** option. **LDAP Server URI** will send an LDAP server URI to the client if requested. This may also be referred to as DHCP option 95. It takes the form of a fully qualified LDAP URI, such as `ldap://ldap.example.com/dc=example,dc=com`. This option can help clients using certain kinds of systems, such as OpenDirectory, to find their server.

22.1.13 Network Booting

These options control how the DHCP server will direct clients to boot over the network (e.g. PXE).

Warning: Both a filename and a boot server must be configured for this to function properly. For UEFI & ARM to boot properly, all five filenames and a configured boot server are required.

Enable
Enables Network Booting options for DHCPv4.

Next Server
The IPv4 address from which boot images are available.

Default BIOS File Name
Filename to use when a client does not specify an architecture, such as for legacy BIOS booting.

UEFI 32 bit File Name
Filename to supply for 32-bit UEFI clients.

UEFI 64 bit File Name
Filename to supply for 64-bit UEFI clients.

ARM 32 bit File Name
Filename to supply for 32-bit ARM clients.

ARM 64 bit File Name
Filename to supply for 64-bit ARM clients.

UEFI HTTPBoot URL
URL to boot files for clients which support booting using the HTTPBoot method. Must be in the format `http://<server-name>/<firmware-path>`.

Root Path
String to target a specific device as the client's root filesystem device, such as `iscsi:<server-name>:<protocol>:<port>:<LUN>:<target-name>`.

22.1.14 Custom Configuration (KEA Only)

The KEA GUI allows administrators to configure Kea directly with JSON-formatted configuration blocks. See *Custom Configuration* for details.

22.1.15 Additional BOOTP/DHCP Options (ISC Only)

Other numeric DHCP options can be sent to clients using the **Additional BOOTP/DHCP Options** controls. To view these options, click **Display Advanced** in this section. To add a new option, click  **Add Custom Option**.

Number
The DHCP option code number. IANA maintains a list of all valid DHCP options.

Type
The choices and formats for each type may be a little counter-intuitive, but the labels are used directly from the DHCP daemon.

The proper uses and formats are:

Text
Free-form text to be sent in reply, such as `http://www.example.com/wpad/wpad.dat` or `Example Company`.

String
A string of hexadecimal digits separated by a colon, such as `c0:a8:05:0c`.

Boolean
Either `true` or `false`.

Unsigned 8, 16, or 32-bit Integer
A positive Integer that will fit within the given data size, such as `86400`.

Signed 8, 16, or 32-bit Integer
A positive or negative Integer that will fit within the given data size, such as `-512`.

IP address or host
An IP address such as `192.168.1.1` or a hostname such as `www.example.com`.

Value
The value associated with this numeric option and type.

For more information on which options take a specific type or format, see the linked list above from the IANA.

Note: When using numbered custom options, be careful of the type. Some will be OK on text/string but others are not.

For example, DHCP options for code `132` (and presumably `133`) for VLAN ID must be set for a type of unsigned integer `32`.

22.1.16 Save Settings

After making changes, click **Save** before attempting to create static mappings. Changes to settings will be lost if the browser leaves this page without saving.

22.1.17 Static Mappings

Static DHCP mappings express a preference for which IP address will be assigned to a given client based on its MAC address. In a network where unknown clients are denied, this also serves as a list of "known" clients which are allowed to receive leases or have static ARP entries. Static mappings can be added in one of two ways:

- From this screen, click  **Add Static Mapping**.
- From the DHCP leases view, click  on a lease row.

On this screen, only the **MAC address** is necessary.

MAC Address
The client MAC address which identifies a host. This can be used to deliver customized options on this page. Alternately, by entering only the MAC address it will be added to the list of known clients for use when the **Deny unknown clients** option is set.

Note: Client MAC address can be obtained from a command prompt on most platforms. On many UNIX-based or UNIX-work-alike operating systems including macOS, typing `ifconfig -a` will show the MAC address for each interface. On Linux, use `ip link`. On Windows, `ipconfig /all` will show the MAC address. The MAC address may also sometimes be found upon a sticker on the network card, or near the network jack for integrated adapters. For hosts on the same subnet, the MAC can be determined by pinging the IP address of the host and then running `arp -a`.

Client Identifier
An optional ID sent by the client to identify itself as per RFC 2132. This is used for matching, similar to the MAC address, it does not set a value for the client.

IP Address
The IP address field is needed if this will be a static IP address mapping instead of only informing the DHCP server that the client is valid.

This IP address is a **preference**, not a reservation. Assigning an IP address here will not prevent another host from using the same IP address. If the IP address is in use when this client requests a lease, the server will instead assign the client an address from the general pool. For this reason, the GUI does not allow assigning static mappings inside of pools.

See also:

Static Mappings Inside DHCP Pools

Hostname
The hostname of the client. This does not have to match the hostname set on the client. The hostname set here will be used when registering DHCP addresses in the DNS resolver.

Description
Cosmetic only, and available for use to help track any additional information about this entry. It could be the name of the person who uses the PC, its function, the reason it needed a static address, or the administrator who added the entry. It may also be left blank.

ARP Table Static Entry
If checked, this entry will receive a static ARP entry in the OS tying this IP address to this MAC address.

Note: If this option is used rather than using the global static ARP option, it does not prevent that MAC address from using other IP addresses, it only prevents other MAC addresses from using this IP address. In other words, it prevents another machine from using that IP address to reach the firewall, but it doesn't stop the user from changing their own IP address to something different.

The remaining options available to set for this client are the same in behavior to the ones found earlier in this section for the main DHCP settings.

Click **Save** to finish editing the static mapping and return to the DHCP Server configuration page.

22.2 DHCPv6 Server

The DHCPv6 server in pfSense® software allocates addresses to DHCPv6 clients and automatically configures them for network access. By default, the DHCPv6 server is enabled on the LAN interface and set to use a prefix obtained by tracking a DHCPv6 delegation from the WAN interface.

To alter the behavior of the IPv6 DHCP server, navigate to **Services > DHCPv6 Server** in the web interface. This page contains a tab for each interface capable of offering DHCPv6 service. The behavior of the IPv6 DHCP server for an interface is controlled on each tab, along with static IP address mappings and related options.

Warning: The DHCPv6 server cannot be active on any interface if the *DHCPv6 Relay* service is in use.

Note: For clients to query DHCPv6, *Router Advertisements* must also be enabled and set to either *Managed* or *Assisted* mode under **Services > Router Advertisements**.

22.2.1 Settings Tab

When using the Kea DHCP backend there is a **Settings** tab with global options to control DHCP server behavior not specific to a given interface. The options on the **Settings** tab are covered in *Kea Settings Tab*.

22.2.2 Choosing an Interface

The DHCPv6 daemon can run and be configured on interfaces with a Static IP address or interfaces which track delegated prefixes from upstream sources. If a tab for an interface is not present, check that it is enabled and configured either with a Static IPv6 address or to track a DHCPv6 type WAN which obtains a prefix delegation from an external source.

Note: The settings available on the page vary depending on the active DHCP backend (Kea or ISC DHCP). Differences are noted where applicable.

Note: DHCPv6 does not provide gateway information. *Router Advertisements* inform hosts on the network about available routers. DHCPv6 is for other host configuration such as DNS, delegation, and so on.

See also:

See the *DNS Forwarder* article for information on the default DNS server behavior.

22.2.3 General Options

DHCP Backend
This read-only field displays the current DHCP backend, either Kea DHCP or ISC DHCP.

The backend can be changed under **System > Advanced**, **Networking** tab (*Server Backend*).

Enable
The first setting on the tab enables or disables DHCPv6 service for the interface. To turn on DHCPv6 for the interface, check **Enable DHCPv6 server on [name] interface**. To disable the service, uncheck the box instead.

Deny unknown clients
Controls how the DHCP server handles requests from clients which it does not know.

Note: This option is per-pool, meaning that if unknown clients are denied in the default range, another pool of IP addresses may be defined that allows clients instead.

Can be set to one of the following values:

Allow All Clients
This is the default behavior. The DHCPv6 server will answer requests from any client requesting a lease. In most environments this is normal and acceptable behavior, but in restricted or secure environments this behavior is undesirable.

Allow known clients from any interface
With this option set, clients with static mappings defined on any interface will receive leases from this pool. This is a more secure practice but requires much more management overhead.

Allow known clients from only this interface
With this option set, clients with static mappings defined on this interface will receive leases from this pool. This is a more secure practice but requires much more management overhead.

Note: This will protect against low-knowledge users and people who casually plug in devices. Be aware, however, that a user with knowledge of the network could hardcode an IP address, subnet mask, gateway, and *DNS* which will still give them access. They could also alter/spoof their DUID to match a valid client and still obtain a lease. Where possible, couple this setting with access control in a switch that will limit access to switch ports for increased security, and turn off or disable unused switch ports.

DNS Registration
Controls the *DNS Registration* behavior of this interface.

Track Server
Follows the default behavior for DNS Registration configured on the **Settings** tab.

Enable
Ignores the default setting and enables DNS Registration for DHCP clients on this interface.

Disable
Ignores the default setting and disables DNS Registration for DHCP clients on this interface.

Early DNS Registration
Controls the *Early DNS Registration* behavior of this interface.

Track Server
Follows the default behavior for Early DNS Registration configured on the **Settings** tab.

Enable
Ignores the default setting and enables Early DNS Registration for DHCP clients on this interface.

Disable
Ignores the default setting and disables Early DNS Registration for DHCP clients on this interface.

22.2.4 Primary Address Pool

Prefix
A read-only field with the current prefix on this interface. If the prefix is delegated, this field also shows the WAN which supplied the tracking data and the subnet ID.

Prefix Range
A read-only field with the total available range of addresses in the prefix.

Address Pool Range
This field defines the start and end of an address range defining a pool from which the DHCP server will allocate addresses. This range can be as large or as small as the network needs, but it must be wholly contained within the subnet.

Addresses between the entered values, inclusive, will be used for clients which request addresses via DHCPv6.

From
The starting address of the pool. For interfaces which obtain a prefix dynamically, the prefix itself may be omitted. The value defined in this field will be added to the prefix automatically.

Must be lower than the **To** address.

To
The ending address of the pool. For interfaces which obtain a prefix dynamically, the prefix itself may be omitted. The value defined in this field will be added to the prefix automatically.

Must be higher than the **From** address.

Tip: Given the vast amount of space available inside even a /64, a good trick is to craft a range that restricts hosts to use an easy to remember or recognize range. For example, Inside a /64 such as `2001:db8:1:1::`, set the DHCPv6 range be: `2001:db8:1:1::d:0000` to

`2001:db8:1:1::d:FFFF`, using the `d` in the second to last section of the address as a sort of shorthand for "DHCP". That example range contains 2^16 (65,536) IPs, which is extremely large by today's IPv4 standards, but only a small portion of the whole `/64`.

Additional Pools

The **Additional Pools** section defines extra pools of addresses inside of the same subnet. These pools can be used to craft sets of IPv6 addresses specifically for certain clients, or for overflow from a smaller original pool, or to split up the main pool into smaller chunks with a GAP of non-DHCPv6 IPv6 addresses in the middle of what used to be the pool.

To add a new pool, click  **Add Address Pool** and the screen will switch to the pool editing view, which is nearly the same as the normal DHCPv6 options, except a few options that are not currently possible in pools are omitted. The options behave the same as the others discussed in this section. Items left blank will, by default, fall through and use the options from the main DHCPv6 range.

22.2.5 DHCPv6 Prefix Delegation

Prefix delegation, covered earlier in *DHCP6 Prefix Delegation* and *Track Interface*, allows automatically dividing and allocating a block of IPv6 addresses to networks that will live behind other routers and firewalls which reside downstream from this firewall (e.g. in the LAN, DMZ, etc). Downstream devices which request a delegation can in turn use prefixes in their delegation for their LAN, VPNs, DMZ, etc. Downstream firewalls can even further delegate their own allocation to routers behind them.

Note: Most users on networks act only in a client capacity and will not need this, so it will likely remain blank.

Prefix delegation can be used to allocate `/60` chunks of a `/48` to downsream routers automatically, or many other combinations. The downstream router obtains an IPv6 address then requests a delegation, the server delegates a prefix and dynamically routes the delegated prefix to that downstream router.

Delegated Prefix
Defines the delegation pool. This block of IPv6 addresses must be routed to this firewall by upstream routers either directly or as part of a larger allocation.

The length of this prefix must be smaller than, or equal to, the **Delegated Length**.

Warning: The deprecated ISC DHCPv6 server defined this value as a range instead of a prefix. As such, it may not be possible to set this value identically to previous configurations. However, it is much easier to specify as a prefix rather than having to calculate the start/end and check boundaries.

Delegated Length
Sets the size of the prefix delegations allocated to clients. This must be larger than, or equal to, the prefix length of the **Delegated Prefix**.

Note: In nearly all cases this should be smaller than `/64` and not larger than or equal to `/64`. A delegated prefix with a length larger than /64 could never be properly utilized by the majority of

clients. While a single `/64` delegation is valid, it is of minimal use to downstream routers as it only allows room for a single proper internal network.

For example, start with a prefix of `2001:db8::ffff:f000/52` earmarked for delegation to downstream routers. This **Delegated Prefix** has a length of `/52`. Using a **Delegated length** value of `/60` accommodates up to **256** downstream router client delegations. Each of these delegations is a contiguous `/60` block of the **Delegated Prefix**, which is equivalent to **16** subnets of size `/64`.

22.2.6 Server Options

Enable
When set, the DHCP server provides DNS servers to DHCPv6 clients upon request.

> **Warning:** Unchecking this box disables the `dhcp6.name-servers` option. Use with caution as the resulting behavior may violate RFCs and lead to unintended client behavior.

DNS Servers
Defines up to four DNS server IPv6 addresses which the server provides to clients. To use custom DNS Servers instead of automatic choices, fill in the DNS server IPv6 addresses.

Tip: When using the DNS Resolver or DNS forwarder in combination with high availability clustering, specify an IPv6 CARP Virtual IP address on this interface as the only DNS server.

When left empty, the firewall will automatically determine which addresses to supply to clients depending on the DNS configuration on this firewall:

- If the firewall is using the built-in DNS Resolver or DNS Forwarder to handle DNS, leave these fields blank and it will automatically assign itself as the DNS server for client devices.
- If the DNS Resolver or Forwarder is disabled and these fields are left blank, the firewall will pass on whichever DNS servers are defined under **System > General Setup**.

Tip: In networks with Windows servers, especially those employing Active Directory, the best practice is to use those servers for client DNS.

22.2.7 Other DHCPv6 Options

Domain Name
Specifies the domain name passed to the client to form its fully qualified hostname. If the **Domain Name** is left blank, then the domain name of the firewall it sent to the client. Otherwise, the client is sent this value.

Domain Search List
Controls the DNS search domains that are provided to the client via DHCP. If multiple domains are present and short hostnames are desired, provide a list of domain names here, separated by a semicolon. Clients will attempt to resolve hostnames by adding the domains, in turn, from this list before trying to find them externally. If left blank, the Domain Name option is used.

Note: The **Domain Search List** is provided via DHCP option 119. Support for this option varies by Operating System and version. See *Using DHCP Search Domains on Windows DHCP Clients*.

Default lease time
Controls how long a lease will last when a client does not request a specific lease length. Specified in seconds, default value is `7200` seconds (2 hours)

Maximum lease time
Limits a requested lease length to a stated maximum amount of time. Specified in seconds, default value is 86400 seconds (1 day).

Time Format Change (ISC Only)
By default, the ISC DHCP daemon maintains lease times in UTC. When this option is checked, the times on the DHCP Leases status page are converted to the local time zone defined on the firewall.

22.2.8 Dynamic DNS (ISC Only)

For Dynamic DNS settings, click **Display Advanced** to the right of that field, which displays the following options:

DHCP Registration
Check the box to enable registration of DHCP client names in DNS using an **external** DNS server (not on the firewall).

DDNS Domain
The domain name used for registering clients in DNS

DDNS Hostnames
When set, forces the dynamic DNS hostname to match the hostname on a static mapping instead of taking the name given by the client.

Primary DDNS Address
The DNS server used for registering clients in DNS

Secondary DDNS Address
The secondary DNS server used for registering clients in DNS

DNS Domain Key Name
The name of the encryption key used for DNS registration

Key Algorithm
The algorithm used to generate the **DDNS Domain Key Secret** value.

DDNS Domain Key Secret
The secret for the key used for DNS registration

DDNS Client Updates
How the DHCP server handles Forward entries when a client indicates it wishes to update DNS itself.

Allow
Prevents DHCP from updating Forward entries, allowing the client to make the update request itself.

Deny
Indicates that DHCP will do the updates and the client should not.

Ignore
Specifies that DHCP will do the update and the client can also attempt the update, usually using a different domain name.

DDNS Reverse
When set, attempts to add reverse DNS entries.

22.2.9 NTP Servers

To specify NTP Servers (Network Time Protocol Servers), click the **Display Advanced** button to the right of that field, and enter IP addresses for up to four NTP servers.

22.2.10 Network Booting

Enable
Enables Network Booting options for DHCPv6

Boot File URL
URL containing boot files.

22.2.11 Custom Configuration (KEA Only)

The KEA GUI allows administrators to configure Kea directly with JSON-formatted configuration blocks. See *Custom Configuration* for details.

22.2.12 Additional BOOTP/DHCP Options (ISC Only)

Other numeric DHCP options can be sent to clients using the **Additional BOOTP/DHCP Options** controls. To view these options, click **Display Advanced** in this section. To add a new option, click  **Add Option**.

Number
The DHCP option code number. IANA maintains a list of all valid DHCP options.

Value
The value associated with this numeric option and type.

> **Warning:** When using numbered custom options, be aware that numbered options do NOT correspond exactly to the DHCP numbered options for IPv4
>
> For more information on DHCP option numbers and types, see https://tools.ietf.org/html/draft-ietf-dhc-v6opts-00

22.2.13 Save Settings

After making changes, click **Save** before attempting to create static mappings. Changes to settings will be lost if the browser leaves this page without saving.

22.2.14 DHCPv6 Static Mappings

Static mappings on DHCPv6 work differently than IPv4. On IPv4, mappings were matched and identified using the MAC address of a device. For IPv6, the designers decided that wasn't good enough, since the MAC address of a device could change, but still be the same device. Thus, the designers came up with the DHCP Unique Identifier (DUID) which in theory would be a unique ID per device without the same constraints as using MAC addresses.

DHCP Unique Identifier (DUID)

The **DHCP Unique Identifier**, or **DUID**. The DUID of the host is generated by the operating system of the client and, in theory, will remain unique to that specific host until such time as the user forces a new DUID or the operating system is reinstalled. The DUID can range from 12 to 20 bytes, and varies depending on its type.

This field expects a DUID for a client PC in a special format, represented by pairs of hexadecimal digits, separated by colons, such as `00:01:00:01:1b:a6:e7:ab:00:26:18:1a:86:21`.

How to obtain this DUID depends on the operating system. The easiest way is to allow the device to obtain a lease via DHCPv6, and then add an entry from the DHCPv6 Leases View (Status > DHCPv6 Leases). In Windows, it can be found as DHCPv6 Client DUID in the output of `ipconfig /all`.

Note: On Windows, the DUID is generated at install time, so if a base image is used and workstations are cloned from there, they can all end up with the same DUID, and thus all end up pulling the same IPv6 address over DHCPv6.

Clear the DUID from the registry before making an image to clone, by issuing the following command:

```
reg delete HKLM\SYSTEM\CurrentControlSet\Services\Tcpip6\Parameters /f /v Dhcpv6DUID
```

That command may also be run on a working system to reset its DUID if needed.

DUID Format

The DUID format is listed on the page, but it roughly follows the format:

```
DUID-LLT - ETH -- TIME --- ---- address ----
```

DUID-LLT is link-layer plus time, which means it uses the link type of a network interface on the system (Generally `00:01` to indicate the format, plus `00:01`, or `00:06` for Ethernet), plus the timestamp at which the DUID was generated in hex, plus the MAC address of the first NIC. It may be difficult or impossible to predict the DUID for a device. Unless the operating system has a way to look it up, it may be best to allow the client to obtain a dynamic lease and then copy the DUID from the leases view.

The DUID may be entered in colon-separated or dash-separated format.

Static Mapping Settings

DHCPv6 Static Mappings have the following settings:

DHCP Unique Identifier
The DUID, as discussed in *DHCP Unique Identifier (DUID)*, using the format specified in *DUID Format*.

IPv6 Address
The IPv6 address field is needed if this will be a static IPv6 address mapping instead of only informing the DHCP server that the client is valid.

This IPv6 address is a **preference**, not a reservation. Assigning an IPv6 address here will not prevent another host from using the same IPv6 address. If the IP address is in use when this client requests a lease, the server will instead assign the client an address from the general pool. For this reason, the GUI does not allow assigning static mappings inside of pools.

See also:

Static Mappings Inside DHCP Pools

Hostname
The hostname of the client. This does not have to match the hostname set on the client. The hostname set here will be used when registering DHCP addresses in the DNS resolver.

Description
Cosmetic only, and available for use to help track any additional information about this entry. It could be the name of the person who uses the PC, its function, the reason it needed a static address, or the administrator who added the entry. It may also be left blank.

22.3 IPv6 Router Advertisements

Automatic address and router assignment for IPv6 works much differently than IPv4. Even so, most of the DHCP options are similar, but there are notable differences in behavior in how things are assigned and also how items like the gateway are handed off to clients. Unless otherwise noted, options of the same name work the same for DHCP and DHCPv6. DHCPv6 is configured under **Services > DHCPv6 Server** and Router Advertisements (RA) are configured under **Services > Router Advertisement**.

22.3.1 DHCPv6 vs Stateless Address Autoconfiguration

There are a few clients that do not have support for DHCPv6. Some clients only support Stateless Address Autoconfiguration, or SLAAC for short. There is no way for the firewall to have direct knowledge of a list of hosts on the segment using SLAAC addresses, so for some environments it is much less desirable because of the lack of control and reporting of addresses. Consider address tracking and operating system support requirements when deciding how to allocate IPv6 addresses to clients on the network.

Many operating systems such as Windows, macOS, FreeBSD, Linux, and their cousins contain DHCPv6 clients that are capable of obtaining addresses as expected via DHCPv6. Some lightweight or mobile operating systems such as Android do not contain a DHCPv6 client and will only function on a local segment with IPv6 using SLAAC.

22.3.2 Router Advertisements (Or: "Where is the DHCPv6 gateway option?")

In IPv6, hosts locate a router through Router Advertisement (RA) messages sent from routers instead of by DHCP; IPv6-enabled routers that support dynamic address assignment are expected to announce themselves on the network to all clients. As such, DHCPv6 does not include any gateway information. So clients can obtain their addresses from DHCPv6 or SLAAC, but unless they are statically configured, they always locate their next hop by using RA packets sent from available gateways.

To enable the RA service:

- Navigate to **Services > Router Advertisement**
- Click the interface tab for the interface being configured
- Select a mode other than *Disabled* from the **Router Mode** drop-down list
- Click **Save**

The other options to control RA behavior may be set as needed for the network:

Router Mode
The modes for the RA daemon control the services offered by pfSense® software, announce the firewall as an IPv6 router on the network, and direct clients on how to obtain addresses.

Disabled
The RA daemon is disabled and will not run. IPv6 gateways must be entered manually on any client hosts.

Router Only
This firewall will send out RA packets that advertise itself as an IPv6 router. DHCPv6 and SLAAC are disabled in this mode.

Unmanaged
The firewall will send out RA packets and clients are directed to assign themselves IP addresses within the interface subnet using SLAAC. DHCPv6 is disabled in this mode.

Managed
The firewall will send out RA packets and addresses will **only** be assigned to clients using DHCPv6.

Assisted
The firewall will send out RA packets and addresses can be assigned to clients by DHCPv6 or SLAAC.

Stateless DHCP
The firewall will send out RA packets and addresses can be assigned to clients by SLAAC while providing additional information such as DNS and NTP from DHCPv6.

Router Priority
If multiple IPv6 routers exist on the same network segment, they can indicate to clients in which order they should be used. If a high priority router becomes unavailable, clients will try a normal priority router, and finally a low priority router. Select either *Low*, *Normal*, or *High* from the list. If there is only one router on the network, use *Normal*.

Note: Clients may lose a few packets or experience a delay when attempting to determine which router to use when relying on this type of failover between routers.

RA Interface
Chooses a specific address to advertise as the router instead of the link-local address on this interface.

This is used when using IPv6 in a High Availability cluster (*High Availability*). Advertising a link-local CARP VIP allows cluster members to direct clients to send traffic to whichever node is active, rather than trying to make each client determine the router on its own.

This option is only offered when the firewall has CARP VIPs configured.

Note: While it is possible to advertise a GUA IPv6 address, using a link-local address is more appropriate. Some client operating systems may not behave properly when given a non-link-local address for a router.

Valid Lifetime
Length of time, specified in seconds, that the advertised prefix will be valid. The default value is `86400` seconds (one day).

Preferred Lifetime
Length of time, specified in seconds, that the client addresses generated in this prefix using SLAAC are valid. The default value is `14400` seconds (four hours).

Minimum & Maximum RA interval
The router sends advertisements on each interface configured to transmit messages. Advertisements include route information and indicate to network hosts that the router is operational. The router sends these unsolicited multicast router advertisements periodically, with a time range defined by minimum and maximum values in seconds.

The maximum interval for sending RA messages should be less than or equal to the router lifetime in RA messages.

Router lifetime
The lifetime associated with the default router in seconds. A value of `0` indicates that the router is not a default router and that associated default routes should be discarded.

The default is three times the maximum RA interval seconds.

NAT64 Prefix
Enables PREF64 support and configures a prefix for *NAT64*. This allows IPv6-only clients to automatically discover NAT64 prefixes which they can use to reach IPv4-only hosts through this firewall.

In most cases this value should be `64:ff9b::/96`. NAT64 must also be configured.

See also:

- *NAT64*
- *Configuring NAT64 for IPv6-only Clients*
- RFC 8781

NAT64 Prefix Lifetime
The length of time in seconds (relative to the time the packet is sent) that the prefix is valid for the purpose of NAT64 existence determination. The default is `3 * Maximum RA Interval` seconds.

RA Subnets
This section allows defining a list of subnets for which this firewall will send RA packets. Enter as many subnets as needed, each with an appropriate prefix (typically */64*.). To create an additional row for another subnet, click  **Add RA Subnet**.

DNS Configuration
Obtaining DNS information from RA messages is not universally supported, but for clients that do

support it, using SLAAC to give an IP address and DNS from RA can do away with the need for using DHCPv6 entirely.

Enable
Enables providing DNS configuration using the RA daemon.

Mirror DHCPv6
Uses the DNS values configured in the DHCPv6 settings.

DNS Servers
Enter up to four IPv6 addresses for DNS Servers, or leave the fields blank to use the system default DNS servers or DNS Resolver/DNS forwarder if enabled.

Domain Search List
Operates identically to the DHCP option of the same name.

22.4 DHCPv4 & DHCPv6 Relay

DHCP requests are broadcast traffic. Broadcast traffic is limited to the broadcast domain where it is initiated. To provide DHCP service on a network segment without a DHCP server, use the DHCP relay to forward those requests to a defined server on another segment.

Warning: It is not possible to run both a DHCP server and a DHCP Relay at the same time. To enable the DHCP relay, first disable the DHCP server on all interfaces.

22.4.1 DHCP Relay Options

The DHCP Relay service has the following options:

Enable DHCP Relay
Checked to enable the service.

Downstream Interfaces
Select one or more local interfaces containing clients for which the service will relay requests.

CARP Status VIP
A CARP type VIP which will be used to indicate whether the relay service will be started or stopped based on its status. For example, in an HA cluster, the service will only run when the chosen VIP is in CARP MASTER status, not when it is in BACKUP status. This ensures the HA nodes do not send conflicting relay messages.

Append circuit ID and agent ID to requests
Check this to add a circuit ID (interface number on the firewall) and the agent ID to the DHCP request. This may be required by the DHCP server on the other side, and can help distinguish where the requests originated.

Upstream Servers

A a list of target DHCP server(s). If there is more than one upstream server, click **Add** to create more entries.

22.4.2 DHCP Relay Configuration

To configure the DHCP Relay:

- Disable the DHCP Server on each interface where the Relay will run
- Navigate to **Services > DHCP Relay**
- Click the tab for the interface to use with DHCP Relay
- Configure the options as described in *DHCP Relay Options*.
- Click **Save**

The DHCPv6 Relay function works identically to the DHCP Relay function for IPv4.

22.5 DNS Resolver

The DNS Resolver in pfSense® software utilizes `unbound`, which is a validating, recursive, caching DNS resolver that supports DNSSEC, DNS over TLS, and a wide variety of options. It can act in either a DNS resolver or forwarder role.

Note: The DNS Resolver is enabled in resolver mode by default in current versions of pfSense software.

22.5.1 DNS Resolver Mode

The DNS Resolver can act in either a DNS resolver or forwarder role. These roles are described in detail on *DNS Resolution Process*.

Resolver mode

In resolver mode (default) the DNS Resolver contacts root DNS servers and other authoritative servers directly in search of answers to queries submitted by clients. This eliminates issues typically encountered by users with missing or incorrect local DNS configuration since it does not require forwarding DNS servers to operate. Resolver mode also enables the use of Domain Name System Security Extensions (DNSSEC) which makes the DNS results more trustworthy and verifiable.

Note: Some ISPs block or rate limit these types of DNS queries and instead prefer users to contact forwarders. If resolver mode does not work, use forwarding mode.

As this mode contacts servers which cannot be known beforehand, it must utilize the default route on the firewall to make outbound connections. This may not be optimal with multiple WANs, but there are ways around this limitation such as configuring failover for the default gateway. See *Interface and DNS Configuration*.

Forwarding mode

In forwarding mode the DNS Resolver will forward DNS queries to the list of servers configured under **System > General Setup** or those obtained automatically from a dynamic WAN.

Tip: For increased privacy these forwarded queries can be made using *DNS over TLS*.

This method tends to work better with multiple WANs as each forwarding DNS server may be configured to use a different WAN, allowing queries to be sent over whichever WAN is available at a given moment. See *Interface and DNS Configuration*.

While in forwarding mode the DNS Resolver monitors response timing from all available DNS servers in its infrastructure cache. The daemon will direct queries to servers based on their current status so it can avoid using servers which are slow or unavailable. This data is available in the GUI at **Status > DNS Resolver** (*DNS Resolver Status*).

22.5.2 DNS Resolver Configuration

To configure the DNS Resolver, navigate to **Services > DNS Resolver**

DNS Resolver Options

Enable
Controls whether or not the DNS Resolver is enabled. Check the box to enable the DNS Resolver service, uncheck to disable the service.

Two DNS services cannot both be active at the same time on the same ports. This includes, but is not limited to, the DNS Resolver, the DNS Forwarder, and the BIND package. Ensure other services are disabled or moved to different ports before attempting to enable the DNS Resolver.

Listen Port
The TCP and UDP port on which the DNS Resolver will listen for queries from clients. By default this is port `53`. This is the normal port for any DNS server, as it is the port expected by clients.

Certain use cases may involve moving the DNS Resolver to another Listen Port, such as `5353` or `54`, and then specific sources may be forwarded there via port forwards.

Enable SSL/TLS Service
Configures the DNS Resolver to act as a DNS over TLS server which can answer queries from DNS over TLS **clients**.

Note: Activating this option disables automatic interface response routing behavior, thus it works best with specific interface bindings.

SSL/TLS Certificate
The server certificate to use when acting as an SSL/TLS server.

For clients to properly validate the server, they must trust this certificate. One way to accomplish that easily is to use a certificate generated by the *ACME package*.

SSL/TLS Listen Port
The TCP and UDP port on which the DNS Resolver will listen for queries from DNS over TLS clients. By default this is port `853`.

Network Interfaces
The network interface(s) to which the DNS Resolver will bind when listening for queries from clients.

By default the DNS Resolver listens on every available interface and IPv4 and IPv6 address. This option limits the interfaces where the DNS Resolver will accept and answer queries. This can be used to increase security in addition to firewall rules.

If specific interfaces are selected, both the IPv4 and IPv6 addresses on those interfaces will be used for answering queries. Additionally, The unbound daemon will only bind to the selected interfaces. Queries sent to other IP addresses on the firewall will be silently discarded.

Outgoing Network Interfaces
Controls which interfaces the firewall will utilize when sending its own queries to other DNS servers.

By default the DNS Resolver utilizes all interfaces for outbound queries so it will source the query from whichever interface and IP address is closest to the target server from a routing perspective. Selecting specific interfaces will limit the choices to only specific interfaces that may be used as a source of queries.

System Domain Local Zone Type
This option determines the type of `local-zone` configured in unbound for the system domain. The zone type governs the type of response given to clients when there is no match in local data such as Host Overrides, DHCP hosts, etc. In each case, if there is a local match, the query is answered normally. The available types to govern non-matching responses are:

Deny
Drops the query and does not answer the client.

Refuse
Notifies the client that the query was refused (Using `rcode REFUSED`).

Static
Returns a `NODATA` or `NXDOMAIN` response to the client.

Transparent
This is the default behavior. If the query is for a name that does not exist locally, it is resolved as usual. If the name has a local match but the type is different, a `NOERROR`, `NODATA` response is sent to the client

Type Transparent
Similar to *Transparent* but it also passes through queries where the name matches but the type does not. For example, if a client queries for an AAAA record but only an A record exists, the AAAA query is passed on rather than resulting in a negative response.

Redirect
Handles queries from local data and redirects queries for zones underneath the local zone (e.g. subdomains). This can be used to control queries for all subdomains under the given domain.

Inform
Answers normally, but logs the client query.

Inform Deny
Denies and logs the query.

No default
Disables any default content for the zone without affecting query behavior.

DNSSEC
Enables Domain Name System Security Extensions (DNSSEC), which allows clients to trust the origin and content of DNS responses. This is enabled by default.

DNSSEC protects against manipulation of DNS responses, such as DNS cache poisoning or other query interception, but it does not make the contents of responses secret.

DNSSEC works best when using the root servers directly, unless the forwarding servers support DNSSEC. Even if the forwarding DNS servers support DNSSEC, the response cannot be fully validated.

If upstream DNS servers do not support DNSSEC in forwarding mode or with domain overrides, DNS queries are known to be intercepted upstream, or clients have issues with large DNS responses, DNSSEC may need to be disabled.

Python Module

Enables the DNS Resolver Python module. This feature utilizes a Python script to act on queries or results. For example, a script could prevent certain domains or record type combinations from being resolved.

Python Module Order

Controls the position of the Python module in the DNS resolution process. If DNSSEC is disabled, this option has no effect.

Pre Validator

The script is run before DNSSEC validation.

Post Validator

The script is run after DNSSEC validation.

Python Module Script

The python script file to execute. The script must be uploaded to the firewall in `/var/unbound/`. The filename must end in `.py`.

DNS Query Forwarding

Controls whether unbound uses resolver mode (unchecked) or forwarding mode (checked). See *DNS Resolver Mode* for an explanation of the modes.

The default is resolver mode (unchecked).

When checked, unbound will use the system *DNS Servers* from **System > General Setup** or those received from a dynamic WAN, rather than using the root servers directly.

Certain situation require or work better with forwarding mode, such as when utilizing *DNS over TLS* for outgoing queries or for *optimal multi-WAN configurations*.

Use SSL/TLS for outgoing DNS Queries to Forwarding Servers

Sends queries to all upstream forwarding DNS servers using SSL/TLS on the default port of `853`. Requires **DNS Query Forwarding** to be checked.

See *Configuring DNS over TLS* for detailed instructions.

> **Warning:** **All** upstream forwarding servers **must** support SSL/TLS queries on port `853`.

DHCP Registration

Controls whether or not internal machine names for DHCP clients are registered in the DNS Resolver. The domain name from **System > General Setup** is used as the domain name on the hosts.

This feature allows systems using the DNS Resolver as their DNS server to resolve these names using DNS.

Note: This only works for clients that specify a hostname in their DHCP requests.

Warning: The DNS Resolver is reloaded when updating hostnames it learns from DHCP lease data. On busy networks with many DHCP clients, this can result in temporary DNS outages as `unbound` reloads. In most cases this is only a factor when using add-on packages which increase the burden on the DNS Resolver or which make it take longer than usual to reload.

Static DHCP
: This works the same as **Register DHCP leases in DNS resolver**, except that it registers the DHCP static mapping addresses.

OpenVPN Client
: Controls whether or not OpenVPN client names are registered in the DNS Resolver.

  If this option is set, then the common name (CN) of connected OpenVPN clients will be registered in the DNS Resolver along with the client address inside the VPN. The domain in **System > General Setup** is used as the domain name on these entries.

Note: This option requires an OpenVPN server to be operating in *Remote Access SSL/TLS* mode or in *User Auth* mode with **Username as Common Name** active.

Custom Options
: A text area for advanced `unbound` directives not directly supported by the GUI.

Tip: If `unbound` does not start correctly after entering custom options, add `server:` on a line at the top of the custom options text area.

22.5.3 Host Overrides

Custom DNS entries can be created in the **Host Overrides** section of the DNS Resolver configuration.

Host overrides define new records or override existing records so that local clients receive the configured responses instead of responses from upstream DNS servers.

This is useful for split DNS configurations (see *Split DNS*) and as a semi-effective means of *blocking access to certain specific websites*.

Warning: Do not use DNS override functionality as the only means of blocking access to sites.

Blocking via DNS requires that local clients utilize the firewall as their only DNS source. See *Redirecting Client DNS Requests* and *Blocking External Client DNS Queries* for suggestions on ensuring clients get their DNS responses from the firewall. It will stop non-technical users, but it is easy to circumvent for those with more technical aptitude.

Multiple records may be defined for the same hostname and all IP addresses will be returned in the result. This can be used to supply both an IPv4 (A) and IPv6 (AAAA) result for a single hostname.

Host
: This field defines the hostname portion of the DNS override record (without the domain), e.g. `www`.

This may be left blank to make an override record for the domain itself, similar to an `@` record.

Domain
Defines the domain name portion of the DNS override record, e.g. `example.com`.

This field is required.

IP Address
The IP address (either IPv4 or IPv6) to return as the result for a DNS lookup of this entry. May be a single address or a comma-separated list of multiple addresses.

Description
A text description used to identify or give more information about this entry.

Additional Names for This Host
Defines additional hostnames for the same IP address to keep them in a single override entry.

22.5.4 Domain Overrides

Domain overrides are found at the bottom of the DNS Resolver configuration. These entries specify an alternate DNS server to use for resolving hosts in a specific domain.

A common use of domain overrides is to resolve internal DNS domains at remote sites using a DNS server at the main site accessible over VPN. In such environments all DNS queries are typically resolved at the central site for centralized control over DNS, however some organizations prefer to let Internet DNS resolve with a local caching resolver at each site, and only forward queries for internal domains to the central DNS server (e.g. for *Split DNS*).

Note: A static route may be necessary for this to function over IPsec. See *Accessing Firewall Services over IPsec* for more information.

This can also be leveraged as a semi-effective means of *blocking access to certain specific websites*.

Warning: Do not use DNS override functionality as the only means of blocking access to sites.

Blocking via DNS requires that local clients utilize the firewall as their only DNS source. See *Redirecting Client DNS Requests* and *Blocking External Client DNS Queries* for suggestions on ensuring clients get their DNS responses from the firewall. It will stop non-technical users, but it is easy to circumvent for those with more technical aptitude.

Domain
The domain name that will be resolved using this entry.

This does not have to be a valid TLD, it can be anything (e.g. `local`, `test`, `lab`), or it can be an actual domain name (`example.com`).

IP Address
Specifies the IP Address of the DNS server to which the queries for hostnames in Domain are sent. If the target DNS server is running on a port other than `53`, add the port number after the IP address with an `@` separating the values, for example: `192.0.2.3@5353`

TLS Queries
Controls whether or not **all** queries for this domain going to this server are sent using SSL/TLS.

TLS Hostname
An optional hostname used to validate the SSL/TLS server certificate.

Description
A text description used to identify or give more information about this entry.

22.5.5 DNS Resolver Advanced Options

pfSense® software provides a GUI to configure some of the more common advanced options available in the DNS Resolver (Unbound).

See also:

The options below are documented as found in the unbound.conf man page.

Advanced Privacy Options

Hide Identity
Controls whether or not Unbound will allow queries for the server identity. This offers extra privacy.

When set, Unbound rejects queries for `id.server` and `hostname.bind`.

Hide Version
Controls whether or not Unbound will allow queries for the server version. This offers extra privacy.

When set, Unbound rejects queries for `version.server` and `version.bind`.

Query Name Minimization
Controls whether or not Unbound attempts to minimize the amount of data sent with a query for extra privacy. Default is unchecked.

When set, Unbound only sends the minimum required labels of the `QNAME` and sets `QTYPE` to `A` when possible.

Note: This is a best effort approach; Unbound sends the full `QNAME` and original `QTYPE` when an upstream server replies with an `RCODE` other than `NOERROR`, except when receiving `NXDOMAIN` from a `DNSSEC` signed zone.

See also:

Refer to RFC 7816 for in-depth information on Query Name Minimization.

Strict Query Name Minimization
Controls whether Unbound performs Query Name Minimization in a strict manner for even stronger privacy at the expense of potentially failing to resolve a large number of queries. Default is unchecked.

When set, enables `QNAME` minimization in strict mode, which does not fall back to sending the full `QNAME` and original `QTYPE` to potentially broken name servers.

This option requires Query Name Minimization.

Warning: Use with extreme caution. A significant number of domains will fail to resolve when this option in enabled.

Advanced Resolver Options

Prefetch Support
Controls whether or not Unbound prefetches message cache elements before they expire to help keep the cache up to date.

This option can cause an increase of around 10% more DNS traffic and load on the server, but frequently requested items will not expire from the cache.

Prefetch DNS Key Support
Controls whether or not Unbound fetches DNSKEYs earlier in the validation process when a Delegation Signer record is encountered.

This helps lower the latency of requests but utilizes a little more CPU, and requires the cache to be set above zero.

Harden DNSSEC Data
Controls whether or not Unbound requires DNSSEC data for trust-anchored zones.

When checked (default), if DNSSEC data is absent in a response for a trust-anchored zone, the zone becomes bogus.

If unchecked and Unbound does not receive DNSSEC data then Unbound behaves as if the zone had no trust anchor; the zone is marked insecure but the data is still used. This can work around issues with receiving DNSSEC data, but also opens up the results to a potential downgrade attack.

Serve Expired
Controls whether or not Unbound will serve cache records with a TTL of `0`.

When enabled, allows Unbound to serve a query even with a TTL of `0`. If the TTL is `0` then a new record will be requested in the background when the cache is served to ensure that the cache is updated without adding latency to the client DNS request.

Drop Old UDP Queries
Timeout in seconds before dropping UDP queries waiting in the socket buffer. Queries that have waited for a long time don't need to be processed and can be dropped. A value of 3 should be safe in most setups.

Aggressive NSEC
Controls how aggressively Unbound attempts to predict negative responses based on the contents of the DNSSEC NSEC chain.

When enabled, Unbound uses the DNSSEC NSEC chain to synthesize `NXDOMAIN` and other denials, using information from previous `NXDOMAIN` answers. This helps to reduce the query rate towards targets with high nonexistent name lookup rates.

Message Cache Size
Controls the amount of memory used to cache DNS response codes and validation statuses. The default is *4 MB*.

Note: The resource record set (RRSet) cache will automatically be set to twice this amount. The RRSet cache contains the actual resource record data.

Outgoing TCP Buffers
The number of outgoing TCP buffers to allocate per thread. The default value is *10*.

If set to *0*, TCP queries will not be sent to authoritative servers.

Incoming TCP Buffers
The number of incoming TCP buffers to allocate per thread. The default value is *10*.

If set to *0*, TCP queries will not be accepted from clients.

EDNS Buffer Size
Number of bytes size to advertise as the EDNS reassembly buffer size. This value is placed in UDP datagrams sent to peers.

The default is *Automatic* and is calculated based on the MTU values of active interfaces. A variety of other common values are provided in a drop-down list.

Automatic mode sets optimal buffer size by using the smallest MTU of active interfaces and subtracting the IPv4/IPv6 header size. If fragmentation reassembly problems occur, usually seen as timeouts, then try a value of `1432`.

The `512`, `1220`, and `1232` values bypass most IPv4 and IPv6 MTU path problems but can generate an excessive amount of TCP fallback.

Number of Queries per Thread
The number of queries that every Unbound thread will service simultaneously. The default value is *512*.
